## S1. Collecting crop statistics

## S1.1. Administrative units $\left(A D M_{k}\right)$

The coverage of FAO's Global Administrative Unit Layers (GAUL) is generally sufficient, despite some inconsistencies and incorrect assignments of administrative levels:

- The Bangladesh district Pirojpur is classified as belonging both to the Barisal division (which is correct) and the Khulna division (which is incorrect). The correct name of the district in the Khulna division is Bagerhat. Adjustments to the name for Bagerhat were made within the main code-link table, rather than the GAUL shapefile.
- In India the larger portion of Arunachal Pradesh is classified as 'disputed' area and considered as a 'country', which leaves Arunachal Pradesh with too few ADM2 units.
- Algeria has 1,541 ADM2 units (districts) in GAUL, which in Algeria's official publications were classified as ADM3 units (municipalities). SPAM2010 only has data for Algeria at ADM0 and ADM1 levels.

GAUL identified ADM2 units for China by numbers rather than explicit names. Thus, we opted to use the Database of Global Administrative Areas (GADM) Version 1 shapefiles for China, and attributed any overlaps between China (as designated by GADM) and neighboring countries (as designated by GUAL) to the neighbors (i.e., took some area away from China). For example, Disputed areas like Kashmir were not included in SPAM2010.

The country-specific administrative level used for the model is defined as the statistical reporting unit (SRU). For most countries SPAM is run at an ADM0 level, because of the SRUs are not universally available at the ADM1 level. Table S 1 lists the countries which were modelled at an ADM1 level ( $\operatorname{SRU}=k_{1}$ ). All countries not listed in this table were modelled at an ADM0 level $\left(S R U=k_{0}\right)$.

Table S1 Countries modeled at an ADM1 level statistical reporting unit (SRU)

| Region | Country |
| :--- | :--- |
| Asia | Bangladesh |
|  | China |
|  | India |
|  | Indonesia |
|  | Japan |
|  | Pakistan |

| Region | Country |
| :---: | :---: |
|  | Vietnam |
| Russia | Russia |
| Europe | Germany |
| Latin America and the Caribbean | Italy |
|  | Turkey |
|  | Argentina |
|  | Bolivia |
|  | Brazil |
|  | Colombia |
|  | Costa Rica |
|  | Mexico |
|  | Venezuela |
| Middle East | Israel |
|  | Iran |
|  | Yemen |
| North America | Canada |
|  | United States |
| Oceania | Australia |
|  | New Zealand |
| Sub-Saharan Africa | Angola |
|  | Benin |
|  | Ethiopia |
|  | Kenya |
|  | Nigeria |
|  | Senegal |
|  | Sudan |
|  | Tanzania |
|  | Zambia |

Note: All countries not listed in this table have a statistical reporting unit at an ADM0 level.

## S1.2. Crop production statistics (CropHPY)

Data sources for crop statistics include FAOSTAT, EUROSTAT, CountrySTAT, ReSAKSS, national statistical offices, ministries of agriculture or planning bureaus of individual countries, household surveys and a variety of ad hoc reports related to a particular crop within a particular country. The data sources are slightly different between SPAM2005 (Wood-Sichra et al., 2016) and SPAM2010 (see details in Table S2).

Table S2 Sources of crop production statistics by country and sub-national coverage

| Country | Data Source | Year | Data |  | Harvested Area |  |

## S2. Defining crop types ( Crop $_{j}$ )

When individual countries reported on a crop of which the FAOSTAT category was not immediately apparent, efforts were made to identify the English name of the crop and assign it to the appropriate category. Table S3 lists the SPAM2010 crops and their respective FAO code. The list is comprised of 33 individual crops (millet and coffee are each split into two sub-categories) and crop aggregates. For millet and coffee we used countrylevel data to determine the shares in the respective sub-categories, and partitioned FAO's country totals accordingly.

Table S3 SPAM2010 crop categories

| ID | SPAM2010 Crop |  | FAO Crop |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Long Name | Short Name | Name | Code | Group | Classification |

|  |  |  | Tree Nuts, Other | $689,692,693,698,702,711,720,$ |  |  |
|  |  |  | Sugar Crops, Mate, <br> Rubber) | $723,748,754,836,839$ |  |  |

Source: Developed using information from FAOSTAT (FAO 2015).
Note: ++ indicates that all crops identified by the FAO code in the adjacent column are also assigned to the respective SPAM2010 crop. For example, "Yautia ++" would read "Yautia, Taro, Roots and Tubers, nes".
${ }^{\text {a }}$ Also known as finger millet which includes foxtail, proso, japanese and Kodo varieties.
${ }^{\mathrm{b}}$ FAO's millet crop was split between pearl and small at a ratio specific to the country in question.
${ }^{\text {c }}$ Teff was part of 'other cereals' in SPAM and FAOSTAT, despite the explanation in FAOSTAT that it was part of the 'millets' commodity.
${ }^{\text {d }}$ FAO's coffee crop was split between Arabica and Robusta at a ratio specific to the country in question.

## S3. Adjusting the crop statistics (AdjCropHPY $\boldsymbol{Y}_{j k}$ )

SPAM2010 calculations were based on the 2009-2011 average of the crop production statistics. All efforts were made to collect statistics from these three years, but if data was missing from this time period the average was calculated from the available data spanning the years 2005 to 2015:

$$
\begin{array}{ll}
A v g C r o p H P Y_{j k}= & \frac{\sum_{t=2009}^{t=2011} \operatorname{CropHPY}_{j k t}{ }^{1}}{3} \\
\text { if } \exists \operatorname{CropHPY}_{j k t} \forall t \in[2009,2011] \\
\text { AvgCropHPY }_{j k}=\frac{\sum_{t=m_{1}}^{t=m_{n}} \operatorname{CropHPY}_{j k t}}{n} & \text { if } \nexists \operatorname{CropHPY}_{j k t} \forall t \in[2009,2011]
\end{array}
$$

where $k_{0}, k_{1}, k_{2} \in k, m_{1}, \ldots, m_{n}$ are the set of years with data available on crop $j$ and administrative unit $k$ closest to the 2009-2011 time period (but not earlier than 2005 or later than 2015), $n$ was the total number of years used to calculate the average for crop $j$ and administrative unit $k$.
Note: Average statistics on yield were always taken as a harvested area weighted average

To improve the comparability of the crop production statistics and better align the sub-national data with data derived from the cropland and irrigation maps, we adjusted all national and sub-national statistics using the national 2009-2011 average from FAO ( $\left.A v g F A O C r o p H P Y_{j k 0}\right)$ by crop $j$ and country $k_{0}$ :
i. National (ADM0) harvested area $(H)$, production $(P)$ and yield $(Y)$ statistics

$$
\begin{gathered}
\text { AdjCropHP }_{j k_{0}}=\text { AvgFAOCropHP } P_{j k_{0}} \\
\text { AdjCrop }_{j k_{0}}=\frac{\text { AdjCrop }_{j k_{0}}}{\operatorname{AdjCrop~}_{j k_{0}}}
\end{gathered}
$$

ii. Sub-national (ADM1 or ADM2) harvested area $(H)$, production $(P)$ and yield $(Y)$ statistics

$$
\begin{gathered}
\operatorname{AdjCropHP}_{j k}=\frac{\operatorname{AvgCropHP}_{j k}}{\operatorname{AvgCropHP} P_{j k_{0}}} \times \operatorname{AvgFAOCropHP} P_{j k_{0}}, \forall k=k_{1}, k_{2} \\
\text { AdjCrop }_{j k}=\frac{\operatorname{AdjCrop~}_{j k}}{\operatorname{AdjCropH}_{j k}}, \forall k=k_{1}, k_{2}
\end{gathered}
$$

In situations where a country only reported one of the three variables for a crop (i.e., harvested area, production or yield), we used FAO national statistics $\left(A v g F A O C r o p H P Y_{j k 0}\right)$ to infer the missing variables.

Issues of measurement might arise because FAO occasionally updates historical data without documenting which years or crops were changed. This can lead to inconsistencies when users compare SPAM2010 results with published FAO numbers which have been retroactively adjusted since the version used in SPAM2010.

[^0]
## S4. Obtaining the farming system shares (Percent ${ }_{l}$ )

The four farming systems are referred to as irrigated (I), rainfed - high (H), rainfed - low (L) and subsistence $(S)$. To run, the model requires knowledge of the share of area cropped by each farming system $l$, crop $j$ and administrative unit $k$ ( Percent $_{j l k}$ ); where $l=(I, H, L, S)$. Farming system shares were constructed either at the $k$ $=k_{0}(\mathrm{ADM} 0$ level $)$ or $k=k_{1}(\mathrm{ADM} 1$ level $)$ depending on country's SRU.

The share of crop area and production belonging to each of these farming systems when total area and production are given is often times hard to come by. We rely extensively on expert judgment, but some documented assessments were assembled from household surveys, FAO publications and publications from national statistical offices. It was often necessary to use farming system shares from one crop as proxies for similar crops (e.g., farming system shares for beans were used for all pulses) or shares from one country and apply them to similar countries (e.g., Kuwait, Oman and Qatar were assigned the same farming system shares).

For a small number of large countries, listed in Table $S 4$, we were able to source data on farming system shares at the ADM1 level. For the remaining countries we first assigned the national farming system shares to each ADM1 level, and then adjusted individual ADM1 farming system shares in light of the supporting evidence. For example, if the national share for irrigation of wheat was 30 percent, we assigned that to all ADM1 units. Then we looked at individual units, and if supporting evidence (e.g., the Global Map of Irrigation Areas (GMIA) data) indicated that there was no irrigated area present in a particular AMD1 unit, we set the irrigation share of wheat to zero in that administrative unit. Finally the farming system shares at national level were recalculated as the weighted average of the adjusted ADM1 estimates.

Table S4 Sources of sub-national farming systems data

| Country | All/Some Crops | Source of data |
| :--- | :--- | :--- |
| Argentina | All | Irrigation from MIRCA, rest expert judgment |
| Australia | Some | Irrigation from MIRCA, rest expert judgment |
| Bangladesh | Some | 2013 Statistical Yearbook for Bangladesh |
| Bolivia | All | Same as national, adjust for some crops |
| Brazil | All | Irrigation from MIRCA, rest expert judgment |
| Canada | All | Irrigation from StatCanada, rest expert judgment |
| China | All | Expert judgment |
| Congo, DRC | All | Same as national, adjust for some crops |
| Ethiopia | Some | Irrigation from Agricultural Sample Surveys from 2009 - 2011, rest expert judgment |

| Country | All/Some Crops | Source of data |
| :--- | :--- | :--- |
| India | All | Irrigation from MIRCA, rest India Statistics and expert judgment |
| Indonesia | All | Same as national, adjust for some crops |
| Japan | All | Same as national, adjust for some crops |
| Mexico | All | Same as national, adjust for some crops |
| Nigeria | All | Same as national, adjust for some crops |
| Pakistan | All | Water Management Research Centre, Pakistan, personal contact |
| Russia | All | Same as national, adjust for some crops |
| Sudan | All | Sudan Statistical Yearbook for 2014 |
| Uganda | Some | Same as national, adjust for some crops |
| United States | All | USDA for irrigated shares, rest is rainfed high, expert judgment |

Note: Any countries from Table S1 not listed in this table were sourced from MIRCA. Countries listed in this table were adjusted as needed according to expert judgment.

Shares on irrigated production by crop $j$ and administrative unit $k$ ( Percent $_{j i l k}$ ) were derived by dividing the harvested area cultivated under full control irrigation IrrArea $_{j k}$ obtained from AQUASTAT, MIRCA, and
 Percent $_{j s k}$ ) were primarily estimated based on generalized assumptions for individual countries and crops. For example, all cereals in Western Europe were either grown under irrigated or rainfed - high farming systems, whereas 20 percent of each of the cereals in SSA were grown under a subsistence farming system. We also assumed that fertilization was a proxy for high-input use, so if irrigated crop areas and overall fertilized and non-fertilized areas of a crop were known, it was possible to deduce rainfed high input shares by subtracting the irrigated areas from fertilized areas. The remainder of fertilized area was then classified as rainfed - high area and the non-fertilized areas ( $1-$ Percent $_{j l k}-$ Percent $_{j H k}$ ) were split, using expert judgment, between rainfed - low ( Percent $_{j L k}$ ) and subsistence $\left(\right.$ Percent $\left._{j S k}\right)$ shares. Assignment of rainfed - subsistence shares occurred frequently when there was not enough suitable area for rainfed - low conditions to satisfy the completeness of disaggregated crop statistics in terms of area extent and/or production quantity. In such cases a portion of the rainfed-low statistics were assumed to stem from rainfed - subsistence agriculture, for which area was allocated solely on the condition of rural population and not any crop suitability criteria.

Table S5 shows the shares of production under irrigated and rainfed systems for selected crop groups and countries. We choose Brazil, China, Ethiopia, France, India, Indonesia, Nigeria, Turkey and the United States, because they vary in agro-ecology, region, income level and geographical size. For cereal crops, the three Asian countries (China, India and Indonesia) have the highest shares of irrigated area, whereas the two Sub-Saharan
countries (Ethiopia and Nigeria) have the lowest shares of irrigated area. For roots, tubers and pulses production, the United States and both European countries have the highest shares of irrigated areas, while the Sub-Saharan countries again have less than one percent each. Aggregating across all crops, the three Asian countries rank highest in terms of irrigated area shares while the two Sub-Saharan countries rank lowest.

Table S5 Farming system shares (in area) by crop groups and selected countries

| Country | Farming | Cereals | Roots | Pulses | Oil | Sugar | Fiber | Stimulants | Fruits <br> Vegetables | Other <br> Crops | All |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |  |  |  |  |  |  |  |

Source: Developed by authors using data from AQUASTAT and MIRCA (Portmann et al., 2010), the FAO's World Agriculture: Towards 2015/30 report and expert judgment.

Note: Farming systems - irrigated (I); rainfed (R). Farming system shares for rainfed production are an area weighted average of rainfed high input, rainfed low input and rainfed subsistence production. Shares of rain fed production are the sum of production under rain fed - high inputs, low inputs and subsistence and have been aggregated for this table only.

## S5．Disaggregating the crop statistics by farming systems（AdjCropHPY $\boldsymbol{Y}_{j l k}$ ）

To run the model requires disaggregate harvested area $\left(A d j C r o p H_{j k}\right)$ and yield $\left(A d j C r o p Y_{j k}\right)$ for each of the four farming systems．Harvested area by farming system $l\left(\right.$ AdjCrop $\left._{j l k}\right)$ was calculated as follows：
i．National（ADM0）harvested area $(H)$ statistics

$$
\text { AdjCrop }_{j l k_{0}}=\text { AdjCropH } j_{j k_{0}} \times \text { Percent }_{j l k_{0}}
$$

ii．Sub－national（ADM1 or ADM2）harvested area $(H)$ statistics

$$
\begin{array}{ll}
\text { AdjCrop }_{j l k}=\text { AdjCropH }_{j k} \times \operatorname{Percent}_{j l k_{1}}, \forall k=k_{1}, k_{2} & \text { if } \exists \text { Percent }_{j l k_{1}} \\
\text { AdjCrop }_{j l k}=\text { AdjCropH }_{j k} \times \text { Percent }_{j l k_{0}}, \forall k=k_{1}, k_{2} & \text { if } \nexists \text { Percent }_{j l k_{1}}
\end{array}
$$

Yields by farming system $l$ were more complicated to calculate．These computations used the farming system shares $\left(\right.$ Percent $\left._{j l k}\right)$ and the yield conversion factors $\left(\alpha I R R_{j k 0}, \alpha H L R_{j k 0}\right)$ to calculate an $\operatorname{AdjCrop} Y_{j l k}$ variable for both national and subnational yield $\operatorname{AdjCrop} Y_{j k}$ statistics．The relevant yield conversion factors included yield ratios for irrigated versus rainfed systems $\left(\alpha I R R_{j k 0}\right)$ and rainfed－high versus rainfed－low systems $\left(\alpha H L R_{j k 0}\right)$ ． In many instances we used expert judgement to define these factors．Occasionally data was available from reported statistics or field trials（e．g．，rainfed－high input／low input ratios were calculated from trials that compared yields with fertilizer applications to those without）．Additionally，some yield conversion factors were applied from similar crops（e．g．，lentil factors used for＇other pulses＇）or from similar agro－ecological zones and similar countries（e．g．，the same factor was used for all humid tropics areas in SSA）．

Table S6 Yield conversion factors by select crops and countries

|  | $\begin{aligned} & \text { た్ㅣㄹ } \\ & \text { た } \end{aligned}$ | $\stackrel{\rightharpoonup}{\mathrm{O}} .$ | $\stackrel{3}{3}$ |  |  |  | $\begin{aligned} & \text { 关 } \\ & \text { 曾 } \\ & \vdots \\ & \vdots \end{aligned}$ |  | $\begin{aligned} & \ddot{0} \\ & \text { 范 } \end{aligned}$ |  |  | $\begin{aligned} & \text { O} \\ & \text { O} \\ & \text { Nowin } \end{aligned}$ | $\begin{aligned} & \stackrel{O}{\ddot{7}} \\ & \stackrel{\rightharpoonup}{7} \\ & \stackrel{\rightharpoonup}{\circ} \end{aligned}$ |

Source: Developed by authors using data from the FAO's (2002) World Agriculture: Towards 2015/30 report and expert judgment.

Note: Farming systems - irrigated (I) lists factor for irrigated vs. rainfed; rainfed (R) lists factor for rainfed high vs. rainfed low.

In order to disaggregating crop yield by farming systems, the following were assumed to hold:

- The observed yield $\left(\operatorname{AdjCrop} Y_{j k}\right)$, by definition, was the average of input-specific yields weighted by area:

$$
\begin{align*}
\operatorname{AdjCrop~}_{j k}= & \text { Percent }_{j I k} \times \text { AdjCrop }_{j I k}+\text { Percent }_{j H k} \times \text { AdjCrop }_{j H k} \\
& + \text { Percent }_{j S k} \times \text { AdjCrop }_{j L k}  \tag{A-1}\\
& +\left(1-\text { Percent }_{j I k}-\text { Percent }_{j H k}-\text { Percent }_{j S k}\right) \times \text { AdjCrop }_{j L k}, \forall k=k_{0}, k_{1}
\end{align*}
$$

- Weighted rainfed yield, by definition, was equal to the sum of weighted rainfed - high, weighted rainfed
- low yield and weighted subsistence yield (subsistence has cancelled out below):

$$
\begin{align*}
\left(1-\text { Percent }_{j l k}\right) & \times \text { AdjCrop }_{j R k} \\
& =\text { Percent }_{j H k} \times \text { Yield }_{j H k}  \tag{A-2}\\
& +\left(1-\text { Percent }_{j l k}-\text { Percent }_{j H k}\right) \times \text { AdjCrop }_{j L k}, \forall k=k_{0}, k_{1}
\end{align*}
$$

- By definition of $\alpha I R R_{j k_{0}}$ :

$$
\begin{equation*}
\operatorname{AdjCrop}_{j I k}=\alpha I R R_{j k_{0}} \times \operatorname{AdjCrop} Y_{j R k}, \forall k=k_{0}, k_{1} \tag{A-3}
\end{equation*}
$$

- By definition of $\alpha H L R_{j k_{0}}$ :

$$
\begin{equation*}
\text { AdjCrop }_{j H k}=\alpha H L R_{j k_{0}} \times \operatorname{AdjCrop} Y_{j L k}, \forall k=k_{0}, k_{1} \tag{A-4}
\end{equation*}
$$

Given the four equations listed above, we can define the following term:

$$
\begin{align*}
& \beta_{j k}=\left(\text { Percent }_{j H k} \times \alpha H L R_{j k_{0}}+1-\text { Percent }_{j I k}-\text { Percent }_{j H k}\right) \times \frac{\alpha I R R_{j k_{0}}}{1-\text { Percent }_{j l k}}, \forall k  \tag{A-5}\\
& =k_{0}, k_{1} .
\end{align*}
$$

Equations A-1 - A-5 were then used to calculate statistical yields by crop $j$ and input $l$. Depending on the values of Percent $_{j l k_{0}}, \alpha H L R_{j k_{0}}$ and $\beta_{j k_{0}}$, there were three cases for calculating these yields:

Case 1: Percent $_{j I k_{0}}<>100$ or $\left(\alpha H L R_{j k_{0}}<>0\right.$ and $\left.\beta_{j k_{0}}<>0\right)$ :

- The national (ADM0) yield $(Y)$ statistics were equal to

$$
\begin{gathered}
\text { AdjCropY }_{j L k_{0}}=\frac{\text { Adjcrop }_{j k_{0}}}{\text { Percent }_{j I k_{0} \times \beta_{j k_{0}}+\text { Percent }_{j H k_{0}} \times \alpha H L R_{j k_{0}}+1-\text { Percent }_{j l k_{0}} \text { Percent }_{j H k_{0}}} ;} \begin{array}{c}
\text { AdjCropY }_{j H k_{0}}=\alpha H L R_{j k_{0}} \times \text { AdjCrop }_{j L k_{0}} ; \\
\text { AdjCropY }_{j I k_{0}}=\beta_{j k_{0}} \times \text { AdjCropY }_{j L k_{0}} ; \\
\text { AdjCropY }_{j S k_{0}}=\text { AdjCrop }_{j L k_{0}} .
\end{array}, ~
\end{gathered}
$$

- The sub-national (ADM1 or ADM2) yield $(Y)$ statistics were equal to

$$
\begin{gathered}
\text { AdjCrop }_{j L k}=\frac{\text { AdjCrop }_{j k}}{\text { Percent }_{j I k} \times \beta_{j k}+\text { Percent }_{j H k} \times \alpha H L R_{j k}+1-\text { Percent }_{j l k}-\text { Percent }_{j H k}}, \forall k=k_{1}, k_{2} ; \\
\text { AdjCrop }_{j H k}=\alpha H L R_{j k_{0}} \times \text { AdjCrop }_{j L k}, \forall k=k_{1}, k_{2} ; \\
\text { AdjCropY }_{j I k}=\beta_{j k_{1}} \times \operatorname{AdjCrop}_{j L k}, \forall k=k_{1}, k_{2} ; \\
\text { AdjCropY }_{j S k}=\operatorname{AdjCropY}_{j L k}, \forall k=k_{1}, k_{2} .
\end{gathered}
$$

Case 2: Percent $_{j I k_{0}}=100$ (i.e., no rainfed agriculture)

- National (ADM0) yield (Y) statistic

$$
\begin{gathered}
{\operatorname{AdjCrop} Y_{j I k_{0}}=\operatorname{AdjCropY}_{j k_{0}}} \\
\text { AdjCropY }_{j H k_{0}}=\text { AdjCrop }_{j L k_{0}}=\operatorname{AdjCrop}_{j S k_{0}}=0 .
\end{gathered}
$$

- Sub-national (ADM1 or ADM2) yield $(Y)$ statistics

$$
\begin{aligned}
\text { AdjCrop }_{j I k} & =\operatorname{AdjCrop}_{j k} ; \\
\text { AdjCrop }_{j H k}=\text { AdjCrop }_{j L k} & =\text { AdjCrop }_{j S k}=0, \forall k=k_{1}, k_{2} . \\
\text { Case 3: } \alpha H L R_{j k_{0}} & =0 \text { and } \beta_{j k_{0}}=0
\end{aligned}
$$

- National (ADM0) yield ( $Y$ ) statistic

$$
\begin{gathered}
\text { AdjCrop }_{j H k_{0}}=\frac{\left(1-\text { Percent }_{j l k_{0}}\right) \times \text { Adjcrop }_{j k_{0}}}{\left(1-\text { Percent }_{j l k_{0}}+\text { alRR }_{j k_{0}} \times \text { Percent }_{j l k_{0}}\right) \times \text { Percent }_{j H k_{0}}} ; \\
\text { AdjCropY }_{j_{j l}}=\frac{{\alpha I R R_{j k_{0}}} \times \text { Percent }_{j{ }_{j k}} \times \text { Adjcrop }_{j H k_{0}}}{\left(1-\text { Percent }_{j l k_{0}}\right)} .
\end{gathered}
$$

- Sub-national (ADM1 or ADM2) yield $(Y)$ statistics

$$
\begin{gathered}
\text { AdjCrop }_{j H k}=\frac{\left(1-\text { Percent }_{j l k}\right) \times \text { AdjCropY }_{j k}}{\left(1-\text { Percent }_{j l k}+\text { dIRR }_{j k_{0}} \times \text { Percent }_{j l k}\right) \times \text { Percent }_{j H k}}, \forall k=k_{1}, k_{2} ; \\
\text { AdjCropY }_{j I k}=\frac{\text { aIRR }_{j k_{0}} \times \text { Percent }_{j H k} \times \text { Adjcrop }_{j H k}}{\left(1-\text { Percent }_{j l k}\right)}, \forall k=k_{1}, k_{2} .
\end{gathered}
$$

The farming system-specific yields were further modified if they fell outside the lower and upper bounds of acceptable yields for each crop and farming system. These minimum ( MinYield $_{j l k}$ ) and maximum ( MaxYield $_{j l k}$ ) yields were calculated by crop $j$, farming system $l$ and administrative unit $k$. The minimum yield (for any farming system) was equal to one-tenth of the average adjusted yield:

$$
\text { MinYield }_{j l k}=0.1 \times \text { AdjCrop }_{j k}, \forall k=k_{0}, k_{1}
$$

The maximum yield were either equal to the average adjusted yield or two or three times its value, depending on the farming system:

$$
\begin{gathered}
\text { MaxYield }_{j l k}=3 \times \text { AdjCrop }_{j k}, \forall k=k_{0}, k_{1} \\
\text { MaxYield }_{j H k}=2 \times \text { AdjCrop }_{j k}, \forall k=k_{0}, k_{1} \\
\text { MaxYield }_{j L k}=\text { AdjCropY }_{j k}, \forall k=k_{0}, k_{1} \\
\text { MaxYield }_{j S k}=\text { MaxYield }_{j L k}, \forall k=k_{0}, k_{1}
\end{gathered}
$$

The resulting minima and maxima used in SPAM2010 were MinYield $j_{j l k}$ and MaxYield $d_{j l k}$ and they were reported at ADM0 and AMD1 levels only.

## S6. Generating physical area

For each crop in a country we needed to establish how often it was harvested per year on the same area, or if it was grown simultaneously with other crops. If data existed on the area harvested per season $s$ (SeasHarvArea ${ }_{j l k s}$ ), then it was used to calculate the relevant cropping intensity for that particular crop $j$, farming system $l$ and administrative unit $k$. If statistics on seasonal areas were not available, then expert judgment was used to estimate cropping intensities. Cropping intensities by crop $j$, farming system $l$ and administrative unit $k$ were calculated as follows:
i. National (ADM0) and sub-national (ADM1) statistics for $l=I, H, L$

CropIntensity $_{j l k}=\frac{\sum_{s} \text { SeasHarvArea }_{j l k s}}{\max _{i \in S U R_{k}}\left(\text { SeasHarvArea }_{j l k s}\right)}, \forall l=I, H, L \forall k=k_{0}, k_{1} \quad$ if $\exists$ SeasHarvArea $_{j l k s}$
CropIntensity $_{j l k}$ based on expert judgement, $\forall l=I, H, L \forall k=k_{0}, k_{1} \quad$ if $\nexists$ SeasHarvArea $j_{j l k s}$
ii. National (ADM0) and sub-national (ADM1) statistics for subsistence farming systems, $l=S$

$$
\text { CropIntensity }_{j S k}=\text { CropIntensity }_{j L k}, \quad \forall l=S \forall k=k_{0}, k_{1}
$$

Physical area $(A)$ by crop $j$, farming system $l$ and administrative unit $k$ was then calculated using the relevant harvested area $\left(\right.$ AdjCrop $\left._{j k}\right)$ and cropping intensity (CropIntensity $j_{j l k}$ ):

$$
\text { AdjCropA }_{j l k}=\frac{\text { AdjCrop }_{j l k}}{\text { CropIntensity }_{j l k}}
$$

Cropping intensity values were generally one in temperate and cool climates, and for crops which had long growing periods, like sugar cane or oil palm. Cropping intensities were larger than one for irrigated crops like cereals, especially in Asia, and areas with bimodal rain regimes. Vegetables typically also have higher cropping intensities. The terms of irrigation/rainfed in the current study indicates to farming systems rather than to seasons. It means that the value of cropping intensity for a I farming system indicates for a year around situation, regardless of the dry/wet seasons. The calculation of cropping intensity is based on the statistics in a few selected sampling areas: cropping intensity $=$ harvested area / cropland area, and the values are further adjusted by expert judgements. Table S11 lists cropping intensities for crop groups in a few countries.

Table S7 Cropping intensities by crop groups and selected countries

| Country |  | $\begin{aligned} & \stackrel{\otimes}{\mathbb{N}} \\ & \stackrel{\rightharpoonup}{6} \end{aligned}$ | $\pi$ 0 0 0 0 0 0 0 0 | $\begin{aligned} & \vec{\theta} \\ & \text { E } \\ & \text { R } \end{aligned}$ | $\begin{aligned} & 0 \\ & 0 \\ & 0 \\ & 0 \\ & 0 \\ & \hline 0 \end{aligned}$ | $\begin{aligned} & \underset{\sim}{\sim} \\ & \stackrel{0}{0} \\ & \tilde{0} \\ & \underset{\sim}{0} \\ & \stackrel{0}{0} \end{aligned}$ | $\begin{aligned} & \text { T1 } \\ & \underset{0}{0} \\ & 0 \\ & 0 \\ & 0 \\ & 0 \\ & \hline 0 \end{aligned}$ | 管 | Fruits \& Vegetables | $$ | $$ |

Source: Developed by authors using data from national statistics and expert judgment.
Note: Farming systems - irrigated (I); rainfed (R). Cropping intensities for rainfed production are an area weighted average of rainfed high input, rainfed low input and rainfed subsistence cropping intensities.

Cropping intensities are one of the instruments used to "force" the optimization to solve. If all of the cropland has been used within a grid, but there is still physical area unused within the allocation process, we can assume that the relevant harvested area did not properly account for intercropping or sequential cropping, and thus increase the cropping intensity. See Section 4.3 in the main text for further discussion on the interventions used to facilitate an allocation process solution if one has not been reached.

## S7. Cropland extent

The CAAS-IFPRI cropland dataset fuses national and subnational statistics with multiple existing global-level land cover maps including GlobeLand30, CCI-LC, GlobCover 2009, MODIS C5 and Unified Cropland (Lu et al., 2020). It reports three major parameters by $500 \times 500 \mathrm{~m}$ grid cells around year 2010: the median and maximum cropland percentage (MedCropLand ${ }_{i}$ and MaxCropLand ${ }_{i}$ ) and an estimate of the probability of cropland existence (i.e., greater than zero cropland) within a grid (ProbCropLand ${ }_{i}$ ) for those measures. We aggregate these three parameters from 500 m grid cells to 5 arc-minute grid cells: AggMedCropLand ${ }_{i}$, AggMaxCropLand $_{i}$ and AggProbCropLand $_{i}$ (Figure S1).

Differences between median and maximum cropland estimates reveal the extent to which the various sources used in generating the cropland surface differ in their measure of cropland. The maps of median (Figure S1a) and maximum (Figure S 1 b ) cropland show the respective statistics on the estimated share of cropland per grid across all data sources. The probability of cropland (Figure S1c) gives a grid by grid indication of the degree of agreement between the various sources used in the hybrid map regarding the existence of cropland.

Figure S1 Median cropland percentage (a), maximum cropland percentage (b) and probability of cropland (c).

Source: Developed using data from Lu et al. (2020).

## S8. Crop suitability

For allocation purposes we apply three of GAEZ's water regime/input level combinations: irrigated water/high input levels, rainfed water/high input levels and rainfed water/low input levels. The latter water regime/input level combination was used to represent both rainfed - low and subsistence farming systems. GAEZ's suitability index (SuitIndex $x_{i j}$ ) was used to estimate the suitable area for grid $i, \operatorname{crop} j$ and input $l$ via the following formula:

$$
\text { SuitArea }_{i j l}=\text { SuitIndex }_{i j l} \times \text { Area }_{i} \times \lambda
$$

Where Area $_{i}$ is the physical area in grid $i$ and $\lambda$ is a discount factor.

The suitability index categorized as "very suitable land" represents land estimated to be able to achieve $80 \%$ $100 \%$ of maximum attainable yield. In order to remain conservative on our estimation of very suitable land, and lesser suitability ratings, we choose a discount factor $(\lambda)$ of 0.8 . The major crops surveyed by GAEZ include most of the SPAM2010 crops - those not included were assigned values from similar GAEZ crops. Table S8 details these relationships. Suitable areas for maize irrigated, rainfed - high and rainfed low farming systems are mapped in Figure S2.

Table S8 Concordance between GAEZ crops and SPAM2010 crops

| ID | SPAM2010 Crop | GAEZ Crop |
| :--- | :--- | :--- |
| 1 | Wheat | Wheat |

Figure S2 Suitable area in irrigated (a), rainfed-high (b) and rainfed-low (c) farming systems.

Source: Developed using data from GAEZv3.0 (Fischer et al., 2012).
Note: Suitable area equals the GAEZ's suitability index multiplied by grid size and a discount factor (set to 0.8 ).

## S9. Irrigated area

Coupled with the cropland information described above, geo-referenced data on the share of irrigated area within a grid is used to estimate the extent of irrigated cropland per grid. The Land and Water Division of FAO and the University of Frankfurt jointly developed the Global Map of Irrigation Areas (GMIA) version 5.0, which estimates the amount of area equipped for irrigation $\left(\right.$ IrrArea $\left._{i}\right)$ at a 5 arc-minute resolution around the year 2005 (Siebert et al., 2013). IrrArea $_{i}$ is mapped in Figure S3.

MIRCA (Portmann et al., 2010) can provide crop-specific irrigated area, whereas GMIA cannot. We use GMIA to derive information on irrigation equipped area mainly because MIRCA is for 2000 . In fact the SPAM team has collaborating and discussing with MIRCA team for a long time. SPAM modelling technique is very different from MIRCA's and we don't want to bring their modelling errors into SPAM. Instead, we used GMIA (MIRCA also used it) and derived some of irrigation input parameters from MIRCA. Anderson et al. (2015) compared MIRCA and SPAM and had a good discussion on that.

Figure S3 Area equipped for irrigation (5 arc-minute resolution)

Source: GIMAv5.0 (Siebert et al., 2013).

## S10. Protected area

Protected areas are designated by the World Database on Protected Areas 2003 from the International Union for Conservation of Nature, and include both international and national definitions: (a) international designation of protected areas are areas designated or proposed through international or regional conventions, and (b) national designations are proposed at the national or sub-national level.

The data, originally in a polygon format ( Protect $_{\text {shape }}$ ), was converted to 5 arc-minute grids ( Protect $_{i}$ ) using GIS software. Protected areas are mapped in Figure S4.

Figure S4 Protected areas (5 arc-minute resolution)

Source: Developed by authors using data from the World Database on Protected Areas (Deguignet et al., 2014).

## S11.Accessibility

The population count from the Gridded Population of the World database (GPWv4.0) (CIESIN, 2016) a 30 arcsecond resolution is applied to calculate the population density at 5 arc-minute resolution for SPAM2010 (Figure S5). When it overlays with cropland data, rural population $\left(\operatorname{AggRurPop}_{i}\right)$ will be selected where population grids intersect with cropland grids.

Figure S5 Population density (persons/km2) (5 arc-minute resolution)

Source: Developed by authors using data from GPWv4.0 (CIESIN, 2016).

A measure of market accessibility $\left(\right.$ Access $\left._{i}\right)$ was created from the grid-level estimates of rural population using the following equation:

$$
\begin{array}{ll}
\text { Access }_{i}=0 & \text { if AggRurPop }{ }_{i}<\text { MinPop }_{k_{0}} \\
\text { Access }_{i}=0 & \text { ifAggRurPop } i>\text { MaxPop }_{k_{0}} \\
\text { Access }_{i}=\sqrt{\text { AggRurPop }_{i}-\text { MinPop }_{k_{0}}} & \text { Otherwise }
\end{array}
$$

where rural population densities were constrained by the maximum $\left(\operatorname{MaxPop}_{k 0}\right)$ and minimum ( $\operatorname{MinPop} p_{k 0}$ ) rural population densities within a country. Table S 9 shows the maximum and minimum rural population densities for select countries. These max-min cutoffs were determined by expert judgment.

Table S9 Minimum and maximum rural population densities in select countries

| Country | Rural Population Density |  |
| :--- | :--- | :--- |
|  | Minimum | Maximum |
|  | (people $\left./ \mathrm{km}^{2}\right)$ |  |

|  | Rural Population Density |  |
| :--- | :--- | :--- |
| Country | Minimum | Maximum |
| Brazil | 5 | 1,000 |
| China | 5 | 600 |
| Ethiopia | 5 | 250 |
| France | 5 | 1,000 |
| Indonesia | 5 | 2,000 |
| India | 5 | 2,000 |
| Nigeria | 10 | 300 |
| Turkey | 5 | 1,000 |
| United States | 5 | 350 |

Source: Developed by authors.

## S12. Crop revenue

According to the assumption of risk aversing and profit maximizing, crop revenure (Rev) would substantially influence farmers' decisions on selecting crops. In SPAM2010, we assume Rev is a function of crop prices (Price), crop potential yield (PotYield) and market accessibility (Access):

$$
\text { Rev }_{i j l}=\text { Price }_{j} \times \text { Access }_{i j} \times \text { PotYield }_{i j l}
$$

We adopt the crop-specific prices $\left(\right.$ Price $\left._{j}\right)$ from FAO's Gross Production Value. Prices for crop aggregates (e.g., tropical fruit) are calculated as a weighted average from FAO world totals (Table S10)

Table S10 SPAM2010 crop prices (constant 2009-2011 Int \$)

| ID | SPAM2010 Crop | International Price |
| :---: | :---: | :---: |
|  |  | (constant 2004-2006 Int \$/mt) |
| 1 | Wheat | 157.8 |
| 2 | Rice | 278.7 |
| 3 | Maize | 141.7 |
| 4 | Barley | 119.0 |
| 5 | Pearl Millet | 181.5 |
| 6 | Small Millets | 181.5 |
| 7 | Sorghum | 153.8 |
| 8 | Other Cereals | 135.9 |
| 9 | Potato | 168.8 |
| 10 | Sweet Potato | 75.5 |
| 11 | Yams | 255.0 |

| 28 | Sugarcane | 32.8 |
| 29 | Sugarbeet | 43.0 |
| 30 | Cotton | 330.0 |
| 31 | Other Fibre Crops | 385.3 |
| 32 | Coffee Arabica | $1,074.4$ |
| 33 | Coffee Robusta | $1,074.4$ |
| 34 | Cocoa | $1,038.5$ |
| 35 | Tea | $1,063.5$ |
| 36 | Tobacco | $1,592.8$ |
| 37 | Banana | 281.6 |
| 38 | Plantain | 206.5 |
| 39 | Tropical Fruit | 265.9 |
| 40 | Temperate Fruit | 520.1 |
| 41 | Vegetables | 279.1 |
| 42 | Rest Of Crops | $1,316.5$ |

Source: Developed by authors using price data from FAO's (2012) gross value of production.
Note: Prices of pearl and small millet were set equal. Prices of Arabica and Robusta coffee were set equal.

We estimate the crop-specific potential yield ( PotYield $_{i j l}$ ) as a composite measure of yield based on GAEZ. In addition to estimates of suitability indices by grid, GAEZ also published data on potential dry weight yields by grid $i$, crop $j$ and farming system $l$ (PotDryYield ${ }_{i j l}$ ). To run SPAM2010 requires that this variable be measured in terms of harvested weight, which was derived by dividing the respective dry matter yield by crop-specific conversion factors provided by GAEZ in their Model Documentation (Fischer et al., 2012). If a crop-specific conversion factor was not available for a particular crop or crop aggregate, it was assigned from a similar "standin" crop as follows:

$$
\begin{gathered}
\text { OthFact }_{j_{1}, j_{2}}=\frac{\sum_{t=2009}^{t=2011} F^{\prime} \text { AOCrop }_{j_{1} t}}{\sum_{t=2009}^{t=2011} F^{\prime} \text { AOCrop }_{j_{2} t}} \\
\text { TotFact }_{j_{2}}=\text { GAEZfactor }_{j=j_{1}} \times \text { OthFact }_{j_{1}, j_{2}}
\end{gathered}
$$

where $G A E Z a c t_{j}$ is the dry-to-harvested weight yield conversion factor and FAOCrop $Y_{j}$ is the $2009-2011$ average FAO statistic on world yield by crop $j$. Table S11 lists the GAEZ factors to convert dry matter yields to harvested yields. Potential harvested yield (PotHarvYield $d_{i j}$ ) for grid $i$, crop $j$ and farming system $l$ was then calculated as follows:

$$
\text { PotHarvYield }_{i j l}=\frac{\text { PotDryYield }_{i j l}}{\text { TotFact }_{j}}
$$

Then, the potential yield ( PotYield $_{i j l}$ ) is calculated as follows:

$$
\text { PotYield }_{i j l}=\text { AdjCrop }_{j l \mathrm{k}} \times \frac{\text { PotHarvYield }_{i j l}}{\text { AvgPotHarvYield }_{j l k}}, \quad \forall k \in\left(k_{0}, k_{1}, k_{2}\right)
$$

and

$$
\text { AvgPotHarvYield }_{j l k}=\frac{\sum_{i \in k}\left(\text { PotHarvYield }_{i j l} \times \text { AdjSuitArea }_{i j l}\right)}{\sum_{i \in k} \text { AdjSuitArea }_{i j l}}, \quad \forall k \in\left(k_{0}, k_{1}, k_{2}\right)
$$

Table S11 Conversion factors to calculate harvested yield from dry matter yield

| ID | SPAM2010 Crop | GAEZ Crop | GAEZ Factor | Other Factor | Total Factor |

Source: Developed by authors using data from GAEZv3.0 (Fischer et al., 2012) and own-calculations.
Note: Column "GAEZ Factor" lists the factors from GAEZv3.0 to convert from dry matter to harvested crop; Column "Other Factor" was a second factor introduced by the authors to convert a "borrowed" yield (e.g., from maize, to be used with temperate fruit); Column "Total Factor" was the final factor by which GAEZ yields were divided to arrive at SPAM2010 yields: GAEZ Factor/Other Factor.

## S13. Adjusting areas

We first adjust the grid-level data on cropland, irrigated area and suitable area before calculating the priors of physical area, in order to satisfy the constraints at the administrative unit level. These constraints are:
(i) that the total land in crops must be greater than or equal to the sum of area equipped for irrigation;
(ii) that statistical physical area summed over all crops and farming systems must be less than or equal to the sum of cropland;
(iii) that irrigated statistical physical area summed over all crops must be less than or equal to the sum of area equipped for irrigation; and
(iv) that statistical physical area must be less than or equal to the suitable area per crop and farming system. In many cases these conditions are not met.

In many cases these conditions are not met due to the different sources of the data, inaccuracies, different times of measurement, different scales, inconsistencies in classification, and various other reasons. Therefore, we make adjustments following a hierarchy of "credibility" that we defined in decreasing order of importance:
(i) statistical data;
(ii) cropland;
(iii) area equipped for irrigation; and
(iv) suitable area.

This is because statistical data was not changed, except in the unusual case when a model run failed to yield a solution, and only after all other modification options were exhausted. The general approach to the grid-level area adjustments was to upscale each variable so that they matched the statistical totals reported for the smallest available administrative unit, checking back that the corresponding totals at higher administrative units also continued to align. If scaling was not enough, we would calculate the missing amounts, and depending on the control parameters condAg ${ }_{i}$ and condSuit, distributed those amounts equally to grids which could still be expanded (up to total grid area). In a further step we could unconditionally increase areas of cropland, equipped for irrigation or suitable area by a given percentage to try and satisfy the conditions. If constraints were not met after these new adjustments, the specific problem was noted and manual adjustments of other parameters were made to resolve any area discrepancies, guided by expert judgment. Cropland area is worthy of special mention, since not all cropland in an administrative unit was necessarily used within the allocation model. To choose how
much cropland would be used in each administrative unit, the grids of cropland for that unit were sorted by the reliability factor $\left(\right.$ ProbCropLand $\left._{i}\right)$ in descending order. Then the cropland was added up until it reached the physical area statistical value. Any excess grids (those with the lowest probabilities) were discarded from the SPAM2010 cropland surface.

In the processing phase, we first introduce the $\gamma$ parameter which represents a relaxation factor for land constraints from sources less reliable than the statistical offices. Initially, the $\gamma$ parameter is set to $5 \%$ for all of the three measures of gridded area. Adjusting $\gamma$ may have some effect on the model's ability to solve if there were enough grids which did not yet have 100 percent cropland, suitable area or irrigated area (see "Temporary Irrigation Step 1", "Temporary Cropland Step 6" and "Temporary Suitable Area Step 1"). We have another adjustment option in this pre-processing phase which is to relax the conditions on irrigated area, cropland and suitable area when assigning area to grids with zero reported irrigation, cropland or suitable area (see the equation conditions in "Temporary Irrigation Step 2", "Temporary Cropland Step 7" and "Temporary Suitable Area Step 2"). This adjustment could further relax the more restrictive "AND" condition to the less restrictive "OR" condition, and effectively allows zero values to be substituted with non-zero values. The details are written as:

- Temporary Cropland Step 1: Set cropland as median cropland value

$$
\text { T1 CropLand }_{i}=\text { AggMedCropLand }_{i}
$$

- Temporary Cropland Step 2: Adjustment of cropland for irrigation

If T1CropLand ${ }_{i}<$ IrrArea $_{i}$,

$$
\text { T2CropLand }_{i}=\text { IrrArea }_{i}
$$

If T1CropLand $_{i} \geq$ IrrArea $_{i}$,

$$
\text { T2CropLand }_{i}=\text { T1 CropLand }_{i}
$$

- Temporary Cropland Step 3: Adjustment of cropland with additional cropland to satisfy physical area statistics

If $\sum_{i \in k}$ T2CropLand $_{i}<\sum_{j} \sum_{l}$ AdjCrop $_{j l k}$,

$$
\text { T3CropLand }_{i}=\min \left[\text { AggMaxCropLand }_{i}, \text { PixelArea }_{i \in k}\right], \quad \forall k=k_{0}, k_{1}, k_{2}
$$

Otherwise

$$
\text { T3CropLand }_{i}=\text { T2CropLand }_{i}
$$

- Temporary Cropland Step 4: Only use cropland grids with highest probability
i. Sort grids $\left(i \in k_{0}\right)$ by AggProbCropLand ${ }_{i}$ from largest to smallest
ii. Sum grids (in order of sort) until sum of cropland is equal to (or slightly greater than) the total physical area. Mark remaining cells for deletion.
iii. Begin with ADM0, then ADM1, then ADM2 statistics. Note: Cells marked for deletion at an administrative level but not marked for deletion at a lower administrative level are retained. For example, if a cell is marked for deletion at an ADM0 level, but not at an ADM1 level, then the cell is kept for the remainder of the analysis.

If $\sum_{i \in k}$ T3CropLand $_{i} \geq \sum_{j} \sum_{l}$ AdjCropA $_{j l k}$,

$$
\text { T4CropLand }_{i}=\text { T3CropLand }_{i}, \quad \forall k=k_{0}, k_{1}, k_{2}
$$

Otherwise

$$
\text { T4CropLand }_{i}=\text { Mark for Deletion }
$$

Delete all $\mathrm{T}_{4} \mathrm{CropLand}_{i}$ grids marked for deletion

- Temporary Irrigation Step 1: Scale irrigation area to reflect physical area

$$
\begin{aligned}
\text { If } \sum_{i \in k} \text { IrrArea }_{i} & <\sum_{j} \text { AdjCropA }_{j I k}, \\
& \text { T1IrrArea }_{i}
\end{aligned}=\min \left[\text { IrrArea }_{i} \times \frac{\sum_{j} \text { AdjCropA }_{j l k}}{\sum_{i \in k} \text { IrrArea }_{i}} \times(1+\gamma), \text { PixelArea }_{i \in k}\right], \quad \forall k=k_{0}, k_{1}, k_{2} .
$$

Otherwise

$$
\text { T1IrrArea }_{i}=\text { IrrArea }_{i}
$$

where $\gamma$ normally starts at 5 percent, and is increased as necessary

- Temporary Irrigation Step 2: Adding irrigation to grids with zero irrigation

If $\sum_{i \in k}$ T1IrrArea $_{i}<\sum_{j}$ AdjCropA $_{j I k}$, and T1IrrArea $_{i}=0$, and (T4CropLand ${ }_{i}>0$ AND AggRurPop ${ }_{i}>0$ ),

T2IrrArea $_{i}=\min \left[\frac{\sum_{j} \text { AdjCropA }_{j l k}-\sum_{i \in k} \text { T1IrrArea }_{i}}{\text { count }_{i \in k}(T 1 \text { IrrArea }}=0\right) \quad$ PixelArea $\left._{i \in k}\right], \quad \forall k=k_{0}, k_{1}, k_{2}$
Otherwise

$$
\text { T2IrrArea }_{i}=\text { T1ITrArea }_{i}
$$

- Temporary Cropland Step 5: Adjustment of cropland for modified irrigation If T4CropLand $_{i}<$ T2IrrArea $_{i}$,

$$
\text { T5CropLand }_{i}=\text { T2IrrArea }_{i}
$$

Otherwise

$$
\text { T6CropLand }_{i}=\text { T4CropLand }_{i}
$$

- Temporary Cropland Step 6: Adjustment of modified cropland for statistics

If $\sum_{i \in k}$ T5CropLand $_{i}<\sum_{j} \sum_{l}$ AdjCrop $_{j l k}$ and Protect $_{i}=0$,

$$
\begin{aligned}
\text { T6CropLand }_{i}= & \min \left[\text { T5CropLand }_{i} \times \frac{\sum_{j} \sum_{l} \text { AdjCrop }_{j l k}}{\sum_{i \in k} \text { T5CropLand }_{i}} \times(1+\gamma), \text { PixelArea }_{i \in k}\right] \\
& \forall k=k_{0}, k_{1}, k_{2}
\end{aligned}
$$

Otherwise

$$
\text { T6CropLand }_{i}=\text { T5CropLand }_{i}
$$

if scaling only results in the addition of 10 ha, increase $\gamma$ by a factor of 10 and repeat.

- Temporary Cropland Step 7: Adding cropland to grids with zero cropland

If $\sum_{i \in k}$ T6CropLand $_{i}<\sum_{j} \sum_{l}$ AdjCropA $_{j l k}$, and T6CropLand $_{i}=0$, and Protect $_{i}=0$, and $\left(\right.$ SuitArea $_{i}>0$ AND/OR AggRurPop $\left.i>0\right)$,
T7CropLand $_{i}=\min \left[\frac{\sum_{j} \sum_{l} \text { AdjCropA }_{j l k}-\sum_{i \in k} \text { T6CropLand }_{i}}{\text { Count }_{i \in k}\left(\text { T6CropLand }_{i}=0\right)}\right.$, PixelArea $\left._{i \in k}\right], \quad \forall k=k_{0}, k_{1}, k_{2}$
Otherwise

$$
\text { T7CropLand }_{i}=\text { T6CropLand }_{i}
$$

- Temporary Suitable Area Step 1: Adjustment of suitable areas

If $\sum_{i \in k}$ SuitArea $_{i j l}<$ AdjCrop $_{j l k}$,

$$
\begin{aligned}
\text { T1SuitArea }_{i j l}= & \min \left[\text { SuitArea }_{i j l} \times \frac{\text { AdjCropA }_{j l k}}{\sum_{i \in k} \text { SuitArea }_{i j l}} \times(1+\gamma), \text { PixelArea }_{i \in k}\right] \\
& \forall j \forall l \forall k=k_{0}, k_{1}, k_{2}
\end{aligned}
$$

Otherwise

$$
\text { T1SuitArea }_{i j l}=\text { SuitArea }_{i j l}
$$

- Temporary Suitable Area Step 2: Adding suitable area to grids with zero suitable areas

If $\sum_{i \in k}$ T1SuitArea $_{i j l}<$ AdjCropA $_{j l k}$, and T1SuitArea ${ }_{i j l}=0$, and (T7CropLand $_{i}>0$, AND/OR AggRurPop $\left._{i}>0\right)$,

$$
\text { T2SuitArea }_{i j l}=\min \left[\frac{\text { AdjCrop }_{j l k}-\sum_{i \in k} \text { T1SuitArea }_{i j l}}{\text { count }_{i \in k}\left(\text { T1SuitArea }_{i j l}=0\right)}, \text { PixelArea }_{i \in k}\right], \quad \forall k=k_{0}, k_{1}, k_{2}
$$

Otherwise

$$
\text { T2SuitArea }_{i j l}=\text { T1SuitArea }_{i j l}
$$

The final adjusted variables used in the model are

$$
\begin{aligned}
\text { AdjCropLand }_{i} & =\text { T7 CropLand }_{i} \\
\text { AdjIrrArea }_{i} & =\text { T2IrrArea }_{i} \\
\text { AdjSuitArea }_{i j l} & =\text { T2SuitArea }_{i}
\end{aligned}
$$

If the model run has not yielded a solution any or all of the three variables can be readjusted unconditionally to

$$
\begin{aligned}
& \overline{\text { AdjCropLand }_{l}}=\min \left[\text { AdjCropLand }_{i} \times\left(1+\gamma_{1_{k_{S R U}}}\right), \text { PixelArea }_{i}\right] \\
& \overline{\text { AdjIrrArea }_{\iota}}=\min \left[\text { AdjIrrArea }_{i} \times\left(1+\gamma_{2_{k_{S R U}}}\right), \text { PixelArea }_{i}\right] \\
& \overline{\text { AdJSultArea }_{l \jmath l}}=\min \left[\text { AdjSuitArea }_{i} \times\left(1+\gamma_{3_{k_{S R U}}}\right), \text { PixelArea }_{i}\right]
\end{aligned}
$$

## S14. Adjusting entropy conditions

If the model does not solve after these area adjustments, we would relax constraints within the entropy optimization process on the availability of cropland (constraint ii), irrigated area (constraint iii) or suitable area (constraint iv), by increasing the percentage values ( $\gamma$ ) in each cell of cropland, irrigated area or suitable area. These percentages can vary between area types, but cropland can only be increased if the cell is not classified as a protected area. Areas in each grid can only be increased up to the point that their sum does not exceed the grid size.

If the first entropy condition adjustment does not yield an optimal solution, and it is obvious from the control output that suitable areas were not satisfying the constraints, it is possible to selectively eliminate suitability constraints for individual crops - including all crops if necessary. This means that the allocation would be guided only by cropland, irrigated areas (and crop distribution if data was available), but not by crop suitability considerations.

## S15.Adjust data harmonization rules

If the previous interventions failed to achieve a solution, the primary data used to create the constraints and priors may be problematic. To address this problem, countries were run at an ADM1 rather than an ADM0 level. This is only possible if the area and yield statistics are also available for all ADM1 units and all crops in the country in question. In the case of large countries, which are already run at an ADM1 level (e.g., the United States, Canada, China, Russia or India), the details for all ADM1 units were available with few exceptions (e.g. crops which were only grown in small quantities, or "rest of crops" which often were an aggregation of all other crops not reported individually). For other countries we relied on secondary information or own-estimates to complete the statistics. For example, the FAO reported that China grew oil palm, but the Chinese sources did not break down oil palm by ADM1 units. Further literature review revealed that oil palm was grown only in the Hainan province. Thus national totals for oil palm were all assigned to Hainan, while all other provinces were assigned zero oil palm production.

If additional information was not forthcoming, we applied some rules-of-thumb to assign crop production data to ADM1 units when only national data was available. For example, where required we often assigned crop aggregates to ADM1 units in the same shares as the sum of similar crops. Hence, the national value of "rest of crops" for some countries was allocated to ADM1 units using the same share as the sum of all other crops within each sub-national administrative unit. Or "other cereals" was assigned in the same proportion as the sum of all cereals for which there were data. However, the exact method of assigning national statistical totals to the relevant sub-national units was dependent on the crop, country and expert judgment. If a country is run at an ADM1 level, it is necessary to also have data on the farming system shares and cropping intensities at the same administrative level. Absent of existing ADM1 statistics on farming system shares and cropping intensities, we used the national level values. Table S12 summarizes the various interventions methods described above. Not all countries needed interventions, as can be seen in Table S13, which lists a subset of interventions for select ADM1 units.

Table S12 Points of interventions in spatial allocation process

| Variable | Meaning | Values |
| :---: | :---: | :---: |
| Intervention Type 1 |  |  |
| $\gamma$ | Increase the amount of cropland, suitable area or irrigated area by $\gamma$ percent | $1 \leq \gamma \leq 100$ |
| condAgi | Conditionally assign positive area to AdjCropLand ${ }_{i}=0$ and AdjIrrArea $_{i}=0$ by relaxing conditions from (SuitArea $>0$ AND AggRurPop $\left._{i}>0\right)$ to (SuitArea $>0$ OR AggRurPop $_{i}>0$ ) | $1=$ And; $2=$ No |
| condSuit $_{\text {ijl }}$ | Conditionally assign positive area to AdjSuitArea $a_{i j l}=0$ by relaxing conditions from ( CropLand $_{i}>0$ AND AggRurPop $_{i}>0$ ) to $\left(\right.$ CropLand $_{i}>0$ OR AggRurPop $\left.i>0\right)$ | $1=$ And; $2=$ No |

Intervention Type 2

| isA $_{k_{S R U}}$ | Indicator variable to add more cropland |
| :--- | :--- |
| $\gamma_{1_{k_{S R U}}}$ | $\gamma_{1_{k_{S R U}}}$ percent to be added to AdjCropLand ${ }_{i}$ |
| isSuit $_{k_{S R U}}$ | Indicator variable to add more suitable area |
| $\gamma_{2_{k_{S R U}}}$ | $\gamma_{2_{k_{S R U}}}$ percent to be added to AdjSuitArea ${ }_{i j l}$ |
| isIrr $_{k_{S R U}}$ | Indicator variable to add more irrigated area |
| $\gamma_{3_{k_{S R U}}}$ | $\gamma_{3_{k_{S R U}}}$ percent to be added to AdjIrrArea ${ }_{i}$ |
| noSuit $_{j k_{S R U}}$ | Do not apply suitability constraints for |
|  | All crops $j$ OR |
|  | Any crop $j=1,2, \ldots, 42$ |

$$
\begin{aligned}
& \begin{array}{l}
0=N o ; 1=Y e s \\

## S16.Supporting documents for the qualitative validation process

We build up a system through which we are able to send the crop maps to collaborators and users alike for comments or assessment. These collaborators mainly include IRRI, CIMMYT, IIASA and CAAS. We carried out field trips and workshops onsite or online where local experts were asked to confirm or validate the crop production maps by providing hand-written comments or posting comments online at the MapSPAM website. The SPAM maps were evaluated crop by crop, and country by country. As an example, some of rice map validation documents are presented below. Similar documentations can be found from the MapSPAM website.

## China:

Generally, the cover for China appears to match the studies which we have found online (The light purple means lower value while the pink and red colors mean higher value in the upper figure), although the following map highlights some difference in the north eastern parts of the country between the DNDC study and our data:

(1. SPAM Harvested Rice Area - China)

(2. Single crop Rice production-
http://www.dndc.sr.unh.edu/boles/d_jpeg/singlerice.jpg)

The comparison is fair accept for the area in the north Eastern part of the country indicated by the Arrows A and B on 1 and 2. This may be explained by the following two maps, which although crude, demonstrate that there is a significant difference between the double crop and single crop rice harvest in the North Eastern Part of the country:

(3.http://www.usda.gov/oce/weather/pubs/Other/MW CACP/Graphs/chi/chisric.gif)

(4.http://www.usda.gov/oce/weather/pubs/Other/M WCACP/Graphs/chi/chidric.gif)

India:
We were unable to find any detailed studies of rice in India at Provincial or district level, but generally the data appears to correlate fairly well with the basic country level information that we found except for a few anomalies:

(7.http://www.usda.gov/oce/weather/pubs/Other/MWCACP/Graphs/ind/indk_ric.gif 8.http://www.usda.gov/oce/weather/pubs/Other/MWCACP/Graphs/ind/indr_ric.gif)

There are although several differences in the province indicated by Arrow C on 6 , and the USDA maps are suggesting that our data should be showing significantly more production in this province, but data from a more accurate or detailed study would need to be found to confirm this either way. The following map for example shows the province in question (marked with Arrow E) to be one the highest producing province in India, which reinforces the USDA maps:

(9. http://www.knowledgebank.irri.org/gis/images/irw.jpg)

On 6 Arrow D indicates two Indian Provinces which are shown to have no data. Although the comparative studies we have found on these provinces is limited, 7 and 8 both suggest that there is rice production on the North side of the Bangladeshi border. Unfortunately, 9 also has no data on the areas in question.

## Pakistan:

The SPAM data shows an interesting pattern in the growing areas of Pakistan. This is compared below with a very basic study in 11 by the FAO. It can be seen that the Rice production tracks the river and there are some strong similarities in the patterns, which both follow the river with similar clusters of production in the South. The striped blue lines which appear in the river tributaries in the North Eastern part of Part of Pakistan are an area which the FAO data suggests to be under intense Rice production. There is no real explanation for the horizontal lines in the SPAM data at that point which suggests an error. Again a more in depth study would likely need to be found to verify this.

(11-12 http://www.iamhedged.com/research/pakric.gif and SPAM data for Pakistan)

## Thailand, Cambodia and Vietnam:

One study which serves as a reference, was carried out on the Bac Kan Province of Vietnam, indicated by Arrow
F on 13. It can be seen that the SPAM data even at this level is fairly accurate.

(13. SPAM data for Vietnam)

(14. Total Rice production per Capita, Bac Kan Province -
http://www.knowledgebank.irri.org/sam/SAM/site_en/atlas_en/map_agricult001_en.html)

The Philippines:
The following study charts the changes of distribution of rice production in the main provinces of the Philippines over the last three decades

(15. http://www.knowledgebank.irri.org/gis/images/phprod.jpg)

When looking at the SPAM data below, it can clearly be seen that there is some unusual patterning especially in the south. The data from 15 clearly demonstrates that there should be a significant amount of Rice production in the South, but the SPAM data in 16 Below shows some unusual patterning which does not really hold any particular reference to the landscape:

(16. SPAM Data for the Philippines)

(17-18. Prime Rice Lands and Topography)
Generally the areas of the SPAM data showing higher levels of production correspond with Prime Rice Land areas shown in 17 , but this data also reinforces the fact that the patterning on the Spam Data, should be more clustered, and the horizontal patterning does not correspond with any other available studies. The void in the northern part of the Philippines indicated by Arrow G corresponds to an area of highlands, and it can be seen also that the prime rice land run vertically along the sides of the mountainous region, which is correctly indicated by the red areas on the SPAM data, although the patterning again appears to be unusual.

The area indicated by arrow $H$ for example is shown to be highlands, and 17 shows that the patterns of Prime

Rice areas corelate with the topography of the region. The SPAM data on the other hand appears to have no real correlation with the topography of the land or the patchy prime rice growing areas in this southerly part.

## Brazil:

The following page shows the SPAM data compared with a broad provincial level study of rice production Brazil, comparative to other areas of the world, rice production is much lower here, but the provinces reported to have the highest production, from the FAO study, appear to correlate with the SPAM data. There is only one major exception, which is that the provinces marked with Arrows I and J appear to be completely contradictory. Otherwise, the only other observation is that areas abruptly change from higher to lower production along provincial boundaries as if the data was entered only as an average for each province, with the result that it looks remarkably like the FAO Provincial level Study.

(19. SPAM data for Brazil)

(20. http://www.iamhedged.com/research/brzric.gif)

## Argentina:

In Argentina for example the following USDA study (21) shows that rice production is highly concentrated in one very small part of the country.

(21.http://www.usda.gov/oce/weather/pubs/Other/MWCACP/Graphs/Argentina/ArgentinaRice.pdf)

The SPAM data for this region is particularly interesting for rice production, and specific circular patterning can be seen in the provinces surrounding the river mouth which is unlike any other patterning observed in the data set:

A brief comparison of the data will reveal numerous anomalies between the two. The highest producing areas in the USDA study are the two marked in red which appear to correlate with the patterning which is shown in these provinces on the SPAM data. A brief examination of some topographical maps for the region have provided no reasonable explanation for the circular patterning.

The North Eastern Province in the Iguazu falls areas is shown by the SPAM data to have no registered production, but USDA believe this province to be producing up to $3 \%$ of the country's output, now it may be that this is simply too low a level of production to register on the SPAM study, which seem to tie in with the fact that the other provinces marked in grey on the FAO study, except for the fact that the area marked with Arrow L shows production in the only area which the FAO study believes to have no production at all. Particularly noticeable because they have gone to the trouble of dividing the Santa Fe province into three different grades, with the specific purpose of showing that there is no significant production in the southerly part but 3-20 \% of the country's total output in the north.

## Kenya:

There appears to be little correlation between the SPAM data for Kenya and the Province level study we discovered. Some of the areas appear to correlate with the highest producing areas, but there is little evidence of the vertical band of production which can be seen in 24 but this may just be due to the fact that the production
is too low for the SPAM model to recognize.

(23. SPAM data for Kenya, Country borders only)

(24. http://www.ilri.org/gis/search.asp?id=334)

## S17.Confidence assessment

The confidence rating by users, local experts and collaborators is presented in Table S14. The rating is collected from the feedback and comments from users, local experts and collaborators. We combine all the information together to give a subjective rating on how confidence we, SPAM team, think of our final crop maps (both area and yield).

Table S14 Confidence rating by users, local experts and collaborators

| COUNTRY NAME | Confidence Category(1-highest, 5- lowest) |
| :---: | :---: |
| Armenia | 1 |
| Angola | 2 |
