19 **Abstract:** The recent release of the International Satellite Cloud Climatology Project  
20 (ISCCP) HXG cloud products and new ERA5 reanalysis data enabled us to produce a  
21 global surface solar radiation (SSR) dataset: a 16-year (2000-2015) high-resolution (3  
22 h, 10 km) global SSR dataset **using** an improved physical parameterization scheme.  
23 The main inputs were cloud optical depth from ISCCP-HXG cloud products, the  
24 water vapor, surface pressure and ozone from ERA5 reanalysis data, and albedo and  
25 aerosol from Moderate Resolution Imaging Spectroradiometer (MODIS) products.  
26 The estimated SSR data was evaluated against surface observations measured at 42  
27 stations of the Baseline Surface Radiation Network (BSRN) and 90 radiation stations  
28 of the China Meteorological Administration (CMA). Validation against the BSRN  
29 data indicated that the mean bias error (MBE), root mean square error (RMSE) and  
30 correlation coefficient ( $R$ ) for the instantaneous SSR estimates at 10 km scale were  
31  $-11.5 \text{ W m}^{-2}$ ,  $113.5 \text{ W m}^{-2}$ , and 0.92, respectively. **When the estimated instantaneous**  
32 **SSR data were upscaled to 90 km, its error was clearly reduced with RMSE**  
33 **decreasing to  $93.4 \text{ W m}^{-2}$  and  $R$  increasing to 0.95.** For daily SSR estimates at 90 km  
34 scale, the MBE, RMSE and  $R$  at the BSRN were  $-5.8 \text{ W m}^{-2}$ ,  $33.1 \text{ W m}^{-2}$  and 0.95,  
35 respectively. These error metrics at the CMA radiation stations were  $2.1 \text{ W m}^{-2}$ ,  $26.9$   
36  $\text{W m}^{-2}$  and 0.95, respectively. Comparisons with other global satellite radiation  
37 products indicated that our SSR estimates were generally better than those of the  
38 ISCCP flux dataset (ISCCP-FD), the global energy and water cycle experiment  
39 surface radiation budget (GEWEX-SRB), and the Earth's Radiant Energy System  
40 (CERES). Our SSR dataset will contribute to the land-surface process simulations and  
41 the photovoltaic applications in the future. The data set is available  
42 at <https://doi.org/10.11888/Meteoro.tpsc.270112> (Tang, 2019).

43 **Keywords:** Surface solar radiation; Global product; High-resolution; Parameterization

45 **1. Introduction**

46 Surface solar radiation (SSR), which drives the energy, water and carbon cycles  
47 of Earth's system, is the driving input for simulations of hydrology, ecology,  
48 agriculture and land-surface processes (Wild, 2009; Wang et al., 2012). The accuracy  
49 of SSR data influences simulations of runoff, gross primary productivity,  
50 growth and yield of crops, and land data assimilation (Wild, 2012; Jia et al., 2013).  
51 SSR is also an important variable that affects the speed of glacier melting (Yang et al.  
52 2011). Variations of SSR also affect the rate of global warming and the change of pan  
53 evaporation (Wild, et al., 2007; Qian et al., 2006).

54 Information on the spatiotemporal distribution of SSR is fundamental for  
55 selection of sites for solar power plants, decisions on energy policy, optimization of  
56 solar power systems, and operations management (Mondol et al., 2008; Sengupta et al.,  
57 2018). To address issues such as these, historical SSR data has been obtained mainly  
58 through ground-based observations, station-based estimates, and satellite-based  
59 retrievals (Pinker & Laszlo, 1992; Li and Leighton, 1993; Liang et al., 2006; Zhang et  
60 al., 2004; Wang et al. 2011; Huang et al., 2011; Kato et al., 2013; Ma & Pinker, 2012;  
61 Zhang et al., 2014; Wang et al., 2015; Niu and Pinker, 2015).

62 Measurement by accurately calibrated and well-maintained radiometer of  
63 pyranometer is the most effective method to obtain reliable long-term SSR data.  
64 Although these data are valuable for simulations of land surface processes, solar  
65 power applications and evaluation of satellite retrievals (Sengupta et al., 2018), the  
66 high cost of maintaining radiation radiometers means that networks of radiation  
67 stations are too sparsely distributed. However, networks of routine meteorological  
68 stations are denser than those of radiation stations, and the variables observed at  
69 routine meteorological stations can be used to estimate SSR. For example, based on

70 sunshine duration data, Tang et al. (2013, 2018) constructed long-term datasets of  
71 both daily global radiation and direct radiation over China at more than 2400 routine  
72 meteorological stations of the China Meteorological Administration (CMA). These  
73 datasets are generally more accurate than those derived from satellite retrievals (Yang  
74 et al., 2010). However, station-based estimates of SSR can be conducted only at  
75 routine weather stations, many of which are sparsely distributed, often in remote  
76 regions and harsh environment.

77 Alternatively, remote sensing retrievals based on satellites can provide reliable  
78 spatiotemporally continuous SSR data, either globally or regionally. **The many**  
79 **methods that have been developed to retrieve SSR from satellite data can be roughly**  
80 **divided into two categories: statistical methods and methods based on radiative**  
81 **transfer processes (Huang et al., 2019). According to Sengupta et al. (2018), these**  
82 **methods can also be subdivided into three types: empirical, semi-empirical and**  
83 **physical.**

84 Empirical methods build function relationships between SSR measured at limited  
85 numbers of stations and satellite data by applying regression or artificial intelligence  
86 technology (Lu et al., 2011; Wei et al., 2019). Empirical methods may work well at  
87 some locations, but the ability to expand their coverage to broader regions is limited.

88 Semi-empirical methods generally combine a physical model for clear-sky  
89 conditions with an empirical scheme for cloudy conditions. A well-known  
90 semi-empirical method is the Heliosat method of Cano et al. (1986), from which  
91 several improved versions have since been developed (Hammer et al., 2003; Mueller  
92 et al., 2009; Posselt et al., 2012; and Wang et al., 2014).

93 Physical methods are generally well-suited to generalization because they take  
94 into account the physics processes of transfer of solar radiation from the top of the

95 atmosphere to the Earth's surface. The look-up table (LUT) and physical  
96 parameterization methods (Pinker & Laszlo, 1992; Liang et al., 2006; Lu et al, 2010;  
97 Qin et al., 2015; Xie et al., 2016; Huang et al., 2018) are two typical physical methods  
98 that were widely used to estimate SSR from satellite data.

99 Several well-known global SSR datasets have been produced by physical  
100 methods. These include the global energy and water cycle experiment surface  
101 radiation budget (GEWEX-SRB, Pinker and Laszlo, 1992), the International Satellite  
102 Cloud Climatology Project flux dataset (ISCCP-FD, Zhang et al., 2004) and the  
103 Earth's Radiant Energy System (CERES) radiation products (Kato et al., 2013).  
104 Although each of these have been widely used in various fields, the spatial resolutions  
105 ( $\geq 100$  km) of these SSR products is too coarse to meet the requirements of  
106 high-resolution SSR data. A high-resolution (5 km, 3 hours) global SSR product of  
107 the Global Land Surface Satellite (GLASS) were recently released, but it contains  
108 data spanning only three years (Zhang et al., 2014). The GLASS SSR products were  
109 retrieved by a look-up table method with the visible band top-of-atmosphere (TOA)  
110 radiance from multi-source geostationary and polar-orbiting satellite data. Tang et al.  
111 (2016) also produced a high-resolution SSR product (5 km, 1 hour) by combining data  
112 from polar-orbit and geostationary satellites, but the product covers only China and  
113 the dataset spans only eight years.

114 The greatest uncertainty in satellite retrievals of SSR is the lack of a high-quality  
115 cloud product, which severely limits the development of high-resolution, long-term  
116 global satellite SSR products. However, the release in 2017 of new, global, long-term  
117 ISCCP H-series cloud products at a spatial resolution of about 10 km has provided an  
118 opportunity to develop a long-term high-resolution global-scale climate dataset of  
119 SSR.

120 We developed a global-scale 16-year dataset (2000-2015) of SSR data from the  
121 new ISCCP H-series cloud products and ERA5 reanalysis data, validated the accuracy  
122 of this dataset with surface observations, and compared its performance with other  
123 global satellite products. Section 2 introduces the method we used to estimate SSR.  
124 Section 3 describes the input data we used for SSR estimation and the observations  
125 data used for SSR validation. In Section 4, we presented our evaluation of the SSR  
126 product and compared it with other satellites products. Data availability is given in  
127 Section 5, and Section 6 presents some conclusions and explores future work to  
128 further improve SSR products.

129

## 130 **2 Estimation of SSR**

131 The method we used to estimate SSR with ISCCP H-series cloud data is mainly  
132 based on the SUNFLUX scheme, which was developed by Sun et al. (2012; 2014) and  
133 first used by Tang et al. (2017) to retrieve SSR data from Moderate Resolution  
134 Imaging Spectroradiometer (MODIS) atmospheric and land products. Their validation  
135 of their results against measurements at BSRN stations indicated a mean root mean  
136 square error (RMSE) of  $\sim 90 \text{ W m}^{-2}$  for instantaneous SSR. Although Tang et al.  
137 (2017) achieved higher accuracy than we did in this study (because the MODIS cloud  
138 products they used are generally of better quality than the ISCCP H-series cloud data),  
139 the instantaneous SSR they retrieved is slightly overestimated at most stations because  
140 the original method they used only considers the effect of aerosol scattering on SSR,  
141 but ignores the effect of aerosol absorption. To overcome this issue, we replaced the  
142 aerosol parameterization scheme used by Tang et al. (2017) with that used by Qin et  
143 al. (2015) and Tang et al. (2016). The resultant method is a pure physical  
144 parameterization scheme with an efficient calculation speed. The inputs to the method

145 include cloud optical depth (COD) in the visible band, cloud cover, aerosol optical  
146 depth (AOD), surface pressure, precipitable water, total ozone, surface albedo, and  
147 carbon dioxide concentration (fixed at 375 ppm by volume). Detailed information  
148 about the method is provided by Tang et al. (2017) and Tang et al. (2016).

149

## 150 **3 Data**

### 151 **3.1 Input data**

152 To produce the 16-years SSR products at global scale, we used three types of  
153 input data.

154 The first of these was the level 2 ISCCP H-series cloud product HXG (H-series  
155 pixel-level global, here called ISCCP-HXG), which is a globally merged product  
156 generated based on the HGS (H-series gridded by satellite) product. The resolutions of  
157 HXG are 3 h and 10 km, and the HXG cloud products are available for the period  
158 from July 1983 to December 2015. Note that the ISCCP-HXG data are  $0.1^\circ$  gridded  
159 snapshots (or instantaneous) available every 3 h not the average value over 3 h. More  
160 information about the ISCCP-HXG cloud product is provided by Young et al. (2018).  
161 Four variables were used in the ISCCP- HXG cloud product: cloud mask, VIS  
162 retrieved liquid cloud optical depth, VIS retrieved ice cloud optical depth and cloud  
163 top temperature. The cloud mask was used to distinguish clear-sky pixels from cloudy  
164 pixels and the cloud top temperature was used to distinguish liquid cloud and ice  
165 cloud. **In the ISCCP H-series cloud product, cloud types are roughly defined by two  
166 phases (liquid and ice), which are determined by cloud top temperature (TC) with  
167 liquid for  $TC \geq 253.1$  K, and ice for  $TC < 253.1$  K.**

168 The second data type we used was the new ERA5 reanalysis data. Three  
169 variables of the ERA5 reanalysis data were used: surface pressure, total column water

170 vapor and total column ozone. The resolutions of the ERA5 reanalysis data are 1 h  
171 and 25 km. To derive the same spatial resolution as the ISCCP- HXG cloud product,  
172 we re-sampled the three variables of ERA5 reanalysis data to a spatial resolution of 10  
173 km.

174 The third data type comprised aerosol and albedo data. The MODIS aerosol  
175 (MOD08\_D3 or MYD08\_D3) and albedo (MCD43A3, Schaaf et al., 2002) daily  
176 products were used. The MODIS AOD product of the combined dark target and deep  
177 blue AOD at 0.55 micron for land and ocean was used. MOD and MYD denote  
178 product obtained from Terra and Aqua platforms, respectively, and MCD indicates a  
179 combined product processed from both platforms (King et al., 2003). The spatial  
180 resolution of MODIS aerosols and albedo data are about 100 km and 5 km,  
181 respectively, so we re-sampled them both to 10 km. To match the temporal of ISCCP  
182 HXG products, we re-sampled MODIS aerosols and albedo to 3 hour by assuming  
183 that their values are constant within a day. Missing values in the MODIS aerosol and  
184 albedo products (included the period of 1 Jan 2000 to 23 Feb 2000) were replaced  
185 with the corresponding values of monthly mean climatological data. Note that the use  
186 of climatological data to replace the real information of aerosol and albedo would  
187 have introduced some uncertainty. Thus, care should be taken when using the SSR  
188 dataset we derived for trend analysis.

189

### 190 **3.2 Validated data**

191 In this study, we used radiation observations made in 2009 to validate the  
192 accuracy of the global-scale SSR estimate. These radiation observations were  
193 collected at two networks. The first set was the radiation observations (with temporal  
194 resolution of 1 minute) measured at 42 stations of Baseline Surface Radiation

195 Network (BSRN, Ohmura et al, 1998), which were marked as red crosses in Figure 1.  
196 Radiation observations measured at BSRN stations are regarded as the most reliable  
197 radiation data due to the instruments of highest available accuracy and careful  
198 maintenance (see website: <https://bsrn.awi.de/>). To reduce uncertainty caused by  
199 cosine response error of the pyranometers, we did not use the measured global  
200 radiation data; instead we used the total of the measured direct and diffuse radiation to  
201 evaluate the accuracy of the retrieved SSR.

202 The second set was the daily radiation observations measured at 90 CMA  
203 radiation stations, which were denoted by black circles in Figure 1. Though the  
204 pyranometers used to measure global radiation at CMA radiation stations were  
205 calibrated by a series of standard procedures (Yang et al., 2008), the observed  
206 radiation data collected at CMA radiation stations frequently include questionable  
207 values, which may have been a result of improper operation of instruments and/or  
208 instrument defects (Shi et al., 2008). To reduce the uncertainty caused by the  
209 questionable radiation data, we used a quality-check procedure (Tang et al. 2010) to  
210 exclude the spurious and erroneous measurements. **The quality-check procedure**  
211 **consists of two steps. One is the physical threshold test to eliminate the obvious errors,**  
212 **and the other is the statistical test using artificial neural network method to eliminate**  
213 **the more insidious errors. More detailed information about the two-steps procedure**  
214 **can be found in the article of Tang et al. (2010).**

215

## 216 **4 Results and Discussion**

### 217 **4.1 Validation of estimated SSR against observations at BSRN stations**

218 Firstly, the estimated SSR were validated against the observations measured at  
219 the 42 BSRN stations at both instantaneous and daily scales. To reduce the

220 uncertainties induced by broken clouds, we validated the estimated instantaneous SSR  
221 against hourly mean observed ones centered on the time of satellite overpass,  
222 according to the suggestion of Wang and Pinker (2009). To examine the effect of  
223 different spatial resolutions on the accuracy of our SSR estimates, in addition to the  
224 10 km spatial resolution, we also evaluated our estimated SSR at spatial resolutions of  
225 30, 50, 70, 90 and 110 km derived by averaging the SSR values observed at the  
226 original scale of 10 km.

227 Accuracy for instantaneous SSR at 90 km scale ( $RMSE = 93.4 \text{ W m}^{-2}$ ,  $R = 0.95$ ;  
228 Fig. 2, Table 1) was clearly superior to that at 10 km scale ( $RMSE 113.5 \text{ W m}^{-2}$ ,  $R =$   
229  $0.92$ ), which may indicate that the surface observation points are generally  
230 representative of more than 10 km, especially under cloudy conditions. Another  
231 possible reason for this phenomenon would be caused by the time mismatch between  
232 satellite observation and surface observation because the satellites do not take  
233 instantaneous snapshots of the entire Earth. Generally, the last generation  
234 geostationary satellites, such as the Geostationary Operational Environmental Satellite  
235 (GOES), take about 30 min to scan the entire Earth. The averaging inherent in  
236 upscaling of spatial resolution would tend to decrease these time mismatches.

237 To further illustrate this issue, the performances of our instantaneous SSR with  
238 different spatial resolutions at the 42 BSRN stations were given in Table 1, which  
239 suggests that the accuracy was clearly improved when the data were upscaled to 30  
240 km, with a further slight improvement at 70 km, but that accuracy started to decrease  
241 at 90 km. The performance of the ISCCP-FD was also presented in Table 1.  
242 Apparently, the accuracy of our estimated instantaneous SSR is significantly higher  
243 than that of the ISCCP-FD. A further advantage of our dataset is that its spatial  
244 resolution is far higher than that of the ISCCP-FD products.

245 Figure 3 shows the spatial distribution of RMSE for the estimated instantaneous  
246 SSR (spatial resolution 90 km) at all individual BSRN stations. The RMSE was  $< 90$   
247  $\text{W m}^{-2}$  at 30 of the 42 BSRN stations. RMSE values were between 90 and  $105 \text{ W m}^{-2}$   
248 at five stations and  $> 105 \text{ W m}^{-2}$  at seven stations. The 12 stations where RMSE  
249 values were  $\geq 90 \text{ W m}^{-2}$  are generally in coastal areas, on islands and in the  
250 Antarctic polar region. Part of the reasons for these large error are the same as that  
251 explained by Tang et al. (2017), who estimated instantaneous SSR with MODIS  
252 level-2 land and atmospheric products. For example, the large RMSE value for station  
253 IZA can be attributed to the poor representativeness of the station, which is located on  
254 a mountain top, and this station point can not represent the satellite observations.  
255 Another reason for the large RMSE values may be the uncertainties contained in the  
256 inputs, especially uncertainties in cloud and aerosol data. The great uncertainties for  
257 the MODIS AOD retrieval over coastal or island stations (Anderson et al, 2013)  
258 would lead to large RMSE values at these stations. The large errors for the two  
259 Antarctic stations (SYO and GVN) may reflect failure of cloud detection, which is  
260 difficult over Antarctica region because the similarity of the properties of cloud and  
261 surfaces snow over the Antarctica Pole, and because the temperature of cloud is  
262 generally not lower than that of surface snow (Zhang et al. 2013).

263 Figure 4 presents the validation results for our estimated daily SSR at 42 BSRN  
264 stations. The MBE values were  $-6.1$  and  $5.8 \text{ W m}^{-2}$  for spatial resolutions of 10 and 90  
265 km, respectively. The RMSE for 10 km was  $38.0 \text{ W m}^{-2}$ , and its value was decreased  
266 to  $33.1 \text{ W m}^{-2}$  for 90 km. The  $R$  for 10 km was 0.93 and its value was increased to  
267 0.95 for 90 km. Table 2 also lists the performances of our daily SSR estimate with  
268 different spatial resolutions and the performance of the ISCCP-FD daily SSR product.  
269 Our estimates of daily SSR at all spatial resolutions were clearly more accurate than

270 that of ISCCP-FD, and they obviously improved when upscaled to more than 30 km.

271 The spatial distribution of RMSE for our estimated daily SSR at spatial  
272 resolution of 90 km (Fig. 5) showed that RMSE at most of the 42 BSRN stations were  
273  $<35 \text{ W m}^{-2}$ , although there were four stations with RMSE between 35 and  $40 \text{ W m}^{-2}$   
274 and six with RMSE  $>40 \text{ W m}^{-2}$ . These higher RMSE values may be attributed to lack  
275 of representativeness for some stations, errors in the inputs and uncertainty of the  
276 algorithm, similar to the reasons for the higher errors in our estimates of instantaneous  
277 SSR.

278 GEWEX-SRB and CERES are two other well-known and widely used global  
279 satellite radiation products. Zhang et al. (2013; fig. 8) evaluated the performance of  
280 GEWEX-SRB SSR products with the mean 3-h observed data from the BSRN and  
281 found that RMSEs for the instantaneous and daily SSR of GEWEX-SRB were 88.3  
282 and  $35.5 \text{ W m}^{-2}$ , respectively. To compare our results with those derived from  
283 GEWEX-SRB by Zhang et al. (2013), we re-evaluated our estimated SSR with the  
284 mean 3-h observed data from the BSRN. The RMSEs for our estimated instantaneous  
285 and daily SSR at 10 km spatial resolution were 108.1 and  $36.5 \text{ W m}^{-2}$ , respectively,  
286 both of which are greater than those of GEWEX-SRB. However, when we upscaled our  
287 estimated SSR to 90 km scale, RMSEs for our instantaneous and daily SSR were  
288 lower, 82.4 and  $30.6 \text{ W m}^{-2}$ , respectively, indicating that our estimates of SSR were  
289 more accurate than those of GEWEX-SRB at the same spatial resolution. We also  
290 compared the performance of our estimates of SSR with that of CERES  
291 (SYN1deg\_Ed4A, Fig. 6). The accuracies of CERES were generally higher than those  
292 of ISCCP-FD at both instantaneous and daily scales, but obviously lower than those  
293 of our estimates at all spatial resolutions from 10 to 110 km (Fig. 6 and Table 2).

294 Thus, our estimated SSR based on ISCCP-HXG cloud products provided a more

295 accurate, higher spatial resolution dataset than those of ISCCP-FD, GEWEX-SRB and  
296 CERES products.

297

#### 298 **4.2 Validation of estimated SSR against observations at 90 CMA radiation** 299 **stations**

300 Our estimated SSR were further evaluated against the observations collected at  
301 the 90 CMA radiation stations at both daily and monthly scales. Figure 7 presents the  
302 validation results for the estimated daily SSR at spatial resolutions of 10 and 90 km.  
303 The MBE, RMSE and  $R$  for our estimated daily SSR at 10 km spatial resolution were  
304  $1.8 \text{ W m}^{-2}$ ,  $32.4 \text{ W m}^{-2}$  and 0.93, respectively. Accuracy clearly improved for spatial  
305 resolutions up to 90 km, for which the corresponding metrics were  $2.1 \text{ W m}^{-2}$ ,  $26.9 \text{ W}$   
306  $\text{m}^{-2}$  and 0.95. The RMSE for our estimate of daily SSR at 10 km spatial resolution is  
307 comparable to that of GEWEX-SRB daily SSR, which was also validated against  
308 observations at the CMA radiation stations (RMSE  $32.2 \text{ W m}^{-2}$ ; see figure 7b of Qin  
309 et al., 2015). However, the RMSE for the GEWEX-SRB daily SSR is clearly higher  
310 than that of our estimate of daily SSR at 90 km spatial resolution, thus indicating that  
311 the accuracy of our daily SSR estimates is superior to that of the GEWEX-SRB daily  
312 SSR product at the same spatial resolution.

313 Table 3 shows that the accuracy of our estimates of daily SSR clearly improved  
314 when upscaled to 30 km spatial resolution and were most accurate at 90 km spatial  
315 resolution. RMSE and  $R$  ( $36.5 \text{ W m}^{-2}$  and 0.91, respectively) for daily SSR of  
316 ISCCP-FD show that our estimates are more accurate at all spatial resolutions. The  
317 spatial distribution of RMSE for our daily SSR estimate at 90 km spatial resolution  
318 was also given in Figure 8. Only nine CMA stations had  $\text{RMSE} > 35 \text{ W m}^{-2}$  (Fig. 8);  
319 most of these stations are in southern China where there is generally more cloud and

320 its distribution is more complicated than in other parts of China (Yu et al., 2001).

321 Figure 9 presents the validation results for our estimated monthly SSR. The MBE,  
322 RMSE and  $R$  for our estimated monthly SSR at 10 km spatial resolution were 1.9 W  
323  $\text{m}^{-2}$ , 16.3 W  $\text{m}^{-2}$  and 0.97, and the corresponding values for 90 km were changed to  
324 2.2 W  $\text{m}^{-2}$ , 14.9 W  $\text{m}^{-2}$  and 0.97. It can be clearly seen that the accuracy of the  
325 ISCCP-FD monthly SSR are inferior to our estimated monthly SSR at scales from 10  
326 to 110 km (Table 4).

327 The performances for CERES daily and monthly SSR were evaluated against  
328 observations at the 90 CMA radiation stations (Fig. 10) and also compared with  
329 those of our estimates from ISCCP-HXG (Table 4). The MBEs for CERES daily and  
330 monthly SSR were greater than those of our estimates at all scales, and the RMSE  
331 for CERES daily SSR was slightly smaller than that of our estimates at 10 km spatial  
332 resolution, but obviously greater than our estimates at spatial resolutions from 30 to  
333 110 km. The RMSE for CERES monthly SSR was greater than those of our  
334 estimates at all scales. Thus, the accuracy of our estimates is generally higher than  
335 that of CERES.

336

### 337 **4.3 Spatial distribution of the annual SSR**

338 Figure 11 presents the comparison of the global distribution of the annual mean  
339 SSR in 2009 between our retrievals and the ISCCP-FD SSR product. From the figure,  
340 it can be seen that the global distribution for our SSR estimate based on the ISCCP-  
341 HXG cloud products is almost the same as that of the ISCCP-FD SSR product, but the  
342 spatial resolution of our estimate is far higher than that of ISCCP-FD. There  
343 is no doubt that we can get more details than the coarse resolution product ISCCP-FD  
344 can not capture. For example, the region of high SSR clearly identified over the

345 Tibetan Plateau by our estimate (Fig. 11a) is barely discernible in the  
346 ISCCP-FD-derived data (Fig. 11b). The high values are mainly from  
347 around the equator and the low latitudes, and the low values mainly over the high  
348 latitudes and the Arctic and Antarctic regions. This phenomenon is primarily  
349 determined by the solar elevation angle. In addition, the relatively high values are also  
350 found over the Bolivian Plateau, the Tibetan Plateau, and other high altitude regions  
351 due to less radiative extinction over high altitudes.

352

### 353 **5 Data availability**

354 The 16-year dataset of global SSR is available at the National Tibetan Plateau  
355 Data Center (<https://doi.org/10.11888/Meteoro.tpdc.270112>, Tang, 2019), Institute of  
356 Tibetan Plateau Research, Chinese Academy of Sciences.

357

### 358 **6 Conclusions and Future work**

359 This study produced a 16-year (2000-2015) global dataset of SSR (with  
360 resolutions of 3 h and 10 km) based on recently updated ISCCP H-series cloud  
361 products, new ERA5 reanalysis data and MODIS albedo and aerosol products with a  
362 physically based scheme. The retrieved SSR dataset was evaluated globally with  
363 observations collected at BSRN and CMA radiation stations. Validation against  
364 observations collected at BSRN showed that the MBE and RMSE were  $-11.5$  and  
365  $113.5 \text{ W m}^{-2}$  for the instantaneous SSR estimates, and  $-6.1$  and  $38.0 \text{ W m}^{-2}$  for the  
366 daily SSR estimates, but their accuracies were clearly improved when upscaled to  
367 more than 30 km. For example, the RMSEs were decreased to  $93.4$  and  $33.1 \text{ W m}^{-2}$   
368 when our estimates were upscaled to 90 km. Validation against observations collected  
369 at CMA indicated that our estimates of daily and monthly SSR produced RMSE

370 values of 32.4 and 16.3 W m<sup>-2</sup>, respectively, but these values were decreased to 26.9  
371 and 14.9 W m<sup>-2</sup> when our estimates were upscaled to 90 km. Comparisons with other  
372 global satellite SSR products indicated that the accuracies of our SSR estimates were  
373 clearly higher than those of GEWEX-SRB, ISCCP-FD and CERES products.

374 The spatial resolution and accuracy of the new dataset are both higher than those  
375 of the global satellite radiation products of GEWEX-SRB, ISCCP-FD, and CERES  
376 and will contribute to photovoltaic applications and research related to simulation of  
377 land surface processes. When reliable global aerosol and albedo datasets become  
378 available, we intend to expand our dataset of SSR estimates back to mid-1983. We  
379 also plan to expand the dataset beyond 2015 by using SSR estimates from  
380 new-generation geostationary satellites.

381

382 **Author contributions.** All authors discussed the results and contributed to the  
383 manuscript. WT calculated the dataset, analyzed the results, and drafted the  
384 manuscript.

385

386 **Competing interests.** The authors declare that they have no conflict of interest.

387

388 **Acknowledgments.** The CMA radiation station data were obtained from the National  
389 Meteorological Information Center (NMIC) and. The ISCCP-HXG cloud products  
390 were obtained from the NOAA's National Centers for Environmental Information  
391 (NCEI). The ERA5 reanalysis data and MODIS albedo and aerosol data were  
392 downloaded from official websites (<https://www.ecmwf.int> and  
393 <https://ladsweb.modaps.eosdis.nasa.gov>). The authors would like to thank the  
394 Baseline Surface Radiation Network (BSRN) observation teams for their maintenance

395 work.

396

397 **Financial support.** This work was supported by the National Key Research and  
398 Development Program of China (Grants No. 2018YFA0605400 and  
399 2017YFA0603604), the National Natural Science Foundation of China (Grants No.  
400 41671372), the Youth Innovation Promotion Association CAS (No. 2017100),  
401 and the 13th Five-year Informatization Plan of Chinese Academy of Sciences  
402 (Grant No. XXH13505-06), and the Strategic Priority Research Program of Chinese  
403 Academy of Sciences (Grant No.XDA20100102).

637 **Figure 1** Distribution of radiation measurement stations used to evaluate the  
638 performance of the estimated SSR. The blue circles mark the locations of  
639 the 90 CMA radiation stations, and the red crosses mark those of the 42  
640 BSRN stations. Note that two stations (labeled as DAR and DWN) in  
641 Australia and two stations (labeled as BIL and E13) in America are very  
642 close to each other.

643 **Figure 2** Comparisons of our estimated instantaneous SSR at spatial resolutions of (a)  
644 10 km and (b) 90 km with observed SSR for 42 BSRN stations.

645 **Figure 3** Spatial distribution of RMSE ( $W m^{-2}$ ) for our estimated instantaneous SSR  
646 (spatial resolution 90 km) at 42 BSRN stations.

647 **Figure 4** Comparisons of our estimated daily SSR at spatial resolutions of (a) 10 km  
648 and (b) 90 km with observed SSR for 42 BSRN stations.

649 **Figure 5** Spatial distribution of RMSE ( $W m^{-2}$ ) for our estimated daily SSR (spatial  
650 resolution 90 km) at 42 BSRN stations.

651 **Figure 6** Comparison of CERES SSR products with observed SSR at 42 BSRN  
652 stations for both (a) instantaneous and (b) daily scales.

653 **Figure 7** Comparisons of our estimated daily SSR at spatial resolutions of (a) 10 km  
654 and (b) 90 km with observed SSR at 90 CMA radiation stations.

655 **Figure 8** Spatial distribution of RMSE ( $W m^{-2}$ ) for our estimated daily SSR (spatial  
656 resolution 90 km) at 90 CMA radiation stations.

657 **Figure 9** Comparisons of our estimated monthly SSR at spatial resolutions of (a) 10  
658 km and (b) 90 km with observed monthly SSR at 90 CMA radiation  
659 stations.

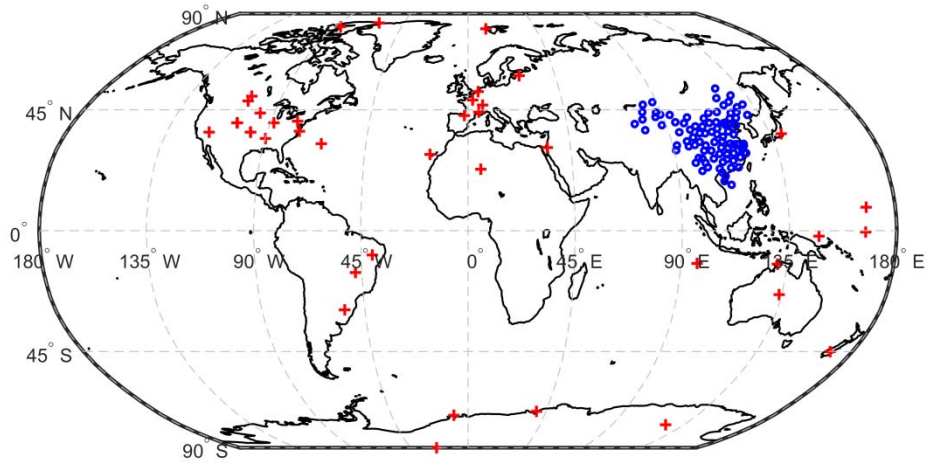

660 **Figure 10** Comparison of CERES (a) daily and (b) monthly SSR products with those

661 observed at 90 CMA stations.

662 **Figure 11** Spatial distribution of global annual mean SSR ( $\text{W m}^{-2}$ ) of (a) ISCCP-HXG

663 and (b) ISCCP-FD in 2009.

664

665

666 **Figure 1** Distribution of radiation measurement stations used to evaluate the  
 667 performance of the estimated SSR. The blue circles mark the locations of  
 668 the 90 CMA radiation stations, and the red crosses mark those of the 42  
 669 BSRN stations. Note that two stations (labeled as DAR and DWN) in  
 670 Australia and two stations (labeled as BIL and E13) in America are very  
 671 close to each other.

712

713 **Figure 10** Comparison of CERES (a) daily and (b) monthly SSR products with those

714 observed at 90 CMA stations.

715

716

717

718 **Figure 11** Spatial distribution of global annual mean SSR ( $\text{W m}^{-2}$ ) of (a) ISCCP-HXG  
 719 and (b) ISCCP-FD in 2009.

720

721

722 **Table 1.** Effect of spatial resolution on accuracy of our estimated instantaneous SSR  
 723 compared to observations at the 42 BSRN stations. A comparisons with  
 724 instantaneous SSR of ISCCP-FD is also shown.

	Spatial resolution	MBE ( $\text{W m}^{-2}$ )	RMSE ( $\text{W m}^{-2}$ )	<i>R</i>
ISCCP-HXG	10 km	-11.5	113.5	0.92
ISCCP-HXG	30 km	-11.0	96.5	0.94
ISCCP-HXG	50 km	-11.3	93.5	0.95
ISCCP-HXG	70 km	-11.3	93.2	0.95
ISCCP-HXG	90 km	-11.1	93.4	0.95
ISCCP-HXG	110 km	-11.4	94.3	0.95
ISCCP-FD	280 km	-11.2	131.4	0.89

725

726 **Table 2.** Effect of spatial resolution on accuracy of our estimated daily SSR compared  
 727 to observations at 42 BSRN stations. A comparisons with daily SSR of  
 728 ISCCP-FD is also shown.

	Spatial resolution	MBE ( $\text{W m}^{-2}$ )	RMSE ( $\text{W m}^{-2}$ )	R
ISCCP-HXG	10 km	-6.1	38.0	0.93
ISCCP-HXG	30 km	-5.8	33.9	0.94
ISCCP-HXG	50 km	-6.0	33.4	0.95
ISCCP-HXG	70 km	-5.9	33.3	0.95
ISCCP-HXG	90 km	-5.8	33.1	0.95
ISCCP-HXG	110 km	-6.0	33.4	0.95
ISCCP-FD	280 km	-6.7	51.0	0.87

729

730 **Table 3.** Effect of spatial resolution on accuracy of our estimated daily SSR compared  
 731 to observations at 90 CMA radiation stations. A comparison with daily SSR  
 732 of ISCCP-FD is also shown.

	Spatial resolution	MBE ( $\text{W m}^{-2}$ )	RMSE ( $\text{W m}^{-2}$ )	R
ISCCP-HXG	10 km	1.8	32.4	0.93
ISCCP-HXG	30 km	2.1	28.5	0.95
ISCCP-HXG	50 km	2.2	27.4	0.95
ISCCP-HXG	70 km	2.2	27.1	0.95
ISCCP-HXG	90 km	2.1	26.9	0.95
ISCCP-HXG	110 km	2.1	26.9	0.95
ISCCP-FD	280 km	-1.2	36.5	0.91

733

734 **Table 4.** Effect of spatial resolution on accuracy of our estimated monthly SSR  
 735 compared to observations at 90 CMA radiation stations. A comparison with  
 736 monthly SSR of ISCCP-FD data is also shown.

	Spatial resolution	MBE ( $\text{W m}^{-2}$ )	RMSE ( $\text{W m}^{-2}$ )	R
ISCCP-HXG	10 km	1.9	16.3	0.97
ISCCP-HXG	30 km	2.2	15.3	0.97
ISCCP-HXG	50 km	2.2	15.0	0.97
ISCCP-HXG	70 km	2.2	14.9	0.97
ISCCP-HXG	90 km	2.2	14.9	0.97
ISCCP-HXG	110 km	2.1	14.8	0.97
ISCCP-FD	280 km	-1.3	20.0	0.95
