

Response to Reviewer 2's comments

Re: Manuscript essd-2020-16

Earth System Science Data

2020-06-24

Dear Reviewer,

Thank you very much for your time and efforts in reviewing our manuscript and providing encouraging and constructive comments. We have carefully revised the manuscript following your comments/suggestions. The comments are in *italic* and each comment is followed by a response and a description of the tracked change in the manuscript.

With best regards,

Sincerely,

Lei Wang, Dr., Prof.

Key Lab. of Tibetan Environmental Changes and Land Surface Processes,

Institute of Tibetan Plateau Research, Chinese Academy of Sciences

No. 16 Lincui Road, Chaoyang District, Beijing 100101, China

Tel: +86-10-84097107 Fax: +86-10-84097079

Email: wanglei@itpcas.ac.cn

General comment:

Comment 1: *In the paper, the authors integrated five satellite/reanalysis data to generate a new precipitation dataset set in the Yarlung Tsangpo basin in South Tibetan Plateau (TP). Actually, the issue is important for the hydrological studies in TP including this study area, but it is also a difficult issue, as there lacks enough observed data. The authors did a good try to generate this precipitation dataset, and it would be useful for the relevant studies in the basin. Overall, I suggest the authors consider more the following issues before its acceptance.*

Response: Many thanks for your constructive comments. We have revised the manuscript accordingly following your kind suggestions.

Detailed Comments:

Comment 1: *The authors assumed that daily precipitation conforms to a normal distribution. However, precipitation data generally follow skew distribution. The reasonability of this assumption should be discussed more.*

Response: Of course, the assumption of a normal distribution may lead to uncertainty when analyzing extremely high daily precipitation. Generally, the non-normal (skewed) distribution of precipitation is caused by the zero rainfall events at single observational site (Kumar et al., 2009; Semenov, 2008; Slougher et al., 2007). We calculated the average values of the observed precipitation from 166 rain gauges to reduce the zero rainfall values. Another associated problem is the quantity and reliability of the data that are used to fit the distribution. If we use different probability distributions to describe the observed time series of daily precipitation, different extreme values may be obtained (Angelidis et al., 2012). This study provides a foundation from which further studies can be carried out to explore these aspects in more detail.

Change: We have added discussions and references in the revised manuscript (L360-L366).

Comment 2: *Some contents can be added to discuss more about the altitude effects on the quality of the new precipitation data, especially on the IDW practices, although some discussions have been given in Conclusions.*

Response: Thank you for the comments. Generally, these rain gauges were installed at relatively plain area, which may lead to large uncertainty in estimating precipitation (rain or snow) at high mountains, especially in the daily or finer time scales (Ahrens, 2006; Haiden and Pistotnik, 2009). This limitation can be even more severe, due to the orographic effect on precipitation rates, in mountainous regions and transition zones between the low and high altitudes, which will results in the underestimates of the actual basin-wide precipitation (Anders et al., 2006; Hashemi et al., 2020).

Regarding the IDW practices, on the one hand, most of the studied operational precipitation products have already dealt with the altitude effects during data production, and thereby we didn't repeatedly consider the altitude effects when interpolating and integrating these products into 5 km grids with the IDW method. On the other hand, the available gauges (number and distribution) are still far from enough to derive a reasonable spatial distribution of basin-wide altitude gradient for precipitation, due to the complex topography in the study area.

Change: We have added discussions and references in the revised manuscript (L347-L356).

- Hashemi, H., Fayne, J.V., Lakshmi, V., and Huffman, G.J.: *Very high resolution,*

altitude-corrected, TMPA-based monthly satellite precipitation product over the CONUS. Sci. Data, 7(1), 2020.

Comment 3: *In lines 252-253, it is interesting to find that the weights become smaller with time periods, why? Is it due more reliable quality of the five datasets in recently years? or due to more observed data used? Some contents can be added to simply explain this.*

Response: We finally adopted the same weight of each product through the trial-and-error method. Table 1 lists the time ranges of different precipitation products, which are very different and lead to different weights during different periods. As a result, during 1981-1997 (only GLDAS, ITP-Forcing, MERRA2 are available), the weight of each product is 1/3. Similarly, during 1998-2007 and 2008-2016, the weights of each product are 1/4 and 1/5 respectively.

Table 1. The precipitation products used in this study.

Precipitation products	Time range	Temporal resolution	Spatial resolution
CMA gridded data	2008-2016	hourly	0.1°×0.1°
GLDAS	1981-2016	3-hour	0.25°×0.25°
ITP-Forcing	1981-2016	3-hour	0.1°×0.1°
MERRA2	1981-2016	hourly	0.5°×0.625°
TRMM	1998-2016	3-hour	0.25°×0.25°

Change: We add some descriptions to explain the weight (L252-L257) in the revised manuscript.

Comment 4: *In Figure 6, does the P_{int} have similar PDF as the CMA? Why?*

Response: Yes, the PDF of the P_{int} is the closest to that of CMA. Parameters of the normal distribution for the P_{int} and the CMA data are also very similar, with a mean value of 77.0 and 75.3 mm, a standard deviation of 62.3 and 62.6 mm, respectively.

The advantage of the CMA product is that it has incorporated more gauge observations (including many unpublished ones of CMA). The short time duration may be the demerit of this product, since it is only available from 2008.

For our newly integrated data, we have incorporated valuable observational gauge

data from Ministry of Water Resources (MWR), China. This greatly helps us to calibrate and validate the P_{int} .

Therefore, both of two data products have utilized lots of observational information (that provides the ground truth), which leads to the similar PDF.

Change: There is no relevant change in the manuscript.

Comment 5: *This study area should be called “Yarlung Tsangpo” or “Yarlung Zangbo”? please check it.*

Response: This area can be called as “Yarlung Zangbo” or “Yarlung Tsangpo”, both of which are acceptable since they are transliterated from Tibetan language (also mentioned in Abstract).

Change: There is no relevant change in the manuscript.

22

23 **Abstract:** As the largest river basin of the Tibetan Plateau, the Upper Brahmaputra
24 River Basin (also called “Yarlung Zangbo” in Chinese) has profound impacts on the
25 water security of local and downstream inhabitants. Precipitation in the basin is
26 mainly controlled by the Indian Summer Monsoon and Westerly, and is the key to
27 understand the water resources available in the basin; however, due to sparse
28 observational data constrained by a harsh environment and complex topography, there
29 remains a lack of reliable information on basin-wide precipitation (there are only nine
30 national meteorological stations with continuous observations). To improve the
31 accuracy of basin-wide precipitation data, we integrate various gauge, satellite and
32 reanalysis precipitation datasets, including GLDAS, ITP-Forcing, MERRA2, TRMM
33 and CMA datasets, to develop a new precipitation product for the 1981-2016 period
34 over the Upper Brahmaputra River Basin, at 3-hour and 5-km resolution. The new
35 product has been rigorously validated at different temporal scales (e.g. extreme events,
36 daily to monthly variability, and long-term trends) and spatial scales (point- and
37 basin-scale) with gauge precipitation observations, showing much improved
38 accuracies compared to previous products. An improved hydrological simulation has
39 been achieved (low relative bias: -5.94%; highest NSE: 0.643) with the new
40 precipitation inputs, showing reliability and potential for multi-disciplinary studies.
41 This new precipitation product is openly accessible at
42 <https://doi.org/10.5281/zenodo.3711155> (Wang et al., 2020) and, additionally at the
43 National Tibetan Plateau Data Center (<https://data.tpsc.ac.cn>, login required).

44

45 **1. Introduction**

46 Precipitation plays a very important role in the research of hydrology, meteorology,
47 ecology, and even social economics, as it is a critical input factor for various models
48 (e.g. hydrological and land surface models) (Qi et al., 2016; Wang et al., 2017a; Fang
49 et al., 2019; Miri et al., 2019; Wang et al., 2019a). Specifically, precipitation is a key
50 part of the water balance and energy cycle and will directly impact runoff generation
51 and soil moisture movement (Su et al., 2008). As a result, water resource management
52 tasks such as flood forecasting and drought monitoring, ecological environment
53 restoration (e.g. vegetation growth and protection), and many other scientific and
54 social applications are closely linked with precipitation patterns (Funk et al., 2015).

55 The Tibetan Plateau (TP), known as the highest plateau in the world, is covered by
56 massive glaciers, snow and permafrost, which significantly affect the hydrological
57 processes of all the large rivers that are fed by it; the Brahmaputra, the Salween, and
58 the Mekong, among others. Therefore, it is necessary to explore the hydrological
59 variations over the TP to achieve efficient utilization and protection of its water
60 resources and a better understanding of the effects of climate change on the
61 surrounding region. However, due to the irregular and sparse distribution of national
62 meteorological stations, particularly in the Upper Brahmaputra (precipitation data
63 from only nine stations are available, and are sparsely distributed; see Sang et al.,
64 2016; Cuo et al., 2019), there are large data constraints on research on these
65 hydrological processes and their responses to climate change. Although there are
66 many more rain gauges managed by the Ministry of Water Resources (MWR), most

67 of them are located in middle-stream regions and rainfall datasets are only recorded
68 over short time periods. Simply using the linear mean of these station observations to
69 calculate variations in precipitation for the entire basin is impractical and prone to
70 problems (Lu et al., 2015). Accurate spatial distributions of precipitation are
71 unavailable. This influences the generation of historical runoff data (Mazzoleni et al.,
72 2019), meaning that the specific contributions of glaciers, snow cover, permafrost and
73 vegetation to hydrological processes in this area cannot be analyzed and quantified,
74 posing a threat to regional sustainable development and living conditions (Shen et al.,
75 2010; Guo et al., 2016; Kidd et al., 2017; Shi et al., 2017; Ruhi et al., 2018; Sun et al.,
76 2018).

77 A longer time series of spatially consistent and temporally continuous
78 precipitation products could be used to improve our understanding of feedback
79 mechanisms between different meteorological and hydrological components,
80 especially under the background signal of climate change. Various satellite rainfall
81 products have been widely used in previous studies, such as the National Oceanic and
82 Atmospheric Administration/Climate Prediction Centre (NOAA/CPC) morphing
83 technique (CMORPH) (Ferraro et al., 2000; Joyce et al., 2004), and the Tropical
84 Rainfall Measuring Mission (TRMM) (Huffman et al., 2007). However, there are still
85 problems in estimating daily (Meng et al., 2014; Bai and Liu, 2018) and extreme
86 precipitation (Funk et al., 2015; Zhou et al., 2015b; Fang et al., 2019), especially in
87 mountainous regions with high elevations and fewer ground measurements, such as
88 the Upper Brahmaputra (Xia et al., 2015; Xu et al., 2017; Qi et al., 2018). Additionally,

89 there are several reanalysis datasets that have been widely used by researchers, such
90 as the Global Land Data Assimilation System (GLDAS) (Rodell et al., 2004; Zaitchik
91 et al., 2010; Wang et al., 2011) and the Modern-Era Retrospective analysis for
92 Research and Applications, Version 2 (MERRA2) dataset (Gelaro et al., 2017; Reichle
93 et al., 2017a, 2017b). Evaluation of GLDAS data has generally been limited to the
94 United States and other regions with adequate ground observations (Kato et al., 2007;
95 Qi et al., 2016). Most studies have focused on evapotranspiration, soil moisture and
96 groundwater products derived from GLDAS or MERRA2 (Bibi et al., 2019; Deng et
97 al., 2019; Li et al., 2019a); meanwhile, to the best of our knowledge, there has been
98 less focus on the evaluation of methods of precipitation estimation and little work on
99 the corresponding river discharge simulations within the Upper Brahmaputra River
100 Basin. These precipitation products generally have the advantage of wide and
101 consistent coverage and have shown great potential in many applications (Li et al.,
102 2015; Zhang et al., 2017; Fang et al., 2019), but also suffer from large uncertainties
103 over the Upper Brahmaputra River Basin due to indirect observations, insufficient
104 gauge calibration, and complex topography (Tong et al., 2014; Yong et al., 2015; Xu
105 et al., 2017).

106 In this study, we focus on integrating gauge, satellite and reanalysis precipitation
107 datasets to generate a new dataset over the Upper Brahmaputra, suitable for use in
108 hydrological simulations and other scientific researches related to climate change. The
109 remainder of this study is structured as follows. Section 2 briefly describes the study
110 area, datasets, and methodology used. Section 3 presents and discusses the evaluation

111 results of different products and validates the accuracy and reliability of our integrated
112 dataset. Then Section 4 is the data availability. Finally, conclusions are given in
113 Section 5.

114 **2. Materials and Methods**

115 **2.1. Study Area**

116 This study is conducted in Upper Brahmaputra River Basin (27°-32°N, 81°-98°E)
117 located in the south of the Tibetan Plateau (Figure 1). The Brahmaputra River is an
118 important part of the whole GBM basin (Ganges, Brahmaputra, Meghna) which
119 significant influences the natural resources and social development of the Tibetan
120 Plateau and South Asia. The river is approximately 2,057 km long with a drainage
121 area of 240,000 km². The climatic conditions are complicated by the extremely high
122 altitude and highly varying topography (Wang et al., 2018; Wang et al., 2019b);
123 elevation varies by up to 6,500 m throughout the study region. Generally, the
124 intra-annual distribution of precipitation is extremely uneven, with more precipitation
125 distributed in the warm seasons (Wang et al., 2019a). Since the Indian and East Asian
126 monsoons bring more water vapor in summer and the westerlies dominate in winter
127 (Yi et al., 2013; Wang et al., 2018; Li et al., 2019a, 2019b), there is a declining trend
128 of precipitation from the humid southeast to the arid northwest, on average. In recent
129 decades, the TP has been experiencing a significant warming trend exceeding that in
130 the Northern Hemisphere (Liu and Chen, 2000; Yang et al., 2014), which will affect
131 the generation and distribution of precipitation and influence hydrological processes
132 throughout the Upper Brahmaputra.

133 2.2. Datasets

134 Monthly precipitation data (1981-2016) from nine meteorological stations were
135 obtained from the China Meteorological Administration (CMA), and daily
136 precipitation data (May to October in 2014 and 2016) from 166 rain gauges were
137 accessed through the Ministry of Water Resources (MWR), China (Figure 1). Both of
138 these are regarded as observed precipitation data. Daily river discharge data at Nuxia
139 station (Figure 1) are used to assess the simulation performance when forced by
140 different precipitation products.

141 In this study, we chose five types of satellite and reanalysis precipitation products
142 (Table 1). We, first, evaluated their performance at detecting precipitation, and second,
143 integrated them to generate a better product, designed to enhance the strengths of each
144 product.

145 The three satellite and reanalysis data products, GLDAS, MERRA2 and TRMM,
146 were acquired from the National Aeronautics and Space Administration (NASA)
147 website (<https://disc.gsfc.nasa.gov/>). GLDAS ingests satellite- and ground-based
148 observational data products and applies advanced land surface modeling and data
149 assimilation techniques (Rodell et al., 2004; Zaitchik et al., 2010; Xia et al., 2019); it
150 has been widely used for river discharge simulations, groundwater monitoring and
151 many other fields (Wang et al., 2011; Chen et al., 2013; Qi et al., 2018; Verma and
152 Katpatal, 2019). MERRA2 is the first long-term global reanalysis dataset to assimilate
153 space-based observations of aerosols and represent their interactions alongside other
154 physical processes in the climate system (Marquardt Collow et al., 2016; Reichle et al.,

155 2017a, 2017b), and TRMM is a joint mission between the NASA and the Japan
156 Aerospace Exploration Agency (JAXA) to study rainfall for weather and climate
157 research (Xu et al., 2017; Ali et al., 2019; Wang et al., 2019a). The ITP-Forcing
158 dataset has been developed by the hydrometeorological research group at the Institute
159 of Tibetan Plateau Research, Chinese Academy of Sciences (He, 2010), and has been
160 shown to perform well on the TP (Yang et al., 2010; Chen et al., 2011). These data
161 were downloaded from the Cold and Arid Regions Science Data Center
162 (<http://westdc.westgis.ac.cn/>).

163 **2.3. Methods**

164 In this study, because of the different spatial resolutions of different products, we
165 extracted the precipitation values from each product according to the locations of the
166 gauges to generate product-gauge data pairings for evaluation. Where there are at least
167 two gauges in the pixel of one product, we used the average value of the gauges to
168 evaluate the performance of the corresponding precipitation product data.

169 To ensure the consistency of different products, we interpolated all the products
170 into the same 5 km spatial resolution grid using the inverse distance weighted (IDW)
171 method (Ma et al., 2019; Qiao et al., 2019; Sangani et al., 2019) and calculated them
172 at 3-hourly resolution. Due to its good performance on the TP, we then used the
173 ITP-Forcing data (1981-2016) to derive the multi-year mean 3-hour data as
174 background climatological precipitation. Then, the precipitation anomalies between
175 CMA, GLDAS, ITP-Forcing, MERRA2, TRMM and the background were calculated
176 3-hourly, using:

$$\begin{aligned}
& \varepsilon_c = P_C - P_B \\
& \varepsilon_g = P_G - P_B \\
177 \quad & \varepsilon_i = P_I - P_B \tag{1} \\
& \varepsilon_m = P_M - P_B \\
& \varepsilon_t = P_T - P_B
\end{aligned}$$

178 where P_B , P_C , P_G , P_I , P_M , P_T represent the background precipitation and different
179 products, respectively, and ε denotes the corresponding precipitation anomalies.
180 Considering different weights for these anomalies, we combined the background
181 precipitation with these anomalies,

$$182 \quad P_{_int} = P_B + w_1\varepsilon_c + w_2\varepsilon_g + w_3\varepsilon_i + w_4\varepsilon_m + w_5\varepsilon_t \tag{2}$$

183 where w represents the weight for each anomaly and $P_{_int}$ refers to the new integrated
184 precipitation at 5 km and 3-hourly resolution.

185 After $P_{_int}$ was acquired, we corrected its probability distribution function (PDF)
186 based on the rain gauges, and undertook several validation steps for spatial
187 distribution and at different time scales (e.g. extreme events, seasonal to inter-annual
188 variability, and long-term trends). At the same time, we also analyzed the changing
189 trend over the 36 years, and the extremely high precipitation events during the warm
190 months in 2014 and 2016. In order to identify the extreme events, we first assumed
191 that daily precipitation conforms to a normal distribution. From this we calculated a
192 threshold, above which the probability of precipitation values occurring is less than
193 0.05 (e.g. Fang et al., 2019 use 0.1). We considered events with precipitation values
194 above this threshold as extreme events.

$$195 \quad P(\text{precipitation} \geq \text{threshold}) \leq 0.05 \tag{3}$$

196 where P denotes the probability. Finally, based on the observed discharge data at

197 Nuxia Station, we compared the simulated daily discharges (normalized) from 2008 to
 198 2016 using a water and energy budget-based distributed hydrological model
 199 (WEB-DHM) to check the accuracy and reliability of our integrated precipitation.
 200 Evaluation criteria used in the discharge error assessment include relative bias (RB)
 201 and the Nash-Sutcliffe coefficient of efficiency (NSE).

$$202 \quad Q_{normalized} = \frac{Q - \min Q_{obs}}{\max Q_{obs} - \min Q_{obs}} \quad (4)$$

$$203 \quad RB = \frac{\sum_{i=1}^n Q_{sim} - \sum_{i=1}^n Q_{obs}}{\sum_{i=1}^n Q_{obs}} \times 100\% \quad (5)$$

$$204 \quad NSE = 1 - \frac{\sum_{i=1}^n (Q_{obs} - Q_{sim})^2}{\sum_{i=1}^n (Q_{obs} - \overline{Q_{obs}})^2} \quad (6)$$

205 Where $Q_{normalized}$, Q_{obs} , Q_{sim} represent the normalized discharge, observed discharge,
 206 and simulated discharge, respectively. The perfect value of RB is 0 and that of NSE is
 207 1. More information about this model can be found in many studies (Wang et al., 2009;
 208 Wang and Koike, 2009; Xue et al., 2013; Zhou et al., 2015a; Wang et al., 2016; Wang
 209 et al., 2017a). Figure 2 shows the flowchart of this study and Figure 3 presents the
 210 final spatial distribution of our integrated product.

211 **3. Results and Discussion**

212 **3.1. Evaluation of precipitation products at the basin and grid scale**

213 Figures 4 and 5 analyze the overall regime of different precipitation products at
 214 the basin scale. Figure 4 is the spatial distribution in warm (May to Oct.) and cold

215 (Nov. to Apr.) months, and Figure 5 presents the time series of basin-averaged annual
216 and monthly precipitation values. The spatial pattern indicates that more precipitation
217 occurs in warm seasons and less in cold seasons. During the warm months, GLDAS
218 and TRMM present obvious regional differences between upstream and downstream,
219 while CMA gridded data show the lesser values in the upstream source region. In the
220 cold seasons, all products present almost the same pattern, among which MERRA2
221 gives the lowest precipitation values.

222 For annual precipitation, CMA, ITP-Forcing and MERRA2 show similar
223 characteristics (annual mean value: 615 mm, 550 mm and 506 mm, respectively),
224 while GLDAS and TRMM are 789 mm and 757 mm, respectively. There are also
225 significant ($p < 0.01$) increasing trends in annual precipitation of GLDAS,
226 ITP-Forcing, and MERRA2 (6.42, 3.28, 4.68 mm/year, respectively) over the 36 years
227 of the data. For monthly precipitation, GLDAS and TRMM greatly overestimate
228 summer precipitation compared to the others, which explains why these two products
229 give anomalously high annual values (nearly 200 mm greater than the other three data
230 products). On the other hand, the monthly variations indicate that the intra-annual
231 distribution of precipitation is extremely uneven.

232 Figures 6 and 7 compare the accuracy of monthly rainfall from different products
233 at the grid scale. Due to the coarse spatial resolution of MERRA2 ($0.5^\circ \times 0.625^\circ$), there
234 are fewer product-gauge data pairings available for evaluation. All the products show
235 similar correlation relationships with the observations, with most rain gauges
236 overestimating monthly precipitation (Figure 7). The highest correlation coefficient is

237 0.63 (MERRA2) and the lowest is 0.51 (GLDAS). The PDFs, however, show
238 different characteristics (Figure 6). The CMA data are more consistent with the gauge
239 data, while GLDAS and TRMM exhibit clear overestimations. As for ITP-Forcing, its
240 precipitation is more concentrated on the average value, as indicated by the narrow
241 curve.

242 **3.2. Integration of precipitation products and validation of P_{int}**

243 **3.2.1. Integration of precipitation products and validation against different time** 244 **series**

245 Figure 3 presents the spatial distribution of annual and seasonal precipitation
246 estimated by our integrated dataset, which shows a declining trend from the southeast
247 to northwest. Figure 5 then compares the monthly and annual precipitation calculated
248 from our integrated dataset with the satellite and reanalysis products. As discussed in
249 Section 2.3, we interpolated all the products into a spatial resolution of 5 km using the
250 IDW method, and calculated them at a temporal resolution of 3 hours. Comparing
251 different weights for the anomalies mentioned in Equation 2, we finally adopted the
252 same weight for each product **and the sum of the weights is 1** ($w = 1/3$ from 1981 to
253 1997; $w = 0.25$ from 1998 to 2007; $w = 0.2$ from 2008 to 2016) to develop the new
254 product. **We made the integrated precipitation data using equal weights essentially**
255 **according to the number of available precipitation products at different time periods**
256 **(Table 1). Then we corrected the PDF of the newly integrated data based on the rain**
257 **gauge observations (Figure 6).**

258 After P_{int} was derived, we first validated its performance against short time

259 series (Figure 8). P_{int} shows optimal performance at detecting daily precipitation
260 with the correlation coefficients of 0.43 in 2014 and 0.55 in 2016. In 2014, the
261 average bias is 0.20 mm and the root mean square error (RMSE) is 4.18 mm. P_{int}
262 successfully captures the daily variation of precipitation except for late September and
263 early October. For 2016, the average bias and RMSE are -0.006 mm and 2.62 mm,
264 respectively, much better than those for 2014.

265 We then check the spatial distribution of P_{int} from May to October in 2014 and
266 2016 (Figure 9). Every rain gauge is compared with its corresponding grid in P_{int} to
267 explore the spatial heterogeneity. P_{int} well reproduces the precipitation pattern
268 described by less rain in the upstream (western) regions and more rain in the
269 downstream (eastern) regions. Meanwhile, abundant rainfall occurs in summer,
270 particularly for July.

271 Building on this, further validation was undertaken against a long time series. We
272 chose the average monthly precipitation from the nine meteorological stations as the
273 evaluation standard against which to assess P_{int} (Figure 10). The PDF of P_{int} is
274 consistent with that of the station data, which indicates that the mean value and
275 standard deviation of P_{int} are much closer to the observed value (Figure 10a).
276 Similar to the short time series, the average bias (-4.50 mm) and the RMSE (13.6 mm),
277 especially with respect to the correlation coefficient (0.96), prove that the P_{int} is
278 applicable and reliable.

279 **3.2.2. Trend and extreme events analysis compared across different precipitation** 280 **products**

281 The trend analysis (Figure 11) over 36 years indicates that there are different
282 patterns of precipitation in different seasons and different regions. In summer, there
283 are more complicated trends, as the variations between up and down stream differ
284 greatly. On the contrary, trends of winter precipitation values over most of the study
285 region vary by merely ± 2 mm/year, illustrating that precipitation in winter generally
286 remains unchanged or experiences minimal change. To find if P_{int} is able to reflect
287 the true varying trend, we added a comparison between meteorological stations
288 (triangles in Figure 11 and their direction represent the true trend) and precipitation
289 products. For observed annual precipitation, all the stations give an insignificant
290 increasing trend, except for Bomi station, which is located in the easternmost part of
291 the study region. For seasonal precipitation, different stations present different
292 patterns. As a result, P_{int} appears to reflect the changing pattern of more stations
293 than any other product, with the exception of the ITP-Forcing dataset on an annual
294 timescale or over autumn (Figure 12).

295 We notice that there is increasing trend in annual precipitation almost in the
296 whole basin for P_{int} ; only precipitation in the midstream area near the Himalaya
297 mountains and small part of the upstream region are decreasing. Moreover, the
298 majority of the increased precipitation in the downstream regions occurs over spring
299 and summer, with only slight changes found in autumn and winter.

300 After the volume, the spatial distribution, and the trend of P_{int} at different time
301 scales were completely verified, we continued to inspect if P_{int} could capture the
302 extreme events from May to October in 2014 and 2016 according to the rain gauge

303 data (Figure 13). There are 27 days in total (19 days in 2014 and 8 days in 2016)
304 when extremely high daily precipitation occurred. All the products are comparable
305 with each other in underestimating the frequency of extreme events. Nine days are
306 identified out of the P_{int} data, lesser only to the number of days detected by
307 ITP-Forcing (11 days).

308 **3.2.3. Evaluation of daily discharges simulated by different precipitation** 309 **products**

310 All the comparison and validation steps undertaken above support the accuracy
311 and reliability of our integrated dataset. Furthermore, Figure 14 indicates the superior
312 suitability and application of P_{int} in hydrological simulation and investigation, with
313 an RB of -5.94% and an NSE of 0.643 (the highest). We simulate the daily discharge
314 of Nuxia station using the various precipitation datasets as the input with the same
315 initial conditions and physical parameters. All products overestimate the daily
316 discharge, except for P_{int} (-5.94%) and MERRA2 (-2.24%). In terms of NSE, P_{int}
317 (0.643), ITP-Forcing (0.543) and MERRA2 (0.544) are higher than others, explaining
318 their better simulation performance. GLDAS and TRMM offer the worst performance
319 in discharge simulation, which is consistent with their overestimation of precipitation
320 in summer (Figure 5). This indicates that these datasets should be corrected when
321 undertaking hydrological research over the Upper Brahmaputra.

322 **4. Data availability**

323 This high spatiotemporal resolution (5km, 3h) precipitation dataset over the
324 Upper Brahmaputra River Basin from 1981 to 2016 is freely available at

325 <https://doi.org/10.5281/zenodo.3711155> (Wang et al., 2020), which can be
326 downloaded in TXT format.

327 **5. Conclusion**

328 In order to acquire suitable and accurate precipitation datasets which are helpful
329 in hydrology, meteorology and other scientific research over the Upper Brahmaputra,
330 we produced a new precipitation product by integrating gauge, satellite and reanalysis
331 precipitation datasets to reduce the uncertainties associated with a single product and
332 limitation of few observation stations. Our integrated dataset performs better than the
333 input datasets in estimating daily and monthly precipitation, describing the spatial
334 heterogeneity, capturing variation trends and extreme events and simulating river
335 discharges. Furthermore, it is successful in reproducing daily precipitation variation,
336 with smaller average biases (0.2 mm in 2014 and -0.006 mm in 2016) and RMSE
337 values (4.18 mm in 2014 and 2.62 mm in 2016). Monthly precipitation shows higher
338 correlation coefficients with the in-situ data for various time series (0.69 for all the
339 rain gauges in the warm months of 2014 and 2016; 0.86 for the nine meteorological
340 stations over 1981-2016). This high spatio-temporal resolution assures us that we can
341 use this new dataset to explore more detailed physical processes and further
342 understand the impacts of climate change on the water resources of the Upper
343 Brahmaputra River Basin, and we are confident that our precipitation dataset will
344 greatly assist future research in this basin.

345 With this in mind, we note some aspects of this study that deserve further
346 consideration. The effect of altitude on precipitation has not been taken into account

347 in the development of this dataset. The 166 rain gauges used in this paper, are all
348 located at the elevations above 3500 m, except for several eastern gauges. Generally,
349 these gauges were installed at relatively plain area, which may lead to large
350 uncertainty in estimating precipitation (rain or snow) at high mountains, especially in
351 the daily or finer time scales (Ahrens, 2006; Haiden and Pistotnik, 2009). This
352 limitation can be even more severe, due to the orographic effect on precipitation rates,
353 in mountainous regions and transition zones between the low and high altitudes,
354 which will result in the underestimates of the actual basin-wide precipitation (Anders
355 et al., 2006; Hashemi et al., 2020). Increasing the density and the distribution area of
356 observational stations can directly weaken this altitude effects. We also note
357 uncertainties that may arise from the re-gridding of the remotely sensed datasets in
358 order to pair with the in-situ gauge data. In addition, the assumption of normal
359 distribution when analyzing extremely high daily precipitation can also lead to
360 uncertainty. Generally, the non-normal (skewed) distribution of precipitation is caused
361 by the zero rainfall events at single site (Kumar et al., 2009; Semenov, 2008;
362 Sloughter et al., 2007). An associated problem is the quantity and reliability of the
363 data used to fit the distribution. Different probability distributions are used to describe
364 the observed time series of daily precipitation, then different extreme values may be
365 obtained (Angelidis et al., 2012). This study provides a foundation from which further
366 studies can be carried out to explore these aspects in more detail.

367 In the future, more studies are needed to validate the method and data in regions
368 with complex topography and climatic conditions, and to further improve the retrieval

369 algorithm. This will greatly benefit hydrological applications, especially in areas with
370 sparse and irregular observation networks. Furthermore, no products used in this
371 study accurately represent extreme precipitation events, thus, it is necessary to
372 improve the ability of all of these products to capture extreme events.

657 **Table and figure captions**

658 **Table 1.** The precipitation products used in this study.

659 **Figure 1.** The Upper Brahmaputra River Basin originates from the Tibetan Plateau
660 (TP) with the spatial distribution of nine meteorological stations from the China
661 Meteorological Administration (CMA) and 166 rain gauges from Ministry of Water
662 Resources (MWR), China. The green arrow indicates the direction of the westerlies,
663 the Indian monsoon and the East Asian monsoon. The elevation data was obtained
664 from the SRTM DEM datasets (www.earthexplorer.usgs.gov).

665 **Figure 2.** The flowchart used to produce the spatio-temporal continuous precipitation
666 dataset (P_{int}).

667 **Figure 3.** The spatial distribution of P_{int} (mm) averaged from 1981 to 2016 (a.
668 annual; b. seasonal).

669 **Figure 4.** The spatial distribution of different precipitation products during the warm
670 season (May to October) and the cold season (November to April) averaged from
671 2008 to 2016.

672 **Figure 5.** Variations in basin-averaged precipitation from multi-year monthly mean
673 values (top), annual values (middle) and monthly values (bottom) for the different
674 products.

675 **Figure 6.** A comparison of the probability distribution function (PDF) between all the
676 monthly observations and different precipitation products in the warm seasons (May
677 to October in 2014 and 2016).

678 **Figure 7.** As for Figure 6 but with scatter plots.

679 **Figure 8.** A validation of P_{int} against short time series by comparing with daily
680 gauge-averaged precipitation from May to October in 2014 and 2016.

681 **Figure 9.** A validation of P_{int} (mm) against short time series: spatial distribution of
682 the observations and corresponding grids in P_{int} from May to October in 2014 and
683 2016.

684 **Figure 10.** A validation of P_{int} against a long time series: (a). PDF and scatter plots
685 for monthly precipitation at nine CMA stations, (b). station-averaged monthly
686 precipitation from 1981 to 2016.

687 **Figure 11.** A trend analysis of the annual and seasonal precipitation (a: annual; b:
688 spring; c: summer; d: autumn; e: winter) over 36 years (1981-2016) between P_{int} ,
689 GLDAS, ITP-Forcing and MERRA2. The triangles represent the observed trend of
690 the corresponding meteorological stations.

691 **Figure 12.** The number of meteorological stations (total of nine) which present the
692 same trends as the different precipitation products, according to Figure 11.

693 **Figure 13.** A comparison of extreme events, as captured by different precipitation
694 products.

695 **Figure 14.** An evaluation of simulated daily discharge at Nuxia station from 2008 to
696 2016 forced by different precipitation products. All the discharge values have been
697 normalized.

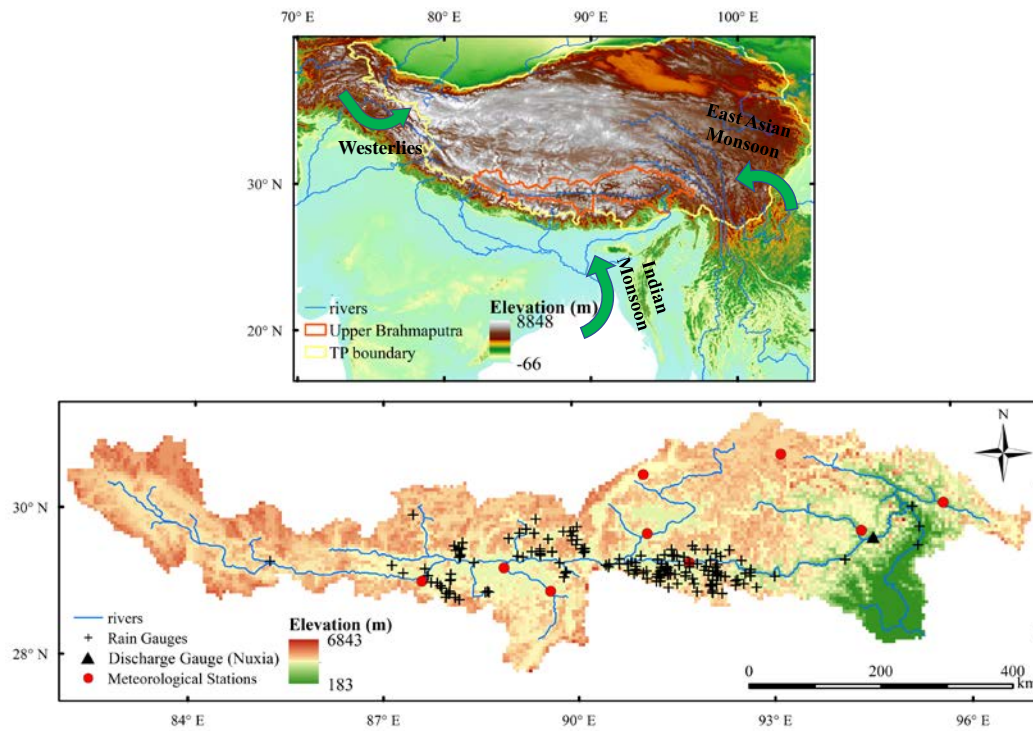

698

699 **Table 1.** The precipitation products used in this study.

Precipitation products	Time range	Temporal resolution	Spatial resolution
CMA gridded data	2008-2016	hourly	0.1°×0.1°
GLDAS	1981-2016	3-hour	0.25°×0.25°
ITP-Forcing	1981-2016	3-hour	0.1°×0.1°
MERRA2	1981-2016	hourly	0.5°×0.625°
TRMM	1998-2016	3-hour	0.25°×0.25°
