Abstract. The continental divide along the spine of the Canadian Rockies in southwestern Canada is a critical headwater region for hydrological drainages to the Pacific, Arctic, and Atlantic oceans. Major flooding events are typically attributed to heavy precipitation on its eastern side due to upslope (easterly) flows. Precipitation can also occur on the western side of the divide when moisture originating from the Pacific Ocean encounters the west-facing slopes of the Canadian Rockies. In other storms, substantial precipitation can fall on both sides. Meteorological data over this critical region are sparse, with few stations located at high elevations. Given the importance of all these types of events, the Storms and Precipitation Across the continental Divide Experiment (SPADE) was initiated to enhance our knowledge of the atmospheric processes leading to storms and precipitation on either side of the continental divide. This was accomplished by installing specialized meteorological instrumentation on both sides of the continental divide and carrying out manual observations during an intensive field campaign from 24 April–26 June 2019. On the eastern side, there were two field sites: (i) at Fortress Mountain Powerline (2076 m ASL) and (ii) at Fortress Junction Service, located in a high elevation valley (1580 m ASL). On the western side, Nipika Mountain Resort, also located in a valley (1087 m ASL), was chosen as a field site. Various meteorological instruments were deployed including two Doppler LiDARs, three vertically pointing micro rain radars and three optical disdrometers. The three main sites were nearly identically instrumented, and observers were on site at Fortress Mountain Powerline and Nipika Mountain Resort during precipitation events to take manual observations of precipitation type and microphotographs of solid particles. The objective of the field campaign was to gather high temporal frequency

35 meteorological data and to compare the different conditions on either side of the divide to study the precipitation
processes that can lead to catastrophic flooding in the region. Details on field sites, instrumentation used, and
collection methods are discussed. Data from the study are publicly accessible from the public Federated Research
Data Repository at <https://dx.doi.org/10.20383/101.0221> (Thériault et al., 2020). This dataset will serve as a baseline
for future work on atmospheric conditions over major orographic features by comparing the varying conditions on
either side of a large topographic feature. This paper also provides a sample of the data gathered during a
40 precipitation event.

1 Introduction

Precipitation over the Canadian Western Cordillera has high spatial variability and is influenced by the complex
orography of the region and its interaction with air masses from a variety of sources (Stoelinga et al., 2013). The
continental divide is oriented north-south along the Canadian Rockies and drains into several major bodies of water
45 including westward into the Pacific Ocean, northeastward into the Arctic Ocean and eastward into the Atlantic
Ocean. Therefore, the location where precipitation occurs can determine into which watershed it drains. Usually the
prevailing westerly winds transport moisture-laden Pacific air off the coast of British Columbia (BC) with
orographic lift along the Coast Mountains. These maritime air masses lose moisture as they move inland as much of
it is precipitated along the Coast Mountains and other interior ranges. Some moisture, however, travels farther inland
50 to the Canadian Rockies. Moisture to the region can also originate from the Great Plains and the Gulf of Mexico,
which is forced upslope on the eastern slopes of the Canadian Rockies. This is a mechanism that has previously led
to extreme flooding, such as in southern Alberta and British Columbia in 2013 (Pomeroy et al., 2016; Kochtubajda
et al., 2016; Liu et al., 2016).

55 To understand the contribution of these different moisture flows on precipitation across the Canadian Rockies, the
Storms and Precipitation Across the continental Divide Experiment (SPADE) was initiated wherein precipitation
events across the continental divide were investigated from 24 April– 26 June 2019. Over the two-month period, 13
storms with varying atmospheric conditions and precipitation amounts and types were documented on both sides of
the continental divide in southwestern Canada. This project enhances knowledge of both the large- and fine-scale
60 atmospheric processes that contribute to storms and precipitation across the continental divide, and that may lead to
major flooding events in western Canada.

The objective of this paper is to describe the methods of data collection during the SPADE project. Section 2
outlines the study area and its climatology. Section 3 describes the instrumentation used and specific observations
65 conducted during the project, and Sect. 4 provides examples of the meteorological variables and observations.
Finally, Sect. 5 details the online location of the database, with concluding remarks in Sect. 6.

2 Study area

2.1 Context

70 SPADE expands upon a previous study and field campaign by Thériault et al. (2018) in March and April 2015 that
 studied precipitation characteristics and associated atmospheric driving mechanisms on the eastern slopes of the
 Canadian Rockies. Although that field campaign occurred during a period of above normal temperatures and less
 precipitation than normal, 17 precipitation events were observed. Precipitation events were categorized as either
 75 upslope (easterly) or downslope (westerly) flow, and the precipitation events associated with downslope flows
 typically had deeper precipitation layers and greater instability (Thériault et al., 2018). It was also observed that
 liquid, solid, and mixed-phase precipitation could all occur within the same event. Of the solid precipitation particles
 that were observed, 62% of those particles were rimed, with rimed irregular particles being the most common
 particle type. Additionally, rimed and unrimed particles were observed simultaneously during precipitation events,
 80 although the riming of particles was independent of whether flows were westerly or easterly (Thériault et al., 2018).

2.2 Climatology

The SPADE domain spans both the western and eastern sides of the continental divide in the Canadian Rockies (Fig.
 85 1) from 117° W to 114° W longitude and 50° N to 52° N latitude. This region is subject to spatially variable weather
 conditions, with large orographic features acting as the major catalyst for precipitation. The highest peak in the
 domain is Mount Assiniboine, at an elevation of 3612 m above sea level (ASL). The elevation of the continental
 divide varies from 1130 m to over 3600 m ASL. Meteorological data over the continental divide remain sparse and
 predominantly lie in the valleys where sites are accessible by road and AC power is more readily available (Vionnet
 et al., 2020). There are even fewer stations at higher elevations, hence the paucity of data over high elevation regions
 (Pepin et al., 2015; Hernández-Henríquez et al., 2018). Short, cool summers and long, cold winters characterize the
 region's climate. Precipitation typically peaks in June (Liu et al., 2016) with 60% of the precipitation falling as snow
 in the mountains, which can occur in all months in the high mountains (DeBeer and Pomeroy, 2010). Maximum
 snow water equivalent (SWE) occurs in May and decreases throughout June and early July (Pomeroy et al., 2016).
 95 The three main atmospheric circulation types that induce snow to the Canadian Rocky Mountains were categorized
 by Moran et al. (2007) as northwesterly, westerly, and leeward (upslope). Westerly and northwesterly flows often
 result in significant precipitation accumulation on the western side of the continental divide, while upslope (easterly)
 flows often result in heavy precipitation and greater accumulation on the eastern side of the continental divide.
 Upslope events typically occur from March–May (Sinclair and Marshall, 2009). Additionally, several significant
 100 flooding events have recently impacted the eastern slopes of the Canadian Rockies such as in June 2002 (Szeto,
 2011), June 2005 (Ou, 2008; Shook, 2016), and the recent major flooding in June 2013 (Pomeroy et al., 2016; Liu et
 al. 2016; Kochtubajda et al., 2016). Historical flooding due to rain-on-snow events occurred in the late 19th and early
 20th century on a more frequent basis than in the recent period (Whitfield and Pomeroy, 2016).

2.3 Site description

Two main study areas, on either side of the continental divide, were chosen. Table 1 summarizes information on the SPADE field sites. On the eastern side, there were two field sites: (i) Fortress Mountain Powerline (FMP) at 2076 m ASL and (ii) Fortress Junction Service (FJS), located in a high elevation valley (1580 m ASL) along Alberta Provincial Highway No. 40 (Fig. 1). FMP was chosen as it is the primary field site in the Canadian Rockies Hydrological Observatory (<https://research-groups.usask.ca/hydrology/science/research-facilities/crhc.php#Overview>), operated by the University of Saskatchewan Centre for Hydrology, and is already well instrumented with hydrometeorological equipment and is the site of longstanding research (Smith et al., 2017; Conway et al., 2018; Schirmer and Pomeroy, 2020). Moreover, a maintained road from FJS up to FMP allowed researchers to collect meteorological data during transition regions along the mountainside. FJS and FMP were chosen to collect wind flow data that would allow the comparison of precipitation amounts from the valley floor to above ridgetop. Select data were also gathered on an intermittent basis from the University of Calgary Biogeoscience Institute (BGI) at 1418 m ASL located on the eastern side of the continental divide, off Alberta Highway No. 40, ~25 km north of FMP.

On the western side of the continental divide, Nipika Mountain Resort (NMR), also located in a valley, was chosen as a comparable site to FJS (Fig. 1). It approaches the latitude of the Fortress Mountain area and has an elevation of 1087 m ASL. NMR is easily accessible via an active logging road off the Banff-Windermere Highway (BC Highway 93). This area has a paucity of active meteorological stations and basic weather instruments were deployed on 21 September 2018, well before the start of the field experiment, to collect baseline data.

A fourth site at Storm Mountain Lodge (SML) at 1723 m ASL was used temporarily on 7 June 2019 in anticipation of a forecasted significant precipitation event. SML is located approximately 5 km east of the continental divide, near the midway point between the Fortress Mountain and NMR sites, along BC Highway 93 (Fig. 1).

Table 1: A summary of the field sites that were used during the field campaign including information about their location, elevation, access to AC power, and dates that instruments were operational.

Location	Coordinates		Elevation m ASL	Access to AC Power Y/N	Dates during field campaign
	Latitude (° N)	Longitude (° W)			
Fortress Mountain Powerline	50.824	115.197	2076	Y	2019-04-26 to 2019-06-25
Fortress Junction Service	50.786	115.161	1580	Y	2019-04-26 to 2019-06-25
Nipika Mountain Resort	50.612	115.801	1087	N	2018-09-21 to 2019-06-22
Storm Mountain Lodge	51.253	115.999	1723	Y	2019-06-07 to 2019-06-08
Biogeoscience Institute	51.027	115.034	1418	Y	2019-04-25 to 2019-06-05, 2019-06-09 to 2019-06-25

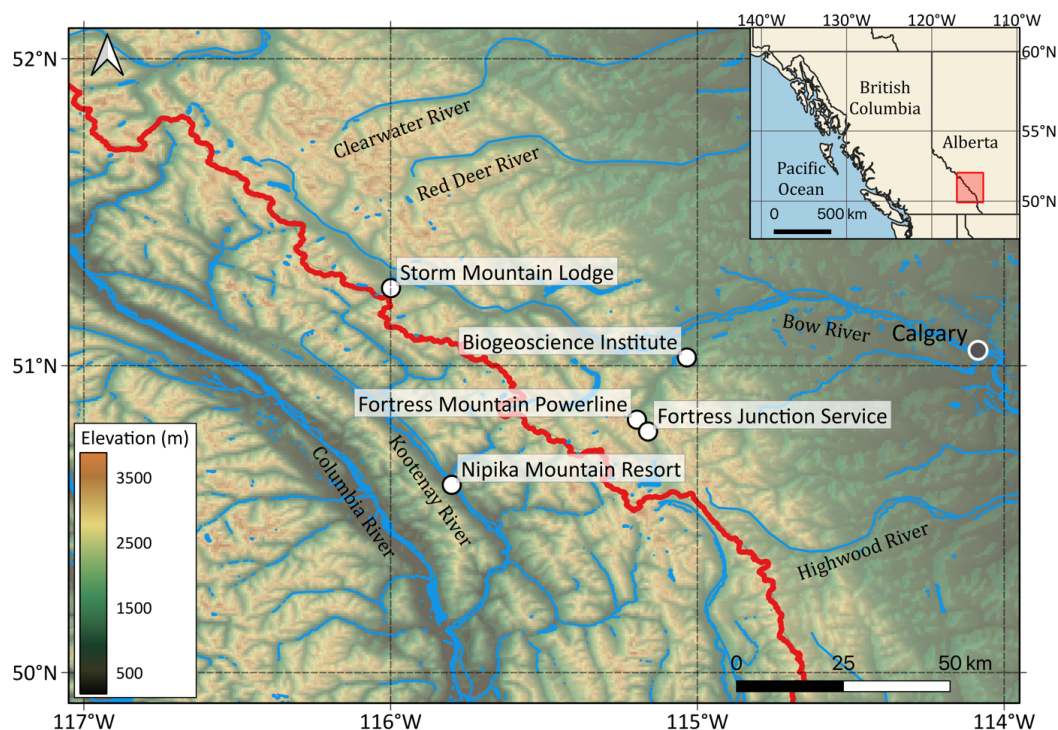

Figure 1: Map of the SPADE field campaign domain in British Columbia and Alberta with the location of the field sites (white dots), which are Nipika Mountain Resort, Storm Mountain Lodge, Fortress Mountain Powerline, Fortress Junction Service, and the University of Calgary Biogeoscience Institute, the major city of Calgary (grey dot), and the continental divide (red line). Local rivers are shown in blue and labelled. The inset map shows the SPADE field campaign area (red outline) in relation to western Canada.

3 Data collection

3.1 Instruments used

Various meteorological equipment was deployed at each field location (Fig. 2). The three main sites were nearly identically instrumented, but due to power constraints and limited equipment, NMR was not equipped with a Doppler Light Ranging and Detection Instrument (LiDAR). Cameras were also set up at FMP and FJS to monitor conditions while observers were not on site. The instruments are described in detail in Sect. 3.2–3.9. The FMP site, also known as the Fortress Mountain Snow Laboratory within the regional Canadian Rockies Hydrological Observatory, and some of the instruments located at FMP, but not used in the SPADE campaign, are described in Smith et al. (2017), Conway et al. (2018), and Schirmer and Pomeroy (2020).

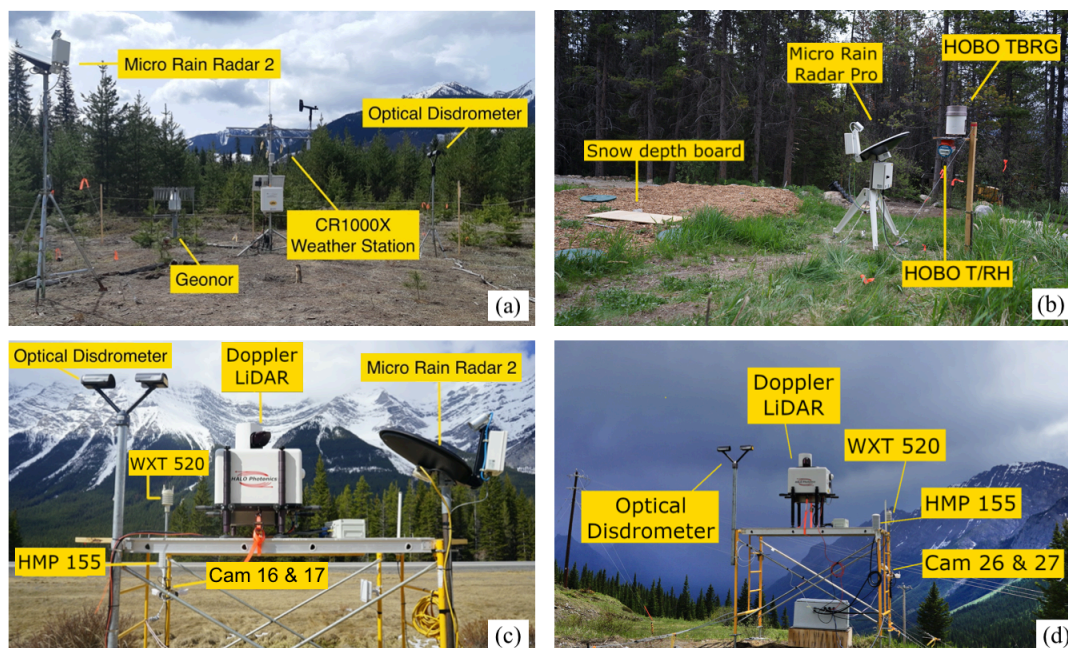

Figure 2: Instrumentation set up at (a) Nipika Mountain Resort, (b) Storm Mountain Lodge, (c) Fortress Junction Service, and (d) Fortress Mountain Powerline with instruments labelled. See Fig. 1 for location of the field sites on a map. Note that not all instruments may be in the photos as some are located a short distance from the scaffolding.

3.2 Weather station

A 3 m tall meteorological station from Campbell Scientific Canada was set up at NMR on 21 September 2018 (Fig. 3a). A CR1000X data logger powered by a 30 W solar panel and 12 V battery was used to operate sensors and collect data. The data logger was configured to sample every 60 s and generate 15 min averages for baseline data from 21 September 2018; this was changed to 5 min average data on 6 May 2019 for the remainder of the field campaign. Parameters measured were: 2 m air temperature and relative humidity (HC2-S3-L), 3 m wind speed and direction (RMY 05103AP-L), snow depth (SR50), atmospheric pressure (CS106), soil and snow temperatures at depths/heights of -17 cm, +15 cm, and +33 cm (T109), and precipitation measurements using a Geonor (T200-b) (see Sect. 3.6.4).

3.3 HMP155

A Vaisala HMP155 air temperature and relative humidity sensor was deployed on the scaffolding at the FMP and FJS field sites (Fig. 3b) at a height of 195 cm and 168 cm above ground level (AGL), respectively. Data were recorded at 1 min resolution throughout the SPADE field campaign from 24 April–26 June 2019.

175 3.4 WXT520

A Vaisala WXT520 was deployed on the scaffolding at the FMP and FJS field sites (Fig. 3c) at a height of 265 cm and 238 cm AGL, respectively. The WXT520 measures six weather parameters in one sensor, including wind speed and direction, precipitation, atmospheric pressure, air temperature, and relative humidity (Vaisala, 2012). Data were collected at 1 min resolution throughout the SPADE field campaign from 24 April–26 June 2019.

180 3.5 HOBO T/RH

The HOBO Pro V2 Temperature and Relative Humidity (T/RH) (U23-001) is a weatherproof data logger with built-in temperature and relative humidity sensors. The HOBO T/RH was temporarily deployed at SML during the 7 June 2019 precipitation event and data were collected at 5 min resolution throughout the storm. The instrument was housed in an improvised radiation shield attached to a wooden post at 120 cm AGL in a clearing and was level to the ground.

190 3.6 Precipitation gauges

3.6.1 HOBO tipping bucket rain gauge

The HOBO tipping bucket rain gauge (TBRG) (RG3-M) measures liquid precipitation at a resolution of 0.2 mm tip⁻¹ (Onset, 2019). Data was only collected when a tip occurred. The TBRG was temporarily deployed at SML during the 7 June 2019 precipitation event. The instrument was attached to a wooden post at 134 cm AGL in a clearing and was level to the ground (Fig. 3d).

3.6.2 Davis Instruments tipping bucket rain gauge

Three Davis Instruments TBRG (7852) were deployed on 12 May 2019 at 23 km (1198 m ASL), 32.5 km (1220 m ASL), and 47 km (1667 m ASL) on the Cross River Resource Road (Fig 3e). The highest elevation location was selected because it was the closest point to the continental divide on the western side that was vehicle accessible from NMR. The other locations were selected to create a transect between the highest elevation gauge and NMR where gauges were roughly equidistant. Liquid precipitation was measured at a resolution of 0.2 mm tip⁻¹. Data was only collected when a tip occurred. Site visits to these remote locations were conducted every two weeks to download data and inspect gauges.

3.6.3 Pluvio

The OTT Pluvio family of precipitation gauges determines precipitation intensity and amount by determining the weight of the collecting bucket every 6 s with a resolution of 0.001 mm (OTT, 2010). The amount is summed every minute. Two Pluvio precipitation gauges placed in a single-Alter shield were used; one was previously installed at

215 FMP (an OTT Pluvio 1) by the University of Saskatchewan Centre for Hydrology, and the other was installed on 24 April 2019 at FJS (OTT Pluvio 2) for the duration of the SPADE field campaign (Fig. 3f).

3.6.4 Geonor

220 A three sensor Geonor T-200b all-weather precipitation gauge in a single Alter shield was installed at NMR on 21 September 2018 on a pedestal mounted into a heavy lumber base and was level to the ground (Fig. 3g). The CR1000X data logger was configured to sample the period average frequency from each vibrating wire sensor, convert the frequencies to depths, and calculate the average depth of the three sensors and the standard deviation across them. Data collection was set on a 15-min interval from 21 September 2018 and a 5-min interval from 6 May 2019 onward for the intensive field campaign. The resultant time series describes cumulative precipitation, including
 225 the average and standard deviations of the three sensor depths.

3.7 Manual observations and microphotography

230 Manual weather observations were conducted at the FMP and NMR field sites during precipitation events throughout the field campaign, and at SML during the 7 June 2019 precipitation event. Manual observers were on site during storms to report precipitation type and to take microphotographs of snow particles. Every 10 minutes, manual observations of precipitation type (solid, liquid, or mixed) were reported and microphotographs of snow particles were taken when conditions allowed. Microphotography equipment was situated at NMR, however, images were not taken because insufficient solid precipitation particles were observed. Microphotographs of snow particles
 235 were taken following the methods established in Gibson and Stewart (2007) and Thériault et al. (2012, 2018). Images at FMP were made with a Nikon D3200 Digital SLR camera and at SML with a Nikon Digital D80 Digital SLR camera, both fitted with a 60 mm macro lens and flash. The photography equipment was mounted vertically (Fig. 3i), and precipitation particles were gathered on a black velvet or felt covered collection pad that was placed outside for a period of time, typically 5 s to 2 min, depending on the rate of snowfall. The collection pad was then
 240 brought inside an unheated fishing tent and a series of nine images were taken using a predefined method that ensured uniform results regardless of the observer. Due to the differing particle size and amount of light available for each photo, the camera settings varied throughout the project, but are noted in the metadata file. An image of the millimeter divisions on a ruler was captured periodically to provide a scale for each series of photographs.

245 3.8 Optical disdrometer

250 Three OTT Parsivels, which are laser-optical disdrometers and present weather sensors, were deployed at FMP and FJS on 24 April 2019, and at NMR on 1 May 2019 for the duration of the field campaign (Fig. 3h). This instrument measures the size and speed of falling hydrometeors with the goal of classifying hydrometeor type and retrieving precipitation particle size distribution. These raw data can also be used to determine the precipitation type, amount, intensity, and kinetic energy, as well as the equivalent radar reflectivity. OTT Parsivel laser-optical disdrometers

function with two sensor heads facing each other, in which one head is a transmitter that emits radiation (at 650 nm wavelength at the red band) in a horizontal plane and the other head is a receiver that senses how much of that radiation is received. The instrument measures the size of the hydrometeor by determining the amount of radiation that is blocked by the particle diameter. The velocity of the hydrometeor is estimated based on the time that a particular hydrometeor blocks the radiation between the transmitter and receiver. Each particle falling through the beam is classified into 32 fall speed and 32 diameter bins. An OTT Parsivel was installed at FMP at a 300 cm height and at FJS at 277 cm, and an OTT Parsivel² was installed at NMR at 256 cm. The OTT Parsivel² is similar in operation to the first Parsivel model and retrieves particle fall speed and size every 10 s providing a cumulative sum every minute.

3.9 Micro rain radar

The Micro Rain Radar (MRR) is a vertically pointing, frequency-modulated continuous wave radar that is used to measure hydrometeor reflectivity and Doppler velocity in a vertical profile. Three MRR-2 instruments were used in this study and were deployed at FMP (installed at a height of $z = 533$ cm above bare ground; vertical resolution of $\Delta z = 200$ m), prior to the field campaign, FJS ($z = 235$ cm; $\Delta z = 35$ m) on 24 April 2019, and at NMR ($z = 273$ cm; $\Delta z = 200$ m) on 1 May 2019 for the duration of the field campaign (Fig. 3j). In addition, one MRR-PRO was primarily located at BGI for the field campaign but was deployed at SML on 7 June 2019 with a vertical resolution of 30 m (Fig. 3k). The MRR-2 version profiles the atmosphere in 32 range gates, operating at a 24.23 GHz frequency (K-band) (METEK, 2010). The newer MRR-PRO operates at the same frequency and profiles the atmosphere with a maximum of 254 range gates and already processes the data in NetCDF format (METEK, 2017). The MRR-PRO used in SPADE was operated with 128 range gates, 30 m vertical resolution, 64 lines per spectrum, and 0.19 m s^{-1} speed resolution. The MRR-2 retrievals were processed with a different noise removal algorithm (Maahn and Kollias, 2012) to increase the instrument sensitivity to -14 dBZ and, therefore, enhancing the detection of light solid precipitation. The MRR also identifies the height of the melting layer through the detection of an abrupt change in reflectivity (i.e., bright band) when the hydrometeor phase changes from solid to liquid state (METEK, 2009).

3.10 Doppler LiDAR

Identical Halo Photonics Streamline XR scanning Doppler LiDARs were installed at FMP and FJS on 24 April 2019 for the duration of the field campaign (Fig. 3l). Doppler LiDARs have demonstrated their usefulness in complex, mountainous terrain such as those in the SPADE domain (Banta et al. 1997, 1999; Darby et al., 1999; Fast and Darby, 2003; Mariani et al., 2018a, b). The Doppler LiDAR emits a pulsed laser and measures the Doppler shift and the intensity of the signal backscattered by small sized targets (i.e., aerosols). The LiDARs operate at $1.5 \mu\text{m}$ using an 80 μJ pulsed laser at 10 kHz with a range resolution of 3 m (60 m overlapping range gates). This range gate length was chosen so that there would be a small vertical overlap between the LiDAR located at FJS and the LiDAR located at FMP. The LiDARs have full scanning capability, allowing them to conduct measurements at any

290 elevation and azimuth, similar to most weather radars. The first measurement is 60 m from the LiDAR due to the
LiDAR's blind spot. Both LiDARs were subjected to identical quality control procedures based on their signal-to-
noise ratio (SNR) within each range gate and filtering outliers and returns from clouds and rain droplets (Mariani et
al., 2018a). The maximum range of the LiDAR is limited by the sensitivity (SNR) and a minimal value of 1.003.
This was used as a lower threshold based on the minimal value of 1.0008 from Päsche et al. (2015) and adjusted
295 according to lower SNR values observed at FMP, due to a lower amount of aerosols. The LiDARs used identical
repeating 10 min scan sequences, performing vertical stare, constant 4° elevation 360° azimuth plan position
indicator, two perpendicular (36° and 167°) constant azimuth over-the-top range height indicator, Doppler beam
swinging, and eight beam velocity-azimuth display (VAD) scans; the latter two of which were used to obtain high-
resolution vertical wind profile data.

305 4 Sample of the available data during a storm

4.1 Overview

Over the course of the field campaign, 13 storms were observed, of which four were categorized as major (>20 mm of precipitation at FMP) (Fig. 4). The storms were caused by a variety of conditions and resulted in varying air
 310 temperatures, durations, amounts, and types of precipitation. The eastern side of the continental divide received more precipitation and was cooler than the western side. An example of some of the data collected during a storm are discussed in Sect. 4.2.

315 **Figure 4: Sub-hourly temperature (red line), dew point (blue line), and log-scale precipitation amount (bars) at (a) NMR and (b) FMP for the duration of the SPADE field campaign (24 April–26 June 2019).** Precipitation is subdivided into rain (green bars), snow (blue bars), or mixed phase (red bars) based on data from the optical disdrometer. The grey shading indicates times when there were manual observations. The yellow box indicates the time period from the data example in Sect. 4.2.

320 4.2 Storm 4–5 May 2019

Data from 1700 UTC 4 May to 1120 UTC 5 May 2019 highlight the disparity in meteorological conditions observed on either side of the divide throughout precipitation events. During this time, a total of 15.3 mm of precipitation was collected at FMP, with an average air temperature of -4.7°C , this is in contrast to the 1.4 mm of precipitation
 325 collected at NMR with an average air temperature of 9.4°C (Fig. 4). Using data from the MRRs, vertical bands of precipitation appear at both FMP and NMR (Fig. 5), however precipitation starts at FMP ~ 10 h before it begins at NMR. Observers were on site at both FMP and NMR throughout the storm to conduct field observations of weather

conditions. These manual observations, combined with data from the optical disdrometer, indicate that precipitation at NMR was mainly liquid, whereas at FMP, precipitation was mainly snow, snow pellets, or mixed phase (Fig. 6).
 At FMP, observers took microphotographs of snow particles and their evolution throughout the course of the storm (Fig. 7). This approach allows for an analysis of the solid particle size distribution, in addition to providing another method for documenting the evolution of atmospheric conditions aloft. Observers at NMR were unable to take microphotographs due to the warm temperatures but observed that there was some mixed precipitation.

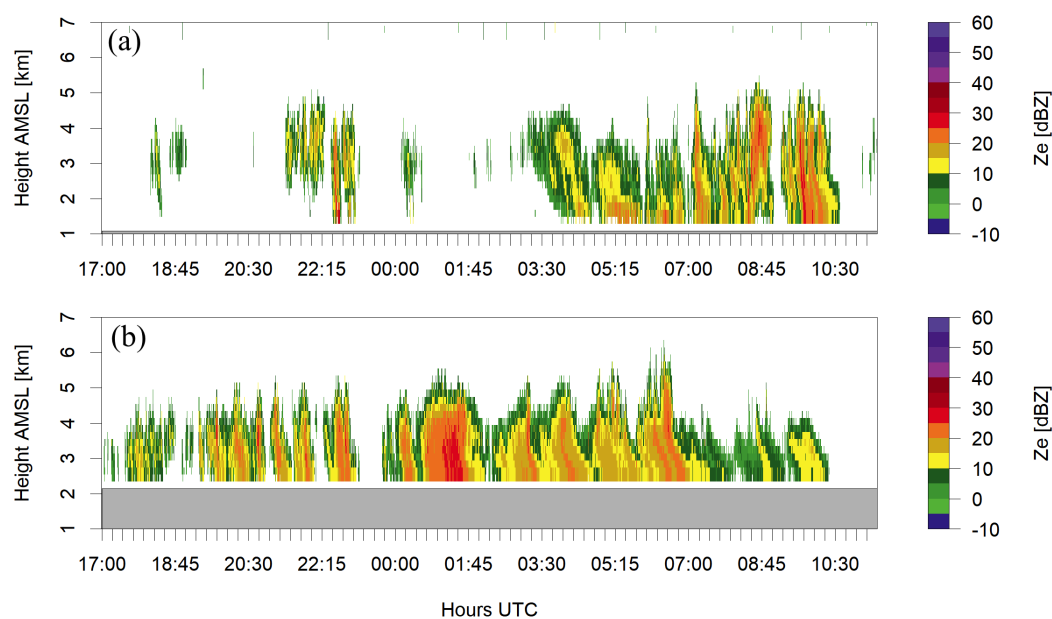

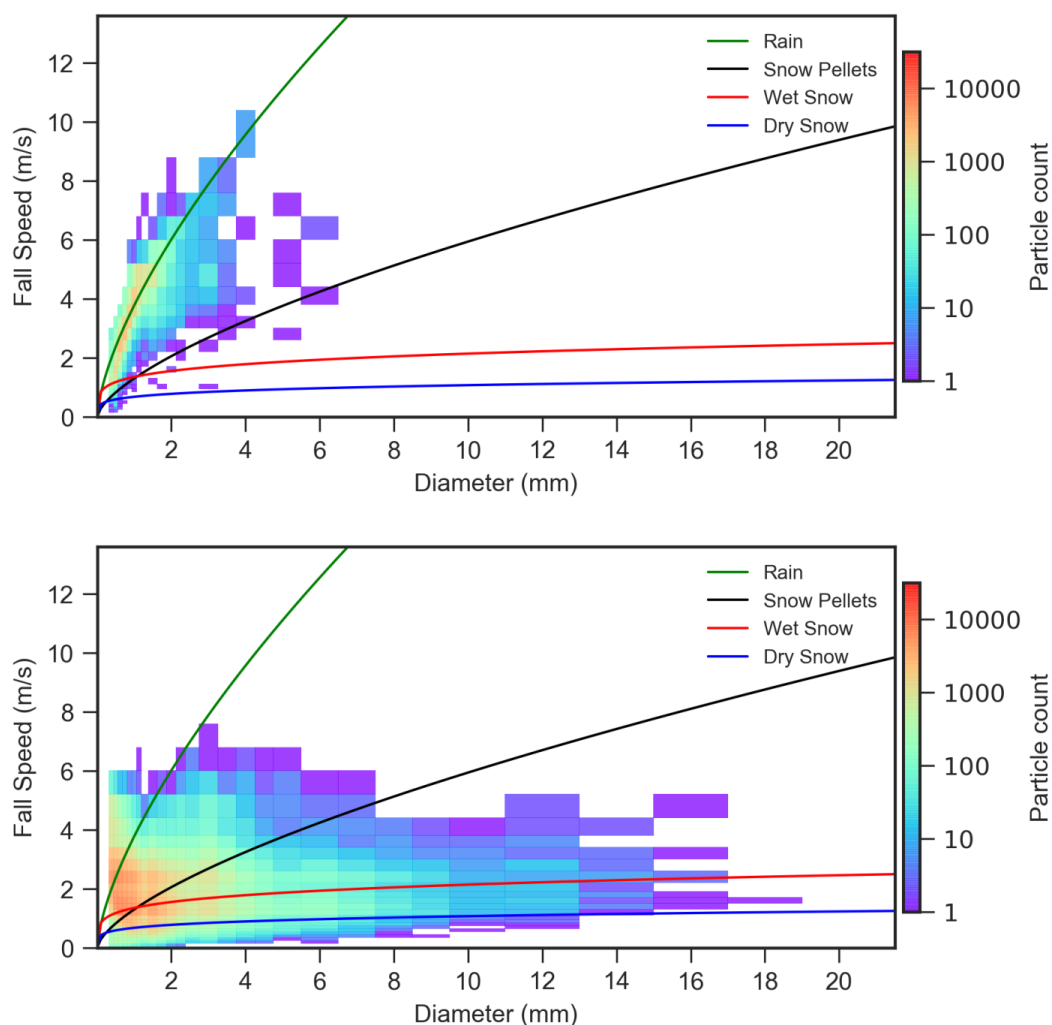

Figure 5: MRR-2 vertical profile of reflectivity (Z_e) from 1700 UTC 4 May–1130 UTC 5 May for (a) NMR and (b) FMP. The grey shading is below ground level. Data from the MRR-2 has been processed using Maahn and Kollias (2012).

345 **Figure 6: The particle diameter and fall speed distribution of hydrometeors from 1700 UTC 4 May–1130 UTC 5 May at (a) NMR and (b) FMP. Rain (green line), wet snow (red line), dry snow (blue line), and snow pellets (black line) particles. The rain fallspeed-diameter relationship is from Atlas and Ulbrich (1977) and the solid precipitation from Rasmussen et al. (1999). The number of particles that fall in each fall speed-diameter bin are indicated by the colour.**

350 **Figure 7: Microphotography from FMP showing the changes in snow crystal type during the 4–5 May 2019 storm. (a) Needles observed at 2355 UTC 4 May 2019, (b) graupel and rimed irregular particles observed at 0121 UTC 5 May 2019, and (c) rimed dendrites and branches observed at 0956 UTC 5 May 2019. Double arrow length indicates 2 mm for scale.**

5 Data availability

355 The SPADE dataset is available from the Federated Research and Data Repository (FRDR) and can be accessed at <https://dx.doi.org/10.20383/101.0221> (Thériault et al., 2020).

6 Final remarks

A valuable and unique dataset was collected during the Storms and Precipitation across the continental divide Experiment that was held in April–June 2019 in the Canadian Rockies. SPADE was initiated to enhance our
 360 knowledge of the atmospheric processes leading to storms and precipitation on either side of a large orographic feature by gathering meteorological data on both sides of the continental divide. A combination of manual and automatic measurements of precipitation and meteorological conditions at the surface and aloft was collected. These include information on the amount, type and characteristics of precipitation particles, including particle size and fall speed, as well as 3D wind fields at lower and higher elevations of Fortress Mountain. Overall, data from the SPADE
 365 field campaign will contribute significantly to our understanding of precipitation processes across the continental divide from the synoptic-scale conditions leading to precipitation to the fine-scale processes associated with precipitation trajectories near the surface.

8 Author contribution

375 HMS wrote the first draft of the manuscript, as well as conducted some analyses. HDT, AB, and JMT conducted some scientific analyses and created plots. JMT, SJD, JA and JWP designed and led the field project. JEM managed the deployment of the NMR weather station. All authors contributed to the manuscript. HMS, JA, AB, AD-L, SM, CH-P, ML, HDT, JEM, SJD, and JMT participated in the field campaign.

9 Competing interests

The authors declare that they have no conflict of interest.

380 10 Disclaimer

Specific instrument manufacturers/models and suppliers mentioned in the manuscript and/or used in the field campaign is not a commercial endorsement of their products.

11 Acknowledgements

385 Funding provided by the Global Water Futures programme, NSERC Discovery Grants (JMT, SJD, JWP and Ronald E. Stewart), the Canada Research Chair programme (JMT, JWP), BC Real Estate Foundation, UNBC (SM), an NSERC undergraduate fellowship (CHP), NSERC CGS-M and a FRQNT fellowships (ADL). Thanks to CFI for providing funding for some instruments, particularly those at Fortress Mountain as well as Nipika Mountain Resort. Thanks to Cécile Carton (UQAM), Robin Heavens, Greg Galloway, Lindsey Langs and the other researchers from the U. Saskatchewan Centre for Hydrology in Canmore who contributed during the field campaign, Adrienne 390 Cunnings, Michelle Ives, and the staff at BGI, Lyle and Dianne Wilson and the staff at Nipika Mountain Resort, Fortress Mountain Resort, Fortress Junction Service, Storm Mountain Lodge, Dr. John Rex at the BC Ministry of Forests, Lands, Natural Resource Operations and Rural Development for the use of the Davis tipping buckets, and Ronald E. Stewart (U. Manitoba) and Shawn Marshall (U. Calgary and ECCC) for their help with the project initiation. The authors would like to acknowledge the contribution of Environment and Climate Change Canada 395 (ECCC) Observation-based Research Section to this work as well as Robert Reed and Micheal Hardwood for assisting with the deployment of the ECCC instruments.

500 Appendix A

Table A1: Detailed information about the instruments used during the field campaign including model number, measurements, units, and the location and dates that they were operational.

Sensor	Model	Measurements	Units	Nipika Mountain Resort	Fortress Junction Service	Fortress Powerline	Storm Mountain Lodge	Biogeoscience Institute
Doppler LiDAR	Halo Photonics Streamline XR	Doppler velocity	m/s					
		Backscatter coefficient	1/(m*sr)					
		Intensity	Signal to noise ratio (SNR) +1					
		Depolarization ratio (ice/water)	%					
		Vertical wind profile (u,v)	m/s		24 Apr - 25 Jun 2019	24 Apr - 25 Jun 2019		
Optical Disdrometer	OTT Parsivel 1	Size of falling particles	mm					
		Speed of falling particles	mm/s		24 Apr - 26 Jun 2019	24 Apr - 26 Jun 2019		
	OTT Parsivel 2	Size of falling particles	mm					
		Speed of falling particles	mm/s	1 May - 22 Jun 2019				26 Apr - 01 May 2019
Micro Rain Radar	Metek MRR 2	Doppler raw spectra	N/A					
		Reflectivity (Ze)	dBZ					
		Doppler Velocity (W)	m/s					
		Spectral Width (σ)	m/s	1 May - 24 Jun 2019	24 Apr - 26 Jun 2019	27 Apr - 26 Jun 2019		
	Metek MRR Pro	Doppler raw spectra	N/A					
		Reflectivity (Ze)	dBZ					
		Doppler Velocity (W)	m/s					24 Apr - 5 Jun 2019, 9 - 25 Jun 2019
		Spectral Width (σ)	m/s				7 Jun 2019	
Precipitation Gauge	Geonor T-200B Vibrating Wire Weighing Gauge	Geonor depth (Average)	mm	21 Sept 2018 - 26 Jun 2019				
		Geonor depth (Std. Dev.)	mm					
	OTT Pluvio 1	Precipitation intensity	mm/h					
		Precipitation amount	mm			24 Apr - 26 Jun 2019		
		Precipitation intensity	mm/h					
	OTT Pluvio 2	Precipitation amount	mm		24 Apr - 26 Jun 2019			
		Precipitation	0.2 mm/tip				7 - 8 Jun 2019	
	Onset RG3-M Tipping Bucket	Precipitation	0.2 mm/tip					
		Precipitation	0.2 mm/tip		12 May - 23 June 2019			
	Davis Tipping Bucket 7852	Precipitation	0.2 mm/tip
