22 **Highlights:**

- 23 • The SPEI has been widely used to monitor and assess the drought characteristics.
- 24 • A multi-scale daily SPEI dataset was developed across the mainland China from
- 25 1961 to 2018.
- 26 • The daily SPEI dataset can identify the start and end day of the drought event.
- 27 • The daily SPEI dataset developed is free, open and persistent publicly available
- 28 from this study.

45 **Abstract:**

46 The monthly Standardized Precipitation Evapotranspiration Index (SPEI) can monitor  
47 and assess drought characteristics with one month or longer drought duration. Based  
48 on data from 1961 to 2018 at 427 meteorological stations across the mainland China,  
49 we developed a daily SPEI dataset to overcome the shortcoming of coarse temporal  
50 scale of monthly SPEI. Our dataset not only can identify the start and end dates of  
51 drought events, but also can be used to investigate the meteorological, agricultural,  
52 hydrological and socioeconomic droughts with different time scales. In the present  
53 study, the SPEI data with 3-month scale were taken as a demonstration example to  
54 analyze spatial distribution and temporal changes in drought conditions for the  
55 mainland China. The SPEI data with 3-month scale showed no obvious intensifying  
56 trends in terms of severity, duration, and frequency of drought events from 1961 to  
57 2018. Our drought dataset serves as a unique resource with daily resolution to a  
58 variety of research communities including meteorology, geography, and natural  
59 hazard studies. The daily SPEI dataset developed is free, open and persistent publicly  
60 available from this study. The dataset is publicly available via the figshare portal  
61 (Wang et al, 2020), with <https://doi.org/10.6084/m9.figshare.12568280>.

64

65

## 66 **1. Introduction**

67 Drought is one of the most destructive natural hazards worldwide. It can lead to  
68 adverse effects on the ecological system, industrial production, agricultural practice,  
69 drinking water availability, hydrological processes and water quality (Bussi and  
70 Whitehead, 2020; Lai et al., 2019; Vicente-Serrano et al., 2012; Wang et al., 2014;  
71 Wang et al., 2017). Drought has brought about ca. 221 billion dollars loss during 1960  
72 to 2016 reported by the International Disaster Database (EM-DAT), and the drought  
73 events in South Asia have influenced over 60 million residents from 1998 to 2001  
74 (Agrawala et al., 2001). Unfortunately, the drought is expected to increase in  
75 frequency and intensity due to the future warming air temperature (Trenberth et al.,  
76 2014; Zambrano et al., 2018). The exacerbated drought conditions have promoted  
77 some national legislation (such as drought preparedness and plan) to carry out the risk  
78 management and adaptive strategy for drought disasters (Garrick et al., 2017).

79 The various drought types result in the difficulty of drought monitoring and  
80 assessment. Drought definition is not unique. Some proposed defining drought  
81 according to the water deficit (Wilhite and Glantz, 1985), while others defined  
82 drought based on the period of abnormal arid conditions (Eslamian et al., 2017). The  
83 popular drought can be classified into four types including (1) meteorological, (2)  
84 agricultural, (3) hydrological, and (4) socioeconomic droughts (Mishra and Singh,  
85 2010). The meteorological drought results from precipitation deficit or evaporation  
86 increases (McKee et al., 1993). The meteorological drought can propagate into the  
87 agricultural drought with the lower soil moisture availability, and it also can lead to

88 hydrological drought with lower streamflow and socioeconomic drought with lower  
89 water availability (Barella-Ortiz and Quintana-Seguí, 2019; Gevaert et al., 2018). In  
90 general, drought indices are normally used to monitor and assess the condition or  
91 spatial-temporal characteristic of drought.

92 Many drought indices have been developed for the drought monitoring and  
93 assessment, such as the Palmer drought severity index (PDSI) (Dai et al., 2004),  
94 standardized precipitation index (SPI) (McKee et al., 1993), vegetation water supply  
95 index (VWSI) (Carlson et al., 1994), vegetation health index (VHI) (Kogan, 2002),  
96 vegetation temperature condition index (VTCI) (Wan et al., 2004), and other drought  
97 indices (Men-xin and Hou-quan, 2016; Wang et al., 2015; Wang et al., 2017). PDSI  
98 and SPI are the most popular drought studies worldwide (Dai et al., 2004; McKee et  
99 al., 1993), however, they have some limitation. PDSI is only suitable to the  
100 agricultural drought through characterizing the soil water deficit, and it cannot  
101 identify the meteorological, hydrological, and socioeconomic droughts (Feng and Su,  
102 2019). In addition, PDSI limits the spatial comparability of drought due to the fact  
103 that it is heavily depending on data calibration (Sheffield et al., 2009; Yu et al., 2014).  
104 Although the SPI can monitor and assess different drought types by multiple spatial  
105 scales at the monthly time step, it only considers the precipitation factor and neglects  
106 effects of evaporation stemmed from temperature and other meteorological factors  
107 (Wang et al., 2014; Wang et al., 2017; Yang et al., 2018). To solve the above problems,  
108 the Standardized Precipitation Evapotranspiration Index (SPEI), which considers the  
109 advantage of both PDSI and SPI, was developed to monitor and assess droughts

110 (Vicente-Serrano et al., 2010). It not only accounts for the effect of evaporation on  
111 drought, but also have the capability of spatial comparability and characterizing  
112 different drought types with multiple time scales (Feng and Su, 2019; Wang et al.,  
113 2015). SPEI has been widely used to delineate drought spatial-temporal evolution,  
114 drought characteristics, and impacts of drought at the regional and global scales  
115 (Mallya et al., 2016; Wang et al., 2014).

116       However, the commonly used SPEI fails to identify droughts with less than  
117 one-month duration (Van der Schrier et al., 2011; Vicente-Serrano et al., 2010). With  
118 the future climate change, flash droughts have been recently categorized as a type of  
119 extreme climate events. Flash droughts occur along with sudden onset, rapid  
120 aggravation, and sudden end of drought leading to severe influences (Pendergrass et  
121 al., 2020). It is imperative for monitoring the flash droughts with the short-term  
122 duration (e.g., several days). To use the sub-month resolution drought index, we have  
123 developed the daily SPEI for the first time, and our daily SPEI has been used to assess  
124 the drought and its impacts in previous studies (Wang et al., 2015; Wang et al., 2017).  
125 The new SPEI can not only identify the drought with one-month and more than  
126 one-month duration, but also monitor the drought with several days duration. In  
127 addition, our new daily SPEI has filled the gap in the capability to monitor the onset  
128 and duration of droughts. Our daily SPEI has similar principles with the commonly  
129 used month SPEI in terms of time accumulation effects (Vicente-Serrano et al., 2010;  
130 Wang et al., 2015; Yu et al., 2014). The daily SPEI data with different time scales can  
131 also meet the requirement of monitoring and assessing of different drought types

132 (meteorological drought, agricultural drought and hydrological drought) at multi-time  
133 scales (Wang et al., 2014).

134 The aim of this study, therefore, is to produce a long record (1961-2018) daily  
135 drought index dataset for the whole mainland China. Specifically, we used the new  
136 daily SPEI algorithm to produce the multi-time scale drought dataset at a daily time  
137 resolution. Meteorological data with 427 stations including multi-factor (daily  
138 precipitation, daily average air temperature, daily minimum air temperature, daily  
139 maximum air temperature and sunshine) are used. The developed drought dataset at  
140 the national scale has the potential to be used to monitor and assess droughts and their  
141 impacts for the different sectors.

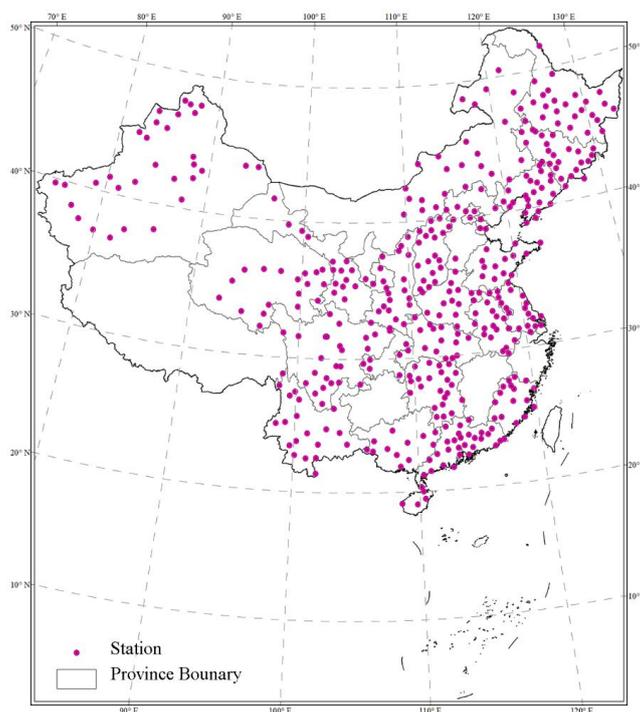

## 142 **2. Data Sources and Methods**

### 143 **2.1 Data Sources**

144 Daily meteorological data from 1960 to 2018 were collected from the National  
145 Meteorological Science Data Sharing Service Platform (<http://data.cma.cn/>). The data,  
146 which have gone through quality controlling, have been used in many studies on  
147 drought (Li et al., 2019; Wang et al., 2019). In total, there are 839 stations with public  
148 data. To ensure continuous and complete data records, we selected 427 stations data  
149 by removing stations with missing data exceeding 30 days. Meteorological variables  
150 include the minimum and maximum air temperature (°C), precipitation (mm) and  
151 sunshine duration (h). The sunshine duration was converted to solar radiation based  
152 on the Ångström function (Chen et al., 2010; Wang et al., 2015). The station location

153 is shown in Figure 1.

154

155 **Figure 1.** The location of meteorological stations across the mainland China.

## 156 **2.2 Daily SPEI Calculation**

157 The daily SPEI can be calculated by the difference between daily precipitation  
158 and daily potential evapotranspiration. Because air temperature and solar radiation  
159 explained at least 80% of evapotranspiration variability (Martí et al., 2015; Priestley  
160 and Taylor, 1972), the Hargreaves model based on temperature and solar radiation can  
161 be used to estimate the daily potential evapotranspiration (Hargreaves and Samani,  
162 1982; Mendicino and Senatore, 2013; Wang et al., 2015). The daily potential  
163 evapotranspiration can be obtained by the following formula:

164  $PET = 0.0023 * (T_{mean} + 17.8) * \sqrt{(T_{max} - T_{min})} * R_a$  (1)

165 where,  $T_{mean}$  is the daily average air temperature ( $^{\circ}\text{C}$ );  $T_{max}$  and  $T_{min}$  are the daily  
166 maximum and minimum air temperatures ( $^{\circ}\text{C}$ ), respectively; and  $R_a$  is the daily net  
167 radiation on the land surface ( $\text{MJ m}^{-2} \text{d}^{-1}$ ).

168 SPEI calculation depends on the accumulating deficit or surplus ( $D_i$ ) of water  
169 balance at different time scales.  $D_i$  can be determined based on precipitations (P) and  
170 PET for a given day  $i$ :

171  $D_i = P_i - PET_i$  (2)

172 The obtained  $D_i$  values are summed at different time scales, following the same  
173 procedure as that for the commonly used SPEI. The  $D_{i,j}^k$  in a given day  $j$  and year  
174  $i$  depends on the chosen time scale  $k$  (days). For example, the accumulated difference  
175 for 1 day in a particular year  $i$  with a 30-day (or other time scales) time scale is  
176 calculated using:

177 
$$X_{i,j}^k = \sum_{l=31-k+j}^{30} D_{i-1,l} + \sum_{l=1}^j D_{i,l}, \quad \text{if } j < k \text{ and}$$
  
$$X_{i,j}^k = \sum_{l=j-k+1}^j D_{i,l}, \quad \text{if } j \geq k$$
 (3)

178 We also need to normalize the water balance into a probability distribution to get  
179 the SPEI index series. The best distribution for SPEI calculation is the generalized  
180 extreme value (GEV) distribution (Stagge et al., 2015), which can overcome the  
181 limitation of original SPEI through generalized logistic distribution for short  
182 accumulation (1–2 months) periods (Stagge et al., 2015; Vicente-Serrano et al., 2010).  
183 Therefore, we adopted the GEV distribution to standardize the D series into SPEI data  
184 series (Monish and Rehana, 2020). The GEV probability density function is:

$$f(x) = \begin{cases} \left(\frac{1}{\sigma}\right) \left[ (1 + \xi z(x))^{-1/\xi} \right]^{\xi+1} e^{-[(1+\xi z(x))^{-1/\xi}]}, & \xi \neq 0, 1 + \xi z(x) > 0 \\ \left(\frac{1}{\sigma}\right) e^{-z(x) - e^{-z(x)}}, & \xi = 0, -\infty < x < \infty \end{cases}$$

185  
 186 (4)  
 187

where,

$$z(x) = \frac{x - \mu}{\sigma} \tag{5}$$

188  
 189

190 where,  $\xi, \sigma$ , and  $\mu$  are the shape, scale, and location parameters respectively.

191 The cumulative distribution function  $F(x)$  of GEV can be calculated by the  
 192 following equation:  
 193

$$F(x) = e^{-t(x)} \tag{6}$$

194  
 195

where,

$$t(x) = \begin{cases} \left( 1 + \xi \left( \frac{x - \mu}{\sigma} \right) \right)^{-1/\xi}, & \text{if } \xi \neq 0 \\ e^{-(x - \mu)/\sigma}, & \text{if } \xi = 0 \end{cases} \tag{7}$$

197 Thus, the probability distribution function of the D series is given by:

$$F(x) = \left[ 1 + \left( \frac{\alpha}{x - \gamma} \right)^\beta \right]^{-1} \tag{8}$$

198 With  $F(x)$ , the SPEI can easily be obtained as the standardized values of  $F(x)$ .

199 Following the classical approximation of Abramowitz and Stegun (1965):  
 200

$$SPEI = W - \frac{C_0 + C_1 W + C_2 W^2}{1 + d_1 W + d_2 W^2 + d_3 W^3} \tag{9}$$

201 where,  $W = \sqrt{-2 \ln(P)}$  for  $P \leq 0.5$  and  $P$  is the probability of exceeding a  
 202 determined  $D$  value,  $P = 1 - F(x)$ . If  $P > 0.5$ , then  $P$  is replaced by  $1 - P$  and the sign  
 203

204 of the resultant SPEI is reversed. The constants are  $C_0 = 2.515517$ ,  $C_1 = 0.802853$ ,  
205  $C_2 = 0.010328$ ,  $d_1 = 1.432788$ ,  $d_2 = 0.189269$ , and  $d_3 = 0.001308$ .

### 206 2.3 Drought Analysis Method

207 The daily SPEI dataset were calculated at multi-time scales (1-month, 3-months,  
208 6-months, 9-months and 12-months) using the daily meteorological data from  
209 1960-2018 at 427 station locations. The classifications for the SPEI drought classes  
210 are presented in Table 1.

211

212 Table 1 Categorization of drought and wet grade according to the SPEI.

Categorization	SPEI values
Extremely Wet	$\text{SPEI} \geq 2$
Severe Wet	$1.5 \leq \text{SPEI} < 2$
Moderate Wet	$1 \leq \text{SPEI} < 1.5$
Mild Wet	$0.5 < \text{SPEI} < 1$
Normal	$-0.5 \leq \text{SPEI} \leq 0.5$
Mild Drought	$-1 < \text{SPEI} < -0.5$
Moderate Drought	$-1.5 < \text{SPEI} \leq -1$
Severe Drought	$-2 < \text{SPEI} \leq -1.5$
Extremely Drought	$\text{SPEI} \leq -2$

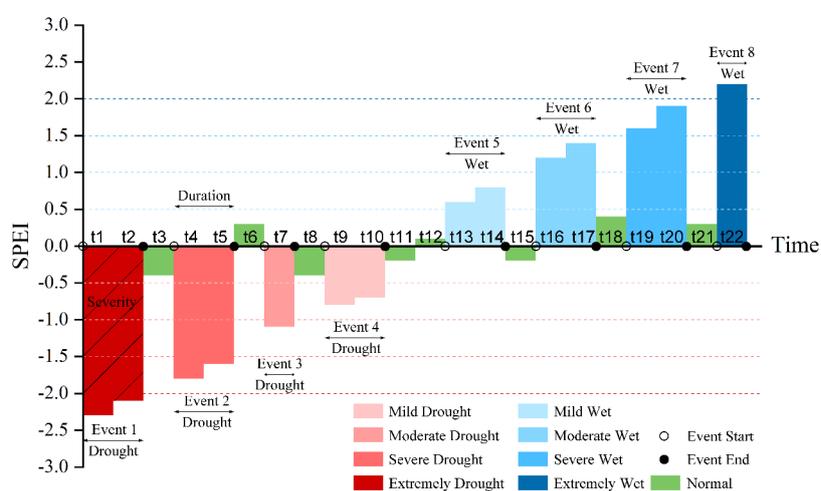

213

214 We used the method described by Yevjevich (1967) too define the drought  
215 characteristics (severity, duration, and intensity). A drought event can be firstly  
216 determined by drought start and end dates, and its duration and severity were then  
217 assigned. Thus, we accounted for the continuity of drought propagation. The  
218 continuous days with SPEI values less than the threshold (such as -0.5,-1.0,-1.5,-2)  
219 are defined as the duration of a drought event.. The severity is the integral area  
220 between absolute value of the SPEI with value  $< -0.5$  and the horizontal axis (SPEI = 0)

221 from the drought start day to the drought end day. The drought frequency is the total  
222 number of drought events in a period. The drought event and its characteristics  
223 (severity, duration, and intensity) can be demonstrated in Figure 2.

224

225

226 **Figure 2.** Schematic diagram of drought and wet events (the red shaded area  
227 denotes the drought events; the blue shaded area denotes the wet events).

228

229 The SPEI data based on 90-day (3-month) time scales can be used to identify soil  
230 moisture or agriculture droughts (Wang et al., 2014). Due to its important applications,  
231 we selected the SPEI data with the 90-day time scales as the example data for  
232 analyzing in the present study. To investigate the spatial-temporal characteristics of  
233 the example data, we defined three variables including Annual Total Drought Severity  
234 (ATDS), Annual Total Drought Duration (ATDD), and Annual Total Drought  
235 Frequency (ATDF). The three variables were obtained by summing the severity,  
236 duration, and frequency of all the drought events in each year at 427 stations.

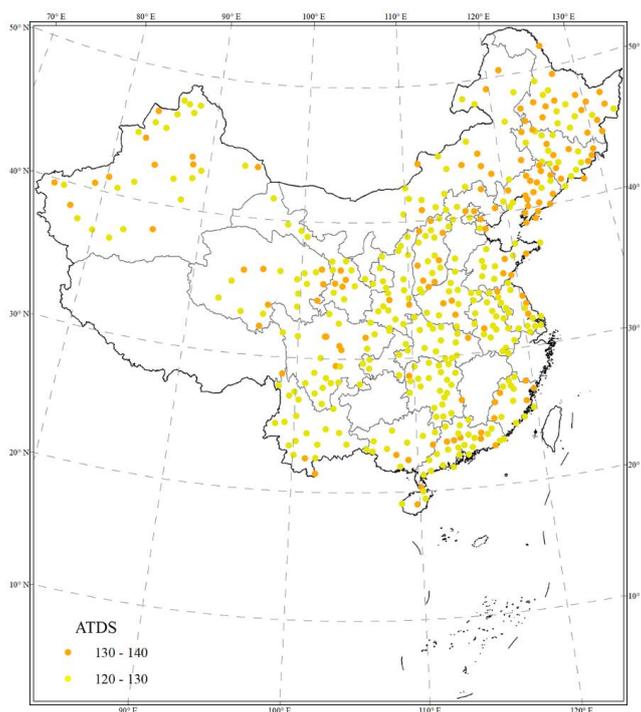

237 We also used the non-parametric Mann–Kendall (MK) test to detect monotonic  
238 trends (Kendall, 1948; Mann, 1945), and computed slopes for ATDS, ATDD and ADF  
239 using the Sen’s method (Sen, 1968). These statistical methods are commonly used in  
240 analyses of water resources, climate, and ecology data. For the MK test, the global  
241 trend for the entire series is significant when P-value < 0.05.

## 242 **3 Analysis Results**

### 243 **3.1 Spatial Distribution of Drought Characteristics**

244 The ATDS can be used to identify hot spots with severer drought conditions. Figure  
245 3 shows the calculated ATDS values across the mainland China. We categorized  
246 ATDS values into two main groups with higher ATDS values indicated more severe  
247 drought conditions. The distribution of ATDS values shows that, in general,  
248 northeastern parts of China had more severe drought conditions than southern parts.  
249 However, our results also indicate that the humid climate zone in the south also  
250 experienced severe drought conditions, though not as much as for northern parts of  
251 China (Figure 3).

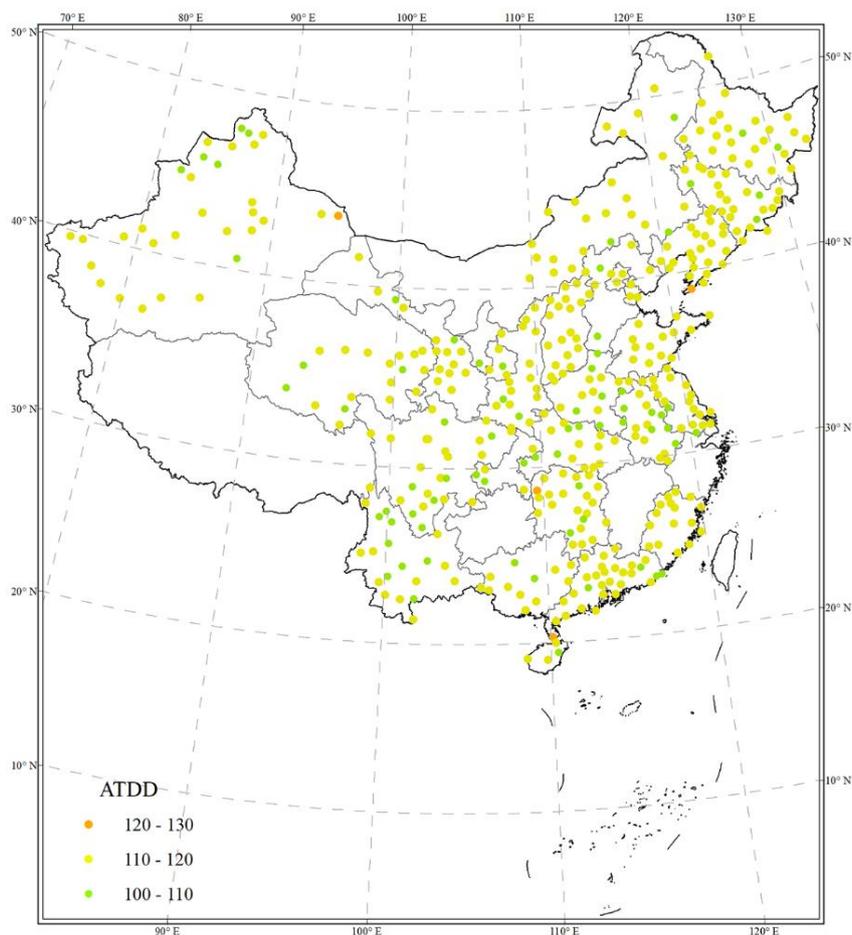

252

253

**Figure 3.** The spatial distribution of ATDS across the mainland China.

254

255 Figure 4 shows that ATDD values ranged from 100 to 110 days for most stations  
256 across the mainland China. This indicates that there was near one-third of a year when  
257 most stations were experiencing drought conditions. More stations with ATDD values  
258 ranging from 100 to 110 were found compared with stations with ATDD values of  
259 120-130 (Fig. 4). For drought years, the duration days of drought events are expected  
260 to be were longer. The ATDD had similar spatial distribution characteristics with the  
261 ATDS, indicating that droughts also occurred in the humid climate zone.

262

263

**Figure 4.** The spatial distribution of ATDD across the mainland China.

264

265

Figure 5 shows the spatial distribution of ATDF values across the mainland China.

266

In general, most stations had 4-6 annual drought events. There were fewer stations

267

with 6-8 annual drought events compared with stations with 2-4 annual drought

268

events. We also detected that drought events could be occurring in both arid and

269

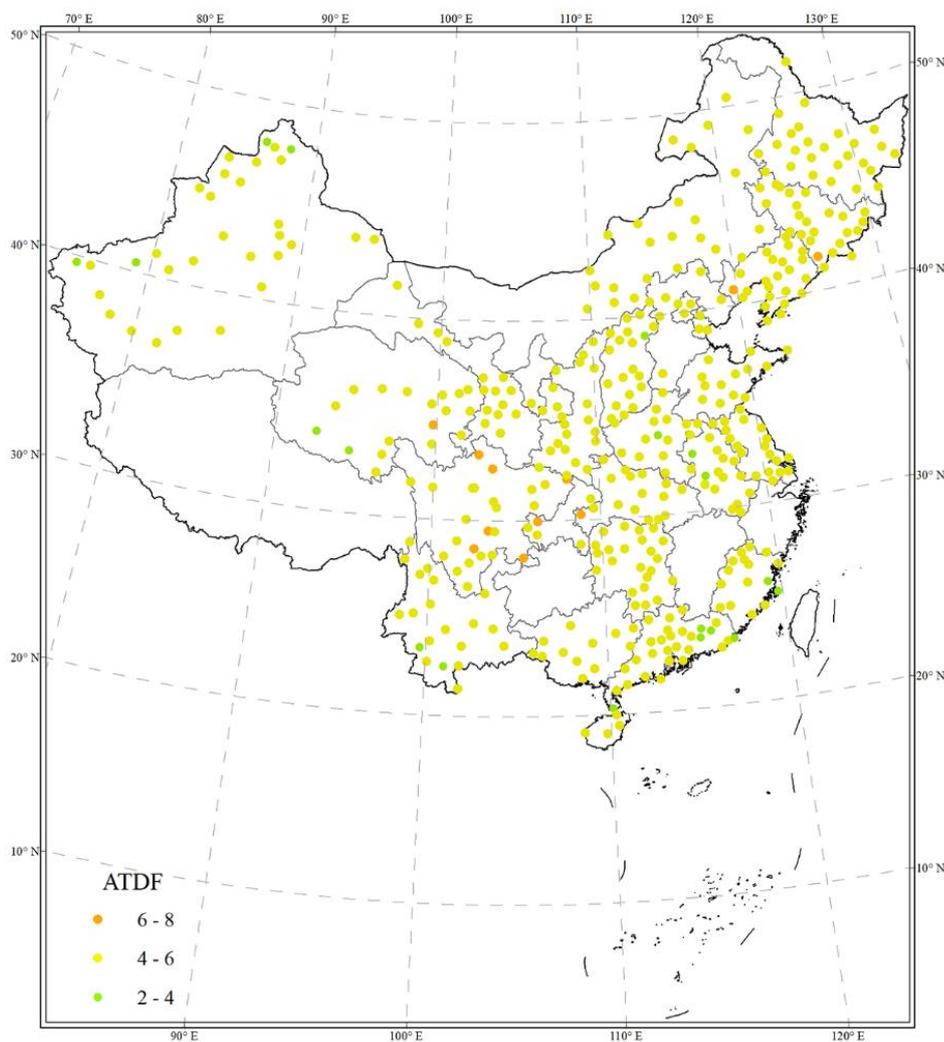

humid regions based on spatial distributions of ATDF values (Figure 5). Since the

270

ATDF indicated only the annual average drought events, we could expect that for the

271 severer drought years the ATDF would have greater values for different stations.

272

273 **Figure 5.** The spatial distribution of ATDF across the mainland China.

274

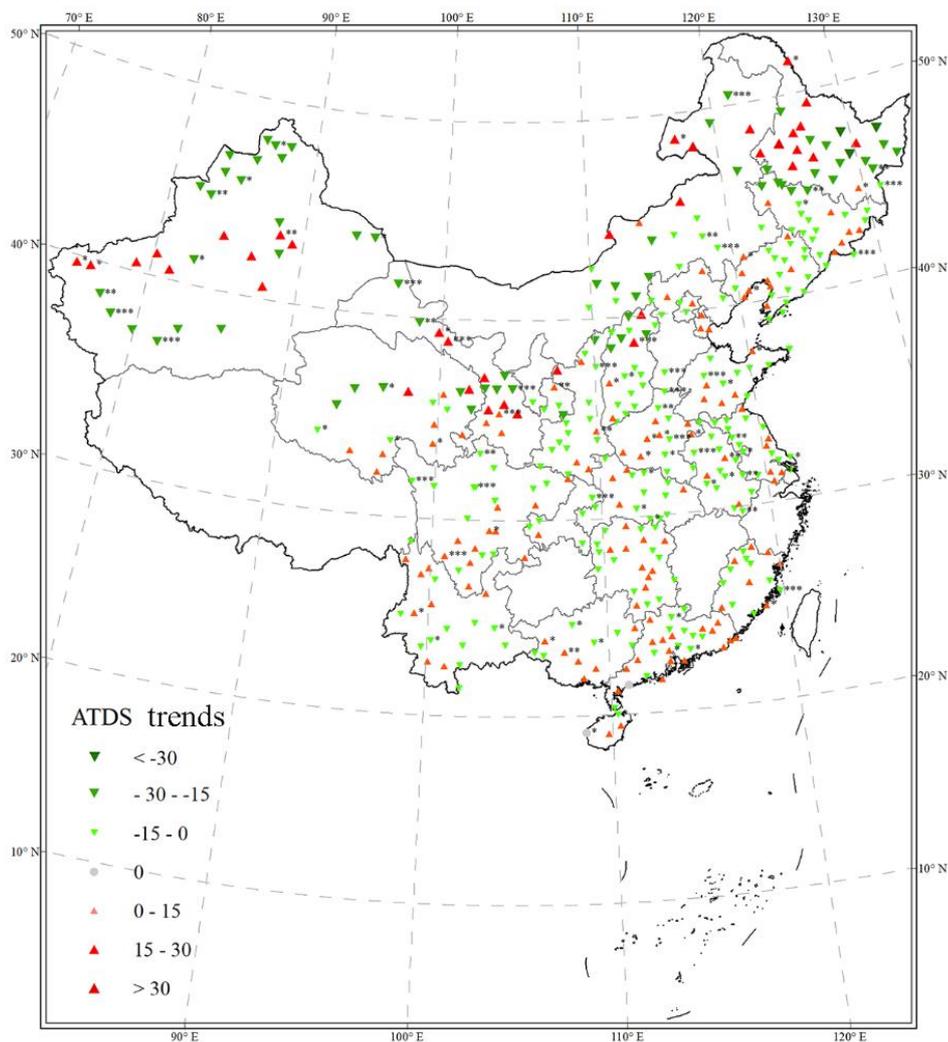

### 275 3.2 Trends in Drought Characteristics

276 The changing trends of ATDS can be used to detect whether drought severity is

277 weakening or intensifying with time, Figure 6 shows that the spatial distribution of

278 changing trends of ATDS from 1961 to 2018 across the mainland China. In general,  
279 there were more stations with weakening trends in drought severity than those with  
280 intensifying trends across all stations (Figure 6). It seems that both weakening and  
281 intensifying absolute values were largest in the northeast, northwest, and central  
282 China compared with other parts. However, after scrutiny, we found that drought  
283 severity tended to weaken in the northeast, northwest, and center China with more  
284 stations having significant weakening trends by statistical test ( $P\text{-value} < 0.05$ ; Figure  
285 6). For southern China, most stations had no significant trends in either weakening or  
286 intensifying of drought severity ( $P\text{-value} > 0.05$ ; Figure 6).

287

288 **Figure 6.** The spatial distribution of the changing trends of ATDS (the red and green  
289 triangular indicate increasing and decreasing trends, respectively. “\*\*\*\*” denotes  
290 P-value < 0.001, “\*\*\*” denotes P-value < 0.01, and “\*\*” denotes P-value < 0.05).

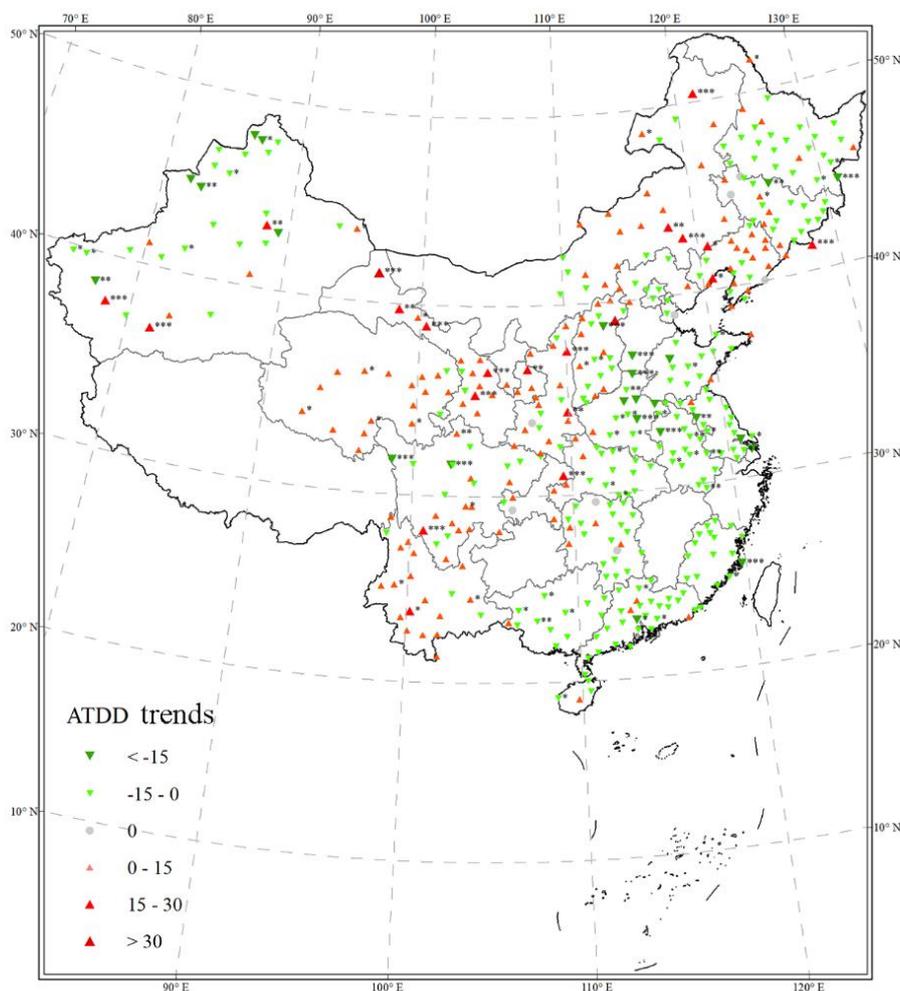

291

292 The changing trends of ATDD can be used to detect whether drought duration is  
293 getting shorter or longer. Figure 7 shows the spatial distribution of changing trends for

294 the ATDD across all stations. In general, stations in the southeast demonstrated  
295 downward trends with shortening drought duration, while stations in the northwest  
296 had upward trends for the ATDD with increasing drought duration (Figure 7). Note  
297 that the increasing or decreasing trends for ATDD were significant ( $P$  value  $< 0.05$ )  
298 for stations across the central China indicating that the central China regions were  
299 suffering dramatic changes of drought conditions.

300

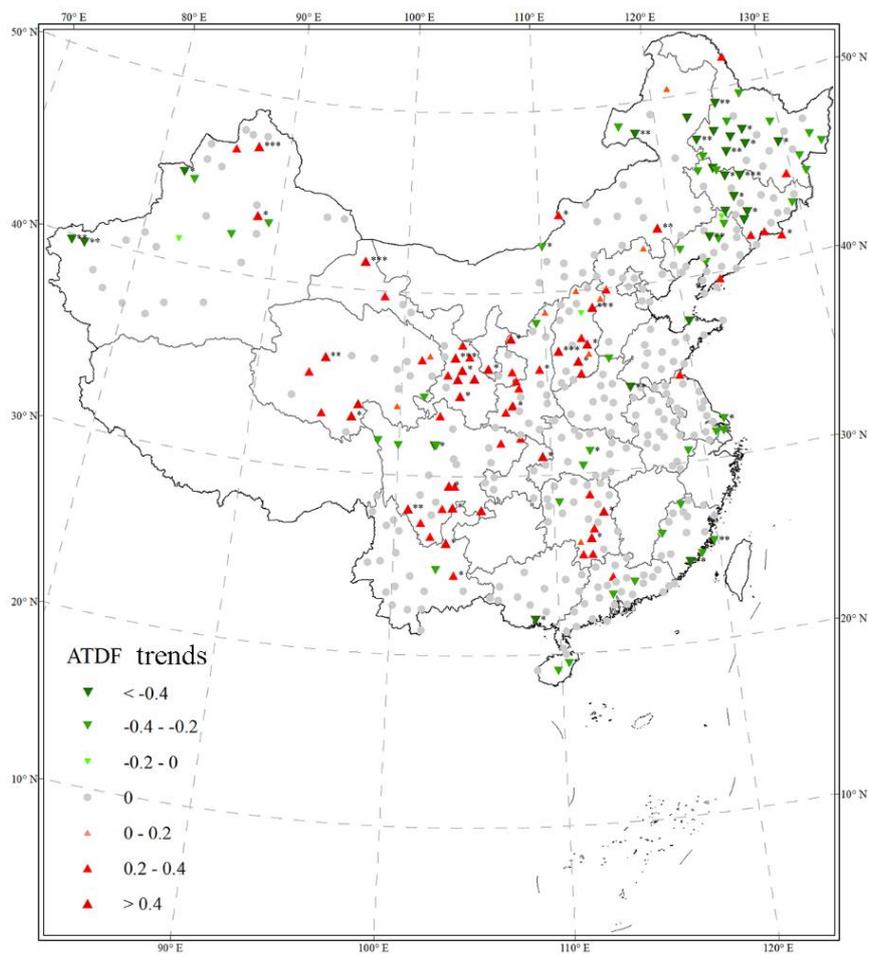

301

302 **Figure 7.** The spatial distribution of the changing trends of ATDD (the red and green  
303 triangular indicate increasing and decreasing trends, respectively. “\*\*\*\*” denotes  
304 P-value < 0.001, “\*\*\*” denotes P-value < 0.01, and “\*\*” denotes P-value < 0.05).

305

306 The changing trends of ATDF can be used to detect whether the frequency of  
307 drought events is increasing or decreasing with time. Figure 8 shows the spatial  
308 distribution of changing trends of ATDF across all stations. Most stations  
309 demonstrated no significant trend in the frequency of drought events, except for  
310 dozens of stations in western China having significant upward trends (P-value < 0.05)  
311 with increasing frequency in drought events, and stations in northeastern China  
312 demonstrated significant downward trends (P-value < 0.05) with decreasing  
313 frequency of drought events.

314

315 **Figure 8.** The spatial distribution of the changing trends of ATDF (the red and green  
316 triangular indicate increasing and decreasing trends, respectively. “\*\*\*” denotes  
317 P-value < 0.001, “\*\*” denotes P-value < 0.01, and “\*” denotes P-value < 0.05).

318

319

#### 320 **4. Discussion**

321       The reason for selecting 3-month scale to assess spatial and temporal  
322 characteristics of drought conditions across the mainland China is because the SPEI  
323 with the 3-month scale can indicate the agricultural drought (or soil moisture) (Van  
324 der Schrier et al., 2011; Wang et al., 2014; Wang et al., 2017), and its results are  
325 comparable with the PDSI (Dai et al., 2004; Van der Schrier et al., 2011) and other  
326 drought indices including Surface Water Supply Index (SWSI) and Moisture  
327 Adequacy Index(MAI) (Doesken and Garen, 1991; McGUIRE and Palmer, 1957).  
328 The commonly used monthly SPEI have been used to assess drought characteristics  
329 and their impacts worldwide from the regional scale to the global scale (Stagge et al.,  
330 2015; Vicente-Serrano et al., 2010; Wang et al., 2014). The SPEI with different time  
331 scales is relevant for meteorological drought (1-month timescale), agricultural drought  
332 (3-6-month timescale), hydrological drought (12-month timescale), and  
333 socioeconomic drought (24-month timescale), respectively (Homdee et al., 2016;  
334 Potop et al., 2014; Tirivarombo et al., 2018; Vicente-Serrano et al., 2010).

335       Our new SPEI dataset with multi-time scales were developed and compiled using  
336 the daily SPEI algorithm in the previous study (Wang et al., 2015). The daily SPEI  
337 has been used in drought monitoring and assessment, and was validated by drought  
338 monitoring and assessment (Jevšenak, 2019; Jia et al., 2018; Salvador et al., 2019;  
339 Wang et al., 2015; Wang et al., 2017). The global SPEI database with monthly  
340 temporal resolution and 0.5 degree spatial resolution is available

341 (<https://spei.csic.es/database.html>). The database covers the period between January  
342 1901 and December 2018. Although the database can be used effectively for the  
343 meteorological, agricultural, hydrological, and socioeconomic droughts, it cannot  
344 identify and detect the flash drought with less than one-month duration. In addition,  
345 the database can only detect the start month and end month of drought events, and  
346 therefore it fails to determine the start and end dates of a drought event, the monthly  
347 SPEI (Kassaye et al., 2020; Vicente-Serrano et al., 2010; Wang et al., 2014). Our  
348 newly developed daily SPEI can compensate the shortcomings of monthly SPEI in  
349 drought monitoring and assessment. In addition, we used the well-received GEV  
350 probability distribution for the SPEI calculation for our dataset (Stagge et al., 2015).

351       Although the daily SPEI has better performance in drought monitoring and  
352 assessment (Jevšenak, 2019; Wang et al., 2017), the uncertainty of daily SPEI still  
353 needs to be evaluated in future works. Our daily SPEI dataset used the simple  
354 Hargreaves model based on temperature and solar radiation to estimate daily potential  
355 evapotranspiration (Hargreaves and Samani, 1982; Wang et al., 2017). We will further  
356 investigate effects of various evapotranspiration models (such as CRAE model,  
357 Penman algorithm, Thornthwait algorithm, Makkink algorithm, and Priestley–Taylor  
358 algorithm) on the calculation of SPEI (Makkink, 1957; Morton, 1983; Penman, 1948;  
359 Priestley and Taylor, 1972; Thornthwaite, 1944). We only chose SPEI based on the  
360 3-month timescale as an example to analyze drought characteristics, and the results  
361 demonstrated that there was no obvious intensifying trends for drought across the  
362 mainland China which is consistent with other studies (Han et al., 2020). Meanwhile,

363 our newly developed daily SPEI will be validated in other regions of the world.

364 Our long-term daily SPEI dataset has contributed significantly to our  
365 understanding of drought evolution, especially flash drought. The dataset can be used  
366 to monitor and assess different drought types (meteorological drought, agricultural  
367 drought, and hydrological drought) through different timescale data. It also can  
368 identify the start and end dates for drought. Our daily SPEI dataset not only have the  
369 capability of monitoring and assessing droughts, but also can be used to evaluate the  
370 impact of droughts on ecological system and natural resources. The dataset is valuable  
371 to meteorological research and natural hazards communities for various purposes such  
372 as assessment of extreme climate or drought effect evaluation.

## 373 **5. Data Availability**

374 All daily SPEI dataset including data and their description at 427 observed  
375 meteorological stations, the data is also provided as open access via figshare (Wang et  
376 al, 2020), available at doi: [doi.org/10.6084/m9.figshare.12568280](https://doi.org/10.6084/m9.figshare.12568280). This depository  
377 includes the five files directory of the daily SPEI data with five scales (1 month, 3  
378 month, 6 month, 12 month, 24 month) and station information for 427 meteorological  
379 stations.

## 380 **6. Summary**

381 In the present study, we have produced a daily SPEI dataset from 1960 to 2018 at  
382 427 meteorological stations across the mainland China. Our open-access dataset is an

383 important contribution to drought assessment, and it can overcome the disadvantages  
384 of the commonly used monthly SPEI database. Our daily dataset can help monitor and  
385 assess the spatial and temporal characteristics of droughts. It can be used to assess the  
386 impacts of droughts on ecological system, hydrological processes, and other natural  
387 resources. Our multi-time scale daily SPEI dataset can be widely used in studies on  
388 meteorological drought (1-month timescale), agricultural drought (3-6-month  
389 timescale), hydrological drought (12-month timescale), and socioeconomic drought  
390 (24-month timescale). The dataset will reduce the time spent on research and avoid  
391 the duplication of efforts, which will be highly attractive to meteorological,  
392 geographical, natural hazard researchers and searchers from other areas.

393

394 **Author contributions.** QFW led the study, developed the method, and wrote the  
395 manuscript with input from all the authors. JYQ and XSZ discussed the results and  
396 revised the manuscript. All the authors contributed to the final manuscript. QFW, JYZ,  
397 RRZ, XPW, and XZZ collected and analysed data over time, providing statistics and  
398 material (graphs and tables) for the paper.

399

400 **Competing interests.** The authors declare that they have no conflict of interest.

401 **Acknowledgements.** This research received financial support from the National  
402 Natural Science Foundation of China (41601562), the Strategic Priority Research  
403 Program of the Chinese Academy of Sciences (XDA13020506) and China  
404 Scholarship Council. The authors sincerely thank James Howard Stagge for his help

405 on the codes and calculation of SPEI. Special thanks go to the meteorological data  
406 provider from China Meteorological Administration (<http://cdc.cma.gov.cn/>).
