31 Abstract

32 Mapping the biogeochemical characteristics of surficial ocean sediments is crucial for  
33 advancing our understanding of global element cycling, as well as for assessment of the  
34 potential footprint of environmental change. Despite their importance as long-term repositories  
35 for biogenic materials produced in the ocean and delivered from the continents,  
36 biogeochemical signatures in ocean sediments remain poorly delineated. Here, we introduce  
37 MOSAIC (Modern Ocean Sediment Archive and Inventory of Carbon; DOI:  
38 <https://doi.org/10.5168/mosaic019.1>, [mosaic.ethz.ch](https://mosaic.ethz.ch), Van der Voort et al., 2019), a  
39 (radio)carbon-centric database that seeks to address this information void. The goal of this  
40 nascent database is to provide a platform for development of regional to global-scale  
41 perspectives on the source, abundance and composition of organic matter in marine surface  
42 sediments, and to explore links between spatial variability in these characteristics and  
43 biological and depositional processes. The database has a continental margin-centric focus  
44 given both the importance and complexity of continental margins as sites of organic matter  
45 burial. It places emphasis on radiocarbon as an underutilized yet powerful tracer and  
46 chronometer of carbon cycle processes, and with a view to complementing radiocarbon  
47 databases for other earth system compartments. The database infrastructure and interactive  
48 web-application are openly accessible and designed to facilitate further expansion of the  
49 database. Examples are presented to illustrate large-scale variabilities in bulk carbon properties  
50 that emerge from the present data compilation.

51

52 1. Introduction

53 Oceans sediments constitute the largest and ultimate long-term global organic carbon (OC)  
54 sink (Hedges and Keil, 1995), and serve as a key interface between short- and long-term  
55 components of the global carbon cycle (Galvez et al., 2020). Assessments of the distribution  
56 and composition of OC in ocean sediments are crucial for constraining carbon burial fluxes,  
57 the role of ocean sediments in global biogeochemical cycles, and in interpretation of  
58 sedimentary records. Constraining the magnitude of carbon stocks, as well as delineating the  
59 sources, pathways and timescales of carbon transfer between different reservoirs (e.g.,  
60 atmosphere, oceanic water column, continents) comprise essential challenges. In this regard,  
61 radiocarbon provides key information on carbon sources and temporal dynamics of carbon  
62 exchange. The half-life of radiocarbon is compatible with assessments of carbon turnover and  
63 transport times within and between different compartments of the carbon cycle, while also  
64 serving to delineate shorter-term (< 50 kyr) and longer-term (> 50 kyr) cycles. Moreover, the  
65 advent of nuclear weapons testing in the mid 20<sup>th</sup> century serves as a time marker for the onset  
66 of the Anthropocene (Turney et al., 2018), and a tracer for carbon that has recently been in  
67 communication with the atmosphere. With on-going dilution of this atmospheric “bomb spike”  
68 with radiocarbon-free carbon dioxide from the combustion of fossil fuels (Graven, 2015; Suess,  
69 1955), radiocarbon serves a particularly sensitive sentinel of carbon cycle change.

70

71 Radiocarbon databases or data collections have been established for the atmosphere (e.g.  
72 University Heidelberg Radiocarbon Laboratory, 2020), ocean waters (Global Data Analysis  
73 Project (GLODAP), Key et al., 2004), and most recently soils (ISRaD; Lawrence et al., 2020)  
74 , with tree-rings, corals and other annually-resolved archives providing information on  
75 historical variations in <sup>14</sup>C in the atmosphere and surface reservoirs (Friedrich et al., 2020;  
76 Reimer, 2020). At present, no such radiocarbon database exists for OC residing in ocean  
77 sediments. As a sensitive tracer of carbon sources and carbon cycle perturbations, there is a  
78 clear imperative to fill this information void given that on-going anthropogenic activities  
79 directly and indirectly influence ocean sediment and resident OC stocks (Bauer et al., 2013;  
80 Breitburg et al., 2018; Ciais et al., 2013; Keil, 2017; Regnier et al., 2013; Syvitski et al., 2003).  
81 Materials accumulating in modern ocean sediments also provide a crucial window into how  
82 on-going processes that are observable through direct instrumental measurements and remote  
83 sensing data manifest themselves in the sedimentary record.

Deleted:

Deleted: (Friedrich et al., 2020; Reimer et al., 2009)

86

87 Over 85% of OC burial in the modern oceans occurs on continental margins, with deltaic, fjord  
88 and other shelf and slope depositional settings constituting localized hotspots for carbon burial  
89 (Bianchi et al., 2018; Hedges and Keil, 1995). As the interface between land and ocean,  
90 continental margins comprise a key juncture in the carbon cycle (Bianchi et al., 2018), provide  
91 crucial habitats for unique marine ecosystems (Levin and Sibuet, 2012), support a major  
92 fraction of the worlds fisheries (Worm et al., 2006), and participate in exchange processes with  
93 the interior ocean (Dunne et al., 2007; Jahnke, 1996; Rowe et al., 1994). These ocean settings  
94 and their underlying sediments are also amongst those most vulnerable to change (Keil, 2017)  
95 through direct perturbations such as contaminant and nutrient discharge from land, loci of  
96 intense resource extraction such as bottom trawling (Pusceddu et al., 2014) and mineral and  
97 hydrocarbon recovery (e.g., Chanton et al., 2015), as well as indirect effects such as ocean  
98 warming (Roemmich et al., 2012), acidification (Feely et al., 2008; Orr et al., 2005) and local  
99 or large-scale deoxygenation (Diaz and Rosenberg, 2008; Keeling et al., 2010). Such influences  
100 may change not only the amount of carbon sequestered in marine sediments but also its  
101 character, with radiocarbon serving as a key metric to detect such change.

102

103 At present, an information gap exists between the numerous in-depth biogeochemical  
104 investigations of carbon burial focused on geographically-localized regions (e.g., Bao et al.,  
105 2016; Bianchi, 2011; Castanha et al., 2008; Kao et al., 2014; Schmidt et al., 2010; Schreiner et  
106 al., 2013) and global-scale syntheses that draw upon large suites of bulk OC concentration  
107 measurements but are limited in diversity of geochemical information (e.g., Atwood et al.,  
108 2020; Premuzic et al., 1982; Seiter et al., 2004, 2005) and lack sedimentological context.  
109 Consequently, current global-scale budgets and global-scale Earth System Models (ESMs) do  
110 not resolve regional or small-scale variability (Bauer et al., 2013), and are limited by our  
111 current understanding of variability in biogeochemical and sedimentary processes that  
112 influence sedimentary organic matter composition and reactivity (Arndt et al., 2013; Bao, R.  
113 et al., 2018; Levin and Sibuet, 2012; Middelburg, 2018). Snelgrove et al., (2018), for example,  
114 argues that robust estimates of sediment carbon turnover are impeded by high spatial variability  
115 in sediment carbon properties. Increasingly powerful Region Oceanic Model Systems (ROMS)  
116 models (e.g., Gruber et al., 2012) and statistical methods for geospatial analysis (e.g., van der  
117 Voort et al., 2018; Atwood et al., 2020) hold the potential to utilize information from local-  
118 scale studies and inform ESMs, but these require mining and collation of existing data and  
119 merging this with new observations. Spatially-resolved datasets for marine sedimentary OC

Deleted: ?/contents?

127 are beginning to emerge (e.g. Inthorn et al., 2006; Schmidt et al., 2010), including radiocarbon  
128 measurements (e.g., Bao et al., 2016; Bosman et al., 2020). The latter information is likely to  
129 increase in availability with the advent of natural-abundance  $^{14}\text{C}$  measurement via elemental  
130 analysis coupled with gas-accepting accelerator mass spectrometry (AMS) systems (McIntyre  
131 et al., 2016; Wacker et al., 2010) that enable routine, high-throughput  $^{14}\text{C}$  measurements.

132

133 Overall, there is a strong need to synthesize information related to not only OC content, but  
134 also its composition and depositional context, from separate region-based studies. Merging of  
135 this information to provide pan-continental margin ocean floor data resources would enable  
136 development of robust budgets and detection in changes in the magnitude or nature of carbon  
137 stocks. In addition to the content and radiocarbon characteristics of OC that are of value in  
138 constraining the provenance and reactivity of OM (Griffith et al., 2010), other geochemical  
139 characteristics of organic matter, including the elemental composition (e.g., C/N ratio)  
140 abundance, stable isotopic ( $^{13}\text{C}$ ,  $^{15}\text{N}$ ) and molecular (biomarker) composition of organic matter,  
141 as well as contextual properties such as sedimentation rate, mixed-layer depth, [bioturbation](#)  
142 [intensity](#), and redox conditions (Aller and Blair, 2006; Arndt et al., 2013; Griffith et al., 2010a)  
143 are needed to provide a holistic depositional perspective. With on-going analytical advances  
144 that facilitate more rapid and streamlined sediment analysis, it is anticipated that there will be  
145 substantial increases in data availability and diversity, highlighting the urgent need to compile,  
146 organize and harmonize existing datasets.

147

## 148 2. The MOSAIC database

149 In this study, we present MOSAIC (Modern Ocean Sediment Archive and Inventory of Carbon)  
150 – a database designed to provide a window into the spatial variability in geochemical and  
151 sedimentological characteristics of surficial ocean sediments on regional to global scales.  
152 MOSAIC represents the starting point of an on-going endeavor to compile from data from prior  
153 and on-going studies in order to build a comprehensive, continental margin-centric picture of  
154 the distribution and characteristics of organic matter accumulating in modern ocean sediments.  
155 The database infrastructure has been configured for facile incorporation of new data, for  
156 expansion of included parameters, as well as for retrieval of data in an accessible and citable  
157 format. MOSAIC is realized in an interactive web environment which allows users to visualize,  
158 select and download data. This infrastructure is built using open-source (or optional open-  
159 source) software (SI Table 1). The overarching goal is for MOSAIC to serve as a data platform

Deleted:

Deleted: a

162 for the scientific community to explore the nature and causes of spatial patterns of  
163 biogeochemical signatures in ocean sediments.

164

## 165 2.1. Database scope and content

166

### 167 2.1.1. Spatial and depth coverage and georeferencing

168 The focus of MOSAIC is on the coastal ocean (continental margins) with limited inclusion of  
169 data from deep ocean settings. Attention is also restricted to surficial sediments (nominally the  
170 upper ~ 1m) that are most effectively sampled with shallow coring systems designed to recover  
171 an intact sediment-water interface (e.g., hydraulically-damped multicorer, box corer). The  
172 rationale is because of the focus on processes associated with deposition, early diagenesis, and  
173 burial of organic matter, rather than on down-core investigations used for paleoceanographic  
174 and paleoclimate reconstruction. Sediment depth profile data [can be](#) primarily used to examine  
175 diagenetic profiles, and to constrain sedimentation rates, mixed layer depths, redox gradients,  
176 as well as to determine carbon fluxes and inventories.

177

### 178 2.1.2 Scope of data acquisition

179 The data currently comprising the MOSAIC database was extracted from over two hundred  
180 publications. No unpublished data is included in the on-line version, and the focus of the  
181 database in this initial phase of implementation is on an initial suite of commonly measured  
182 sediment parameters (e.g. sampling depth, carbon content and  $\delta^{13}\text{C}$ ) that are available in high  
183 abundance. A non-exhaustive list of the most important parameters cataloged in the MOSAIC  
184 database can be found in Table 1. A more comprehensive list of parameters [that are available](#)  
185 [in the SQL framework can be found in the](#) Supplemental Information (SI).

186

### 187 2.1.3 Core parameters

188 The database was established based on selected key parameters, with a particular emphasis on  
189 the radiocarbon content of OC, as well as other basic properties that provide broader  
190 geochemical and sedimentological context (Table 1). The former include total organic carbon  
191 (TOC) and total nitrogen (TN) content, organic carbon/total N ratios, and the [carbon isotopic](#)  
192 composition ( $\delta^{13}\text{C}$  and  $^{14}\text{C}$  values) of OC. Sedimentological parameters are yet to be  
193 implemented in the on-line version but will include parameters such as grain size, mineral

Formatted: Font: (Default) +Body (Calibri)

Deleted: that are targeted for inclusion in the near future can be found in the

Deleted: stable

197 specific surface area, mixed layer depth, oxygen penetration depth, sedimentation rate, porosity  
198 and dry bulk density.

199

## 200 2.2 MOSAIC Structure

201 The normalized relational database structure of the MOSAIC database was created using the  
202 open-source MySQL software (MySQL Workbench Community for Ubuntu 18 version  
203 6.3.10). The relational aspect of the database means that data (e.g., related to sample or  
204 location-specifics) are stored in data tables which are connected (or related) by a unique  
205 identifier. “Normalized” implies that in the structure of the database redundancies are  
206 eliminated (e.g., a variable such as water depth occurs only once in the database, Codd, 1990).  
207 A schematic of the detailed database structure can be found in SI Figure 2. The database  
208 structure contains entries for key geochemical parameters pertaining to ocean sediment core  
209 samples, including organic matter content, isotopic signature, and composition, as well as  
210 texture and sedimentological parameters. Information can be collected for bulk samples as well  
211 as, for example, size and density fractions. Furthermore, it is designed to enable additional  
212 modules that can accommodate data related to other sample suites such as sinking particulate  
213 matter from the ocean water column (e.g., time-series sediment traps), or riverine samples. It  
214 includes an exclusivity option which can be used to indicate if data is in the public domain  
215 or not (e.g., pending publication of separate contributions).

216 Reporting conventions are detailed in the SI Table 2. Units as specified in the original papers  
217 were used (listed in SI). Where possible  $^{14}\text{C}$  information was collected as  $\Delta^{14}\text{C}$ , alternatively it  
218 was collected as  $Fm$ , and all  $\Delta^{14}\text{C}$  values were converted to  $Fm$  [when sampling year was avail-](#)  
219 [able](#) (Stuiver and Polach, 1977). Ongoing efforts are underway to further harmonize the data  
220 and convert all data to  $\Delta^{14}\text{C}$  for the next iteration for the MOSAIC database.

## 221 2.3 The MOSAIC Pipeline

222 There is a five-step pipeline for incorporation of data into MOSAIC. These are: (1) data  
223 ingestion, (2) quality control, (3) transformation and structuring and (4) addition to a user-  
224 friendly MySQL database interface, which is (5) available for users via a [website](#) (Figure 1).  
225 This design enables users to query the collected data and augment and extend the existing  
226 database using familiar spreadsheet software (Microsoft Excel®, LibreOffice). The associated  
227 app allows any user to interactively select, visualize and query data without using database  
228 (SQL) syntax (SI Figure 1).

229

230 2.3.1 Data ingestion

231 Input of data to the database is possible by filling in a pre-structured spreadsheet file with set  
232 vocabularies. The user selects relevant parameter inputs from drop-down menus that streamline  
233 data entry and assist in execution of subsequent SQL queries. Excel files were designed for  
234 specific datasets, and within each Excel file there are three sub-tabs corresponding to groups  
235 of the normalized MOSAIC SQL database (more details on database structure are provided in  
236 the database). These tabs are (i) sample-related tab, (ii) geopoint-related tab (i.e., location), (iii)  
237 author-related tab (i.e., paper). Certain variables pertaining to sample coordinates and depth  
238 are required for data submission (i.e., latitude, longitude, water depth and sample core depth).  
239 In this first version of MOSAIC, filled-in spreadsheet files with specified units and pre-defined  
240 lists can be sent to [mosaic@erdw.ethz.ch](mailto:mosaic@erdw.ethz.ch)<sup>1</sup> for ingestion into the database.

241

242 2.3.3 Data quality

243 2.3.3.1 Initial data collection

244 [The current MOSAIC dataset was initiated by manual mining of an initial subset of peer-re-](#)  
245 [viewed oceanographic papers that contained substantial TO<sub>14</sub>C datasets \(e.g., Griffith et al.,](#)  
246 [2010\) from different continental margin systems. This enabled the collecting researcher to be](#)  
247 [trained in the process of data evaluation and handling. MOSAIC was further expanded by ex-](#)  
248 [tracting data from a broader suite peer-reviewed papers which were found using the search](#)  
249 [engine Google Scholar, with search terms including “organic carbon in surficial/surface sedi-](#)  
250 [ments”, “TOC in surficial/surface sediments” and “radiocarbon/<sup>14</sup>C in surficial/surface sedi-](#)  
251 [ments”. Data was, where necessary, converted to common units. For instance, all coordinates](#)  
252 [were converted to the WSG84 coordinate systems, all total organic carbon was converted to](#)  
253 [percentages, and sample depth to centimeters. More details can be found in SI Table 1.](#)

254

255 2.3.3.2 Data quality control

256 Quality control of the input data is implemented via a python script tailored to the pre-defined  
257 spreadsheet files. This script auto-checks the values of key parameters such as latitude,  
258 longitude, carbon and nitrogen content, <sup>13</sup>C, <sup>14</sup>C, CaCO<sub>3</sub> content, SiO<sub>2</sub> content and sediment  
259 texture-related parameters. The auto-check produces a log file with flags for unexpected values.  
260 In turn, the flags point to the exact line containing possible out-of-bound values. For example,

272 for TOC (%), if values are negative, there will be a prompt “cannot be negative, please check”,  
273 when values are > 2 and <20 there is a prompt “is quite high. Are you sure it is correct?” and  
274 lastly if values are > 20 there is the prompt “value is high. Please check units”. Each flag is  
275 accompanied by a line number to locate the possibly erroneous data. [Additional details can be](#)  
276 [found in the quality control script in the SI](#). These flags then trigger a manual quality check of  
277 the data by an expert in-house user.

278

### 279 2.3.3 Data transformation and structuring

280 The next step involves transforming data (using Python code) from Excel into csv files that are  
281 compatible with the normalized relational database structure in SQL. This is done by (i) adding  
282 unique identifiers to the data and (ii) transforming the data into appropriate csv files.  
283 Importantly for the database structure, unique identifiers are created for each appropriate  
284 database table (SI Figure 2). For example, for a specific location, an individual sediment core  
285 may yield multiple samples (i.e., core sections corresponding to different depth intervals), with  
286 multiple measurements (e.g., <sup>13</sup>C, <sup>14</sup>C and %TOC) performed on each sample (section). In this  
287 example, the location is assigned a unique geopoint location identifier, the core receives a  
288 unique identifier, and each sample (section) is given a unique identifier. These identifiers  
289 resurface in each database table (e.g., on compositional parameters), resulting in the possibility  
290 of multiple cores and multiple sample identifiers for a single geopoint. For the creation of  
291 identifiers, the Python script finds a unique combination of coordinates (i.e., latitude and  
292 longitude), assigns an identifier and eliminates duplicates. It repeats this for all primary keys  
293 in the database.

294

### 295 2.3.4 MySQL interface

296 The Excel files designed for facile data ingestion are transformed in order to be compatible  
297 with the normalized database using a Python script. This script executes this transformation by  
298 auto-creating the compatible csv files, including the unique identifiers for the primary keys.  
299 The script can be adapted to a dataset and is provided in the SI. The MOSAIC SQL database  
300 allows for a direct upload of csv following data quality assessment, addition of identifiers and  
301 creation of csv files. At present, a member of the ETH Biogeoscience group is allocated to  
302 undertake this task upon receipt of files.

303

304 2.3.5 MOSAIC Website: User access and citing of data

305 The website (mosaic.ethz.ch) can be cited using the digital object identifier number (DOI)  
306 <https://doi.org/10.5168/mosaic019.1>. [Additionally, under the tab “about this app & app ver-](#)  
307 [sion”, the date of the most recent update is included.](#) In order to access data, users do not need  
308 to use SQL syntax. Instead, users can select data of interest using drop-down menus or by  
309 selecting data via a visual geographic interface. The selected data resulting from the query is  
310 shown in a table and can be directly downloaded as a csv file (SI Figure 1). [Every datapoint is](#)  
311 [accompanied by the DOI of the original paper.](#) When querying data through the MOSAIC  
312 website, the relational aspects of the database ensures that, for example, when a certain location  
313 is selected, all data pertaining to this point appear in the table and are downloaded. For users  
314 versed in SQL syntax, all accompanying data is available in SQL code, which can be imported  
315 in both MySQL and PostgreSQL graphic user interface software. In this format, all data can be  
316 queried in using SQL syntax.

317 3. Results and Discussion

318 3.1 Excerpts from the MOSAIC database

319 We provide examples of information extracted from MOSAIC (<https://doi.org/10.5168/mosaic019.1>, Van der Voort et al., 2019). The intention here is to illustrate broad-scale variability  
320 in OC properties rather ~~than offer in-depth interpretations. Such interpretations would, of~~  
321 ~~course, evolve as the database develops further and as additional parameters are added.~~ The  
322 latter will be the focus of subsequent contributions.

Deleted: that

Deleted: , and

Deleted: these interpretations will be refined

324 We first ~~show~~ the statistical distributions of geochemical properties (Figure 3). On a  
325 global scale, TOC contents of marine surface sediments (< 100 cm) are lognormally distributed  
326 around ~1 % (mean = 1.63%, median = 1.14%; n= 8688; Figure 3a), consistent with prior  
327 observations (Keil, 2017; Seiter et al., 2004, 2005). The distribution of stable carbon isotope  
328 ( $\delta^{13}\text{C}$ ) values of OC shows two distinct populations (mean = -22.6‰, median = -22.18‰; n =  
329 4297; Figure 3b), likely reflecting relative dominance of terrestrial C3 plant (~27 ‰) and  
330 marine (~22 ‰) sources (Burdige, 2005; Sackett and Thomson, 1963). Corresponding  
331 radiocarbon contents (expressed here as Fm values) exhibit a more unimodal distribution with  
332 an average Fm value of ~0.7 (Mean = 0.7, Median = 0.73, n = 709; Figure 3c), highlighting the  
333 significant proportions of pre-aged OC in globally distributed marine surficial sediments  
334 (Griffith et al 2010).

Deleted: explore

335 Carbon isotopic compositions of surface sediment OC exhibit ~~substantial variability~~  
336 when plotted as a function of water depth (Figure 4). Radiocarbon contents are especially  
337 variable and generally lower in shallow (coastal) areas where TOC is also relatively low  
338 (Figure 4a). Coastal areas are both prone to supply of pre-aged OC from adjacent land masses  
339 (e.g., Tao et al., 2015; van der Voort et al., 2017), as well as ageing associated with sediment  
340 reworking ~~and lateral transport~~ by bottom currents (Bao et al., 2016; Bröder et al., 2018). A  
341 similar pattern of variability is evident in  $\delta^{13}\text{C}$  values (Figure 4b) which exhibit a larger spread  
342 on continental shelves (~-13 to -30 ‰) and converge towards higher (more  $^{13}\text{C}$ -enriched)  $\delta^{13}\text{C}$   
343 values (~- 22 ‰) in the deeper ocean. These trends reflect trajectories and modes carbon supply  
344 both from land and the ocean to the seafloor that govern OC sequestration and resulting  
345 sedimentary signatures (Bianchi et al., 2007; Burdige, 2005). Distinguishing between and  
346 quantifying the relative importance these factors is important for understanding consequences  
347 for carbon burial (Arndt et al., 2013; Bao et al., 2019; Bao et al., 2016), and requires ancillary  
348 geochemical and sedimentological ~~data~~ (e.g., biomarker signatures, grain size distributions) -  
349 information that will be incorporated into a future iteration of the MOSAIC database.

357 Broad-scale variability in OC characteristics of surface marine sediments also emerges  
358 when properties are examined as a function of latitude (Figure 5). For example, despite  
359 considerable scatter in stable carbon isotopic compositions, there is a general trend from higher  
360 to lower  $\delta^{13}\text{C}$  values with increasing latitude (Figure 5a). This could reflect latitudinal  
361 variations in the carbon isotopic composition of marine phytoplankton (Goericke and Fry,  
362 1994), and/or changes in the proportions and  $\delta^{13}\text{C}$  values of terrestrial OC inputs (e.g., balance  
363 of  $\text{C}_3$  vs  $\text{C}_4$  vegetation; Huang et al., 2000). Latitudinal trends in  $^{14}\text{C}$  are less clear due to a  
364 paucity of data with sufficient geographic coverage (Figure 5b), and serve to highlight ocean  
365 regions and domains that are presently understudied with respect to this and other sediment  
366 variables.

367

### 368 3.2 Scientific value of MOSAIC

369 The compilation of data and subsequent re-analyses holds the potential to yield novel insights  
370 into the distribution and composition of OC accumulating in the contemporary marine  
371 environment, shed light on underlying processes, and identify gaps in existing data sets and  
372 spatial coverage. For example, the latter is particularly pertinent for  $^{14}\text{C}$  data and ancillary  
373 measurements that are necessary to broadly apply isotopically-enabled models of organic  
374 turnover and burial in sediments (e.g., Griffith et al., 2010; Isla and DeMaster, 2018), as well  
375 as to constrain geographic variability in the age distribution of sedimentary OC in an analogous  
376 fashion to those of, for example, soil carbon (e.g., Shi et al., 2020). Filling such gaps is also  
377 important given increasing interest in developing robust assessments of carbon stocks in coastal  
378 marine sediments in the context of future greenhouse gas reporting protocols (Avelar et al.,  
379 2017; Luisetti et al., 2020). Moreover, regional-scale data compilation of spatially  
380 comprehensive geochemical and sedimentological information (Bao, et al., 2018; Bao et al.,  
381 2016), coupled with the application of novel numerical clustering methods (Van der Voort et  
382 al., 2018) can facilitate refinement of criteria for delineating biogeochemically provinces  
383 (Longhurst, 2007; Seiter et al., 2004), that reflect both source inputs and hydrodynamic  
384 regimes, in order to improve carbon cycle budgets and models. Spatially-resolved information  
385 on biogeochemical characteristics of seafloor sediments is also value in understanding benthic-  
386 pelagic coupling (e.g., Griffiths et al., 2017) as well as the relationships between sediment  
387 properties and the diversity and functioning of benthic ecosystems (Middelburg, 2018;  
388 Snelgrove et al., 2018). Such examples highlight the value of leveraging existing datasets,

## 449 5. Conclusion and Outlook

450 In this paper, we describe the rationale behind as well as development and structure of a  
451 database (MOSAIC) focused on OC accumulating in contemporary continental margin  
452 sediments. Current data residing within MOSAIC was derived from over 200 peer-reviewed  
453 papers, with the intention that this resource will further expand both regarding data density and  
454 dimensionality, with a specific emphasis on radiocarbon as an underdetermined yet crucial  
455 property for constraining carbon cycle processes. We provide selected examples of spatial vari-  
456 ations in bulk geochemical characteristics (e.g., <sup>14</sup>C content) of organic carbon, and envision  
457 that MOSAIC will serve as a tool to (a) better understand the nature and causes of spatial  
458 variability in biogeochemical characteristics of continental margin sediments, which in turn  
459 has ramifications for (global) carbon dynamics, seafloor ecology and socioeconomic ramifica-  
460 tions of these aspects, and complement existing (e.g., soils, ocean dissolved inorganic carbon)  
461 and planned (riverine carbon, oceanic water column carbon) radiocarbon-centric databases for  
462 other major carbon pools.

463

## 464 6. Video Supplement

465 Accompanying this paper is a short instructional video (in SI) which explains to users how to  
466 download the data from MOSAIC (<https://doi.org/10.5168/mosaic019.1>, Van der Voort et al.,  
467 2019).

468

## 469 7. Author Contributions

470 Tim Eglinton led the conceptual development of the MOSAIC project. Tessa Sophia van der  
471 Voort designed, structured and filled the SQL database and also created the associated  
472 infrastructure in R, Python and Excel/LibreOffice. Thomas M. Blattmann and Daniel  
473 Montluçon provided feedback on the database structure and website development and  
474 contributed to discussion of the data. Mohammed Usman collected the MOSAIC data and  
475 contributed to the data evaluation. Thomas Loeffler enabled the set-up of infrastructure and  
476 contributed to the technical components of the paper. Maria Luisa Tavagna contributed to the  
477 concept development. Nicolas Gruber contributed to the MOSAIC concept development and  
478 project set-up. T.S. van der Voort prepared the manuscript with help of all co-authors.
