Abstract

Although great progress has been made in estimating surface solar radiation (R_s) from meteorological observations, satellite retrieval and reanalysis, getting best estimated long-term variations in R_s are sorely needed for climate studies. It has been shown that sunshine duration (SunDu)-derived R_s data can provide reliable long-term variability, but are available at sparsely distributed weather stations. Here, we merge SunDu-derived R_s with satellite-derived cloud fraction and aerosol optical depth (AOD) to generate high spatial resolution (0.1°) R_s over China from 2000 to 2017. The geographically weighted regression (GWR) and ordinary least squares regression (OLS) merging methods are compared, and GWR is found to perform better. Based on the SunDu-derived R_s from 97 meteorological observation stations, which are co-located with those that direct R_s measurement sites, the GWR incorporated with satellite cloud fraction and AOD data produces monthly R_s with $R^2 = 0.97$ and standard deviation = 11.14 W/m^2 , while GWR driven by only cloud fraction produces similar results with $R^2 = 0.97$ and standard deviation = 11.41 w/m^2 . This similarity is because SunDu-derived R_s has included the impact of aerosols. This finding can help to build long-term R_s variations based on cloud data, such as Advanced Very High Resolution Radiometer (AVHRR) cloud retrievals, especially before 2000, when satellite AOD retrievals are not unavailable. The merged R_s product at a spatial resolution of 0.1° in this study can be downloaded at <https://doi.pangaea.de/10.1594/PANGAEA.921847> (Feng and Wang, 2020).

47 Introduction

48 A clear knowledge of variations in surface solar radiation (R_s) is vitally important
49 for an improved understanding of the global climate system and its interaction with
50 human activity (Jia et al., 2013; Myers, 2005; Schwarz et al., 2020; Wang and Dickinson,
51 2013; Wild, 2009, 2017; Zell et al., 2015). Direct measurements have shown that R_s has
52 significant decadal variability, namely, a decrease (global dimming) from the 1950s to
53 the late 1980s and subsequent increase (global brightening) (Wild, 2009). The variation
54 in R_s is closely related to the Earth's water cycle, the whole biosphere, and the amount
55 of available solar energy. This situation emphasizes the urgency to develop reliable R_s
56 products to obtain the variability in R_s .

57 Great progress has been made in the detection of variability in R_s by
58 meteorological observations, satellite retrieval and radiation transfer model simulations
59 or reanalysis R_s products in previous studies (Rahman and Zhang, 2019; Wang et al.,
60 2015). However, each estimation has its advantages and disadvantages. Direct observed
61 data provide accurate R_s records at short time scales; however, careful calibration and
62 instrument maintenance are needed to maintain its long-term homogeneity. Previous
63 studies have reported that direct observed R_s over China may have major inhomogeneity
64 problems due to sensitivity drift and instrument replacement (Wang, 2014; Wang et al.,
65 2015; Yang et al., 2018). Before 1990, the imitations of the USSR pyranometers had
66 different degradation rates of the thermopile, resulting in an important sensitivity drift.
67 To overcome radiometer ageing problem, China replaced its instruments from 1990 to
68 1993. However, the new solar trackers failed frequently and introduced a high data
69 missing rate for the direct radiation component of R_s (Lu and Bian, 2012; Mo et al.,
70 2008). After 1993, although the instruments were substantially improved, the Chinese-
71 developed pyranometers still had high thermal offset with directional response errors,

72 and the stability of these instruments was also worse than that of the World
73 Meteorological Organization (WMO) recommended first-class pyranometers (Lu et al.,
74 2002; Lu and Bian, 2012; Yang et al., 2010). Yang et al. (2018) show that nearly half of
75 observed R_s (60 out of the 119 R_s observed stations) have inhomogeneity issues. These
76 artificial changes points in observed R_s are mainly caused by instrument change (42
77 shifts), stations relocation (34 shifts), observation schedule change (20 shifts) and
78 remaining 64 changepoints could not be identified.

79 SunDu data are relatively widely distributed and have a long-term record
80 (Sanchezlorenzo et al., 2009; Wild, 2009). Existing studies have also confirmed that
81 SunDu-derived R_s data are reliable R_s data, which can capture long-term trends of R_s
82 and reflect the impacts of both aerosols and clouds at time scales ranging from daily to
83 decadal (Feng and Wang, 2019; Manara et al., 2015; Sanchezlorenzo et al., 2013;
84 Sanchezromero et al., 2014; Tang et al., 2011; Wang et al., 2012b; Wild, 2016). Even
85 though, SunDu data do not provide a direct estimate of R_s and have the different
86 sensitivity of atmospheric turbidity changes, compared with R_s observations, they are
87 still a good proxy for variations of R_s (Manara et al., 2017).

88 Sunshine duration observations collected at weather stations in China have been
89 used to reconstruct long-term R_s (Che et al., 2005; Feng et al., 2019; He et al., 2018; He
90 and Wang, 2020; Jin et al., 2005; Shi et al., 2008; Yang et al., 2006; Yang et al., 2020).
91 Based on the global SunDu-derived R_s records, He et al. (2018) found that SunDu
92 permitted a revisit of global dimming from the 1950s to the 1980s over China, Europe,
93 and the USA, with brightening from 1980 to 2009 in Europe and a declining trend R_s
94 from 1994 to 2010 in China. (Wang et al., 2015) found that the dimming trend from
95 1961 to 1990 and nearly constant zero trend after 1990 over China, as calculated from
96 the SunDu-derived R_s , was consistent with independent estimates of AOD (Luo et al.,

97 2001); they also observed changes in the diurnal temperature range (Wang et al., 2012a;
98 Wang and Dickinson, 2013) and the observed pan evaporation (Yang et al., 2015).
99 Although direct observations and SunDu-derived R_s can provide accurate long-term
100 variations in R_s , both direct observations and sunshine duration records are often
101 sparsely spatially distributed.

102 Satellite R_s retrievals and radiation transfer model simulations or reanalysis R_s
103 products can provide R_s estimation with global coverage at high spatial resolution.
104 However, model simulations and reanalysis R_s products have substantial biases due to
105 the deficiency of simulating cloud and aerosol quantities (Feng and Wang, 2019; Zhao
106 et al., 2013). Previous comparative studies have shown that the accuracies of R_s from
107 reanalyses are lower than those of satellite products (Wang et al., 2015; Zhang et al.,
108 2016) due to the good capability of capturing the spatial distribution and dynamic
109 evolution of clouds in satellite remote sensing data.

110 **Table 1** lists the current satellite-based R_s products, which have been widely
111 validated in previous studies. Zhang et al. (2004) found that the monthly International
112 Satellite Cloud Climatology Project-Flux Data (ISCCP-FD) R_s product had a positive
113 bias of 8.8 w/m^2 using Global Energy Balance Archive (GEBA) archived data as a
114 reference. By comparing 1151 global sites, Zhang et al. (2015) evaluated four satellite-
115 based R_s products, including ISCCP-FD, the Global Energy and Water Cycle
116 Experiment-Surface Radiation Budget (GEWEX-SRB), the University of
117 Maryland/Shortwave Radiation Budget (UMD-SRB) and the Earth's Radiant Energy
118 System energy balanced and filled product (CERES EBAF), and concluded that CERES
119 EBAF shows better agreement with observations than other products. A similar overall
120 good performance of CERES EBAF can also be found (Feng and Wang, 2018; Ma et
121 al., 2015).

122 **Table 1.** Current satellite-derived surface solar radiation (R_s) products

Satellite R_s product	Source	Spatial resolution	Time range
ISCCP-FD	ISCCP	2.5°	1983-2009
GEWEX-SRB	ISCCP-DX	1°	1983-2007
UMD-SRB	METEOSAT-5	0.5°	1983-2007
GLASS-DSR	Terra/Aqua, GOES, MSG, MTSAT	0.05°	2008-2010
CLARA-A2	AVHRR	0.25°	1982-2015
MCD18A1	Terra/Aqua, MODIS	5.6 km	2001-present
Himawari-8 SWSR	Himawari-8	5 km	2015-present
SSR-tang	ISCCP-HXG, ERA5, MODIS	10 km	1982-2017
Cloud_cci AVHRR-PMv3	AVHRR/CC4CL	0.05°	1982-2016

123

124 Although CERES EBAF uses more accurate input data to provide R_s data, its
 125 spatial resolution is only 1° (Kato et al., 2018). Since 2010, new-generation
 126 geostationary satellites have provided opportunities for high temporal and spatial
 127 resolution R_s data, such as Himawari-8 (Hongrong et al., 2018; Letu et al., 2020).
 128 However, the time span of the new-generation satellite-based R_s product is short. The
 129 long-term AVHRR records provide the possibility of building long-term radiation
 130 datasets. The CLOUD, Albedo and RADIATION dataset, the AVHRR-based data-second
 131 edition (CLARA-A2), covers a long time period, but the spatial resolution is only 0.25°
 132 (Karlsson et al., 2017). Recently, Tang et al. (2019) built a satellite-based R_s (SSR-tang)
 133 dataset using ISCCP-HXG cloud data. By using a variety of cloud properties derived
 134 from AVHRR, Stengel et al. (2020) presented the Cloud_cci AVHRR-PMv3 dataset
 135 generated within the Cloud_cci project.

136 Validation against the BSRN data indicated that SSR-tang have the mean bias error
 137 (MBE) of -11.5 W/m² and root mean square error (RMSE) of 113.5 W/m² for the
 138 instantaneous R_s estimates at 10 km scale, but Tang et al. (2019) point out that care
 139 should be taken when using this dataset for trend analysis due to the absent of realistic
 140 aerosols input data. Stengel et al. (2020) also show that R_s derived from Cloud_cci

141 AVHRR-PMv3 reveals a very good agreement against BSRN stations, with low
142 standard deviations of 13.8 W/m^2 and correlation coefficients above 0.98. While the
143 bias for shortwave fluxes is small (1.9 W/m^2). However, default an aerosol optical depth
144 of 0.05 or data from Aerosol cci Level-2 or NASA MODIS Level-2 aerosol data are
145 used in BUGSrad model to calculate clear sky R_s , indicating that impact of aerosols is
146 not perfect parameterized in Cloud_cci AVHRR-PMv3.

147 On the other hand, the long-term cloud records also contain uncertainties. For
148 example, ISCCP cloud products, which directly combine geostationary and polar
149 orbiter satellite-based cloud data, have large inhomogeneity due to different amounts of
150 data from polar orbit and geostationary satellites and their different capabilities for
151 detecting low-level clouds (Dai et al., 2006; Evan et al., 2007). This inhomogeneity of
152 the cloud products might introduce significant inhomogeneity to the R_s values
153 calculated from the cloud products (Montero-Martín et al., 2020; Pfeifroth et al., 2018b),
154 and R_s long-term variability estimation still needs improvement.

155 Efforts have been made to further improve R_s products. Merging multisource data
156 has become an effective empirical method for improving the quality of R_s products
157 (Camargo and Dorner, 2016; Feng and Wang, 2018; Hakuba et al., 2014; Journée et al.,
158 2012; Lorenzo et al., 2017; Ruiz-Arias et al., 2015). For instance, to produce
159 spatiotemporally consistent R_s data, multisource satellite data are used in Global LAnd
160 Surface Satellite (GLASS) R_s products (Jin et al., 2013). By merging reanalysis and
161 satellite R_s data by the probability density function-based method, the reanalysis R_s
162 biases can be substantially reduced (Feng and Wang, 2018). This finding suggests that
163 fusion methods are effective ways to improve the estimation of R_s , especially when R_s
164 impact factors are considered (Feng and Wang, 2019). Although linear regression fusion
165 methods can produce R_s data incorporated with R_s impact factors, the stable regression

166 parameters might have negative effects on the final fusion results due to the complex
167 characteristics of R_s spatial-temporal variability.

168 On the other hand, the spatial resolution of R_s data is crucial for regional
169 meteorology studies, as the minimum requirement of the spatial resolution of R_s data,
170 as suggested by the Observing Systems Capabilities Analysis and Review of WMO
171 OSCAR), is 20 km (Huang et al., 2019). Interpolation methods are often included in R_s
172 fusion methods to further improve the spatial resolutions of R_s data (Loghmari et al.,
173 2018). For example, Zou et al. (2016) estimated global solar radiation using an artificial
174 neural network based on an interpolation technique in southeast China. By integrating
175 R_s data from 13 ground stations with Meteosat Second Generation satellite R_s products,
176 Journée and Bertrand (2010) found that kriging with the external drift interpolation
177 method performed better than mean bias correction, interpolated bias correction and
178 ordinary kriging with satellite-based correction. However, interpolation results have
179 uncertainties due to the lack of detailed high spatial resolution information. Although
180 traditional linear regression fusion methods can incorporate high spatial resolution data
181 during the fusion process, the impacts of the stable regression parameters need further
182 investigation.

183 The performances of different machine learning methods have been evaluated in
184 many previous studies, including simulation R_s at regional scale with support of satellite
185 retrievals (Wei et al., 2019; Yeom et al., 2019) and site scale by using routine
186 meteorological observations (Cornejo-Bueno et al., 2019; Hou et al., 2020). Whatever
187 models or training data are selected, the impacts of spatial relationship are not taken
188 into account in these machine learning based model and therefore large number of input
189 data are required to ensure accuracy.

190 Geographically weighted regression (GWR) is an extension of the traditional

191 regression model by allowing the relationships between dependent and explanatory
192 variables to vary spatially. Researchers have examined and compared the applicability
193 of GWR for the analysis of spatial data relative to that of other regression methods (Ali
194 et al., 2007; Gao et al., 2006; Georganos et al., 2017; LeSage, 2004; Sheehan et al.,
195 2012; Zhou et al., 2019a). Due to the large spatial heterogeneity of R_s over China, the
196 GWR method might produce accurate R_s variability estimations with an improved
197 spatial resolution.

198 This study is established to merge SunDu-derived R_s data with satellite-derived
199 cloud fraction (CF) and AOD data to generate high spatial resolution (0.1°) R_s over
200 China from 2000 to 2017. The GWR and ordinary least squares (OLS) regression
201 merging methods are compared. CF and AOD are important R_s impact factors, however,
202 many long-term R_s satellite products use climatology aerosols data as input. Whether
203 much improvement is made in merging SunDu-derived R_s by incorporating AOD is also
204 evaluated in this study, instead of evaluating direct merging current R_s products with
205 SunDu-derived R_s . Since current R_s high quality R_s such as CERES EBAF have low
206 spatial resolution, the output of this study provides a reliable high resolution grid R_s
207 data to avoid the disadvantage of CERES EBAF for capturing the variability of R_s
208 within a 1 degree box and provide guidance to merge multisource data to generate long-
209 term R_s data over China.

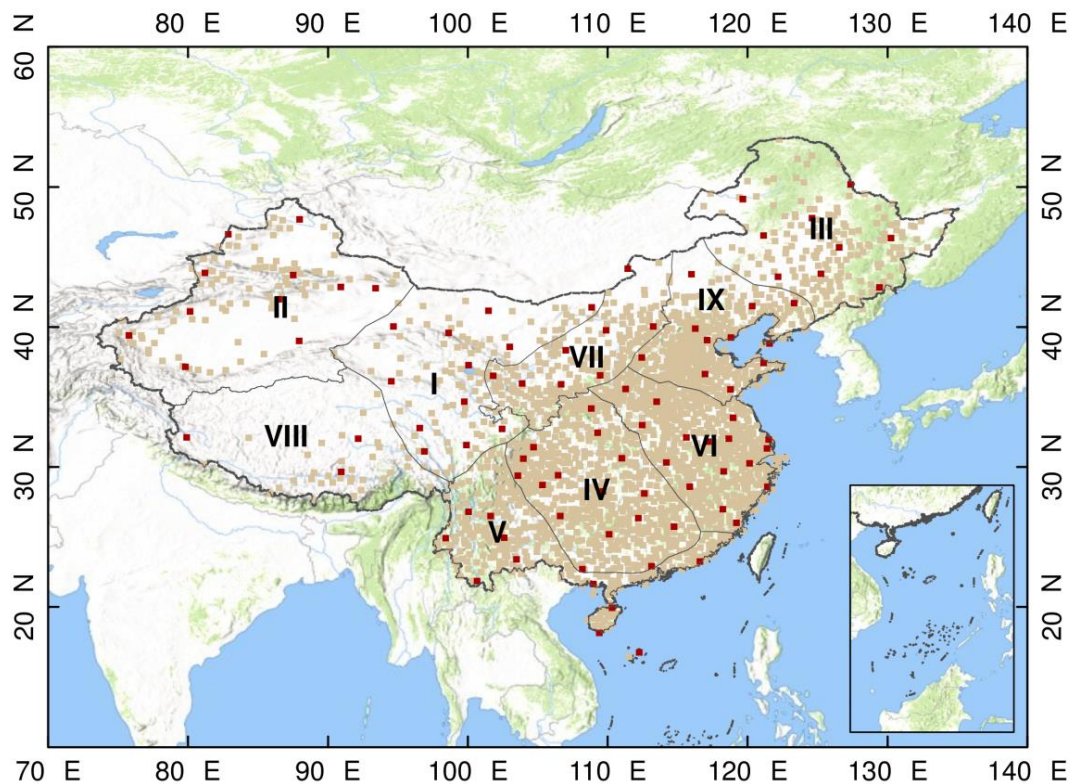

210 **1. Data and Methodology**

211 ***2.1. Ground-based observations***

212 ***2.2.1 Direct observations***

213 R_s direct observations from 2000 to 2017 are obtained from the China
214 Meteorological Data Service Center (CMDC, <http://data/cma/cn/>) of the China
215 Meteorological Administration (CMA). TBQ-2 pyranometers and DFY4 pyranometers

216 have been used to measure R_s since 1993. Daily R_s values from 97 R_s stations are
 217 collected, and we calculated monthly R_s values by averaging daily R_s values when daily
 218 observed data are available for more than 15 days for each month at each radiation
 219 station. These monthly R_s values from direct measurements and collocated SunDu-
 220 derived R_s are used as independent reference data to investigate the performances of the
 221 fusion methods (**Fig. 1**). The whole area over China is further divided into nine zones
 222 by the K-mean cluster method based on geographic locations and multiyear mean R_s
 223 using 97 R_s direct observation sites, as shown in **Figure 1**. The download instructions
 224 of the R_s direct observations can be found in **table 2**.

225
 226 **Figure 1.** The 2,400 sunshine duration (SunDu) merging sites are shown as light brown
 227 points, and 97 independent validation sites, including R_s direct measurements and
 228 SunDu-derived R_s measurements, are shown as brown red points. The whole region is
 229 classified into nine subregions (I to IX) by the K-mean cluster method based on
 230 geographic locations and multiyear mean R_s using 97 R_s direct observation sites. The

231 base hillshade map was produced by an elevation map of China using the global digital
 232 elevation model (DEM) derived from the Shuttle Radar Topography Mission 30
 233 (SRTM30) dataset.

234

235

236 **Table 2.** Summary of availability information for all source data used in this study.

237 CMDC is the China Meteorological Data Service Center. SunDu is the sunshine

238 duration data. R_s is surface solar radiation and AOD is the aerosols optical depth.

239 2.2.2 SunDu-derived R_s

240 Sunshine duration observations (SunDu) and other meteorological data (e.g., air

241 temperature, relative humidity and surface pressure) from 1980 to 2017, which were

242 collected from approximately 2,400 meteorological stations (<http://data/cma/cn/>) from
 243 the CMA, are used to calculate the SunDu-derived R_s (**Fig. 1**). R_s values are calculated
 244 following the method of the revised Ångström-Prescott equation (Eq. (1-2)) (He et al.,
 245 2018; Wang, 2014; Wang et al., 2015; Yang et al., 2006).

$$246 \quad \frac{R_s}{R_c} = a_0 + a_1 \frac{n}{K} + a_2 \left(\frac{n}{K}\right)^2 \quad (1)$$

$$247 \quad R_c = \int (\tau_{c_dir} + \tau_{c_dif}) \times I_0 dt \quad (2)$$

248 where n represents the measured SunDu, and K represents the theoretical value of the
 249 SunDu. a_0 , a_1 , and a_2 are the station-dependent parameters by tuning this equation with
 250 measurements of R_s and SunDu and then the method is applied regionally (Wang, 2014).
 251 Instead using observations from weather stations in Japan (Yang et al., 2006),
 252 observations in CMA are used (Wang, 2014). R_c is the daily total solar radiation at the
 253 surface under clear-sky conditions (Eq. 2). τ_{c_dir} and τ_{c_dif} represent the direct radiation
 254 transmittance and the diffuse radiation transmittance under clear-sky conditions. I_0 is
 255 the solar irradiance at the top of the atmosphere (TOA). For the clear sky R_s , τ_{c_dir} and
 256 τ_{c_dif} are calculated using a modified a broadband radiative transfer model by
 257 simplifying Leckner's spectral model (Leckner, 1978), which the effect of
 258 transmittance functions of permanent gas absorption, Rayleigh scattering, water vapour
 259 absorption, ozone absorption, and aerosol extinction are parameterized using the
 260 surface air temperature, surface pressure, precipitable water, the thickness of the ozone
 261 layer, turbidity, sunshine duration as inputs (Yang et al., 2006). Calculation of R_s also
 262 includes impacts of aerosols because SunDu is impacted by changes in both clouds and
 263 aerosols (Wang, 2014).

264 Based on the classified subregions using 97 direct R_s observations in **Figure 1**, the
 265 intercomparison results in **Figure 2** and **Figure 3** show that the agreement between
 266 SunDu-derived R_s and CERES EBAF R_s estimates is better than that between the direct

267 observations and SunDu-derived R_s estimates, which is likely due to the inhomogeneity
 268 issue of direct R_s observations over China, as mentioned in many previous studies
 269 (Wang, 2014; Yang et al., 2018). The satellite R_s retrievals and SunDu derived R_s are
 270 totally independent, but the high agreements of these two datasets indicate that they
 271 both are of higher accuracy. Similar results are also reported by (Wang et al., 2015) that
 272 low agreement between SunDu derived R_s and direct R_s observation is likely due to the
 273 directional response errors of the direct observations of R_s .

274 The SunDu-derived R_s observations, excluding SunDu observations located at
 275 direct observation sites, are used for merging. Ten percent merging observations are
 276 randomly selected for GWR parameter optimization. The download instructions of the
 277 SunDu observations can be found in **table 2**.

279 **Figure 2.** Statistical summary of annual anomaly R_s from direct observed R_s , SunDu-
 280 derived R_s and CERES EBAF R_s estimates in different subregions. The statistics include
 281 the mean absolute bias (MAB), standard deviation (Std) and root mean square error
 282 (RMSE). We use MAB due to the cancelling out effect of positive bias and negative
 283 bias. Nine subregions (I to IX) over China are shown in Figure 1. S-D represent
 284 comparisons between SunDu-derived R_s and directly observed R_s . C-D represent
 285 comparison between CERES EBAF R_s and directly observed R_s . S-C represent
 286 comparisons between SunDu-derived R_s and CERES EBAF R_s . The unit of y-axis are
 287 w/m^2 .

288
 289 **Figure 3.** Similar to Figure 2, but this statistical summary is for R^2 .

290

291 **2.2. Satellite data**

292 R_s data from the Clouds and Earth's Radiant Energy System energy balanced and

293 filled product (CERES Synoptic (CERES) EBAF) surface product (edition 4.1) (Kato
294 et al., 2018), cloud fraction from MODAL2 M CLD data product (Platnick et al., 2017)
295 and AOD from the CERES SYN1deg) edition 4A product (Doelling et al., 2013) are
296 collected in this study. CERES EBAF R_s data are used as reference data. AOD from
297 CERES SYN1deg and cloud fraction from MODAL2 M CLD are used as input data for
298 fusion methods.

299 CERES is a 3-channel radiometer measuring three filtered radiances, including
300 shortwave (0.3-5 μm), total (0.3-200 μm) and window (8-12 μm). R_s from CERES
301 EBAF are adjusted using radiative kernels, including bias correction and Lagrange
302 multiplier processes. The input data of CERES EBAF are adjusted during the product
303 generating process constrained by CERES observations at the TOA. The biases in
304 temperature and specific humidity from the Goddard Earth Observing System (GEOS)
305 reanalysis are adjusted by atmospheric infrared sounder (AIRS) data. Cloud properties,
306 such as optical thickness and emissivity, from MODIS and geostationary satellites are
307 constrained by cloud profiling radar, Cloud-Aerosol Lidar, and Infrared Pathfinder
308 Satellite Observations (CALIPSO) detectors and CloudSat. The uncertainties of
309 CERES EBAF data, reported by (Kato et al., 2018), in all sky global annual mean R_s is
310 4 W m^{-2} . Previous studies (Feng and Wang, 2019; Feng and Wang, 2018; Ma et al.,
311 2015; Wang et al., 2015) have shown that the CERES EBAF surface product provides
312 reliable estimations of R_s .

313 CERES SYN1deg AOD derived from an aerosol transport model, named
314 Atmospheric Transport and Chemistry Modelling (MATCH) (Collins et al., 2001),
315 which assimilates MODIS AOD data, is used to obtain spatiotemporally consistent
316 AOD data. Different aerosol constituents, including small dust ($<0.5 \mu\text{m}$), large dust
317 ($>0.5 \mu\text{m}$), stratosphere, sea salt, soot and soluble, are used to compute the optical

318 thickness for a given constituent optical thickness for a given constituent. We did not
319 use AOD from MODIS, because MODIS AOD conation missing values and can't meet
320 the requirements of spatiotemporal continuity of AOD input in this study. In addition,
321 MODIS AOD is only available under clear sky conditions while AOD provided by the
322 assimilation system is averaged under all conditions.

323 Cloud fraction data from MODAL2 M CLD are collected as input cloud fraction
324 data with a spatial resolution of 0.1° and time span from 2000 to 2017 (Platnick et al.,
325 2017). The MODAL2 M CLD data are synthesized based on the cloud data from
326 MOD06. Cloud fraction data from MOD06 are generated by the cloud mask product of
327 MOD35 with a spatial resolution of 1 km. The MOD35 cloud mask is determined by
328 applying appropriate single field of view (FOV) spectral tests to each pixel with a series
329 of visible and infrared threshold and consistency tests. Each land type has different
330 algorithms and thresholds for the tests. For each pixel test, an individual confidence
331 flag is determined and then combined to produce the final cloud mask flag. The three
332 confidence levels included in the cloud mask flag output are (i) high confidence for
333 cloudless pixels (Group confidence values > 0.95); (ii) low confidence for unobstructed
334 views on the surface (Group confidence values $Q \leq 0.66$); and (iii) values between 0.66
335 and 0.95, and spatial and temporal continuity tests are further applied to determine
336 whether the pixel is absolutely cloudless. Then, the cloud fraction is calculated from
337 the 5×5 -km cloud mask pixel groupings, i.e., given the 25 pixels in the group, the
338 cloud fraction for the group equals the number of cloudy pixels divided by 25.

339 **2.3. Methods**

340 **2.3.1 Fusion models**

341 OLS regression and GWR are used to build fusion methods for estimating R_s data.
342 Clouds fraction and AOD have been important factors that affect variations in R_s . We
343 compare different combinations of input data for the fusion methods, which can be

344 classified into two types. The first type only contains cloud fraction data. The second
 345 type contains clouds fraction and AOD (Feng and Wang, 2020).

346 The OLS regression model is a commonly used model to estimate dependent
 347 variables by to minimizing the sum of square differences between the independent and
 348 dependent variables. GWR is a regression model that allows the relationships between
 349 the independent and dependent variables to vary by locality (Brunsdon et al., 2010;
 350 Brunsdon et al., 1998). GWR deviates from the assumption of homoskedasticity or
 351 static variance but calculates a specific variance for data within a zone or search radius
 352 of each predictor variable (Brunsdon et al., 1998; Fotheringham et al., 1996; Sheehan
 353 et al., 2012). The regression coefficients in GWR are not based on global information;
 354 rather, they vary with location, which is generated by a local regression estimation using
 355 subsampled data from the nearest neighbouring observations. The principle of GWR is
 356 described as follows:

$$y_i = \delta(i) + \sum_k \delta_k(i)x_{ik} + \varepsilon_i \quad (3)$$

357 where y_i is the value of R_s unit i ; $i=1,2,\dots,n$, n denotes location i , x_{ik} indicates the value
 358 of the x_{ik} variable, such as cloud fraction and AOD, and ε denotes the residuals. $\delta(i)$ is
 359 the regression intercept. $\delta_{k(i)}$ is the vector of regression coefficients determined by
 360 spatial weighting function $w(i)$, which is the weighting function quantifying the
 361 proximities of location i to its neighbouring observation sites; X is the variable matrix,
 362 and b is the bias vector.

$$\delta_k(i) = (X^T w(i)X)^{-1} X^T w(i)b \quad (4)$$

363 The weighting functions are generally determined using the threshold method,
 364 inverse distance method, Gauss function method, and Bi-square method. Due to the
 365 irregular distribution of observation sites and computer ability, the adaptive Gaussian

366 function method is selected as a weighting function that varies in extent as a function
 367 of R_s observation site density.

$$w_{ij} = \exp(-(d_{ij}/b)^2) \quad (5)$$

368 where w_{ij} is the weighting function for observation site j that refers to location i ; d_{ij}
 369 denotes the Euclidian distance between j and i ; and b is the size of the neighbourhood,
 370 the maximum distance away from regression location i , called “bandwidth”, which is
 371 determined by the number of nearest neighbour points (NNPs).

372 2.3.2 GWR parameter comparison

373 To perform the local regression for every local area, the numbers of NNPs are
 374 required to estimate spatially varying relationships between CF, AOD and R_s in the
 375 GWR-based fused method. To identify the best combination of parameter values, we
 376 test the numbers of NNPs ranging from 29 to 1000. Ten percent of merging SunDu-
 377 derived R_s data are randomly selected to validate these GWR parameters (**Fig. 1**). The
 378 results show that R^2 increases and bias decreases when the number of NNPs decreases.
 379 However, when the NNP is smaller than 30, the GWR-based fusion method produces
 380 spatially incomplete R_s data due to the local collinearity problem with large spatial
 381 variability. Therefore, 30 is selected as the NNP parameter (**Table 3**).

382

383 **Table 3.** Statistical summary of GWR parameter optimization. NPP is the number of
 384 nearest neighbour points. GWR-CF presents the GWR-based fused method using only
 385 cloud fraction (CF) input, and GWR-CF-AOD presents that of using both CF and
 386 aerosol optical depth (AOD) as input. MAB is the mean absolute bias. Std is the
 387 standard deviation. RMSE is the root mean square error.

NNP	GWR-CF					GWR-CF-AOD				
	R^2	Bias	MAB	Std	RMSE	R^2	Bias	MAB	Std	RMSE
29	0.91	-0.21	7.45	9.90	9.90	0.91	-0.13	7.47	9.93	9.92
30	0.91	-0.23	7.45	9.90	9.90	0.91	-0.14	7.47	9.92	9.91

31	0.91	-0.24	7.45	9.90	9.90	0.91	-0.14	7.47	9.91	9.91

388

389 **3. Results**

390 **3.1 Site validation**

391 Based on the independent SunDu validation sites, both the GWR and OLS
392 methods explain 97%~86% of R_s variability (**Fig. 4**). The GWR method generally
393 shows an improved performance compared with the OLS method due to the
394 representativeness of the spatial heterogeneity relationship between R_s and its impact
395 factors in GWR. Both the GWR and OLS methods produce better simulations of R_s if
396 satellite and AOD data are incorporated.

397 Direct observations from 2000 to 2016 are also used to further evaluate the
398 performance of the fusion methods (**Fig. 4**). The comparative result shows that both
399 fusion methods show slightly reduced performances when using direct R_s observations
400 rather than the SunDu-derived R_s . Both the GWR and OLS methods explain 91%~82%
401 of R_s variability by using direct observations as reference data. Similarly, the GWR
402 method exhibits better performances than the OLS-based fusion method, with an R^2 of
403 0.91 and root mean square error (RMSE) ranging from 19.89 to 19.97 W/m^2 at the
404 monthly time scale (**Table 4**).

405

406 **Figure 4.** Comparison of surface solar radiation (R_s) derived from the GWR method
 407 and the OLS method. Subplots (a, c, e, g) represent validation results using SunDu-
 408 derived R_s data as a reference, while that of subplots (b, d, f, h) use directly observed
 409 R_s data. Subplots (a, b, c, d) denote the GWR validation results, and subplots (e, f, g, h)
 410 denote the OLS validation results.

411

412 **Table 4.** Validation of fusion methods driven by cloud fraction (CF) and AOD. GWR-
 413 CF and OLS-CF represent the GWR fusion method and OLS fusion method driven only
 414 by CF. GWR-CF-AOD and OLS-CF-AOD represent GWR and OLS fusion methods
 415 driven by CF and AOD, respectively.

	Time scale	Ref	R2	Bias	Std	RMSE
GWR-CF	monthly	SunDu R_s	0.97	-1.17	11.41	11.47

416

417 3.2 Seasonal and annual variations in R_s

418 To analyse the impacts of AOD on the GWR fusion results, the GWR driven with
419 only CF (GWR-CF) and GWR driven with CF and AOD (GWR-CF-AOD) are
420 compared. Two validation sites (Chang Chun, 43.87°N 125.33°E and Bei Hai, 21.72°N

421 109.08°E) are randomly selected to evaluate the seasonal and annual variations in R_s
 422 derived from the GWR method (**Fig. 5**). The multiyear mean of AOD from Changchun
 423 and BeiHai are 0.49 and 0.70, respectively. As shown in **subplots (a and b)**, both GWR-
 424 CF and GWR-CF-AOD produce similar seasonal variation patterns compared with
 425 SunDu-derived R_s and CERES EBAF R_s data. Small differences are found in the
 426 seasonal variation in R_s derived from GWR regardless of whether AOD was
 427 incorporated. Examination of the annual variation R_s from the GWR-CF and GWR-CF-
 428 AOD are shown in **subplots (c and d)** of **Figure 5**. The two fusion methods also
 429 produce similar annual R_s variations. The similar performances of the GWR-CF and
 430 GWR-CF-AOD might suggest that the impacts of AOD have already been included in
 431 the SunDu-derived R_s site data.

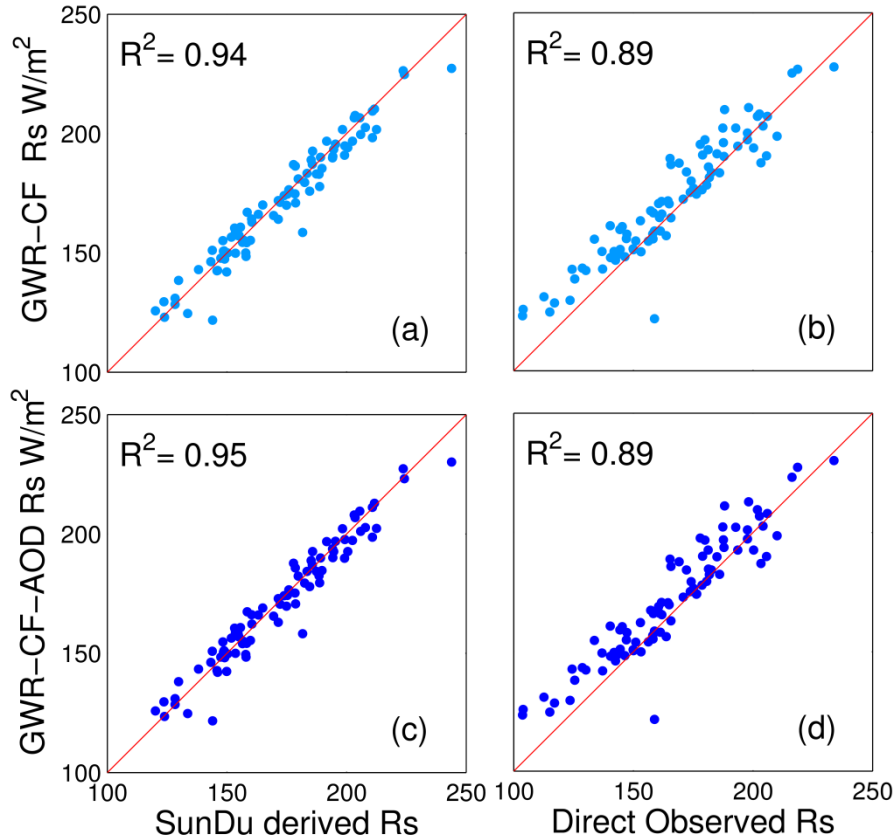

432 **Figure 5.** Seasonal and annual variations in R_s at two sites: Chang Chun (a and c,
 433 43.87°N and 125.33°E) and Bei Hai (b and d, 23.50°N, 99.72°E). SunDu R_s is the
 434 SunDu-derived R_s data, and GWR-CF R_s is R_s produced by the GWR method
 435

436 incorporating only the cloud fraction. GWR-CF-AOD is R_s produced by the GWR
437 method incorporating cloud fraction and AOD. The multiyear mean of AOD from
438 Changchun and BeiHai are 0.49 and 0.70, respectively.

439 We also analyse the performances of fusion methods for different seasons at all
440 validation sites, as shown in **Table 4**. At seasonal scales, both the GWR-CF and GWR-
441 CF-AOD methods have high R^2 values ranging from 0.94 to 0.96, compared with direct
442 R_s measurement or SunDu-derived R_s . GWR-CF and GWR-CF-AOD show slight
443 differences, indicating that both fusion methods produce consistent R_s seasonal
444 variation patterns, which might be because the impacts of AOD have already been
445 included in the SunDu-derived R_s site data at seasonal time scales. Comparatively, the
446 GWR methods perform best in autumn, with RMSEs ranging from 9.23W/m² to 9.56
447 W/m² followed by winter, spring and summer. Both the GWR-CF and GWR-CF-AOD
448 methods produce similar annual variations in R_s from 2000 to 2016, with R^2 values
449 ranging from 0.57 to 0.58 (**Table 4**). The statistics indicate that the GWR can produce
450 reasonable seasonal and annual variations in R_s .

451 **3.3 Multiyear mean and long-term variability in R_s**

452 **Figure 6** shows the performance of GWR-CF and GWR-CF-AOD on simulating
453 the multiyear mean R_s by using 97 direct R_s observation sites and independent SunDu-
454 derived R_s sites. Based on direct R_s measurements, both GWR-based methods show
455 good performances with high R^2 (0.89~0.95) and low RMSE (11.03~11.11 W/m²), and
456 few differences are found for the GWR merging results, whether or not AOD is taken
457 as input data (**Table 4**).

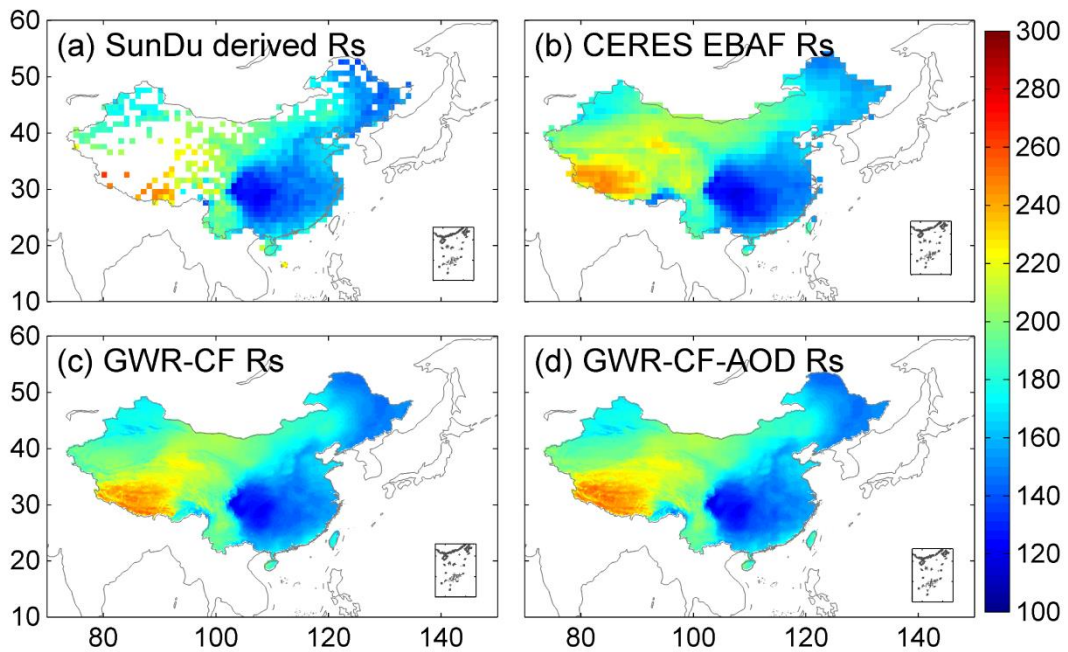

458

459 **Figure 6.** Comparison of multiyear mean surface solar radiation (R_s) derived from the
 460 GWR method. Subplots (a, c) represent validation results using SunDu-derived R_s data
 461 as a reference, while that of subplots (b, d) use direct observed R_s data.

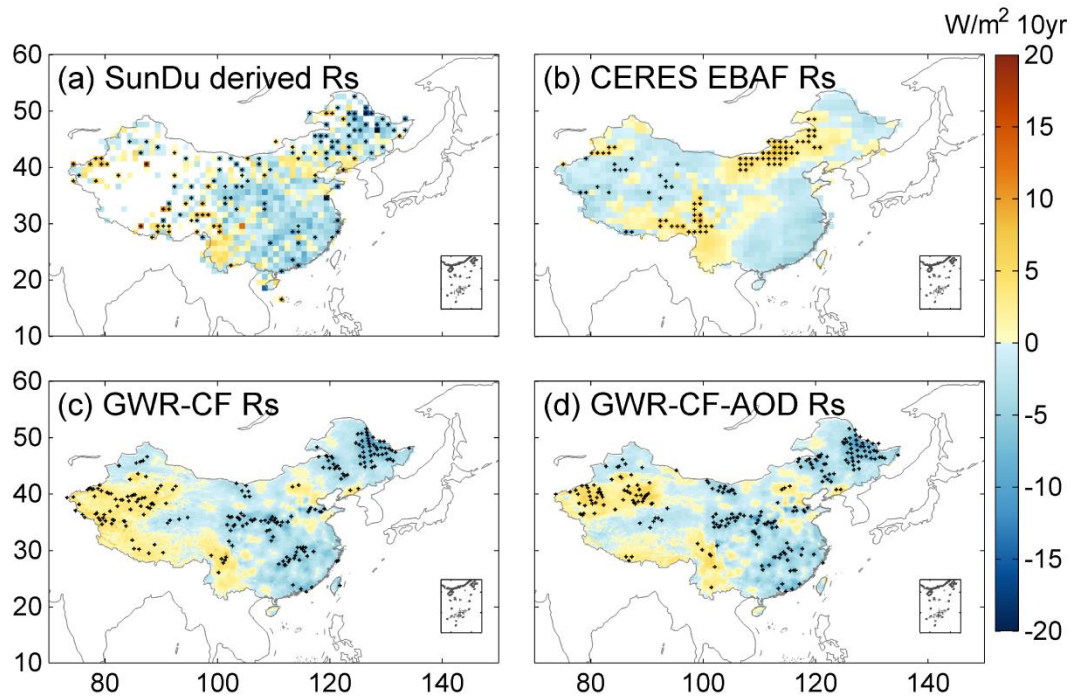

462 The spatial distributions of the multiyear means of R_s from 2000 to 2017 are shown
 463 in **Figure 7**. The SunDu sites show that R_s is high in northwest China, ranging from 180
 464 to 300 W/m², and low in eastern China, ranging from 120 to 180 W/m². Both the GWR-
 465 CF and GWR-CF-AOD methods show consistent R_s spatial patterns with SunDu-
 466 derived R_s observations and CERES EBAFs, indicating that the relationship between
 467 R_s and impact factors is not linearly stable and is closely related to spatial position. The
 468 spatial distribution of the R_s trend derived from the GWR method is also consistent with
 469 the SunDu-derived R_s trend, especially in western China (**Fig. 8**). In order to prove that
 470 SunDu-derived R_s can add value to the 0.1 degree product, instead of cloud fraction
 471 data alone. We perform a similar GWR analysis but using CERES EBAF interpolated

472 to 0.1 degree and 0.1 degree cloud, and compare the results with those using SunDu-
 473 derived R_s and 0.1 degree cloud (**Fig .9**). The results indicate that SunDu-derived R_s
 474 can add value to the 0.1 degree product and the merged R_s by using interpolated
 475 CERES EBAF and 0.1 degree cloud product are also similarly to original CERES
 476 EBAF but not 0.1 degree cloud product.

477

478 **Figure 7.** Spatial distribution of multiyear mean monthly surface solar radiation (R_s)
 479 from 2000 to 2017. The first line (a, b) shows the observed multiyear mean monthly R_s
 480 from SunDu and CERES EBAF; the multiyear mean monthly R_s derived from the GWR
 481 method are shown in the second line (c, d), respectively.

482

483 **Figure 8.** Spatial distributions of monthly anomaly trends of surface solar radiation (R_s)

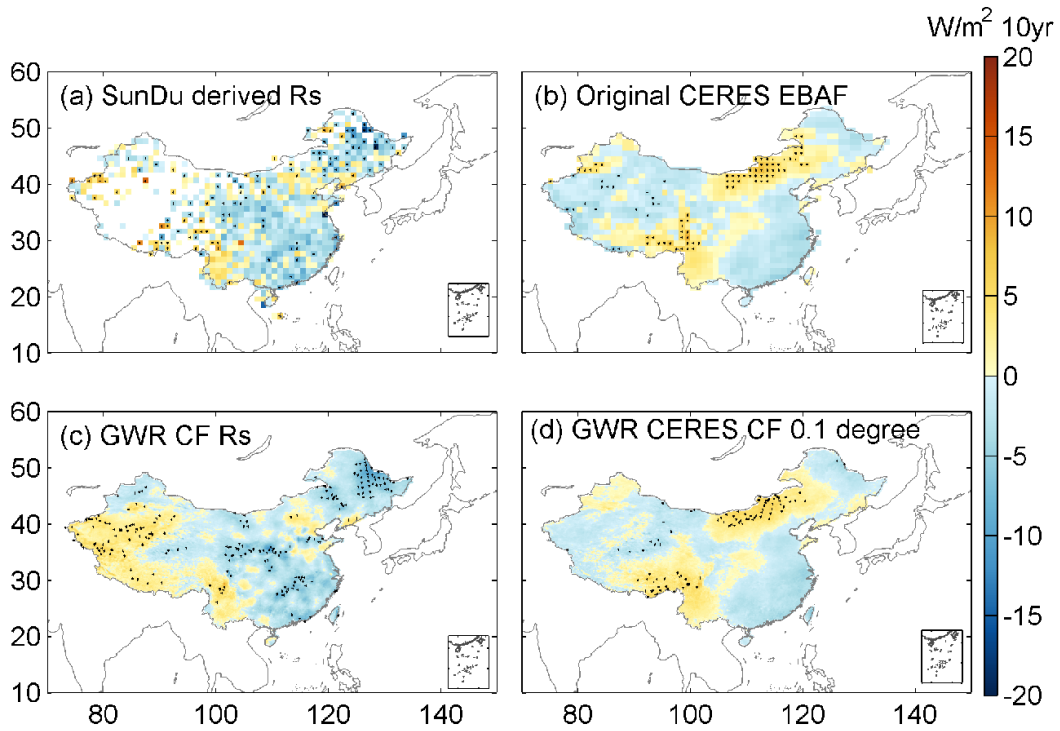

484 from 2000 to 2017. The first line (a, b) shows the SunDu-derived R_s and CERES EBAF

485 R_s ; the R_s -derived GWR fusion methods are shown in the second line (c, d). Subplots

486 (c) incorporate only CF, and subplots (d) incorporate CF and AOD. The black dots on

487 the maps represent significant trends ($P < 0.05$).

488

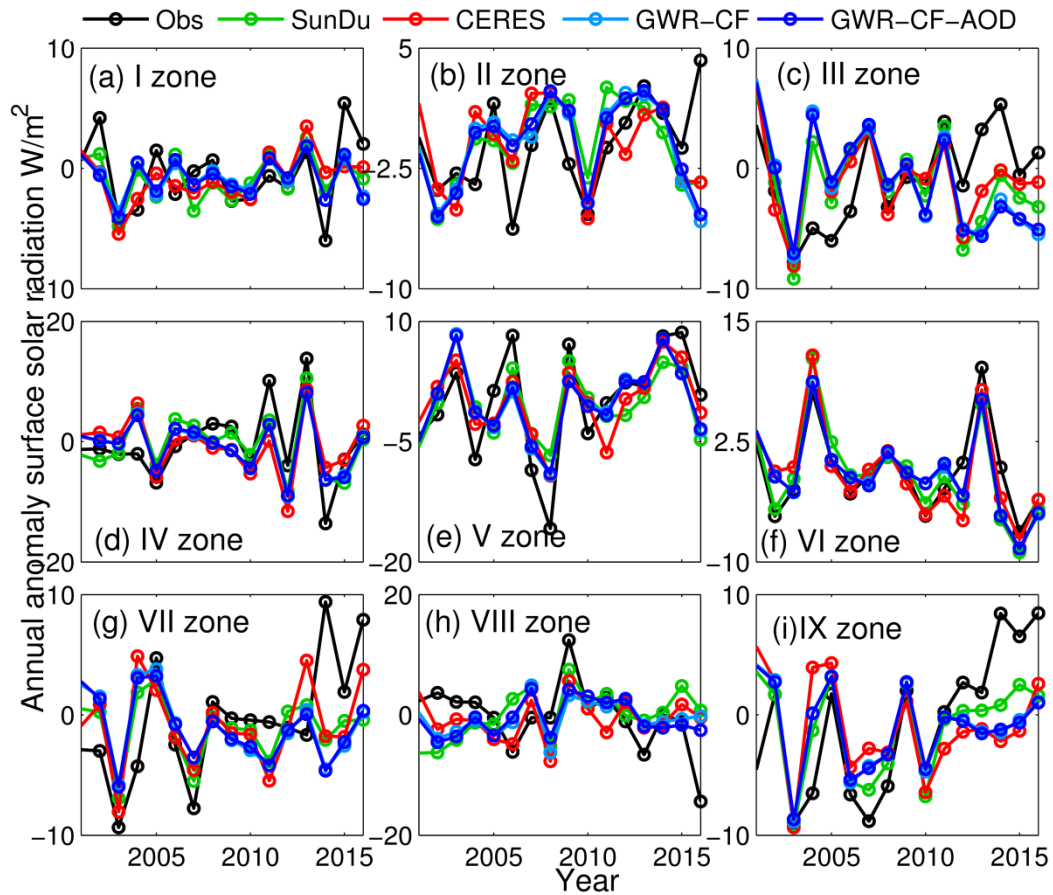

489

490 **Figure 9.** Spatial distributions of monthly anomaly trends of surface solar radiation (R_s)
 491 from 2000 to 2017. The first line (a, b) shows the SunDu-derived R_s and CERES EBAF
 492 R_s ; the R_s -derived GWR fusion methods are shown in the second line (c, d). Subplots
 493 (c) SunDu derived R_s incorporate only CF, and subplots (d) is the results of GWR
 494 analysis using CERES data interpolated to 0.1 degree and 0.1 degree cloud. The black
 495 dots on the maps represent significant trends ($P < 0.05$).

496 Based on the classified subregions using 97 direct R_s observations in **Figure 1**, the
 497 regional means of R_s annual anomaly variation from 2000 to 2016 are shown in **Figure**
 498 **10**. Compared with observations, both the GWR-CF and GWR-CF-AOD methods
 499 produce consistent long-term R_s trends with SunDu-derived R_s and CERES EBAF R_s
 500 (**Figures 2, 3 and 10**), indicating that the GWR-CF and GWR-CF-AOD methods can
 501 produce reasonable annual R_s variations over China.

502 In zones I and II, located in northern arid/semiarid regions, the annual anomaly R_s
 503 variation shows small fluctuations ranging from -10 to 10 W/m^2 . In contrast, zones IV,
 504 V, VIII and IX covering the Sichuan Basin, Yunnan-Guizhu Plateau, Qinghai-Tibet

505 Plateau and North China Plain show large R_s variation trends. Li et al. (2018) found a
 506 sharply increasing R_s trend over East China, especially in the North China Plain, which
 507 is due to controlling air pollution and reducing aerosol loading. However, our results
 508 indicate that the increased surface solar radiation in North China is not confirmed by
 509 satellite retrieval (CERES) and SunDu-derived R_s .

510

511 **Figure 10.** The regional mean of the annual anomaly of the surface solar radiation (R_s)
 512 for different subregions. Nine subregions (I to IX) over China are shown in Figure 1.
 513 Direct R_s observations, SunDu-derived R_s , and CERES EBAF are shown as black lines,
 514 green lines and red lines, respectively. Light and dark blue represent the R_s variation
 515 derived from the GWR-CF and the GWR-CF-AOD methods.

516

517 **4. Discussion**

518 **4.1 Impact factors of R_s**

519 In this study, we merged more than 2400 sunshine duration-derived R_s site data
520 with MODIS CF and AOD data to generate high spatial resolution (0.1°) R_s over China
521 from 2000 to 2017. The results show that the GWR method incorporated with CF and
522 AOD (GWR-CF-AOD) performs best, indicating the non-neglected role of clouds and
523 aerosols in regulating the variation in R_s over China.

524 Clouds and aerosols impact the solar radiation reaching the surface by radiative
525 absorption and scattering (Tang et al., 2017). Recent R_s trend studies over Europe
526 suggest that CF may play a key role in the positive trend of R_s since the 1990s (Pfeifroth
527 et al., 2018a). In terms of input data, our results also indicate that the cloud fraction
528 might be a major factor affecting R_s , which is consistent with our previous studies (Feng
529 and Wang, 2019).

530 Changes in aerosol loading have also been reported to be an important impact
531 factor (Che et al., 2005; Li et al., 2018; Liang and Xia, 2005; Qian et al., 2015; Xia,
532 2010; Zhou et al., 2019b). The atmospheric visibility data show that the slope of the
533 linear variation in surface solar radiation with respect to atmospheric visibility is
534 distinctly different at different stations (Yang et al., 2017), implying that the relationship
535 between R_s and aerosols varies with location.

536 **4.2 Performances of the fusion methods**

537 The good overall performances of the GWR model have been reported in many
538 previous studies, including geography (Chao et al., 2018; Georganos et al., 2017),
539 economics (Ma and Gopal, 2018), meteorology (Li and Meng, 2017; Zhou et al., 2019a),
540 and epidemiology (Tsai and Teng, 2016). Chao et al. (2018) used the GWR method to
541 merge satellite precipitation and gauge observations to correct biases in satellite

542 precipitation data and downscale satellite precipitation to a finer spatial resolution at
543 the same time. Zhou et al. (2019a) used GWR to analyse haze pollution over China and
544 found that the GWR estimate was better than the OLS estimate, with an improvement
545 in correlation coefficient from 0.20 to 0.75.

546 Compared with other traditional interpolation methods, such as optimal
547 interpolation (OI), GWR can theoretically integrate geographical location and R_s impact
548 factors for spatial R_s estimations and reflect the non-stationary spatial relationship
549 between R_s and its impact factors. The thin plate spline method can include CF and
550 AOD as covariates to simulate the approximately linear dependence of these impact
551 factors on R_s , but this linear function cannot fully describe the relationship among CF,
552 AOD and R_s (Hong et al., 2005).

553 Comparison results from (Wang et al., 2017) also indicate that the GWR method
554 is better than the multiple linear regression method and spline interpolation method for
555 near surface air temperature. By using spatial interpolation method, CERES EBAF R_s
556 can also be downscaled to 1km or 30m. These interpolated CERES R_s data cannot
557 represent the detailed R_s distributions at spatial resolution of 1km or 30m due to the
558 variability of R_s within a 1 degree box. Without additional high spatial resolution data,
559 interpolated cannot capture more detail variability of R_s .

560

561 **5. Data availability**

562 The merged R_s product by GWR methods with cloud fraction and AOD data as
563 input in this study are available at <https://doi.pangaea.de/10.1594/PANGAEA.921847>
564 (Feng and Wang, 2020).

565 **6. Conclusions**

566 Accurate estimation of R_s variability is crucially important for regional energy
567 budget, water cycle and climate change studies. Recent studies have shown that SunDu-
568 derived R_s data can provide reliable long-term R_s series. In this study, we merged
569 SunDu-derived R_s data with satellite-derived cloud fraction (CF) and aerosol optical
570 depth (AOD) data to generate high spatial resolution (0.1°) R_s over China from 2000 to
571 2017 (Feng and Wang, 2020). The GWR and OLS merging methods were also
572 compared.

573 Our results show that the spatial resolutions of all fusion results are improved to
574 0.1° by incorporating MODIS cloud fraction data. The GWR shows better performance
575 than OLS, with increases in R^2 by 9.21%~12.81% and RMSEs reduced by
576 49.56%~54.68%, indicating that R_s has complex characteristics of spatial variability
577 over China, which has also indicated the necessity of the high spatial resolution of R_s
578 data. As clouds and aerosols play vital roles in the variability in R_s , apparent
579 improvements in the results of SunDu-derived R_s data merging are found if both cloud
580 fraction and AOD are incorporated. Based on the merging results incorporating only
581 cloud fraction, cloud fraction is suggested to be the major factor impacting R_s , which
582 explained approximately 86%~97% of R_s variability. Generally, SunDu-derived R_s data
583 merging results derived from GWR show more consistent multiyear mean R_s and long-
584 term R_s trends compared with those from OLS. Our results show that the improvement
585 in R_s variability estimation is closely related to R_s impact factors and R_s spatial
586 heterogeneity. The merged R_s products derived from GWR-CF-AOD can be
587 downloaded at <https://doi.pangaea.de/10.1594/PANGAEA.921847>.
