1. Abstract

The Sylt Roads pelagic time series covers physical and hydrochemical parameters at five neighboring stations in the Sylt-Rømø Bight, Wadden Sea, North Sea. Since the beginning of the time series in 1973, sea surface temperature (SST), salinity, ammonium, nitrite, nitrate and soluble reactive phosphorus (SRP) were measured twice a week. Other parameters were introduced later (dissolved silicate (Si) – since 1974, pH - since 1979, dissolved organic nitrogen (DON) - since 1996, dissolved organic phosphorus (DOP) - since 2001, chlorophyll *a* - since 1979, suspended particulate matter (SPM) - since 1975) and in case of dissolved oxygen were already discontinued (1979-1983). In the years 1977, 1978 and 1983 no sampling took place. Since the start of the continuous sampling in 1984, the sea surface temperature in the bight has risen by +1.11 °C, with the highest increases during the autumn months, while the pH and salinity decreased by 0.23 and 0.33 units, respectively. Summer and autumn salinities are generally significantly elevated compared to spring and winter conditions. Dissolved nutrients (ammonium, nitrite, nitrate and SRP) displayed periods of intense eutrophication (1973 – 1998) and de-eutrophication since 1999. Silicate showed significantly higher winter levels since 1999. Interestingly, phytoplankton parameters did not mirror these large changes in nutrient concentrations, as a seasonal comparison of the two eutrophication periods showed no significant differences with regard to chlorophyll *a*. This phenomenon might be triggered by an important switch in nutrient limitation during the time series: With regard to nutrients, the phytoplankton was probably primarily limited by silicate until 1998, while since 1999 SRP limitation became increasingly important.

Repository-Reference: Rick et al. (2017b-e, 2020a-o) and Rick et al. submitted: doi:10.1594/PANGAEA.150032, 873549, 873545, 873547, 918018, 918032, 918027, 918023, 918033, 918028, 918024, 918034, 918029, 918025, 918035, 918030, 918026, 918036, 918031

2. Introduction

The Sylt-Rømø Bight (SRB) is a Marine Protected Area (MPA) in the Wadden Sea UNESCO World Heritage area since 2009. It is a large tidal lagoon (ca. 400 km^2) in the northern part of the Wadden Sea (SE North Sea). In the previous century two causeways connecting the islands of Rømø and Sylt with the mainland were built. Since then a narrow inlet between Sylt and Rømø is the only connection with the open German Bight through which almost 50% of the bights' water is exchanged each tidal cycle. Local riverine discharge is estimated to be 0.1 % of the total water input. Tides are semidiurnal with a range of about 2m. At mean low tide 33% of the bight is exposed, 10% of the remainder comprising deep channels with a maximum depth of 40m and 57% is a shallow subtidal area with depths less than 5m (Gätje & Reise, 1998, Figure 1).

In 1973 the Sylt Roads **L**ong **T**erm **E**cological **R**esearch time series (Sylt Roads LTER) was initiated in this hydrographically and ecologically interesting area. This consists of a "twice a week" sampling of oceanographic, hydrochemical and biological (phyto-, zooplankton, fish) parameters. Meanwhile, most of these Sylt Roads data (> 1000 data sets) has been published online in the open access data bank PANGAEA (www.pangaea.de). In this work we summarize for the first time the information on physical and hydrochemical parameters of this time series and provide a brief overview of the development over the last 45 years.

4. Instrumentation and methods

Sea surface temperature (SST), salinity, ammonium (NH_4^+), nitrite (NO_2^-), nitrate (NO_3^-), soluble reactive phosphorus (SRP) and reactive silicate (Si) measurements were started in 1973 and interrupted temporarily in the years 1977, 1978 and 1983. Temperatures of the sea surface (SST) were gathered using reversing thermometers (Thomas & Dorey, 1967). For the period 1973 – 1982 the inductive salinometer method was used for salinity measurements (Brown & Hamon, 1961). Since 1983, we measured the salinity using a Guildeline AutoSal 8400B salinometer (Kawano, 2010). pH-measurements were initiated in 1979. Until 1984, diverse pH meters were

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

applied and since 1985 a WTW pH 3000 Meter is in use. Dissolved oxygen was measured only during the period from 1979-1983 using the Winkler method (e.g. Culberson et al., 1991). Table 1 gives an overview on the methods applied within the time series for several chemical analyses on nutrient components and chlorophyll *a*. For both DON and DOP filtration we used precombusted CFC filters and filtrates were frozen at -20°C, while for chlorophyll *a* analysis untreated GFC filters were employed instead. For gravimetric suspended matter (SPM) analyses we used precombusted CFC filters from 1975 to 1998, since 1999 0.4 – 0.45 µm NUCLEOPORE filters were employed.

parameter	time period	analysis

Sampling was mostly conducted from small research vessels (RV Mya till 2012, since 2013 RV Mya II), or sometimes, in severe weather conditions it was land-based at the List Ferry Terminal. Figure 1 provides an overview on the geographical position of the main sampling locations in the Sylt-Rømø Bight (SRB).

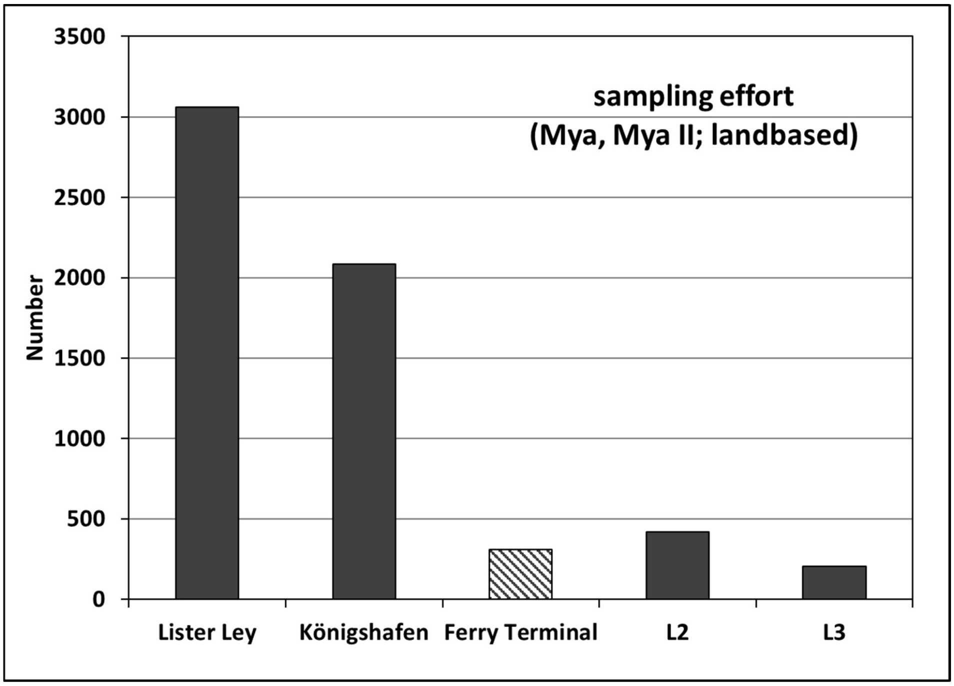

Figure 2a: Overall sampling efforts (ship- and land-based [Ferry Terminal] campaigns) at the five sampling stations (1973-2019)

5. Datasets and Discussion

5.1 General description of the basic data

Ship- and land-based sampling efforts are displayed in Figure 2a. The Lister Ley station (LL) and the Königshafen station (KH) were visited most frequently, while stations List 2 and 3 (L2, L3) were sampled only during the early periods (1973-1976; 1987-1991) of the time series. Since 1999 the List Ferry Terminal station (FT) was

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

used as a backup when ship-based sampling was not possible due to adverse weather conditions. Overall, more than 63.000 data were collected during more than 5.700 RV Mya and Mya II cruises and about 300 land-based sampling efforts at the List Ferry Terminal. Figure 2b provides an overview of the seasonal sampling efforts summarized for all stations. Generally, the number of samples per season varied during the first part of the time series, since 1999 seasonal sampling was more homogenous. The inserted box plots compare the earlier with the more recent parts of the time series. For winter and summer sampling significant differences in sampling effort are obvious (Figure 2b, Table A1 I).

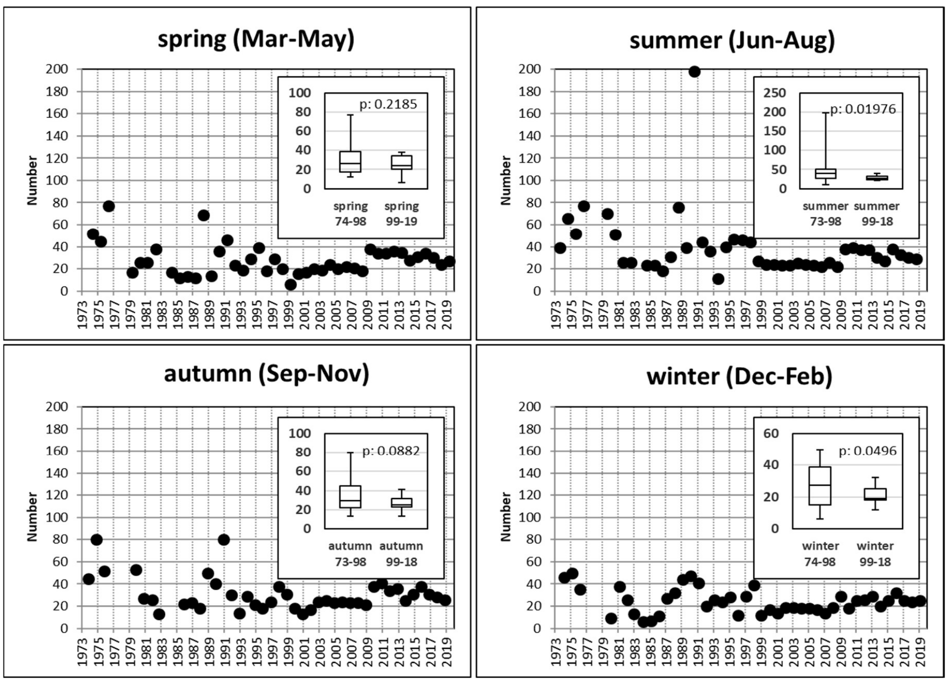

Figure 2b: Seasonal sampling efforts summarized for all Sylt Roads stations in the SRB (1973-2019). The inserts compare seasonal efforts from early days (1973/74 – 1998) with the more recent part (1999-2019) of the time series.

Preprint. Discussion started: 13 May 2022

Open Access Earth System Science Data Discussions

Most of the measured parameters are shown as original data in Figures 3a-j. Due to the physical proximity of stations and the extremely well-mixed waters in the SRB, data from all sampling stations (Figure 1) were included in the graphs. Most of the parameters, even salinity (Figure 3a), show seasonal signals.

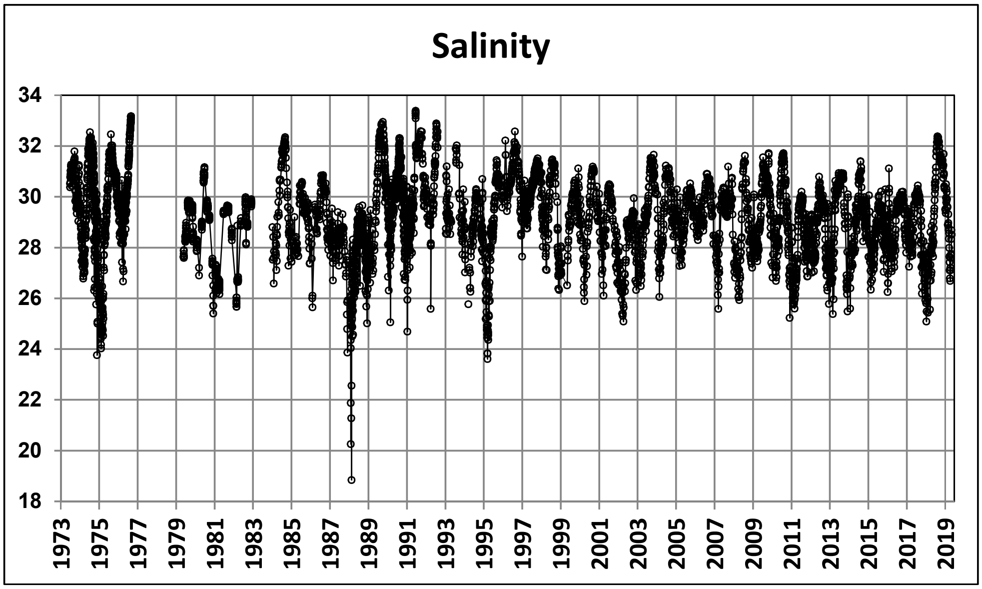

Figure 3a: Salinity time series at Sylt Roads. Data of the five sampling stations (Figure 1) are included in all subgraphs of Figure 3.

For salinity this is mainly triggered by the enhanced freshwater runoff in late winter and spring. Seasonal patterns are most evident for the SST (Figure 3b) and the associated oxygen content of the waters (data not shown) as well as for the major inorganic nutrients as NH_4^+, NO_2^-, NO_3^-, SRP and reactive silicate (Figures 3c-g). Not too much should be read into the nutrient data from early years since some (e.g. NH_4^+, SRP) show quite high variability or exceptionally low values (Si, NO_3^-) especially in the initial period (1973-75). From 1992 to 1994 all NH_4^+ numbers were also exceptionally low, which coincided with a specific analyst (Table 2) and are

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

obviously erroneous. All questionable values were eliminated from the graph (Figure 3c).

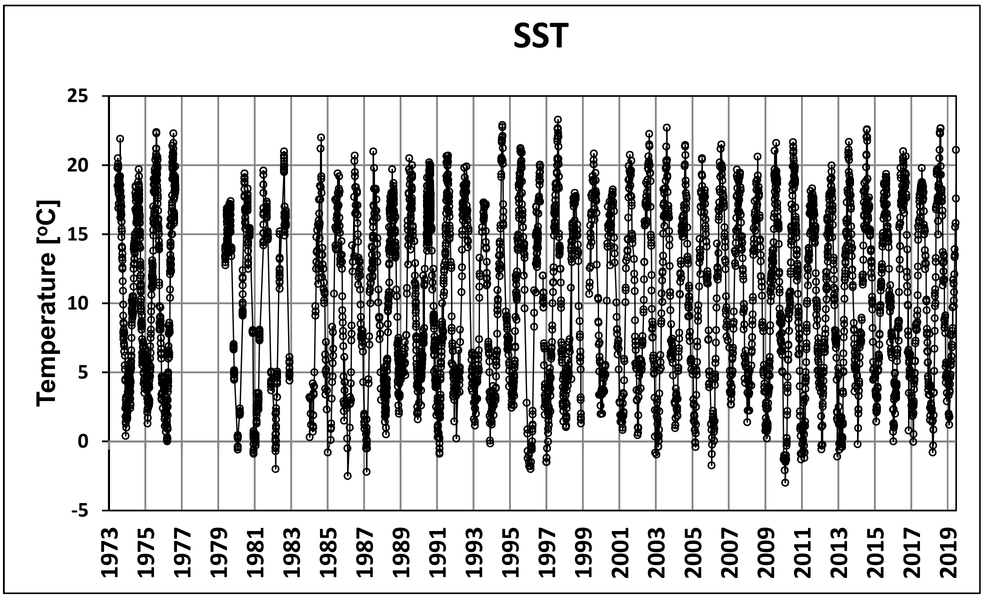

Figure 3b: Time series of the sea surface temperature (SST) at Sylt Roads

Dissolved inorganic nutrients display an opposite behavior compared to the SST with high values in winter/early spring and minimal numbers during summer. As expected Chlorophyll *a*, pH (Figure 3h, i) as well as dissolved organic nutrients (data not shown) are inversely related to levels of inorganic nutrients due to the nutrient uptake by the phytoplankton.

High SPM is mostly found in winter due to the large amounts of sediment mixed into the water column by wind forcing (Figure 3j, Bayerl et al., 1998). In summer SPM decreases to minimum values. A deviation from this pattern was seen in the period from 1993-1997, which is likely due to inaccurate sample treatment: following the filtration process, the sea salt retained by the filter material is normally leached out using distilled water. When the salt is not completely removed in this process the

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

measured SPM load will be biased. This was probably the case for the 1993-1998 SPM measurements and the respective data should not be used and consequently have been omitted from the graph.

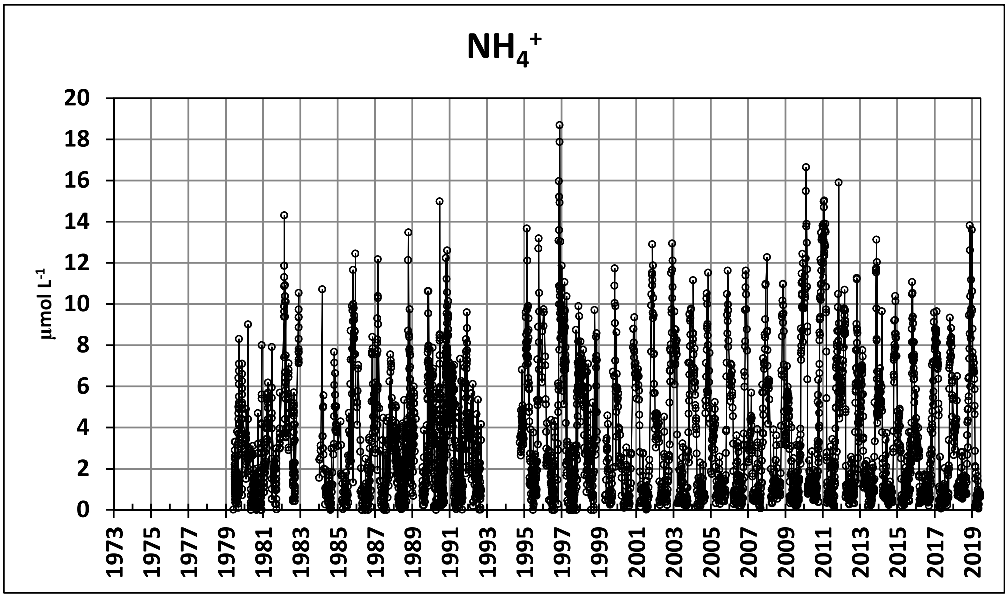

Figure 3c: Development of ammonium concentrations at Sylt Roads (1979-2019). Data from 1973 - 1978 and 1993 - 1994 were biased and are not shown in the graph.

Preprint. Discussion started: 13 May 2022

The nutrient plots (e.g. Figure 3e, f) indicate a change in the eutrophication status of the bight. Until 1998, nitrate as well as SRP concentrations were high, since 1999 they have been decreasing. This is in line with several observations from the southern North Sea area and mainly due to strong reductions of phosphorus and nitrogen loads in the rivers Rhine, Ems, Weser and Elbe (e.g. Carstensen et al., 2006; van Beusekom et al., 2005, 2018, 2019).

Much a higher variability in nutrient values was evident for the high eutrophication period (1973-1998) compared with more recent times (1999 – 2019) of reduced nutrient loads. This high variability might be partly related to the fact that till 1998 only unfiltered nutrient samples were analyzed, from 1999 on the samples were finally filtered (van Beusekom et al., 2009). The early eutrophication period was additionally characterized by intense marine or inshore construction and dredging activities. Sediments originating from the Sylt-Rømø Bight were intensively used for dike building (e.g. the polders Margarethenkoog and Rickelsbüller Koog), the Hoyer lock was constructed, the Ruttebüll Lake dredged out and the river Vidå renatured. All these activities certainly have influenced e.g. the loads of SRP and contributed potentially to the high variability in nutrient concentrations. An intense blue mussel fishery in the early period of the time series with its associated dredging impact as well as the shutdown of the List sewage plant in 2005 might have played an important role in nutrient variability, too.

5.2 Nutrients, chlorophyll *a*, nutrient ratios and SPM

Since most of the parameters show seasonal signals, it was considered appropriate to focus on changes for the four main seasons in the course of the time series. Figure 4a gives an example for the nutrient SRP. For each year in the time series

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

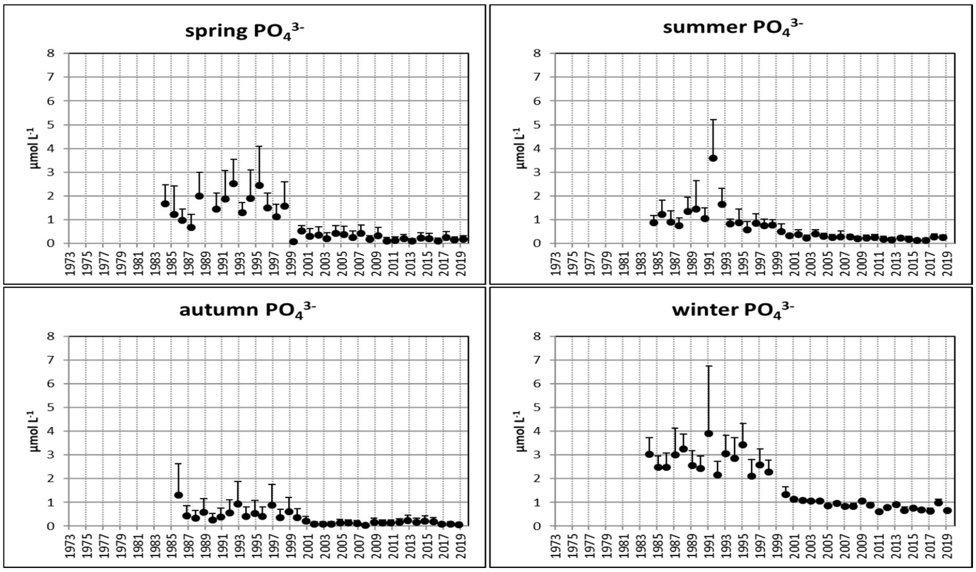

Figure 4a: Development of SRP over the course of continuous measurements (1984-2019) within the Sylt Roads LTER time series. Seasonal averages (Dec, Jan, Feb – winter; Mar, Apr, May – spring; Jun, Jul, Aug – summer; Sep, Oct, Nov – autumn) are displayed with standard error of means (SEM) as error bars.

seasonal averages are presented together with their respective standard errors. As already seen to some extent in Figure 3f, a first period (1984-1998) of relatively high values shifts towards a second one (1999-2019) with a lot lower SRP concentrations. A comparison of both periods using a t-test (two-sided, different variances assumed) results in highly significantly lower (p: 0.0003 – $1.1x10^{-10}$) and much less variable SRP values for all seasons in the period of low eutrophication (1999-2019; Figure 4b, Table A1 a).

Dissolved inorganic nitrogen (DIN, i.e. sum of nitrate, nitrite and ammonium) shows a similar pattern although the respective t-tests yielded significant differences for spring (p: 0.017) and winter (p: 0.001) seasons only (Figure 5, Table A1 b).

Silicate (Si), a nutrient important for diatoms, shows a completely different pattern (Figure 6, Table A1 c). The more recent (1999-2019) low eutrophication winters and

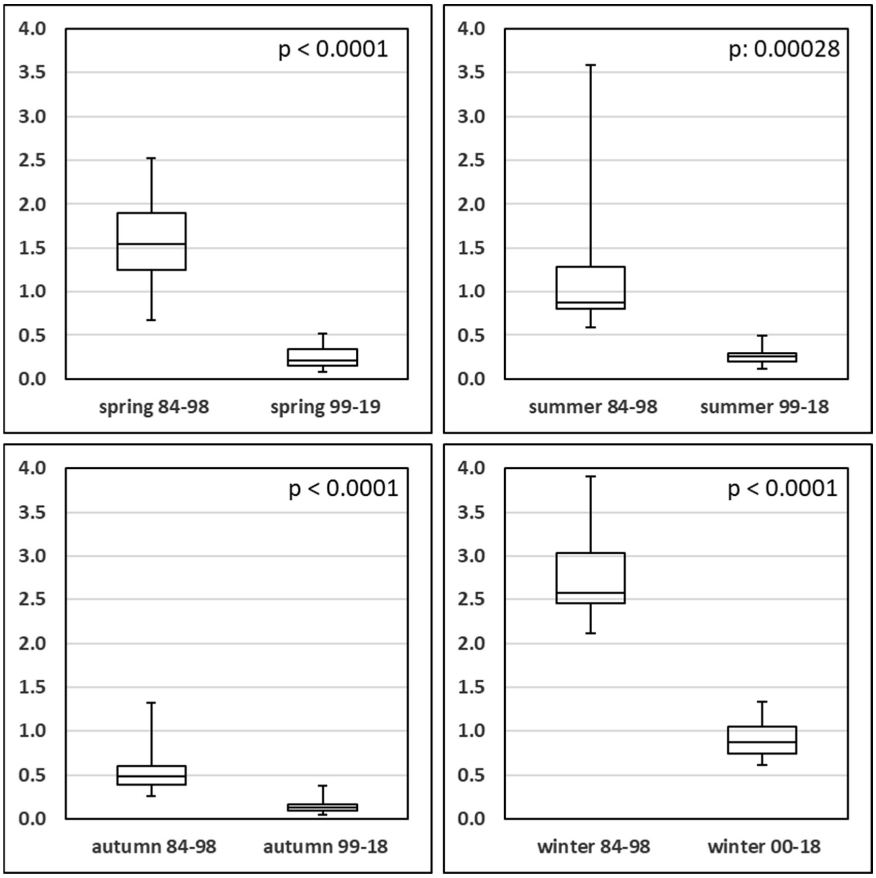

Figure 4b: Seasonal comparison of SPR concentrations [µmol*l^{-1}] for high/low eutrophication periods. Boxplots give median values, with quartiles 1 and 3 attached as boxes and min and max values shown as endpoints of the error bars. All data including possible outliers are shown in the graph. The p-values of the respective t-tests are given in the upper right.

autumns (N and P) showed significantly (p: 1.16 x 10^{-6} and 0.026) elevated Si values compared with the respective data of high eutrophication (1973-1998). For the spring comparison Si values remained in the same range. In summer (p = 0.001), the low eutrophication set showed a significantly lower value. Generally, the variability of Si

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

was a lot higher in the period from 1973-1998 compared to 1999-2019 (Figure 6; Table A1 c). Interestingly, the silicate anomaly from 1988 (Raabe & Wiltshire, 2009) shows its imprint (highlighted in Figure 3g) in the Sylt Roads data, too.

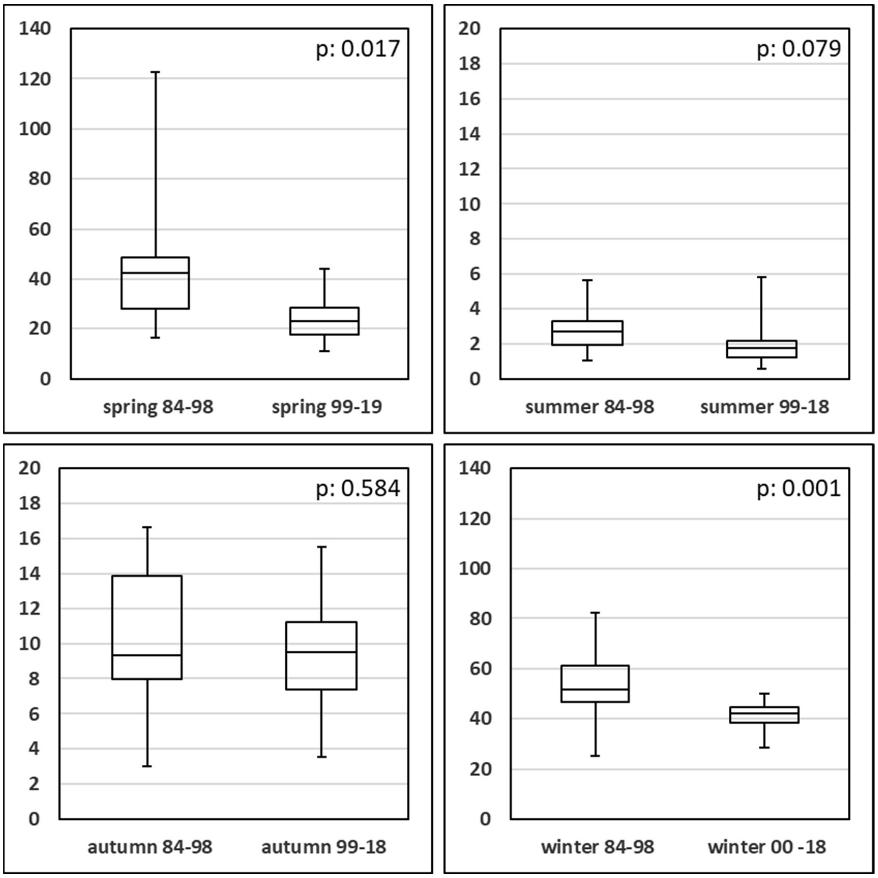

Figure 5: Seasonal comparison (boxplots and t-test p-values) of dissolved inorganic nitrogen (DIN) concentrations [µmol*l^{-1}] for high/low eutrophication periods. Detailed information is available in Figure 4b.

Despite these large changes in nutrient concentrations, phytoplankton parameters such as chlorophyll *a* (Figure 3h, 7 and Table A1 i) or phytoplankton carbon (Rick et al., 2017a) did not shift accordingly, as probably expected (e.g. Cadee & Hegeman, 2002).

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

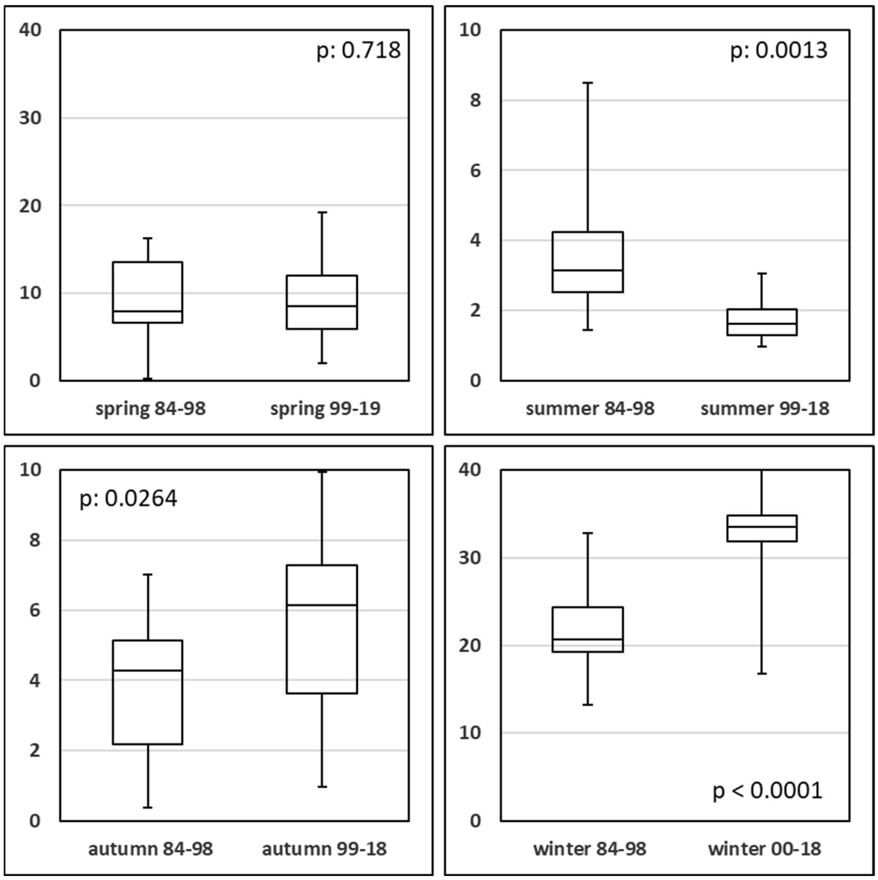

Figure 6: Seasonal comparison of reactive silicate concentrations [µmol*l^{-1}] for high/low eutrophication periods.

Planktonic algae are not solely influenced by the total concentrations of single nutrients – but rather it is the nutrient ratios have an essential impact (Dugdale, 1967). For most algae the DIN/SRP ratio (Figure 8, Table A1 j) is of major importance (Redfield, 1934, 1958), diatoms are additionally affected by the DIN/Si (Figure 9, Table A1 k) ratio (Brzezinski, 1985). In Figures 8 and 9 the optimal nutrient ratios, based on molar concentrations, are highlighted as grey bars.

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

Open Access Earth System Science Data Discussions

Generally, the DIN/SRP ratio in most cases is highly significantly elevated in the low eutrophication period when compared with the high eutrophication period (Figure 8).

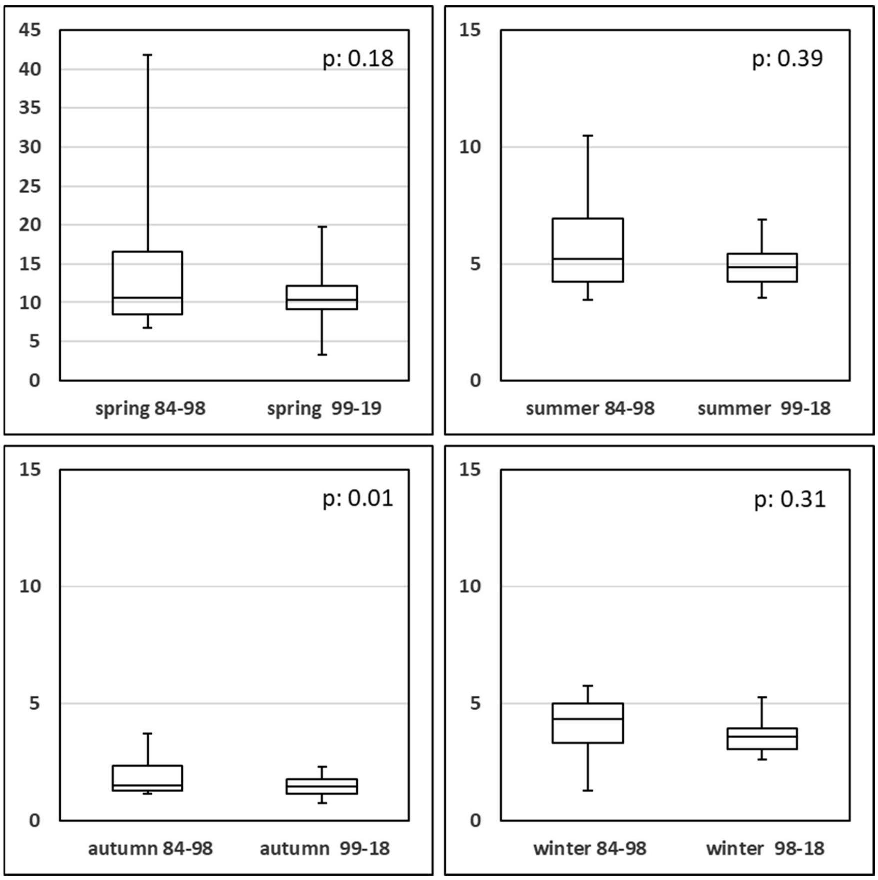

Figure 7: Seasonal comparison of Chlorophyll *a* concentration [$\mu g*l^{-1}$] for high/low eutrophication periods.

For winter and spring this change moved the ratio towards an increasing phosphorous limitation, while for summer and autumn it diminished the N-limitation during the high eutrophication period.

The spring and winter DIN/Si ratios (Figure 9, Table A1 k) moved from higher (1973-1998) to more balanced values (1999-2019). For winter ($p = 0.018$) this change is

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

significant. For the summer and autumn comparisons DIN/Si remained close to a ratio of 1.

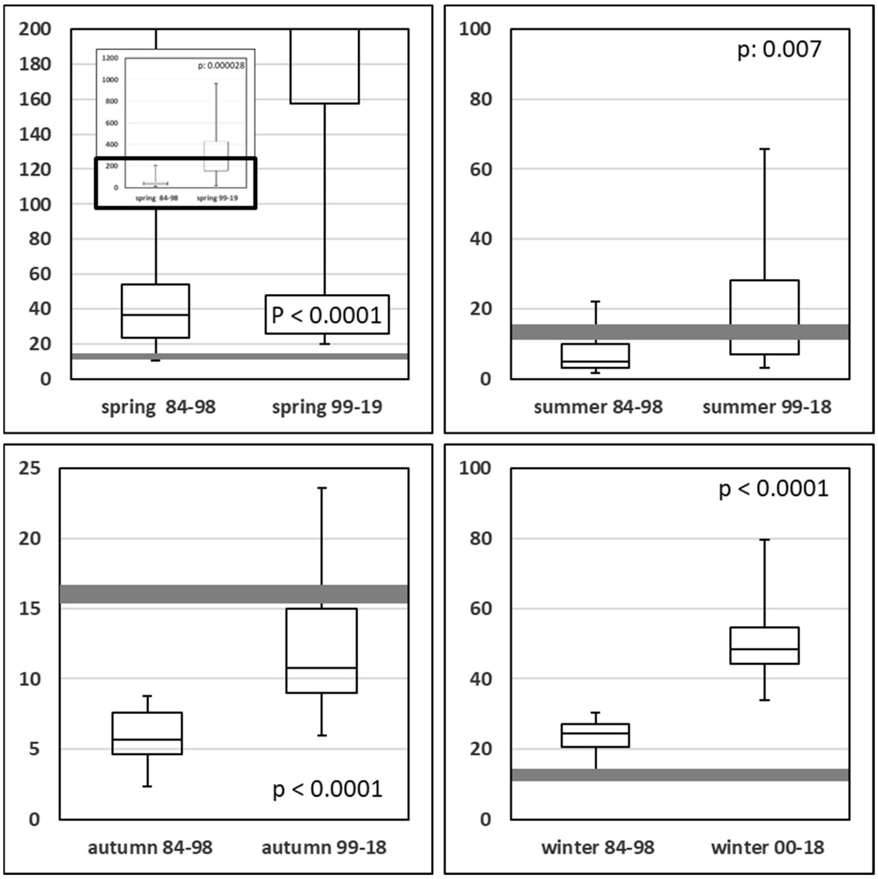

Figure 8: Seasonal comparison of DIN/SRP molar ratios for high/low eutrophication periods. The optimum value around 16 is highlighted as a grey bar. The black boxed part of the spring plot is shown enlarged.

Diatoms are the most prominent phytoplankton group in the bight during all seasons (Rick & Wiltshire, 2016; Rick et al., 2017a, 2018). In addition to diatoms, solely the prymnesiophyte *Phaeocystis globosa* (Scherffel, 1899) may add substantially to the photosynthetic biomass in late spring and early summer (Rick et al., 2017a). During the period of high phosphorus and nitrogen loads (1973-1998), silicate was probably

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

not available in sufficient amounts with the result that the diatoms were, at least for the spring bloom, limited by silicate. Since the decline of SRP and DIN in the second half of the time series (1999-2019) silicate limitation was replaced by a limitation by

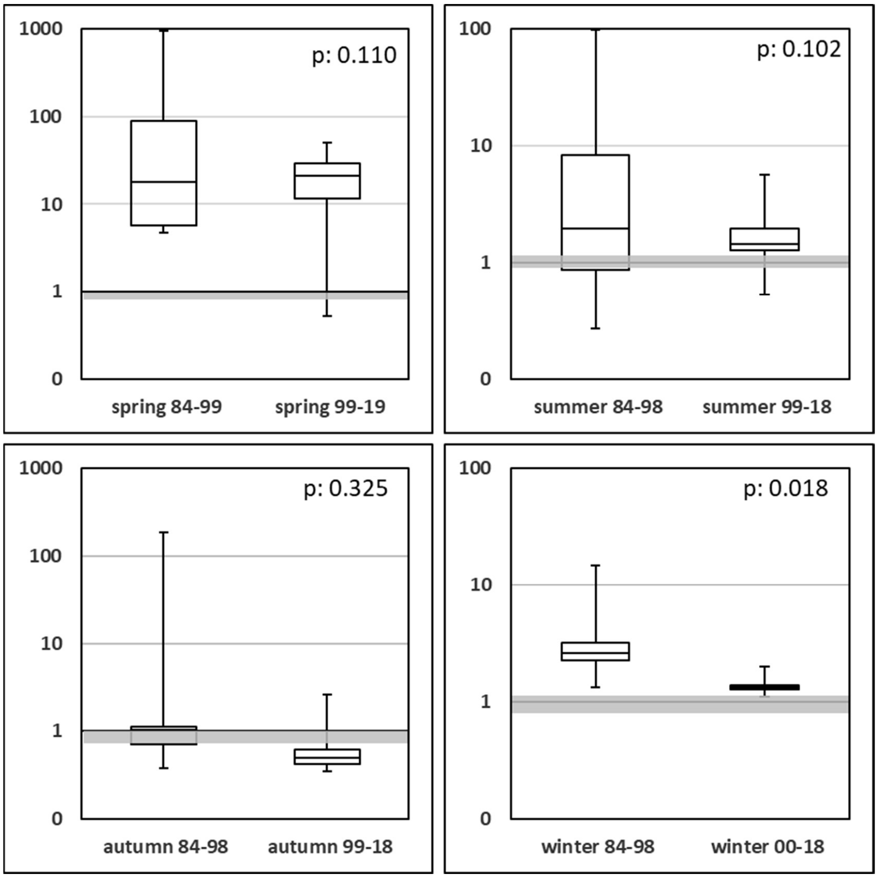

Figure 9: Seasonal comparison of DIN/Si molar ratios for high/low eutrophication periods. The optimum value around 1 is highlighted as light grey bars. Note the log scaled y-axes.

phosphorus. This explains the almost unchanged Chlorophyll *a* pattern despite the strong nutrient changes (Figure 7, Table A1 i). These results are in accordance with the findings of Loebl et al. (2009), who studied patterns of phytoplankton limitation along the southern North Sea coast for the period 1990 to 2005. The authors

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

Earth System Science Data Discussions
Open Access

concluded that aside from underwater light, silicate limitation of the phytoplankton was most common followed by the restraining effects of low phosphorus concentrations.

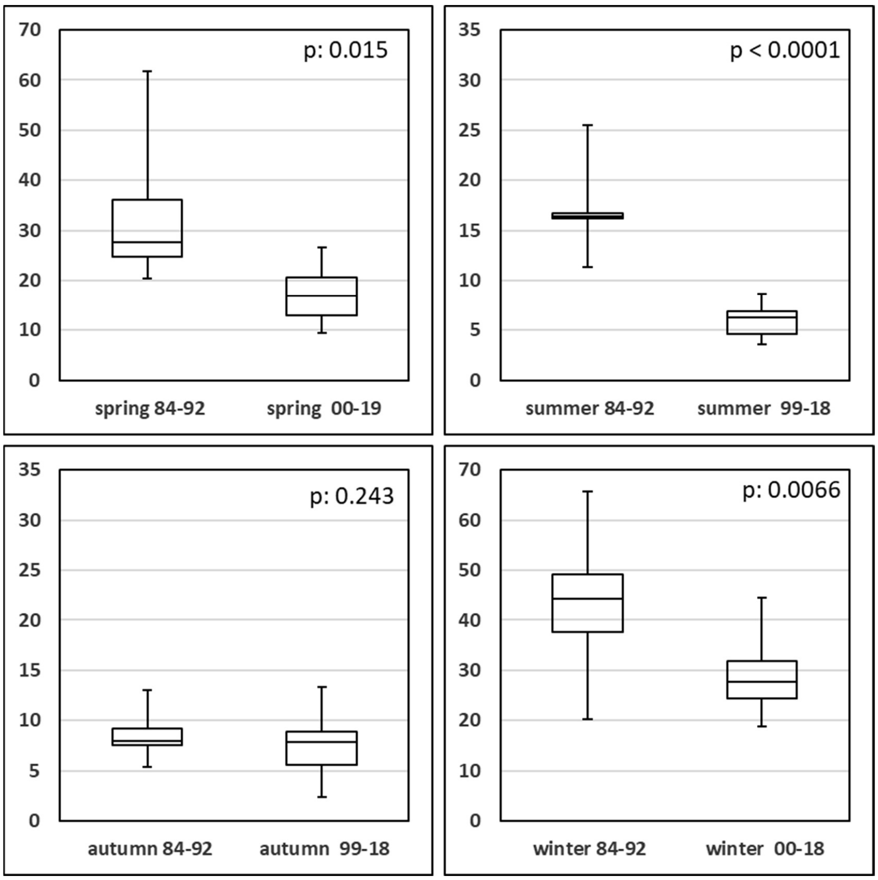

Figure 10: Seasonal comparison of SPM values [mg*l^{-1}] for high/low eutrophication periods.

A comparison of seasonal SPM data for both eutrophication periods is given in Figure 10 and Table A1 h. Despite the omission of the biased values (1993-1997) a

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

Open Access Earth System Science Data Discussions

t-test comparison for all seasons resulted in significantly lower values for the low eutrophication period (1999-2019). This cannot be explained either by lowered plankton biomass (Rick et al., 2017a) or by less sediment input into the water during these years. We assume a change in the SPM methodology might be the cause. Since 1999, Nucleopore filters were used instead of GF/C-filters. Therefore, comparisons of recent and earlier SPM data should be avoided.

5.3 Development of sea surface temperature, salinity and pH

SST rose since the start of continuous measurements in 1984 until 2019 by 1.11 °C, which is close to the temperature development at Helgoland Roads (Wiltshire & Manly, 2004). Summers warmed by 1.24 °C, spring seasons by 1.14 °C, autumn seasons actually by 2.04 °C but winters even cooled slightly by -0.16 °C (Figure 11a).

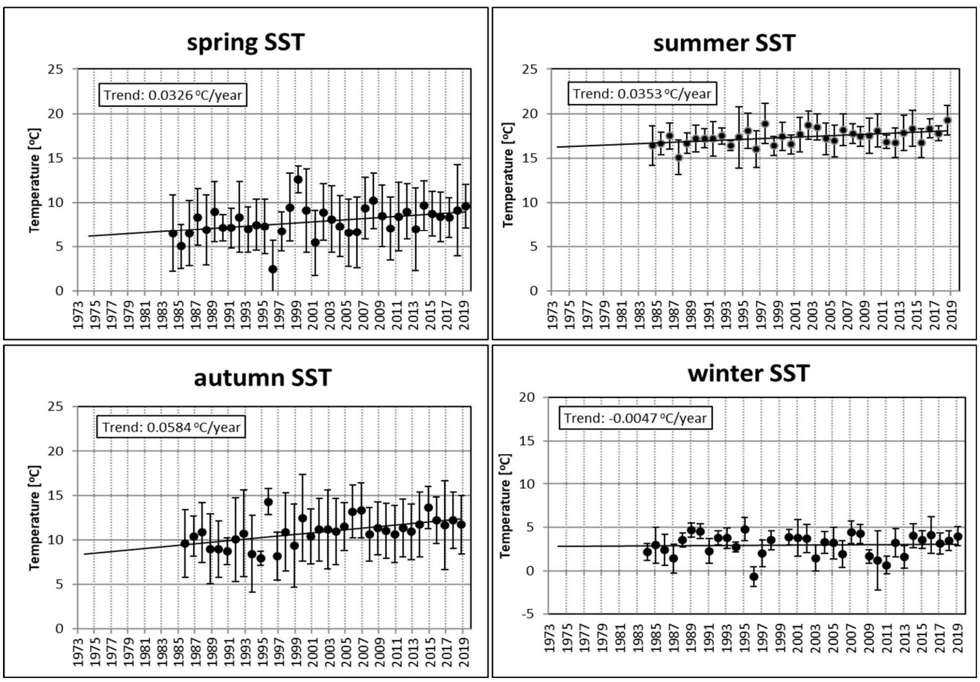

Figure 11a: Development of SST over the course of the Sylt Roads LTER time series. Seasonal averages with standard error of means (SEM) as error bars. Data on linear seasonal trends (1984-2019) are shown in boxes

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

Open Access Earth System Science Data Discussions

Figure 11b and Table A1 d show a t-test comparison of identical seasons for the two periods defined in the previous chapter. For all seasons the period 1999-2019 shows higher average SST values compared with the earlier years of the time series. This finding is significant for summer (p: 0.043) and autumn data (p: 0.0004).

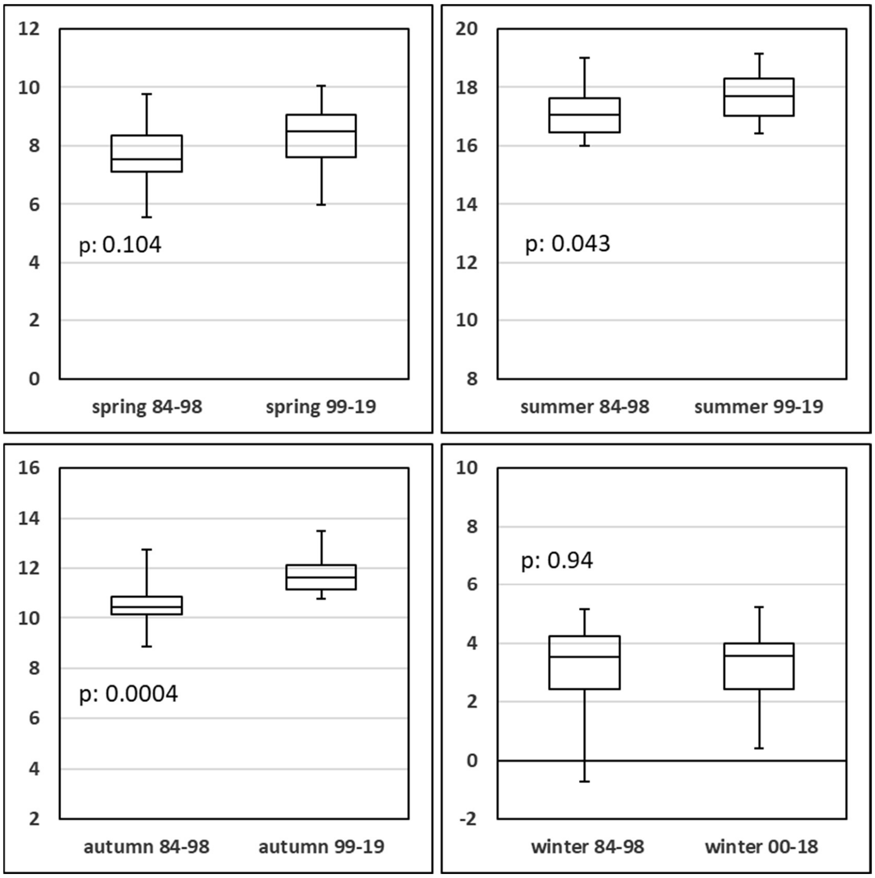

Figure 11b: Seasonal comparison of SST values [ºC] for the early and recent part of the time series.

Figure 12 and Table A1 f give an “all” season comparison of salinity values for the entire time series: Generally, the salinities in winter and spring are highly significantly lower compared to summer and autumn. Additionally, the summers show slightly significantly higher salinities compared to autumn data.

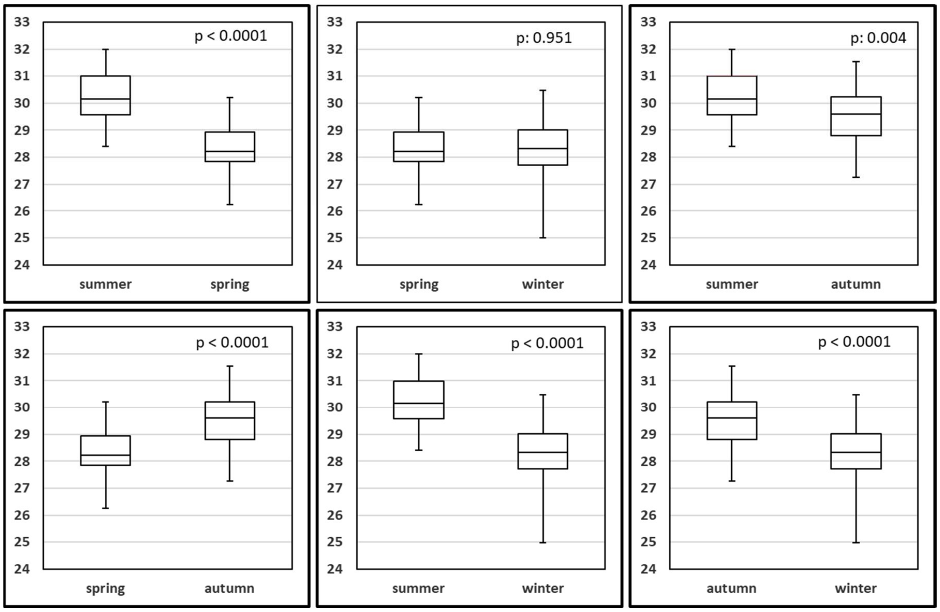

Figure 12: All-season comparison of salinity values for the entire time series.

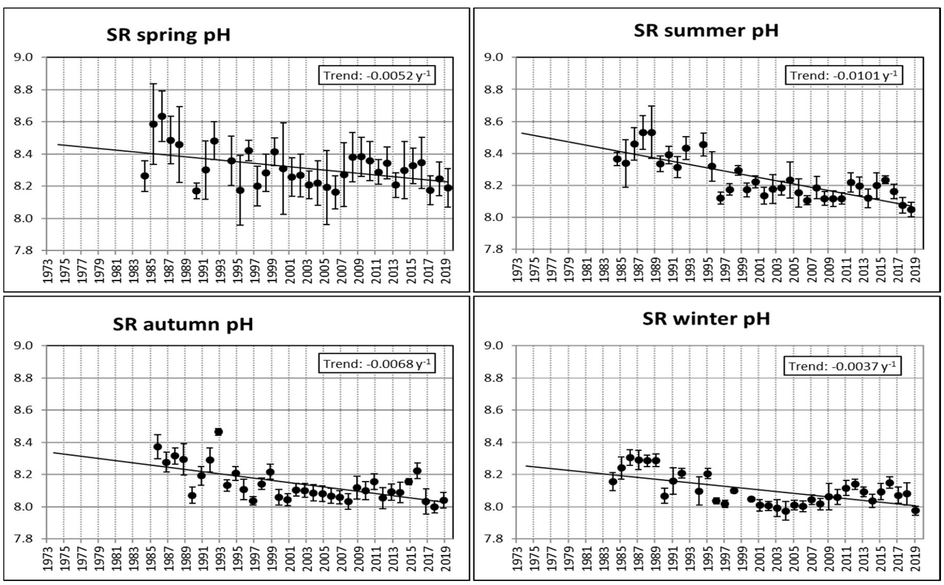

Figure 13a: pH development over the course of the Sylt Roads LTER time series. Seasonal averages with standard error of means (SEM) as error bars. Data on linear seasonal trends are shown in the boxes.

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

This overall picture is explained by the more prominent freshwater impact in winter and spring to the area (Pätsch & Lenhart, 2004; van Beusekom et al., 2017). Comparisons of seasonal salinities for the high and low eutrophication periods yielded in no significant differences at all (Table A1 e).

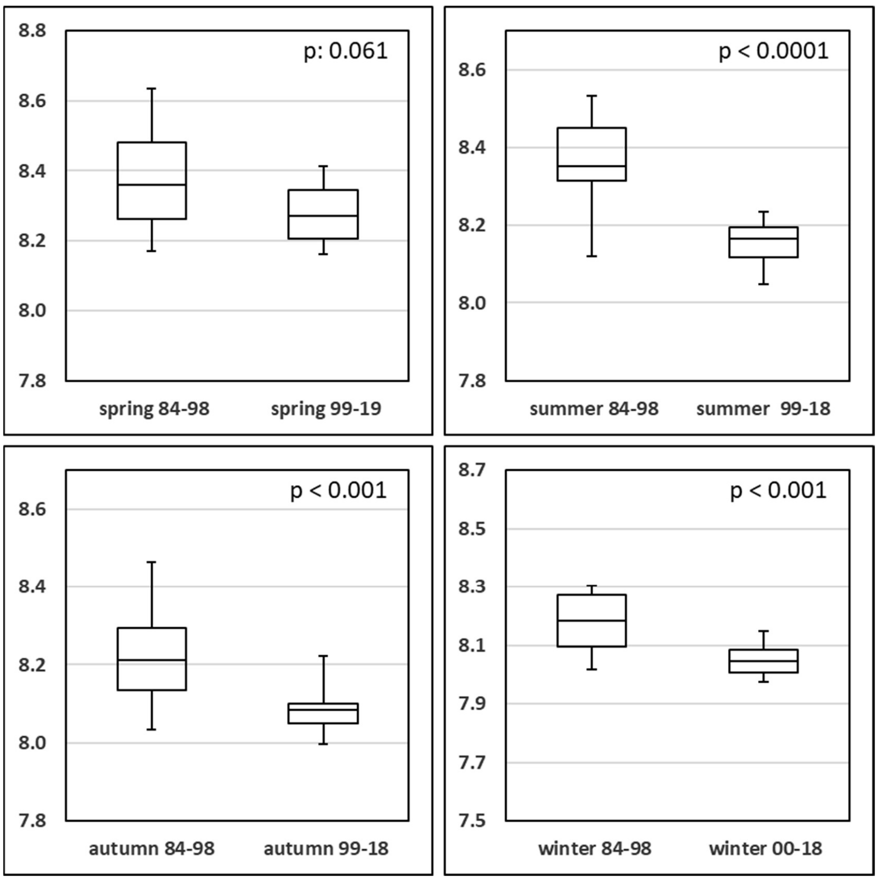

Figure 13b: Seasonal comparison of pH values for high/low eutrophication periods.

On average, the pH decreased since the start of continuous measurements in 1984 till 2019 by 0.23 units. This was evident for all seasons (Figures 13a) with summer, autumn and spring showing most pronounced declines (-0.36, -0.24, -0.18). A t-test

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

comparing pH values from 1984-1998 with values from 1999-2019 yielded significant differences for winter, summer and autumn seasons (p<0.001, Figure 13b, Table A1 g). Progressively declining pH levels in coastal regions have been documented elsewhere e.g. from the US East Coast (Waldbusser et al., 2011, Wallace et al., 2014).

6. Related Datasets

Over the years several data sets closely related to this physical-hydrochemical time series were compiled at the Sylt Marine Observatory:

1. The **Sylt Roads zooplankton time series** was initiated by Peter Martens. Quantification of abundant zooplankton (> 50 species/groups) occurred weekly from 1979 to 2011. For this time period all data (32 years) are stored in the open access repository PANGAEA (e.g. Martens, 2007, 2012). Due to the retirement of the lead scientist the series is on hold since 2012. Zooplankton samples are still taken weekly and stored for further analysis.
2. The **Sylt Roads quantitative microplankton time series** was started in June 1992 by Wolfgang Hickel. Mostly on a twice a week basis microplankton abundance and related biomass parameters, such as plankton biovolume and carbon were recorded. All data until 2013 are compiled in the PANGAEA repository (Rick et al., 2017a)
3. In 1987, the **Sylt Roads semiquantitative microplankton time series** was initiated by Gerhard Drebes, Malte Elbrächter and Hannelore Halliger. Weekly in depth microscopic and regular electron microscopic analyses of

https://doi.org/10.5194/essd-2020-263
Preprint. Discussion started: 13 May 2022

living plankton and fixed, respectively, samples resulted in high quality data sets (> 700 taxa) compiled in PANGAEA until 2020 (Rick et al., 2018; Castillo-Ramírez et al., 2021)

4. In 1994, the **planktonic primary productivity and respiration time series** was started by Ragnhild Asmus. Monthly measurements based on the oxygen method (Gaarder and Gran, 1927) using oxygen sensitive electrodes (WTW OxyCal) are ongoing in the List Königshafen area. All data including 2014 are archived in PANGAEA (Asmus & Hussel, 2010; Asmus, R., 2016a)
5. The **Sylt Roads gelatinous zooplankton time series** was initiated by Ragnhild Asmus. The data are available on a weekly basis since May 2009 (Asmus, R. et al., 2017 a, b)
6. The **Sylt Roads bivalve larvae time series** was established in 1995 by Matthias Strasser (Strasser & Günther, 2001). Twice a week sampling is ongoing and the data are currently available via PANGAEA until 2014 (e.g. Asmus, R., 2010, Asmus & Asmus, 2016)
7. The **Sylt Roads Meroplankton time series** was established in 1996 by Ragnhild Asmus. Sampling (twice a week) is ongoing and the data were submitted to Pangaea in March 2022 (e.g. Kadel et al., submitted)
8. The **Sylt Roads fish survey** was established in 2007 by Harald Asmus in order to analyze the Wadden Sea fish fauna with special focus on migration changes, species composition and feeding habits. Seven stations are sampled monthly inside the Bight while two additional reference stations, one outside the Bight and one close to the Danish border, are sampled four times a year. The data are stored in the PANGAEA repository from 2007 until 2020 (Asmus, H. et al., 2020)

6. Data Access

Data retrieval is ensured via PANGAEA (Rick et al. (2017b-e, 2020a-o & Rick et al., submitted; doi:10.1594/PANGAEA.150032, 873549, 873545, 873547, 918018, 918032, 918027, 918023, 918033, 918028, 918024, 918034, 918029, 918025, 918035, 918030, 918026, 918036, 918031).

Table A1: Descriptive statistics related to boxplot figures (4b, 5-10, 11b, 13b) with p-values of associated t-tests (two sided, unequal variances assumed) comparing seasonal data for two time periods within the Sylt Roads LTER characterized by different eutrophication potential (High: 1978-1998; Low: 1999-2019). In case of salinity (part e. of Table) seasons are compared to each other for the complete series (1973-2019). Q1 = 1st quartile; Q3 = 3rd quartile; SEM: standard error of means; SD: standard deviation

Open Access Earth System Science Data Discussions

8. Author contribution

JR prepared the manuscript with the contribution of the following co-authors (MS, TR, JB, RA, HA, FM, AK, KW). RS compiled the data in Pangaea. TR performed the hydrochemical measurements since 2000.

9. Competing interest

The authors declare that they have no conflict of interests.

10. Acknowledgements

We would like to thank all the devoted people who have been supporting the Sylt Roads LTER time series over more than four decades. Special thanks go to Ludmila Baumann, Tanja Burgmer, Lydia Canals, Marthe Claußen, Gerhard Drebes, Claus-Dieter Dürselen, Malte Elbrächter, Peter Elvert, Alfonso Lopez Gonzales, Alexandra Halbe, Hannelore Halliger, Wolfgang Hickel, Valentin Hildebrand, Birgit Hussel, Petra Kadel, Alexandra Kraberg, Niels Kruse, Peter Martens, Cornelia Reineke, Karsten Reise, Alfred Resch, Anette Tillmann and Kay von Böhlen.
