Response to Referees

The authors thank both referees for providing detailed and helpful comments, suggestions and questions. We have added detail and clarity to the manuscript where suggested.

With regard to comments concerning the inclusion of individual calculations and more detailed explanations of variable derivation and methodology, we believe the manuscript describes the data set at an appropriate level of detail for the intended end users who are interested in soil moisture and hydrometeorology measurements. This description paper is not aimed at researchers looking to further develop the cosmic-ray method of soil moisture measurement.

The COSMOS-UK team is in active discussion with researchers across the European COSMOS community, with the intention of producing a more detailed output to describe specific methodologies for deriving soil moisture from the CRNS.

We address each referee comment (RC) with our response (AR) below.

Response to Referee 1

RC 1: (Title) "empowering UK environmental science" To me this formulation reads a bit "selfish". It may be UK-national soil moisture data, but it should be (and I believe it is) open to anyone who works in the field of environmental science, British or not. I think there are many global or continental models that include the UK and would likewise benefit from your data. So I suggest to change the title into something less "nationalistic".

AR 1

We had no intention for the title to imply any such meaning and we have therefore carefully amended it. The revised title is, “COSMOS-UK: National soil moisture and hydrometeorology data for environmental science research”.

RC 2

35: Could you find another citation Moene and van Dam? I think there are plenty of papers out there that give a more specific introduction to the topic of soil moisture in the Earth System, e.g., by Seneviratne et al.

AR 2

We have referenced the work by Seneviratne et al. (2010).

RC 3

40: "measurement footprint" You may already specify it here to let the reader know what to expect. E.g. "the field scale measurement footprint"

AR 3

We have amended the text to “field scale measurement footprint”.

RC 4

57: 80cm -> blank missing
This has been corrected.

80-85: What’s the reason for not having more stations in Scotland (only 2 stations in the east)? Also for Yorkshire and North-West England the network is more sparse.

Installation of COSMOS-UK sites was initially focussed in areas where soil moisture was expected to have greater variability and where practical and logistical challenges related to access and communication were minimised. Installation of sites in less-represented regions is in consideration but is dependent on the availability of resources. This is now clearer in the manuscript.

Table 1: I think the table needs to be condensed. Since available in the metadata, you can skip the 2 columns for Easting and Northing and also End date can be moved to Start date like this: "Start(end) date" 26/11/2013(-01/10/2016)

The numbers for SAAR and Altitude should be right-adjusted. For the Soil type and land cover you should define abbreviations in the table header (e.g. MS for Mineral soil, IG for Improved grassland). and Soil type should go right of Altitude and SAAR. So finally one line could be as short as: Cochno 23/08/2017 168 662 MS IG and all stations could be overviewed at a glimpse one a single page.

Table 1 has been amended with these suggestions.

120-122: not clear if all CRS1000B sensors have been removed from the network and CRS2000Bs are used now everywhere. If all had been changed, since when is the network pure CRS 2000B? Pls. be more specific.

The text has been revised for clarity. Only the first four sites were installed with a CRS1000B (Chimney Meadows, Sheepdrove, Waddesdon and Wytham Woods), whilst all other sites were installed with a CRS2000B sensor. Wytham Woods was decommissioned in October 2016. In February 2020, CRS2000B sensors were installed at Chimney Meadows, Sheepdrove and Waddesdon alongside the existing CRS1000B sensors which remain connected.

125: Shortly explain what TDT sensors are.

An explanation has been added.

127: What was the reason to remove the PICO profiles?
We experienced issues with this sensor as configured at our sites. Specifically the configuration resulted in a high failure rate for other sensors and resulted in loss of data. Because of this, these instruments were removed during 2019 - 2020 in order to maximise the data capture across the array of instruments. This has been made clearer in the manuscript.

Pluvio wind protection shields were omitted during COSMOS-UK site installations as site locations were identified as being not particularly exposed. It is acknowledged that this decision could impact the extent of wind-induced under-catch, and shields will be considered during future network improvements. This is now clear in the manuscript.

The list has been added.

Soil sampling depths were selected to match typical (moist) UK conditions. Ideally, subject to cost, calibrations should be repeated at different VWCs, preferably capturing the full range of VWC measured at a particular site. Clarity has been added to the text and we have highlighted that the shallow soil layers are given higher weighting than deeper layers to represent the decreasing contribution of deeper soil water (Köhli et al., 2015; Schrön et al., 2017). Figure 7 has been amended to display the correct (lower) values for D86. We apologise for this error; the data set has been corrected.

Soil sampling depths were selected to match typical (moist) UK conditions. Ideally, subject to cost, calibrations should be repeated at different VWCs, preferably capturing the full range of VWC measured at a particular site. Clarity has been added to the text and we have highlighted that the shallow soil layers are given higher weighting than deeper layers to represent the decreasing contribution of deeper soil water (Köhli et al., 2015; Schrön et al., 2017). Figure 7 has been amended to display the correct (lower) values for D86. We apologise for this error; the data set has been corrected.
We have included these details.

Figure 3 has been amended.

We do not currently obtain the bulk densities with the weighting function, however we will consider this in future work. This is now clearer in the manuscript.

Yes these findings have been considered in our approach; when applying the soil sampling calibration, the shallow 5 cm layers are given a higher weighting than the deeper ones. This is now clearer in the manuscript. Please note that the Sheepdrove COSMOS-UK site is unrelated and in a different location to the Sheepdrove monitoring station referred to by Schröen et al. (2017).

Detail has been added to the manuscript and we plan to address this as part of future recalibrations.

These have been added to the data set.

Please be more specific in the description of the derivation of the corrected neutron count signal. This important step should be reproducible by the data users. So you should provide the exact
formulas and specify the constants used (e.g. for the reference pressure). Did you use the same reference pressure for all stations? Did you do or do you plan to do a cross-calibration for the different sites, to get an idea of the variations in sensitivity of the sensors?

AR20

After consideration we believe that the current description with relevant citations provides an acceptable level of detail for the data set’s intended users, who are interested in soil moisture and other environmental data.

We have included additional detail regarding reference pressure and CRNS cross-comparisons. A value of 1000 hPa is used for all sites. A selection of CRS2000/B sensors deployed at COSMOS-UK sites were cross-compared for sensitivity under lab conditions prior to installation. Where necessary, in situ sensitivity comparisons have been completed by collecting several months of data from adjacent sensors.

RC21

224: I think it should be "Physikalisches Institut’s, University of Bern, Jungfraujoch"

AR21

The text has been corrected.

RC22

227: What are the implications of using a neutron monitor with such a large displacement and elevation difference. I assume a big difference in the cutoff rigidity between Jungfraujoch and your sites. Wouldn’t the Kiel monitor be better suited? I think that this should also be discussed in the paper.

AR22

We have added detail to the manuscript. We use normalised count rates in the intensity correction, which are not greatly affected by their cut-off rigidity in the absence of significant space weather events. During such events, the cut-off rigidity of a specific location may change due to magnetic field disturbances, so only matching cut-off rigidity might not compensate for such events. When comparing Jungfraujoch neutron monitor with the available monitors of similar cut-off rigidities to the COSMOS-UK sites, the normalised counts and the associated trends were in good agreement. When choosing the most suitable neutron monitor for this work, Jungfraujoch was identified as a well-maintained monitor with a high level of data completeness, however we will continue to monitor research in this area to improve our methods where possible. The Kiel monitor is currently described as not having efficiency-corrected values available, so we will reconsider this monitor when these data are available.

RC23

241: Are the fits for all the sites performing equally well? You may discuss and add some other cases too.

AR23
There may be some misunderstanding with this question. This figure does not illustrate goodness of fit, it only illustrates the portion of the calibration curve corresponding to the observed count rates. We have made this clearer in the manuscript.

RC24
243: Fig. 4: Please add the formula for the synthetic curve including constants to the legend of the plot
AR24
The formula has been included in the text.

RC25
264: Fig. 5: Please add panel IDs (a, b, c). What is the reason for the counts in a) being half of those in b)? Is it a different aggregation interval? X-axes text (date) should be removed for all but the lowermost panel. Then the margins between panels can be removed in favor of larger legend font sizes. Y-axis text for e) Precipitation is too small (smaller than for other panels). Legends (font sizes) for d) VWC are too small.
AR25
Panel IDs have been added to Figure 5. Data have been replaced with the intended aggregation interval. The figure has also been updated to reflect the other suggestions.

RC26
271: Fig. 6: Please add panel IDs. Resolution of figure needs to be improved. Since colors are rather hard to distinguish (especially with red-green blindness), I would recommend to use gray-scale (maybe with transparency) for the lines and symbols (point, cross, dot, ...) for the regions at the highlighted date.
AR26
Figure 6 has been updated.

RC27
289: "measurements" I wouldn’t see this as a measurement but rather as a derived quantity. Something of "shows the assumed/computed/estimated D86..."
AR27
The text has been amended.

RC28
293: Fig. 7: Add panel IDs. All texts are by far too small. As for Fig. 5 I suggest to remove the x-axes annotation and to cut the margin between the sub-panels. How can the Euston VWC time-series reach 0? Was that reflected by the TDT sensors?
AR28
Figure 7 has been amended. The Euston site is located on very well-draining sandy soil and during the extreme dry event in 2018 the derived soil moisture data were consistently low. The minimum daily average TDT VWC readings between 2018-05-01 and 2018-08-31 were: 1.3, 0.7, 2.3, 0.5, 2.7, 1.6, 2.2, 0.2, 0.3 and 0.4 at the respective depths of 5, 5, 10, 10, 15, 15, 25, 25, 50 and 50 cm.
328: As you provided SnowFox derived SWE in the data set, its derivation should be documented more precisely (formula, calibration). At least provide it as supplementary material.

AR29

The data set only provides SWE derived from the CRNS (not the SnowFox). We have made this clearer in the manuscript.

RC30

334: Fig. 8: Same as before (panel IDs and description in the caption), remove x-axes between sub-panels, increase font sizes and avoid red-green coloring in one graph.

AR30

Figure 8 has been amended.

RC31

353: Please explain what "gauge boards" are

AR31

We have amended the text.

RC32

361-386: The different data sub-products are clearly distinguished and organized in a logical structure. However, on top-level, the user doesn’t want to find a 200 files long list to be downloadable click by click. So all the data should be organized as a single file archive (zip) download.

The user should be able to use the data set without considering the data-description paper just by making use of the metadata.

Thus, the information in table 7 should be provided within 4 additional metadata files (SH, SH...QC, Hourly, Daily). And the JSON format might be a better way to specify things. What’s lacking in the metadata is the information how a certain measurement is derived does the timestamp 00 refer to the period 00-30 minutes or 30-00 minutes and has the value been obtained by averaging or as instantaneous value?

The timestamp in the data files need to be ISO 8601 compliant (e.g. 2018-01-01T12:00:00Z) so that also the time-zone information is contained.

The site metadata should also contain the standard deviations for BD, SOC, and lattice water (which is btw. completely missing). For the easting and northing the projection needs to be specified.

Please provide also the hourly raw neutron counts (uncorrected) as well as the Snow-Fox raw and corrected counts as some people may be interested in using their own corrections.

AR32

Access to the data has been improved with the ability to download zip files. The data set has been updated to include the suggested metadata.
The colours in Figure 10 have been amended.

It would be nice to have also a short outlook. What are the perspectives for COSMOS-UK? Are there plans to extend the network (e.g., for Scotland)? How long is the projected lifetime of the project. How will the CRNS sensors degrade over time? Do you plan to upgrade the network with more sensitive detectors as they become available on the market?

We have amended the manuscript to reflect these points. COSMOS-UK has been designed as a long-term monitoring network and aims to provide easily-accessible soil moisture and hydrometeorological data; this will continue to be the network’s goal whilst dependent on funding. Regarding CRNS sensor degradation, we will consider performing more repeat calibrations to understand any changes. We will continue to consider sensor upgrades when available and feasible.

References

Response to Referee 2

1. The main issue is with an absence of calibration details: Table 5 and the discussion preceding it provide elaborate details of the sampling procedure and determination of soil moisture in the lab. The effectiveness of calibration is however mentioned in just one sentence, “There was < 0.03 cm3 cm-3
difference in VWC between the soil moisture determined from these samples and the corresponding daily VWC value derived using the site’s initial calibration data”. Table 5 only shows the reference values and not the difference between the point scale measurements and the CRNS data. In the absence of such results, it is difficult to judge how good has the calibration been. Perhaps in the supplementary material, more detailed results of calibration could be given.

AR1

The manuscript has been amended to increase clarity regarding calibration. In our experience the point-scale sensor measurements on the day of calibration, generally occurring shortly after installation, are unreliable due to poor contact between the sensor and the soil. This contact improves over time and qualitative comparisons have been made between the CRNS VWC and point measurements. Undertaking quantitative comparisons is planned.

RC2

2. The claim that the spatial data on soil moisture leads to improved hydrometeorological forecasts needs to be substantiated, either by citing appropriate references or through a convincing argument.

AR2

We have amended the text.

RC3

3. Table 1 gives details of the COSMOS-UK stations. Please consider highlighting the mountainous sites, if any among these. The altitude values shown in the table do indicate the heights at which the stations are located, but a higher altitude does not necessarily indicate a station on a mountain. It would also be interesting to see the soil moisture signatures of the mountainous regions as compared to those in the plains.

AR3

The COSMOS-UK sites are installed in non-mountainous and largely flat locations due to the logistical challenges these regions present. We have made this clearer in the manuscript.

RC4

4. Is there any irrigation in the area around the CRNS stations? If yes, how has it affected the soil moisture data? Is it possible to filter out the effect of irrigation in the data?

AR4

We have amended the manuscript. Sites with regular irrigation were avoided when identifying locations for COSMOS-UK installations. We will be notified of any irrigation at the sites and will explore the impact on data if this occurs.

RC5

5. Table 4 shows that at the same depth two TDT point source sensors are located. How are they spaced? How is the data from the two sensors merged?

AR5

All TDT sensors at COSMOS-UK sites are installed in pairs. Each site has one pair of sensors buried at a depth of 10 cm, located 1 m apart. The additional array of 4 pairs of TDT sensors (where available) are
buried at 5, 15, 25 and 50 cm depths, with each sensor located 30 cm from its paired sensor. A horizontal distance of 15 cm is ensured before burying the next pair of sensors at the desired depth. Data from each sensor are provided separately, and the user can choose whether to combine data across pairs. We have made this clearer in the manuscript.

RC6

6. Lines 183-184: Volumetric samples are taken at five depths, up to 0.25 m bgl. However, the CRNS data is between 0.1 m to 0.8 m. Is there any calibration for depths below 0.25 m?

AR6

There is currently no adjusted calibration applied for depths below 0.25 m. Soil sampling depths were selected to match typical (moist) UK conditions. Ideally sites should have repeated calibrations at different VWCs to capture the full range of measured VWC. We have amended the manuscript and emphasised that the shallow soil layers are given higher weighting than deeper layers to accommodate greater water contribution at shallow depths (Köhli et al., 2015; Schrön et al., 2017).

RC7

7. Fig 2 (appearing around line 272) should be Fig. 6.

AR7

This is correct in the manuscript.

RC8

8. It is difficult to understand the “automatic processing” for quality checks. Table 6 provides the flags raised for various events, but how these events are identified in the data is not clear (for example, how does the automatic processing detect simultaneously, missing data and small sample of data?)

AR8

The explanation has been amended to increase clarity.

RC9

9. Fig. 8 caption may be made more descriptive. Also, the caption states that these are the observations required for PE calculation, but the last panel in fact shows the PE calculated! It would also be interesting to see the soil temperature plot along with the other variables shown here (although soil temperature is not used in PE calculation).

AR9

We have improved the caption for Figure 8.

RC10

10. Please also discuss how the soil moisture measured at these 51 stations may be smoothened to upscale it to the national scale (see line no. 396).

AR10

We have amended the manuscript.
