136
137 **Abstract.** Methane (CH₄) emissions from natural landscapes constitute roughly half of global CH₄ contributions to
138 the atmosphere, yet large uncertainties remain in the absolute magnitude and the seasonality of emission quantities
139 and drivers. Eddy covariance (EC) measurements of CH₄ flux are ideal for constraining ecosystem-scale CH₄
140 emissions due to quasi-continuous and high temporal resolution of CH₄ flux measurements, coincident carbon dioxide,
141 water, and energy flux measurements, lack of ecosystem disturbance, and increased availability of datasets over the
142 last decade. Here, we 1) describe the newly published dataset, FLUXNET-CH₄ Version 1.0, the first, open source
143 global dataset of CH₄ EC measurements (available at <https://fluxnet.org/data/fluxnet-ch4-community-product/>).
144 FLUXNET-CH₄ includes half-hourly and daily gap-filled and non gap-filled aggregated CH₄ fluxes and
145 meteorological data from 79 sites globally: 42 freshwater wetlands, 6 brackish and saline wetlands, 7 formerly drained
146 ecosystems, 7 rice paddy sites, 2 lakes, and 15 uplands. Then, we 2) evaluate FLUXNET-CH₄ representativeness for
147 freshwater wetland coverage globally, because the majority of sites in FLUXNET-CH₄ Version 1.0 are freshwater
148 wetlands which are a substantial source of total atmospheric CH₄ emissions; and 3) provide the first global estimates
149 of the seasonal variability and seasonality predictors of freshwater wetland CH₄ fluxes. Our representativeness analysis
150 suggests that the freshwater wetland sites in the dataset cover global wetland bioclimatic attributes (encompassing
151 energy, moisture, and vegetation-related parameters) in arctic, boreal, and temperate regions, but only sparsely cover
152 humid tropical regions. Seasonality metrics of wetland CH₄ emissions vary considerably across latitudinal bands. In
153 freshwater wetlands (except those between 20° S to 20° N) the spring onset of elevated CH₄ emissions starts three

154 days earlier, and the CH₄ emission season lasts 4 days longer, for each degree C increase in mean annual air
155 temperature. On average, the spring onset of increasing CH₄ emissions lags soil warming by one month, with very
156 few sites experiencing increased CH₄ emissions prior to the onset of soil warming. In contrast, roughly half of these
157 sites experience the spring onset of rising CH₄ emissions prior to the spring increase in gross primary productivity
158 (GPP). The timing of peak summer CH₄ emissions does not correlate with the timing for either peak summer
159 temperature or peak GPP. Our results provide seasonality parameters for CH₄ modeling, and highlight seasonality
160 metrics that cannot be predicted by temperature or GPP (i.e., seasonality of CH₄ peak). FLUXNET-CH₄ is a powerful
161 new resource for diagnosing and understanding the role of terrestrial ecosystems and climate drivers in the global CH₄
162 cycle; and future additions of sites in tropical ecosystems and site-years of data collection will provide added value to
163 this database. All seasonality parameters are available at <https://doi.org/10.5281/zenodo.4672601>. Additionally, raw
164 FLUXNET-CH₄ data used to extract seasonality parameters can be downloaded from [https://fluxnet.org/data/fluxnet-](https://fluxnet.org/data/fluxnet-ch4-community-product/)
165 [ch4-community-product/](https://fluxnet.org/data/fluxnet-ch4-community-product/), and a complete list of the 79 individual site data DOIs is provided in Table 2 in the Data
166 Availability section of this document.

167
168
169
170
171

172 **1 Introduction**

173 Methane (CH₄) has a global warming potential that is 28 times larger than carbon dioxide (CO₂) on a 100-
174 year time scale (Myhre et al., 2013), and its atmospheric concentration has increased by >1000 ppb since 1800
175 (Etheridge et al., 1998). While atmospheric CH₄ concentrations are substantially lower than those of CO₂, CH₄ has
176 contributed 20-25% as much radiative forcing as CO₂ since 1750 (Etminan et al., 2016). Despite its importance to
177 global climate change, natural CH₄ sources and sinks remain poorly constrained, and with uncertain attribution to the
178 various biogenic and anthropogenic sources (Saunio et al., 2016, 2020). Bottom-up and top-down estimates differ
179 by 154 Tg/yr (745 versus 591 Tg/yr, respectively); much of this difference arises from natural sources (Saunio et al.,
180 2020). Vegetated wetlands and inland water bodies account for most natural CH₄ emissions, as well as the majority
181 of uncertainty in bottom-up emissions estimates (Saunio et al., 2016). Better diagnosis and prediction of terrestrial
182 CH₄ sources to the atmosphere requires high frequency and continuous measurements of CH₄ exchange across a
183 continuum of time (hours to years) and space (meters to kilometers) scales.

184 Tower-based eddy covariance (EC) measurements provide ecosystem-scale CH₄ fluxes at high temporal
185 resolution across years, are coupled with measurements of key CH₄ drivers such as temperature, water and recent
186 substrate input (inferred from CO₂ flux), and thus help constrain bottom-up CH₄ budgets and improve CH₄ predictions.
187 Although EC towers began measuring CO₂ fluxes in the late 1970s (Desjardins 1974; Anderson et al., 1984), and
188 some towers began measuring CH₄ in the 1990s (Verma et al., 1992), most CH₄ flux EC measurements began within
189 the last decade (2010s). Given that many EC CH₄ sites are relatively new, the flux community has only recently
190 compiled them for global synthesis efforts (e.g., Chang et al., 2021) and is still working to standardize CH₄ flux
191 measurements and establish gap-filling protocols (Nemitz et al., 2018; Knox et al., 2019). Furthermore, the growth of
192 EC networks for CH₄ fluxes has sometimes taken place in a relatively *ad hoc* fashion, often at sites that were already
193 measuring CO₂ fluxes or where higher CH₄ fluxes were expected, potentially introducing bias. The representativeness
194 and spatial distribution of CO₂ flux tower networks have been assessed to evaluate its ability to upscale fluxes
195 regionally (Hargrove et al., 2003; Hoffman et al., 2013; Papale et al., 2015; Villarreal et al., 2018, 2019) and globally
196 (Jung et al., 2009; 2020). However, a relatively sparse coverage of CH₄ flux towers prompts the question of how well
197 the current observation network provides a sufficient sampling of global or ecosystem-specific bioclimatic conditions.

198 Broad-scale wetland CH₄ seasonality estimates, such as when fluxes increase, peak, and decrease and the
199 predictors of seasonality, remain relatively unconstrained across wetlands globally. These key seasonality metrics
200 vary considerably across high-emitting systems such as wetlands and other aquatic systems (Desjardins, 1974; Dise,
201 1992; Melloh and Crill 1996; Wik et al., 2013; Zona et al., 2016; Treat et al., 2018). Few continuous CH₄ flux datasets
202 across representative site-years make it difficult to establish trends in seasonal dynamics, though monthly or annually
203 aggregated estimates of CH₄ fluxes from different seasons do exist for high latitudes (Zona et al., 2016; Treat et al.,
204 2018). Seasonal variability in freshwater wetland CH₄ fluxes is expected to be driven by changes in air and soil
205 temperature, soil moisture (including water table dynamics), and recent carbon substrate availability, which influence
206 the rates of CH₄ production and consumption (Lai, 2009; Bridgham et al., 2013; Dean et al., 2018). Temperature has
207 widely been found to strongly affect CH₄ flux (Chu et al., 2014; Yvon-Durocher et al., 2014; Sturtevant et al., 2016),
208 but the relationship is complex (Chang et al., 2020) and varies seasonally (Koebsch et al., 2015; Helbig et al., 2017).
209 CH₄ flux is also driven by inundation depth since anoxic conditions are typically necessary for methanogenesis (Lai,
210 2009; Bridgham et al., 2013), though CH₄ production under bulk-oxic conditions has been observed (Angle et al.,
211 2017). Substrate availability influences CH₄ production potential and is linked with gross primary productivity (GPP)
212 because recent photosynthate fuels methanogenesis though this relationship can vary by ecosystem type, plant
213 functional type and biome (Meronigal et al., 1999; Chanton et al., 2008; Hatala et al., 2012; Lai et al., 2014; Malhotra
214 and Roulet, 2015; Sturtevant et al., 2016). In process models, the seasonality of CH₄ emissions from wetlands globally
215 is primarily constrained by inundation (Poulter et al., 2017), with secondary within-wetland influences from
216 temperature and availability of carbon (C) substrates (Melton et al., 2013; Castro-Morales et al., 2018). Bottom-up
217 and top-down global CH₄ estimates continue to disagree on total CH₄ flux magnitudes and seasonality, including the
218 timing of annual peak emissions (Spahni et al., 2011; Saunio et al., 2020). Thus, the variability and predictors of
219 wetland CH₄ seasonality globally remain a knowledge gap that high-frequency and long-term EC data can help fill.

220 Here, we first describe Version 1.0 of the FLUXNET-CH₄ dataset (available at
221 <https://fluxnet.org/data/fluxnet-ch4-community-product/>). Version 1.0 of the dataset expands and formalizes the
222 publication of data scattered among regional flux networks as described previously in Knox et al. (2019). FLUXNET-
223 CH₄ includes half-hourly and daily gap-filled and non gap-filled aggregated CH₄ fluxes and meteorological data from
224 79 sites globally: 42 freshwater wetlands, 6 brackish and saline wetlands, 7 formerly drained ecosystems, 7 rice paddy
225 sites, 2 lakes, and 15 upland ecosystems. FLUXNET-CH₄ includes an additional 2 wetland sites (RU-Vrk and SE-
226 St1), but they are not available under the CC BY 4.0 data policy and thus are excluded from this analysis. Since the
227 majority of sites in FLUXNET-CH₄ Version 1.0 (hereafter referred to solely as “FLUXNET-CH₄”) are freshwater
228 wetlands, which are a substantial source of total atmospheric CH₄ emissions, we use the subset of data from freshwater
229 wetlands to evaluate the representativeness of freshwater wetland coverage in the FLUXNET-CH₄ dataset relative to
230 wetlands globally, and provide the first assessment of global variability and predictors of freshwater wetland CH₄ flux
231 seasonality. We quantify a suite of CH₄ seasonality metrics and evaluate temperature and GPP (a proxy for recent
232 substrate input) as predictors of seasonality across four latitudinal bands (northern, temperate, subtropical, and
233 tropical). Due to a lack of high-temporal resolution water table data at all sites, our analyses are unable to evaluate the
234 critical role of water table on CH₄ seasonality. Here we provide parameters for better understanding and modeling
235 seasonal variability in freshwater wetland CH₄ fluxes and generate new hypotheses and data resources for future
236 syntheses.

237 2. Methods

238 2.1 FLUXNET-CH₄ dataset

239 2.1.1 History and data description

240 The FLUXNET-CH₄ dataset was initiated by the Global Carbon Project (GCP) in 2017 to better constrain
241 the global CH₄ budget (<https://www.globalcarbonproject.org/methanebudget/index.htm>). Beginning with a kick off

242 meeting in May 2018 in Washington DC, hosted by Stanford University, we coordinated with the AmeriFlux
243 Management Project, the European Ecosystem Fluxes Database, and the ICOS Ecosystem Thematic Centre (ICOS-
244 ETC) to avoid duplication of efforts, as most sites are part of different regional networks (albeit with different data
245 products). We collected and standardized data for FLUXNET-CH₄ with assistance from the regional flux networks,
246 AmeriFlux’s “Year of Methane”, FLUXNET, the EU’s Readiness of ICOS for Necessities of Integrated Global
247 Observations (RINGO) project, and a U.S. Geological Survey Powell Center working group. FLUXNET-CH₄ is a
248 community-led project, so while we developed it with assistance from FLUXNET, we do not necessarily use standard
249 FLUXNET data variables, formats, or methods.

250 FLUXNET-CH₄ includes gap-filled half-hourly CH₄ fluxes and meteorological variables. Gaps in
251 meteorological variables (TA - air temperature, SW_IN - incoming shortwave radiation, LW_IN - incoming longwave
252 radiation, VPD - vapor pressure deficient, PA - pressure, P - precipitation, WS - wind speed) were filled with the
253 ERA-Interim (ERA-I) reanalysis product (Vuichard and Papale, 2015). We used the REdDyProc package (Wutzler et
254 al., 2018) to filter flux values with low friction velocity (u^*) based on relating nighttime u^* , to fill gaps in CO₂, latent
255 heat, and sensible heat fluxes, and to partition net CO₂ fluxes into gross primary production (GPP) and ecosystem
256 respiration (RECO) using both the daytime (Lasslop et al., 2010) and nighttime (Reichstein et al., 2005) approaches.
257 Data gaps of CH₄ flux were filled using artificial neural network (ANN) methods first described in Knox et al. (2015)
258 and in Knox et al. (2019), and summarized here in Sect. 2.1.2. Gap-filled data for gaps exceeding two months are
259 provided and flagged for quality. Please see Table B1 for variable description and units, as well as quality flag
260 information. For the seasonality analysis in this paper we excluded data from gaps exceeding two months, and we
261 encourage future users of FLUXNET-CH₄ to critically evaluate gap-filled values from long data gaps before including
262 them in analyses (Dengel et al., 2013; Kim et al., 2020).

263 In addition to half-hourly data, the FLUXNET-CH₄ Version 1.0 release also contains a full set of daily mean
264 values for all parameters except wind direction and precipitation. Daily precipitation is included as the daily sum of
265 the half-hourly data, and daily average wind direction is not included.

266 2.1.2 Gap-filling methods and uncertainty estimates

267 As described in Knox et al. (2015) and in Knox et al. (2019), the ANN routine used to gap-fill the CH₄ data
268 was optimized for generalizability and representativeness. To avoid biasing the ANN toward environmental conditions
269 with typically better data coverage (e.g., summer-time and daytime measurements), the explanatory data were divided
270 into a maximum of 15 clusters using a k-means clustering algorithm. Data used to train, test, and validate the ANN
271 were proportionally sampled from these clusters. For generalizability, the simplest ANN architecture with good
272 performance (<5% gain in model accuracy for additional increases in architecture complexity) was selected for 20
273 extractions of the training, test, and validation data. Within each extraction, each tested ANN architecture was
274 reinitialized 10 times, and the initialization with the lowest root-mean-square-error was selected to avoid local minima.
275 The median of the 20 predictions was used to fill each gap. A standard set of variables available across all sites was
276 used to gap-fill CH₄ fluxes (Dengel et al., 2013), which included the previously mentioned meteorological variables
277 TA, SW_IN, WS, PA, and sine and cosine functions to represent seasonality. These meteorological variables were
278 selected for their relevance to CH₄ exchange and were gap-filled using the ERA-I reanalysis data. Other variables
279 related to CH₄ flux (e.g., water table depth [WTD] and soil temperature [TS]) were not included as explanatory
280 variables as they were not available across all sites or had large gaps that could not be filled using the ERA-I reanalysis
281 data (Knox et al., 2019). The ANN gap-filling was performed using MATLAB (MathWorks 2018, version 9.4.0).

282 While the median of the 20 predictions was used to fill each gap, the spread of the predictions was used to
283 provide a measure of uncertainty resulting from the ANN gap-filling procedure. Specifically, the combined annual
284 gap-filling and random uncertainty was calculated from the variance of the cumulative sums of the 20 ANN predictions
285 (Knox et al., 2015; Anderson et al., 2016; Oikawa et al., 2017). The (non-cumulative) variance of the 20 ANN

286 predictions was also used to provide gap-filling uncertainty for each half-hourly gap-filled value. While this output is
287 useful for data-model comparisons, it cannot be used to estimate cumulative annual gap-filling error because gap-
288 filling error is not random, which is why the cumulative sums of the 20 ANN predictions are used to estimate annual
289 gap-filling error.

290 Random errors in EC fluxes follow a double exponential (Laplace) distribution with the standard deviation
291 varying with flux magnitude (Richardson et al., 2006; Richardson et al., 2012). For half-hourly CH₄ flux
292 measurements, random error was estimated using the residuals of the median ANN predictions, providing a
293 conservative “upper limit” estimate of the random flux uncertainty (Moffat et al., 2007; Richardson et al., 2008). The
294 annual cumulative uncertainty at 95% confidence was estimated by adding the cumulative gap-filling and random
295 measurement uncertainties in quadrature (Richardson and Hollinger, 2007; Anderson et al., 2016). Annual
296 uncertainties in CH₄ flux for individual site-years are provided in Table B2. Throughout this paper, we include
297 uncertainties on individual site years when discussing single years of data. In sites with multiple years of data, we
298 report the standard deviation of the multiple years.

299 2.1.3 Dataset structure and site metadata

300 FLUXNET-CH₄ contains two comma-separated data files per site at half-hourly and daily resolutions which
301 are available for download at <https://fluxnet.org/data/fluxnet-ch4-community-product/>, along with a file containing
302 select site metadata. Each site has a unique FLUXNET-CH₄ DOI. All data from the 79 sites used in this analysis are
303 available under CC BY 4.0 (<https://creativecommons.org/licenses/by/4.0/>) copyright license (FLUXNET-CH₄ has an
304 additional 2 sites available under the FLUXNET Tier 2 license (<https://fluxnet.org/data/data-policy/>), though these
305 sites are not included in our analysis).

306 Metadata (Table B3) include site coordinates, ecosystem classification based on site literature,
307 presence/absence and dominance for specific vegetation types, and DOI link, as well as calculated data such as annual
308 and quarterly CH₄ flux values. FLUXNET-CH₄ Version 1.0 sites were classified based on site-specific literature as
309 fen, bog, swamp, marsh, salt marsh, lake, mangrove, rice paddy/field, wet tundra, upland, or drained ecosystems that
310 previously could have been wetlands, seasonally flooded pastures, or agricultural areas. To the extent possible, we
311 followed classification systems of previous wetland CH₄ syntheses (Olefeldt et al., 2013; Turetsky et al., 2014; Treat
312 et al., 2018). Drained systems are former wetlands that have subsequently been drained but may maintain a relatively
313 shallow water table, which can contribute to occasional methane emissions, although we do not have specific water
314 table depth information at all drained sites. Upland ecosystems are further divided into alpine meadows, grasslands,
315 needleleaf forests, mixed forest, crops, tundra, and urban. Freshwater wetland classifications follow hydrological
316 definitions of bog (ombrotrophic), fen (minerotrophic), wet tundra, marshes and swamps, and were designated as per
317 primary literature on the site. For all sites, vegetation was classified for presence or absence of brown mosses (all
318 species from the division Bryophyta except those in the class Sphagnopsida), *Sphagnum* mosses (any species from
319 class Sphagnopsida), ericaceous shrubs, trees (of any height) and aerenchymatous species (mostly Order Poales but
320 includes exceptions). These categories closely follow Treat et al., (2018), except that aerenchymatous species had to
321 be expanded beyond Cyperaceae to incorporate wetlands globally. Presence/absence of vegetation groups was
322 designated based on species lists in primary literature from the site. Out of the vegetation groups present, the dominant
323 (most abundant) group is also reported and is based on information provided by lead site investigators.

324 In addition to the variable description table (Table B1) and the site metadata (Table B3), we provide several
325 more tables to complement our analysis. Table B4 includes the climatic data used in the representativeness analysis.
326 Table 5 provides seasonality parameters for CH₄ flux, air temperature, soil temperature (from the probe closest to the
327 ground surface), and GPP. For sites with multiple soil temperature probes, the full set of soil temperature parameters
328 are in Table B6. Table B7 contains the soil temperature probe depths. Table B2 contains the annual CH₄ flux and
329 uncertainty. All Appendix B tables are also available at <https://doi.org/10.5281/zenodo.4672601>.

330

331 **2.1.4 Annual CH₄ fluxes**

332 Annual CH₄ fluxes were calculated from gap-filled data for site-years with data gaps shorter than two
333 consecutive months, or for sites above 20° N where >2 month data gaps occurred outside of the highest CH₄-emission
334 months of May 1 through October 31. Since we did not sum gap-filled values for >2 month gaps during the winter,
335 annual sums from these years will be an underestimate since winter fluxes can be important (Zona et al., 2016; Treat
336 et al., 2018). Several sites had less than one year of data, and we report gap-filled CH₄ flux annual sums for sites with
337 between six months and one year of data (BW-Gum = 228 days, CH-Oe2 = 200 days, JP-Swl = 210 days, US-EDN =
338 182 days). While these sums will be an underestimate of annual CH₄ flux since they do not span a full year (and we
339 therefore do not use them in the seasonality analysis), their relative magnitude can still be informative. For example,
340 site JP-SWL is a lake site, and even with less than a year of data the summed CH₄ flux of 66 g C m⁻² is relatively high
341 (Taoka et al., 2020). In addition to sites with short time series, the annual CH₄ sum for site ID-Pag represents 365 days
342 spanning June 2016 to June 2017.

343 **2.1.5 Subset analysis on freshwater wetland CH₄ flux**

344 In addition to the FLUXNET-CH₄-wide description of site class distributions and annual CH₄ fluxes, we
345 also include a subset analysis on freshwater wetlands, given that it is the dominant ecosystem type in our dataset and
346 an important global CH₄ source (Saunio et al., 2016). First, we analyze freshwater wetland representativeness, and
347 subsequently the seasonality of their CH₄ emissions. Freshwater wetlands included in the seasonality and
348 representativeness analysis are indicated in Table B3, column “IN_SEASONALITY_ANALYSIS”.

349

350 **2.2 Wetland representativeness**

351 **2.2.1 Principal Component Analysis**

352 To compare the FLUXNET-CH₄ site distribution to the global wetland distribution, we evaluated their
353 representativeness in the entire global wetland cover along four bioclimatic gradients. Only freshwater wetland sites
354 were included in this analysis. Coastal sites were excluded because salinity, an important control on CH₄ production,
355 could not be evaluated across the tower network due to a lack of global gridded salinity data (Bartlett et al., 1987;
356 Poffenbarger et al., 2011). The four bioclimatic variables used were: mean annual air temperature (MAT), latent heat
357 flux (LE), enhanced vegetation index (EVI), and simple ratio water index (SRWI; data sources in Table B4). We use
358 EVI because it is a more direct measurement than GPP from global gridded products and is considered a reasonable
359 proxy for GPP (Sims et al., 2006). Together, these environmental variables account for, or are, proxies for key controls
360 of CH₄ production, oxidation at the surface, and transport (Bridgham et al., 2013). We use a principal components
361 analysis (PCA) to visualize the site distribution across the four environmental drivers at once. For this analysis, we
362 consider the annual average bioclimatic conditions over 2003-2015. In the PCA output, we evaluate the coverage of
363 the 42 freshwater sites over 0.25° grid cells containing >5% wetland mean cover in Wetland Area and Dynamics for
364 Methane Modeling (WAD2M; Zhang et al., 2020; Zhang et al., 2021) for the same time period.

365 **2.2.2 Global Dissimilarity and Constituency Analysis**

366 To further identify geographical gaps in the coverage of the FLUXNET-CH₄ Version 1.0 network, we
367 quantified the dissimilarity of global wetlands from the tower network, using a similar approach to that taken for CO₂
368 flux towers (Meyer and Pebesma 2020). We calculated the 4-dimensional Euclidean distance from the four bioclimatic
369 variables between every point at the land surface to every tower location at the FLUXNET-CH₄ network. We then
370 divided these distances by the average distance between towers to produce a dissimilarity index. Dissimilarity scores

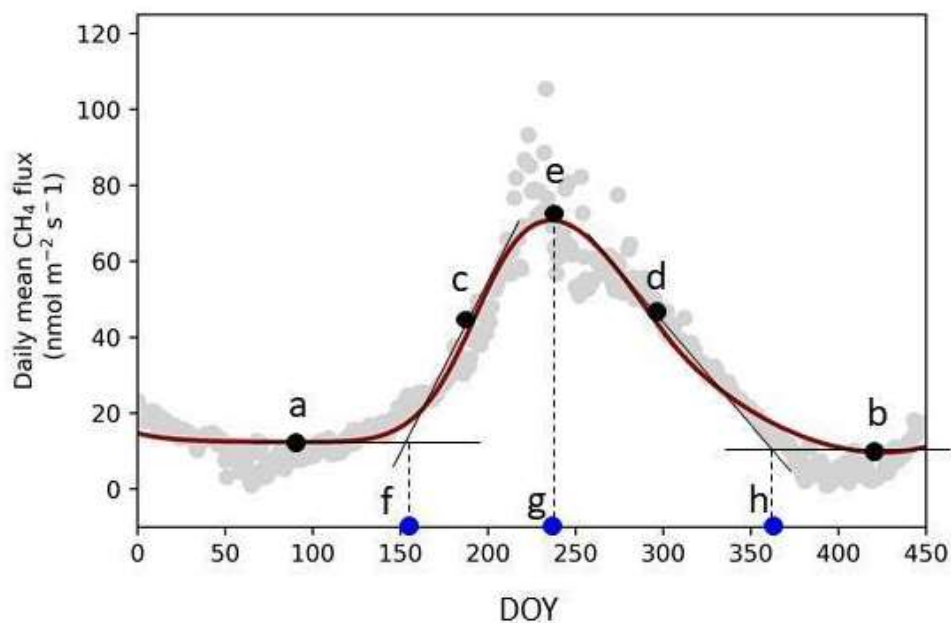

371 <1 represent areas whose nearest tower is closer than the average distance among towers, while areas with scores >1
372 are more distant. Lastly, we identified the importance of an individual tower in the network by estimating the
373 geographical area to which it is most analogous in bioclimate space. We divided the world's land surface according
374 to closest towers in bioclimatic space. The area to which each tower is nearest is defined as the tower's constituency.

375 2.3 Wetland CH₄ seasonality

376 To examine freshwater wetland CH₄ seasonality across the global range of sites in FLUXNET-CH₄, we
377 extracted seasonality parameters for CH₄, temperature, and GPP using Timesat, a software package designed to
378 analyze seasonality of environmental systems (Jönsson and Eklundh, 2002; Jönsson and Eklundh, 2004; Eklundh
379 and Jönsson, 2015). Timesat calculates several seasonality parameters, including baseline flux, peak flux, and the
380 slope of spring flux increase and fall decrease (Fig. 1). We also calculate parameters such as amplitude (peak flux -
381 baseline, which is the average of spring and fall baselines; $(“e” - ((“a” + “b”)/2))$ in Fig. 1), and relative peak timing (
382 $(“g” - “f”) / (“h” - “f”)$ in Fig. 1). Timesat uses a double-logistic fitting function to create a series of localized fits
383 centered on data minima and maxima. Localized fits are determined by minimizing a merit function with the
384 Levenberg-Marquardt method (Madsen et al., 2004; Nielsen, 1999). These localized fits are then merged using a
385 global function to create a smooth fit over the full time interval. To fit CH₄ time-series in Timesat, we used gap-
386 filled data after removing gaps exceeding two months. We do not report Timesat parameters when large gaps occur
387 during CH₄ emissions spring increase, peak, or fall decrease.

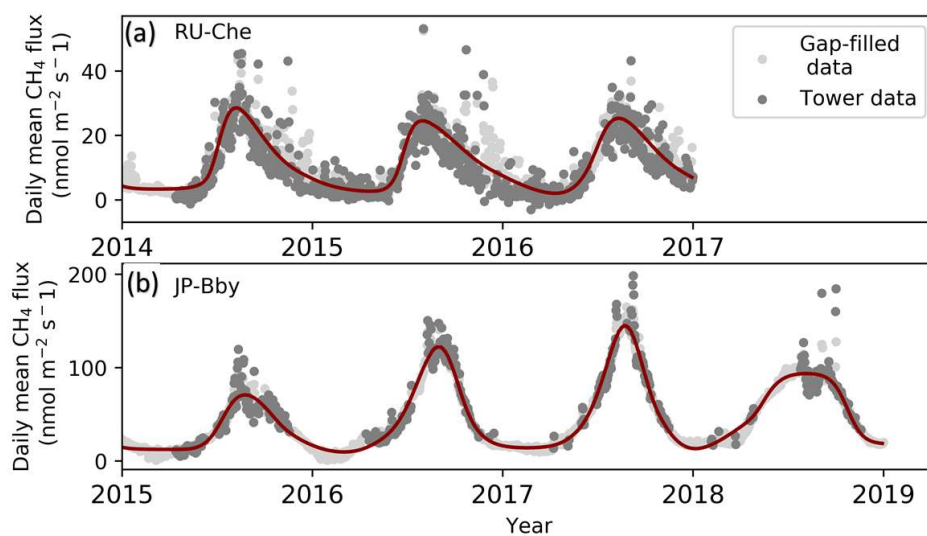

388 We estimate ‘start of elevated emissions season’ when CH₄ emissions begin to increase in the spring (“f”
389 in Fig. 1), and ‘end of elevated emissions season’ when the period of elevated CH₄ flux ends in the fall (“h” in Fig.
390 1), as the intercept between the Timesat fitted baseline parameter and shoulder-season slope (similar to Gu et al.,
391 2009). To extract seasonality parameters with Timesat, sites need a sufficiently pronounced seasonality, a
392 sufficiently long time period, and minimal data gaps (we note that while Timesat is capable of fitting two peaks per
393 year, all the freshwater wetland sites have a single annual peak). We excluded site-years in restored wetlands when
394 wetlands were still under construction. Of the 42 freshwater wetland sites in FLUXNET-CH₄ Version 1.0, 36 had
395 sufficient data series to extract seasonality parameters. These 36 wetlands had 141 site-years of data total, which we
396 fit with the double-logistic fitting method which followed site data well (representative examples in Fig. 2). For
397 extratropical sites in the Southern Hemisphere, we shifted all data by 182 days so that maximum solar insolation
398 seasonality would be congruent across the globe.

399 We also used Timesat to extract seasonality metrics for GPP, partitioned using the daytime-based approach
400 (Lasslop et al., 2010) (GPP_DT), air temperature (TA), and soil temperature (TS_1, TS_2, etc). For sites where
401 winter soil temperatures fall significantly below 0 °C, Timesat fits a soil temperature “start of elevated season” date
402 to periods when the soil is still frozen. In order for Timesat to define the soil temperature seasonality within the
403 thawed season, we converted all negative soil temperatures to zero (simply removing these values results in too
404 many missing values for Timesat to fit). Many sites have more than one soil temperature probe, so we extracted
405 separate seasonality metrics from each individual probe (although we used the metrics from the shallowest
406 temperature probe in our analysis). Tables B4 contain the Timesat seasonality parameters used in the seasonality
407 analysis. We did not include water table depth in the seasonality analysis because many sites either lack water table
408 depth measurements or have sparse data.

409
 410 **Figure 1: TIMESAT parameter description.** (a) and (b) base values (Timesat reports the average of these two values), (c)
 411 and (d) slopes of seasonal curves (lines drawn between 20% and 80% of the amplitude), (e) peak value, and day of year
 412 (DOY) for the start (f), peak (g), and end (h) of the elevated methane (CH₄) emissions season. Data points are the mean
 413 daily gap-filled CH₄ fluxes from site JP-Bby in 2015.

414
 415

416
 417 **Figure 2: Examples of Timesat fits for two FLUXNET-CH₄ sites, (a) RU-Che and (b) JP-Bby. Methane (CH₄) flux data**
 418 **showing daily average flux tower data, with several high outliers excluded to improve the plot (dark gray), gap-filled**

419 values (light gray), and Timesat-fitted curve (dark red line) for sites JP-Bby and RU-Che. Timesat captures the size and
420 shape of peaks (note different scale on y-axes). CH₄ = methane.

421

422 We regressed the CH₄ seasonality parameters from Timesat against annual temperature, annual water table
423 depth, and Timesat seasonality parameters for air temperature, soil temperature, and GPP (proxy for recent carbon
424 input available as substrate) using linear mixed-effect modeling with the *lmer* command (with site as a random
425 effect) from the R (R Core Team 2018, version 3.6.2) package lmerTest (Kuznetsova et al., 2017). For these
426 regressions we present the marginal R² outputs from *lmer*, which represent the variance explained only by the fixed
427 effects. Mixed-effect modeling was necessary to account for the non-independence between measurements taken at
428 the same site during different years (Zona et al., 2016; Treat et al., 2018). We also compared how seasonality
429 metrics varied across latitudinal bands by dividing sites into northern (> 60° N), temperate (between 40° N and 60°
430 N), subtropical (absolute value between 20° and 40° latitude, with site NZ-KOP being the only Southern hemisphere
431 site), and tropical (absolute value below 20°). Site-year totals for the northern, temperate, subtropical, and tropical
432 bands were $n = 57, 36, 39,$ and $9,$ respectively. We used the Kruskal-Wallis test to establish whether groups (either
433 across quarters or across latitudes) were from similar distributions, and the post hoc multiple comparison “Dwass,
434 Steel, Critchlow, and Fligner” procedure for inter-group comparisons. Kruskal-Wallis and post-hoc tests were
435 implemented in Python Version 3.7.4, using stats from *scipy* for Kruskal-Wallis and *posthoc_dscf* from
436 *scikit_posthocs*.

437 We also compared quarterly CH₄ flux sums by dividing data into quarterly periods:
438 January/February/March (JFM), April/May/June (AMJ), July/August/September (JAS), and
439 October/November/December (OND). For the sake of simplicity, we chose to compare quarterly periods rather than
440 site-specific growing/non-growing season periods so that all time periods would be the same length. Quarterly sums
441 were computed from the gap-filled CH₄ fluxes when the longest continuous data gap within the quarter did not
442 exceed 30 days, leading to site-year counts of 67, 92, 95, 72 for JFM, AMJ, JAS, and OND, respectively. We
443 compared quarterly CH₄ fluxes across latitudinal bands both for the total CH₄ flux, and for the quarterly percentage
444 of the annual CH₄ flux. Quarterly statistics were also conducted with the Kruskal-Wallis test and the post hoc
445 multiple comparison “Dwass, Steel, Critchlow, and Fligner” procedure implemented in Python. Quarterly values
446 are provided in Table B3, and the sum of mean quarterly CH₄ flux does not always equal mean annual CH₄ flux
447 because some quarters either do not have data, or have data gaps that exceed 30 days.
448

449 3. Results and Discussion

450 3.1 FLUXNET-CH₄ dataset

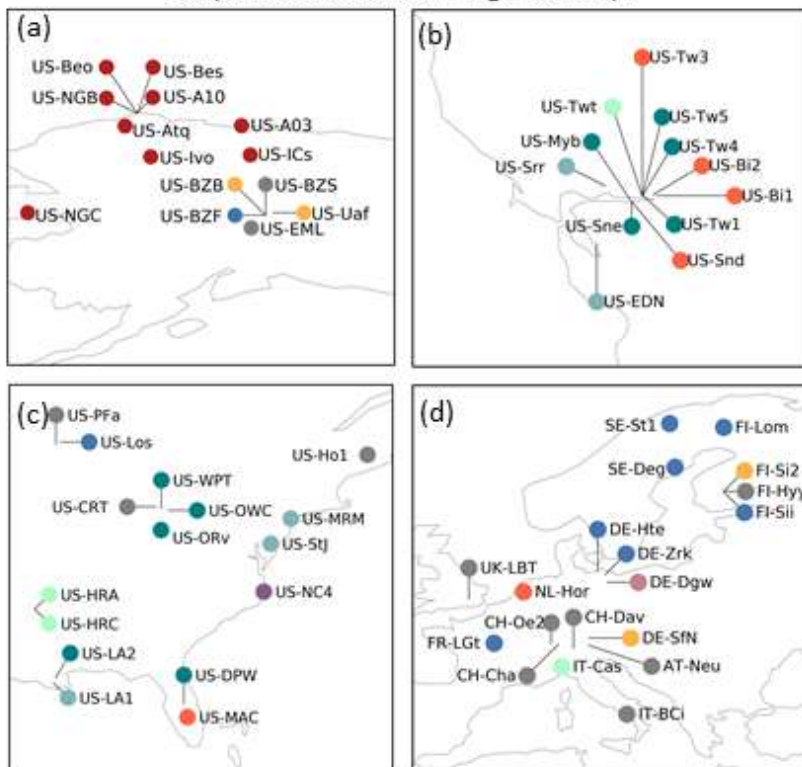

451 3.1.1 Dataset description

452 Version 1.0 of the FLUXNET-CH₄ dataset contains 79 unique sites, 293 total site-years of data, and 201
453 site-years with sufficient data to estimate annual CH₄ emissions. A synthesis paper, published prior to the public data
454 release of FLUXNET-CH₄ Version 1.0, had 60 unique sites and 139 site-years with annual CH₄ emissions estimates
455 (Knox et al., 2019). Freshwater wetlands make up the majority of sites ($n = 42$), and the dataset also includes five salt
456 marshes and one mangrove wetland. Notable additions to FLUXNET-CH₄ from the previous unpublished dataset
457 used in Knox et al., (2019) include six tropical sites (between 20° S and 20° N), including one site in South America,
458 two sites in southern Africa, and three sites in Southeast Asia. The 15 upland sites include six needleleaf forests, three
459 crop sites (excluding rice), two alpine meadows, one grassland, one mixed forest, one tundra, and one urban site. The
460 drained sites represent former wetlands that have been artificially drained for use as grasslands ($n = 3$) or croplands

461 (n = 3). FLUXNET-CH4 sites span the globe, though are concentrated in North America and Europe (Fig. 3). Table
 462 B3 includes characteristics of all sites in the dataset.

Subpanels as defined on global map:

463

464 Figure 3. Global map of FLUXNET-CH4 Version 1.0 site locations colored by site type. Insets (a)-(d) show sites that were
 465 too closely located to distinguish in the global map.

466

467 **Figure 4. Histogram of annual methane fluxes (F_{CH_4} , $g C m^{-2} yr^{-1}$) grouped by site type.**

468 Sites represent a range of ecosystem types, latitudes, median fluxes, and seasonality patterns (Table 1).
 469 Across all FLUXNET-CH₄ sites (including non-wetland sites), mean average annual CH₄ flux is positively skewed
 470 with a median flux of 9.5 $g C m^{-2} yr^{-1}$, a mean flux of 16.9 $g C m^{-2} yr^{-1}$, and numerous annual CH₄ fluxes exceeding
 471 60 $g C m^{-2} yr^{-1}$. Marshes and swamps have the highest median flux, and upland, salt marsh, and tundra sites have
 472 the lowest (Fig. 4). Lake emissions are highly variable due to one high-flux lake site (JP-SWL). Flux data at many
 473 sites show strong seasonality in CH₄ emissions, but data coverage is also lower outside the growing season (Table
 474 1). Data coverage is lowest during the JFM quarter (on average 20% of half-hourly time periods contain flux data)
 475 reflecting the predominance of Northern hemisphere sites and the practical difficulties in maintaining EC tower sites
 476 during colder winter months (Table 1). Bogs, fens, and marshes have pronounced seasonality, with fluxes being
 477 highest in the AMJ and JAS quarters. In contrast, CH₄ fluxes from uplands, drained sites, and salt marshes are more
 478 uniform and low year-round.

479 **Table 1: Summary table of sites grouped by ecosystem class reporting annual mean flux (Ann_Flux) and standard**
 480 **deviation from inter-annual variability (Ann_Flux_SD), site-years of data, % data cover per quarter, and median (med.)**

483

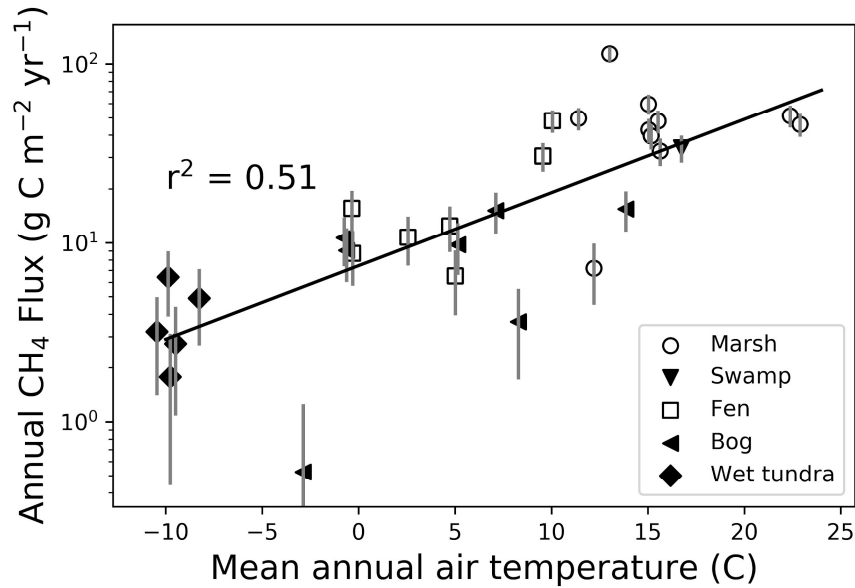

484

485 3.1.2 Freshwater wetland CH₄ characteristics

486 The FLUXNET-CH₄ Version 1.0 dataset contains 42 freshwater wetlands that span 37°S to 69°N, including
487 bogs, fens, wet tundra, marshes, and swamps, and a range of annual CH₄ emission rates (Fig. 4). The majority of
488 freshwater wetlands in our dataset emit 0-20 g C m⁻² yr⁻¹, with 10 emitting 20-60 g C m⁻² yr⁻¹, and one more than 60 g
489 C m⁻² yr⁻¹. Differences in annual CH₄ flux among wetland types is partially driven by temperature (which is often
490 linked to site type), with mean annual air temperature explaining 51% of the variance between sites (Fig. 5, exponential
491 relationship). The global relationship between annual methane emissions and temperature can be described using a
492 Q₁₀ relationship where $Q_{10} = R_2/R_1^{((T_2-T_1)/10)}$, with R₂ and R₁ being the CH₄ emission rates at temperatures T₂ and T₁,
493 respectively (temperature in degrees C). The Q₁₀ based on Fig. 5 data is 2.57. We also note that annual CH₄ flux from
494 individual biomes may have different relationships with temperature, as previous work has shown biome-specific
495 trends in CH₄ flux with environmental drivers (Abdalla et al., 2016). However, there currently are not enough data
496 points in each biome category to compare relationships between mean annual CH₄ flux and temperature. Annual CH₄
497 flux is not correlated with mean annual water table depth in FLUXNET-CH₄, unlike in Knox et al., (2019), which
498 used a subset of the FLUXNET-CH₄ sites where CH₄ flux was correlated with water table depth only for sites with
499 water table below ground for 90% of measured days ($r^2 = 0.31$, $p < 0.05$, $n = 27$ site years). Freshwater wetland
500 seasonality is further described in Sect. 3.3.

501

502

 505 **annual air temperature (°C) for each freshwater wetland site, with wetland type indicated by symbol. Markers represent**
 506 **individual site means, with vertical error bars representing the standard deviation of interannual variability.**

507

508

509 3.1.3 Upland, rice and urban CH₄ characteristics

510 Upland agricultural sites are characterized by a lack of seasonal pattern in CH₄ emissions, relatively low flux,
 511 and sometimes negative daily flux (i.e., CH₄ uptake) averages. All of the upland non-agricultural sites in FLUXNET-
 512 CH₄ Version 1.0 are net (albeit weak) CH₄ sources except for the needleleaf forest site US-Ho1, which has mean
 513 annual CH₄ flux of -0.1 ± 0.1 g C m⁻² yr⁻¹ (see Table B3 for site acronyms and metadata). The average agricultural site
 514 emissions are 1.3 ± 0.8 g C m⁻² yr⁻¹ and non-agricultural site emissions are 1.6 ± 1.2 g C m⁻² yr⁻¹ across sites.

515 Rice sites (n = 7) have average annual emissions across all sites of 16.7 ± 7.7 g C m⁻² yr⁻¹ and are characterized
 516 by strong seasonal patterns, with either one or more CH₄ emission peaks per year depending on the number of rice
 517 seasons and field water management. One peak is typically observed during the reproductive period for the
 518 continuously flooded sites with one rice season (i.e., US-HRC, JP-MSE) (Iwata et al., 2018; Runkle et al., 2019;
 519 Hwang et al., 2020). For sites with only one rice season but with single or multiple drainage and re-flooding periods,
 520 a secondary peak may appear before the reproductive peak (i.e., KR-CRK, IT-Cas, and US-HRA; Meijide et al., 2011;
 521 Runkle et al., 2019; Hwang et al., 2020). Two reproductive peaks appear for sites with two rice seasons (i.e., PH-RiF),
 522 and each reproductive peak may be accompanied by a secondary peak due to drainage events (Alberto et al., 2015).
 523 Even sites with one, continuously flooded rice season may experience a second peak if the field is flooded during the
 524 fallow season to provide habitat for migrating birds (e.g., US-Twt; Knox et al., 2016).

525 The dataset has one year of urban data from site UK-LBT in London, England. UK-LBT observes CH₄ fluxes
 526 from a 190 m tall communications tower in the center of London, and has a mean annual CH₄ flux of 46.5 ± 5.6 g C
 527 m⁻² yr⁻¹. This flux is more than twice as high as the mean annual CH₄ flux across all FLUXNET-CH₄ sites, 16.9 g C
 528 m⁻² yr⁻¹. The London site has higher CH₄ emissions in the winter compared to summer, which is attributed to a seasonal
 529 increase in natural gas usage (Helfter et al., 2016.)

530 3.1.4 Saltwater and mangrove wetland CH₄ characteristics

531 Three of the five saltwater wetlands in FLUXNET-CH₄ (US-Edn, US-MRM, and US-Srr) have a very low
532 mean annual CH₄ flux (see Table B2 for individual site-year CH₄ flux sums and associated uncertainty) and minimal
533 seasonality. Two other FLUXNET-CH₄ saltwater sites (US-La1 and US-StJ) have significantly higher fluxes, with
534 annual sums of 12.6 ± 0.6 and 9.6 ± 1.0 g C m⁻² yr⁻¹, respectively, while the mangrove site HK-MPM has annual mean
535 fluxes of 11.1 ± 0.5 g C m⁻² yr⁻¹. This range of CH₄ fluxes across different saltwater ecosystems could be valuable for
536 exploring the effect of salinity and different biogeochemical pathways of CH₄ production, oxidation, and transport of
537 CH₄ (Bartlett et al., 1987; Poffenbarger et al., 2011). Saltwater wetlands along the coast have unique CH₄ dynamics
538 attributable to the presence of abundant electron acceptors, most importantly sulphates, which inhibit methanogenesis
539 (Pattnaik et al., 2000; Mishra et al., 2003; Weston et al., 2006), but at low concentrations can have no effect (Chambers
540 et al., 2011) or even increase methanogenesis (Weston et al., 2011). In fact, estuarine wetlands with moderate salinity
541 can still be significant sources of CH₄ (Liu et al., 2020). Even under sulfate-rich conditions, high CH₄ production can
542 be found via methylotrophic methanogenesis (Dalcin Martins et al. 2017; Seyfferth et al., 2020,) or because the
543 processes of sulfate reduction and methanogenesis are spatially separated (Koebisch et al., 2019). Consequently,
544 representing the biophysical drivers of ecosystem-scale CH₄ fluxes in non-freshwater wetlands is challenging and may
545 represent a combination of competing or confounding effects (Vazquez-Lule and Vargas 2021).
546

547 3.2 Freshwater wetland representativeness

548 We evaluated the representativeness of freshwater wetland sites in the FLUXNET-CH₄ Version 1.0 dataset
549 against wetlands globally, based on bioclimatic conditions of our sites. When evaluating bioclimatic variables
550 individually, the distribution of freshwater wetlands across the network was significantly different from the global
551 distribution ($\alpha > 0.05$; two-tailed Kolmogorov-Smirnov tests; see Table B4). We exclude wetlands classified as
552 “Salt Marsh” in this representativeness analysis and the seasonality analysis below because of the unique CH₄ flux
553 dynamics in saltwater ecosystems (as discussed in section 3.1.4), though we note that some of the coastal wetlands
554 included in the freshwater analysis periodically experience brackish water (i.e.: US-Myb, US-Sne).

555 When considering the four bioclimatic variables, MAT, LE, EVI and SRWI in a PCA, we found that our
556 tower network generally samples the bioclimatic conditions of global wetland cover, but some noticeable gaps remain
557 (Fig. 6). Three clusters of the world’s wetland-dense regions are identified, but are not equally sampled by the network.
558 A cluster of low temperature wetlands is sampled by a large number of high-latitude sites. The other two wetland
559 clusters are not as well sampled: a high temperature and LE cluster is represented only by two towers (ID-Pag and
560 MY-MLM), while drier and temperate and subtropical wetlands including large swathes of the Sahel in Africa only
561 have a site in Botswana (BW-Npw) as their closest-analog tower.
562

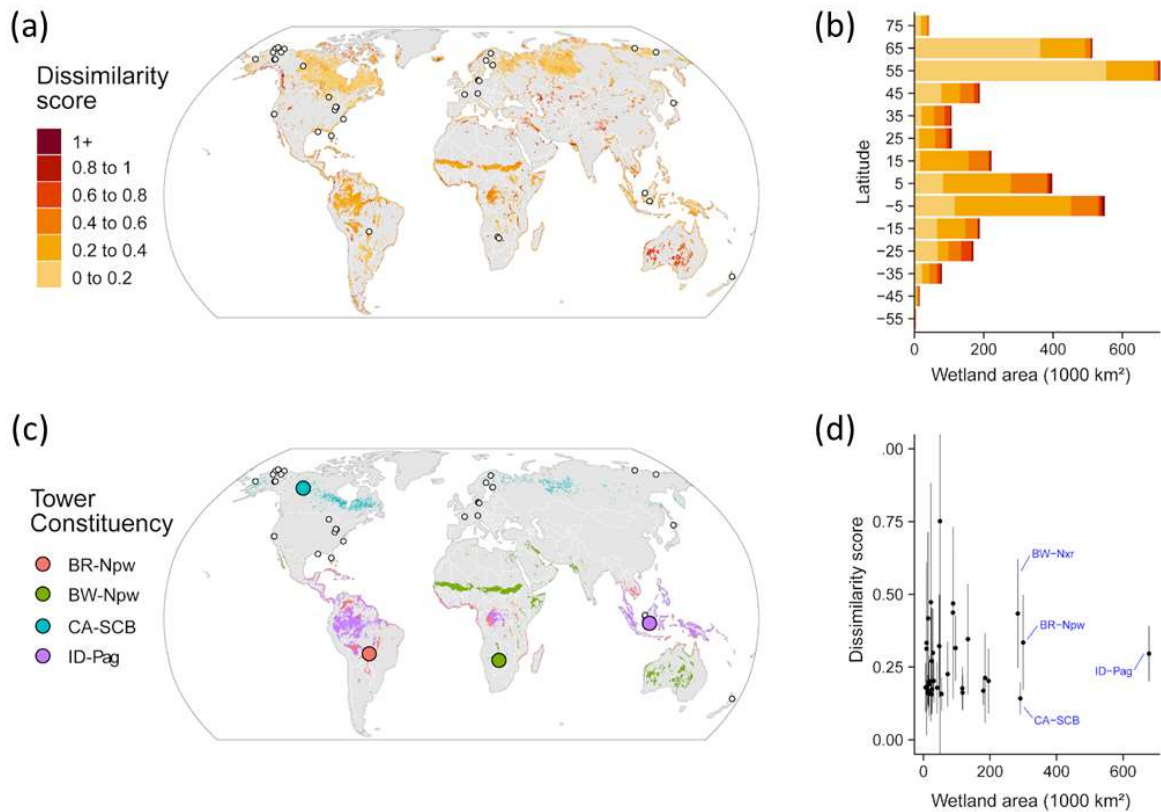

563

564 **Figure 6: Principal Component Analysis displaying the distribution of freshwater wetland sites (points) along the two main**
 565 **principal components together accounting for 91.9% of variance. Tower sites are represented as points with shapes**
 566 **indicating their wetland type and color shade representing the annual methane (CH_4) flux (gray points represent sites for**
 567 **which <6 months of flux data was available to estimate annual budget). Sites codes are labeled in blue text for selected sites**
 568 **deviating from average conditions. Loading variables are represented by the arrows: mean annual temperature (MAT),**
 569 **simple ratio water index (SRWI), latent heat flux (LE) and enhanced vegetation index (EVI). The background shades of**
 570 **gray are a qualitative representation of the density of global wetland pixels and their distribution in the PCA climate-space,**
 571 **with darker color representing higher densities (excluding Greenland and Antarctica). Only grid cells with >5% average**
 572 **wetland fraction according to the WAD2M over 2000-2018 are included (Zhang et al., 2020). The loading variables are**
 573 **represented by the arrows: mean annual temperature (MAT), simple ratio water index (SRWI), latent heat flux (LE) and**
 574 **enhanced vegetation index (EVI).**

575

576 Evaluating the bioclimatic dissimilarity of global wetlands to the FLUXNET- CH_4 network shows the least
 577 captured regions are in the tropics (Fig. 7A). Sparse coverage in the tropics also means that the few existing towers
 578 occupy a critical place in the network, particularly as tropical wetlands are the largest CH_4 emitters (Bloom et al.,
 579 2017; Poulter et al., 2017). Highly dissimilar wetlands are limited in extent and distributed across all latitudes, but the
 580 average dissimilarity is higher in north temperate (55° to 65°) and tropical (-5° to 5°) latitudes (Fig. 7B). To evaluate
 581 the importance of individual towers in the network, we estimated the geographical area to which it is most analogous
 582 in bioclimate-space (Fig. 7C). We found that some towers have disproportionately large constituencies (i.e., wetland
 583 areas that share the same closest bioclimatic analog tower). Towers in Indonesia (ID-Pag), Brazilian Pantanal (BR-
 584 Npw), and Botswana floodplains (BW-Nxr) represent the closest climate analog for much of the tropics (678, 300 and
 585 284 thousand km^2 , respectively) while CA-SCB represents a vast swath (291 thousand km^2) of boreal/arctic regions
 586 (Fig. 7D).

587

588

589 **Figure 7: (a) Distance in bioclimatic space between global land surface and the FLUXNET-CH₄ Version 1.0 tower network**
 590 **(gray areas indicate no mapped wetlands). The Euclidean distance was computed on the four bioclimatic variables and was**
 591 **then standardized by the average distance within-network. Most of the land surface has a dissimilarity score lower than 1,**
 592 **meaning these areas are closer than the average tower distance (lower dissimilarity score means a similar bioclimate to that**
 593 **represented by towers in the network). However, this pattern reflects more the sparsity of the tower network than a**
 594 **similarity of the land surface to the network. Areas with <5% coverage by wetlands were excluded to focus on wetland-**
 595 **dense regions. (b) Latitudinal distribution of dissimilarity score, (c) Map of the four largest tower constituencies, (d)**
 596 **Scatterplot of wetland area in each tower constituency plotted against the average dissimilarity score (point) and +/-**
 597 **standard deviation (error bar).**

598 Our assessment of wetland CH₄ tower coverage determines the ability of our dataset to represent global
 599 wetland distributions and highlights some clear representation gaps in the network, particularly in tropical and humid
 600 regions. Other geographic regions such as India, China, and Australia, where towers exist but are not included in the
 601 current network should be prioritized when expanding the network, even though they are not among the most distant
 602 areas to the current network. Similar representativeness assessments have been developed for CO₂ tower networks to
 603 identify gaps and priorities for expansion (Jung et al., 2009). To improve the geographic coverage of the network for
 604 representing global-scale fluxes, locations for new tower sites can be targeted to cover bio-climatically distant areas
 605 from the current network (Villarreal et al., 2019). Candidate regions for expansion that are both high CH₄ emitting
 606 (Saunio et al., 2020) as well as located in under-sampled climates are: African Sahel, Amazon basin, Congo basin,
 607 South-East Asia. Climatic conditions over boreal and arctic biomes are generally better represented (primarily at lower
 608 elevations), but there is scope to expand the network in wetland-dense regions like the Hudson Bay Lowlands and
 609 Northern Siberian Lowlands. Moreover, establishing sites in other ecosystem types, especially lakes and reservoirs
 610 (see Deemer et al. 2016, Bastviken et al. 2011, Matthews et al. 2020) in most climatic zones would help capture CH₄
 611 fluxes from these ecosystems.

612 Understanding the representativeness of the network is essential when inferring general patterns of flux
 613 magnitude, seasonality, and drivers from the tower data (Villarreal et al., 2018). We produced a first-order

614 representativeness of average bioclimatic conditions, but temporal representativeness (across seasons, climate
615 anomalies and extreme events) is particularly needed given the episodic nature of CH₄ fluxes (Chu et al., 2017;
616 Mahecha et al., 2017; Göckede et al., 2019).

617 Assessing representation of wetland CH₄ sites is complicated by the fact that wetlands occupy only a fraction
618 of most landscapes (except wetland dense regions such as Northern Siberian Lowlands, Hudson Bay Lowlands, Congo
619 basin, etc.) and that not all relevant factors affecting CH₄ production and consumption could be considered in our
620 analysis. For instance, our assessment of representation did not consider wetland types as such maps are limited by
621 the inherent difficulties in remotely sensing wetland features (Gallant, 2015). The attribution of representativeness is
622 further complicated by the fact that many EC tower locations are subject to small-scale variability within the field of
623 view, or footprint, of the sensor. Consequently, the individual time steps within EC flux time series may represent a
624 mixture of different wetland types, or different fractions of wetland contribution to the total CH₄ flux, varying with
625 wind direction, atmospheric stability, or season (Chu et al 2021). This further complicates upscaling efforts.
626 Additionally, this representativeness analysis did not apply weights to the drivers to reflect their varying influence on
627 CH₄ flux. Such weights can be included in future versions as they are generated by a cross-validated machine learning
628 approach (Jung et al., 2020). Future efforts could include the dissimilarity index from this analysis as a metric of
629 extrapolation in a CH₄ flux upscaling effort.

630

631 3.3 Freshwater wetland flux seasonality

632 3.3.1 Seasonal flux comparisons by latitudinal bands

633 CH₄ flux and seasonality varied substantially across latitudinal bands (northern, temperate, subtropical, and
634 tropical) (Fig. 8). Annual CH₄ fluxes for temperate, and subtropical sites were significantly higher than for northern
635 sites (8.7 ± 5.0 , 29.7 ± 25.2 , 40.1 ± 14.6 , and 24.5 ± 20.7 g C m⁻² yr⁻¹ for northern, temperate, subtropical, and tropical,
636 respectively, $p < 0.0001$ using Kruskal Wallis and post hoc comparisons; Fig. 8a), and tropical sites were similar to all
637 other latitudinal bands likely because of their small sample size. The ratio of seasonal amplitude to peak flux provides
638 a measure of the relative seasonal increase in emissions compared with baseline, where a ratio of zero indicates no
639 seasonal change in amplitude, a ratio of one indicates the off-season flux is zero, and values over one means the off-
640 season baseline CH₄ fluxes were negative (i.e., uptake). Average amplitude to peak flux ratios were similar across all
641 latitudinal bands (0.9 ± 0.1 , 0.9 ± 0.1 , 0.9 ± 0.1 , 1.0 ± 0.7 , for northern, temperate, subtropical, and tropical,
642 respectively; Fig. 8b). The spring increase in CH₄ emissions began later in northern sites compared with temperate
643 and subtropical sites (end of May versus April, respectively, $p = 0.001$; Fig. 8c), while tropical sites vary widely in
644 elevated emission season start date. Northern sites also had shorter elevated CH₄ flux season lengths (138 ± 24 days)
645 compared to temperate sites (162 ± 32 days), and both were shorter than subtropical sites (209 ± 43 days; $p < 0.0001$;
646 Fig. 8e). On average, CH₄ flux peaked earlier for temperate sites compared to northern ($p = 0.008$) and subtropical
647 sites ($p = 0.02$; mid to late July compared with early August; Fig. 8f), while tropical sites again vary widely. Given
648 their unique seasonality, and low number of site-years ($n = 9$), tropical systems are discussed separately in Sect. 3.3.3,
649 and not included in the comparisons in the remainder of this section. While our results on CH₄ seasonality corroborate
650 expected trends for these latitudinal bands, they provide some of the first estimates of CH₄ seasonality parameters and
651 ranges across a global distribution of sites.

652

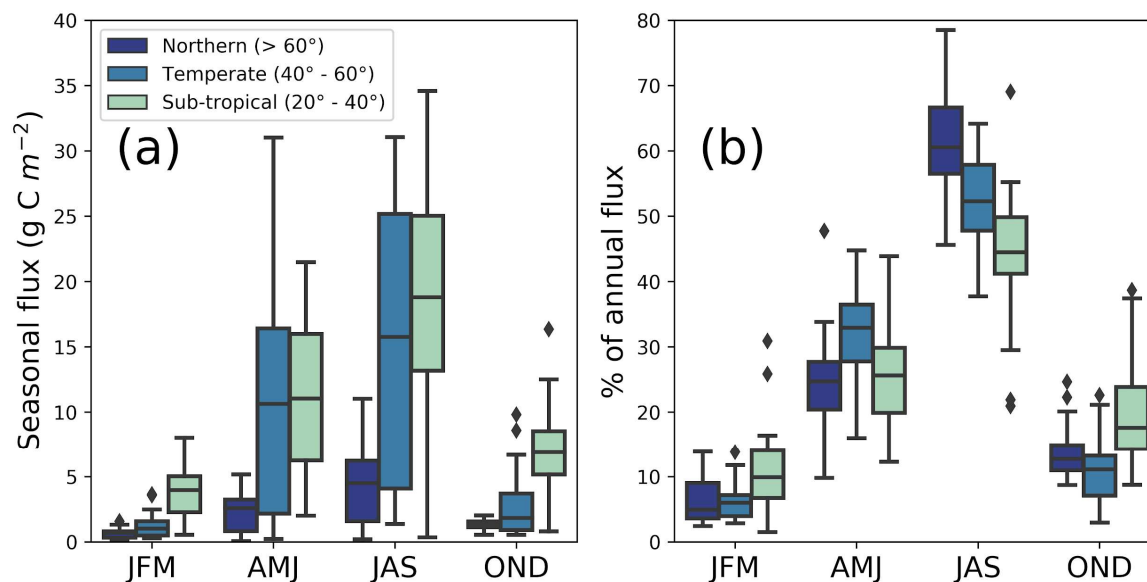

653

654
 655
 656 **Figure 8: (a) Annual methane (CH₄) flux (g C m⁻² yr⁻¹), (b) Ratio of seasonal amplitude to seasonal peak, where values of 0**
 657 **indicate uniform annual CH₄ flux, values of one indicate zero off-season fluxes, and values exceeding one indicate negative**
 658 **off-season fluxes, (c) CH₄ flux (FCH₄) elevated emissions season start by day of year (DOY), (d) FCH₄ elevated emissions**
 659 **season end by DOY, (e) Length of elevated CH₄ flux season (days), and (f) DOY of peak FCH₄. Northern (dark blue, solid**
 660 **line), Temperate (blue, dashed line), Sub-tropical (green, dot-dash line) and Tropical (light green, solid line) wetlands**
 661 **plotted using the kernel density function. Each panel has lines that represent latitudinal bands as follows: northern (> 60°),**
 662 **temperate (between 40° and 60°), subtropical (between 20° and 40°), and tropical (< 20°), though the site-year totals vary**
 663 **between these groups (n = 57, n = 36, n = 39, and n = 9 respectively). All total CH₄ flux values and elevated season start**
 664 **values are positive, and the apparent continuation of the data distribution into negative values is an artifact of the kernel**
 665 **density function. Southern Hemisphere sites below 20° S were shifted by 182 days to make summer the middle of the year**
 666 **for comparability with Northern Hemisphere sites.**
 667

668 We found that latitudinal groups showed strong differences in absolute CH₄ flux across quarters, and narrower
 669 differences in percentage of annual CH₄ flux (Fig. 9a versus 9b). Thus, the AMJ quarter had a similar relative
 670 contribution to the annual CH₄ flux across latitudes, regardless of the absolute annual CH₄ flux. CH₄ fluxes (Fig. 9a)
 671 were highest during JAS for northern, temperate, and subtropical sites and highest in AMJ and JAS for temperate sites
 672 (p<0.01). Though CH₄ fluxes in northern sites are most commonly measured during warm summer months (Sachs et
 673 al., 2010; Parmentier et al., 2011), fluxes in JFM and OND (50% of the yearly duration) on average make up 18.1 ±
 674 3.6%, 15.3 ± 0.1%, and 31.2 ± 0.1% (northern, temperate, subtropical, respectively) of annual emissions. This pattern
 675 indicates that a substantial fraction of annual CH₄ fluxes occurs during cooler months. The contribution of non-

676 growing season CH₄ emissions to annual CH₄ fluxes has previously been described for arctic and boreal regions (Zona
 677 et al., 2016; Treat et al., 2018) and our analysis suggests comparable contributions in temperate and subtropical
 678 systems for the same quarterly periods.
 679
 680
 681

682
 683
 684 **Figure 9: (a) Quarterly contribution to total annual CH₄ flux in g C m⁻², and (b) percentage of annual CH₄ flux. Sites**
 685 **were divided into northern (> 60° N), temperate (40° N - 60° N), and subtropical (20° N - 40° N). Quarters with**
 686 **continuous data gaps exceeding 30 days were excluded. We used the following quarterly periods:**
 687 **January/February/March (JFM), April/May/June (AMJ), July/August/September (JAS), and**
 688 **October/November/December (OND). Tropical sites are discussed separately in Sect. 3.3.3 because of their unique**
 689 **seasonality and low number of sites.**
 690

691 3.3.2 Predictors of CH₄ flux phenology

692 The start of the elevated CH₄ flux season, and how long the elevated flux season lasts, correlated strongly
 693 with mean annual air temperature (Fig. 10; p<0.0001 for each). Methane flux began to increase roughly two months
 694 earlier in the warmest systems (mean annual temperature > 20 °C) compared to the coldest (mean annual
 695 temperature near -10 °C), though several of the warmer sites had high variability. Our data suggest that the CH₄
 696 season started 2.8 ± 0.5 days earlier for every degree Celsius increase in mean annual temperature (Fig. 10a). In
 697 contrast, the end of the CH₄ emission season was not correlated with mean annual temperature, but a positive trend
 698 existed despite high variability in warmest and coldest sites (Fig. 10b). The high variability seen in the end of CH₄
 699 season at northern sites is important to note and would likely be better resolved by incorporating other seasonality or
 700 phenological characteristics, such as moisture, active layer depth, and plant community composition (e.g., Kittler et
 701 al., 2017). Plants with aerenchymatous tissue, for example, influence the timing of plant-mediated CH₄ flux and are
 702 a key source of uncertainty while predicting CH₄ seasonality for northern wetlands (Xu et al., 2016, Kwon et al.,
 703 2017). Despite the relative lack of trend with season end date, the season length was still positively correlated with
 704 mean annual temperature, with the warmest sites having roughly three more months of seasonally elevated CH₄
 705 emissions than the coldest sites (Fig. 10c). CH₄ season length increased 3.6 ± 0.6 days for every degree Celsius
 706 increase in mean annual temperature (note that these relationships are correlations, and we cannot disentangle

707 causality with this analysis). Temperature is highly correlated with other parameters (i.e., radiation, days of snow
 708 cover, etc.), so CH₄ flux is also likely to correlate with other environmental parameters.

709
 710 **Figure 10.** The (a) start of the elevated methane (CH₄) emission season ($y = -2.8x + 130$, with ‘x’ in °C and ‘y’ in day of
 711 year (DOY)), (b) the end of the elevated emission season in DOY, and (c) the length of the emission season with mean
 712 annual site air temperature ($y = 3.6x + 176.6$, with ‘x’ in °C and ‘y’ in days). Each point represents a site-year of data and
 713 all reported r^2 are significant to $p < 0.0001$. Tropical sites are discussed separately in Sect. 3.3.3.

714 Although the spring onset of increasing CH₄ emissions correlated with mean annual air temperature, on
 715 average it lagged the spring increase in the shallowest soil temperatures by 31 ± 40 days (Fig. 11, lag is significantly
 716 different than zero, $p < 0.001$), with very few instances of CH₄ emissions beginning before seasonal soil
 717 temperatures increase (and by 20 ± 50 days for the deepest temperature probes). In contrast, for roughly half of the
 718 sites, CH₄ emission increased prior to seasonal GPP (a proxy for fresh substrate availability) increases. This
 719 suggests that the initiation of increased CH₄ fluxes at the beginning of the season was not limited by availability of
 720 substrate derived from recent photosynthate. Additionally, the onset of CH₄ fluxes tended to occur closer to the
 721 onset of soil temperature increase for cooler temperature sites (sites with later start dates tend to be cooler; Fig. 11a).
 722 This result is likely attributable to the direct influence of increased temperature on microbial processes (Chadburn
 723 et al., 2020), as well as the indirect influences of snow melt, both via release of CH₄ from the snowpack as well as a
 724 higher water table leading to more CH₄ production (Hargreaves et al., 2001; Tagesson et al., 2012; Mastepanov et
 725 al., 2013; Helbig et al., 2017). These observed trends hold for the entire temperature or GPP range of freshwater
 726 wetland sites, but are not necessarily applicable within individual latitudinal bands.

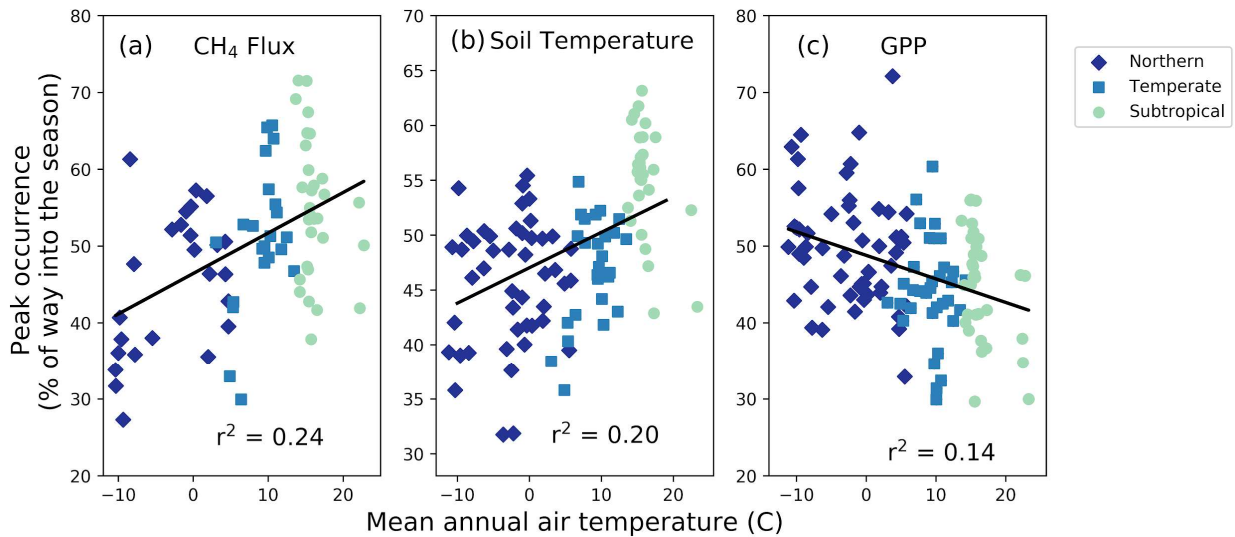

727

728

729 **Figure 11. Relationship between the onset of the methane (CH₄) emission season to (a) the beginning of the air**
 730 **warming by day of year (DOY), (b) soil warming at the shallowest probe depth per site by DOY, and (c) gross primary**
 731 **productivity (GPP) increase for the subset of sites with soil temperature data by DOY. Each point represents a site-year**
 732 **of data. Dashed lines represent a 1:1 relationship, solid lines are significant ($p < 0.05$) regression fits. On average, the**
 733 **CH₄ emission season lags the soil temperature increase by 31 ± 40 days, and is more synchronous with GPP.**

734 In contrast with the CH₄ season-start timing, the timing of the CH₄ peak did not correlate with either the
 735 timing of the soil temperature peak or the GPP peak (Fig. A1). For 63% of the sites, the average timing of peak CH₄
 736 emissions lagged the soil temperature peak, and at 83% of the sites average peak CH₄ lagged peak GPP (Fig. A1).
 737 Although there was no simple relationship between absolute CH₄ peak timing and the environmental drivers we
 738 investigated, there was a correlation ($p = 0.0005$) between the relative timing of peak CH₄ compared to season onset
 739 (calculated as described in Section 2.3) and mean annual air temperature (Fig. 12a). For cooler sites, the peak of
 740 seasonal CH₄ emissions occurred closer to the onset of the CH₄ emission season than the end of the season, resulting
 741 in an asymmetrical seasonal CH₄ flux shape that is illustrated in Fig. 2a. Soil temperature also peaked earlier in the
 742 season for cooler wetlands, though the relationship is not as pronounced ($p = 0.009$, Fig. 12b). In contrast, GPP
 743 peaked later in the season for cooler wetlands ($p = 0.009$, Fig. 12c). Previous work on Arctic sites (sites US-Ivo,
 744 US-Beo, US-Atq, US-Bes, and RU-CH2) highlighted the asymmetrical annual CH₄ peak, with higher fall emissions
 745 being attributed to the “zero curtain” period when soil below the surface remains thawed for an extended period of
 746 time due to snow insulation (Zona et al., 2016; Kittler et al., 2017). Furthermore, soils can stay above the “zero
 747 curtain” range for an extended time into the fall and winter (Helbig et al., 2017), which may also be caused by snow
 748 insulation. The rapid onset of emissions in the spring following snowmelt could be attributed to the release of
 749 accumulated CH₄ (Friborg et al., 1997), and other high latitude sites have seen similarly sharp increases in CH₄
 750 emissions at snowmelt (Dise, 1992, Windsor, 1992). However, not all studies in high latitudes have observed
 751 asymmetrical CH₄ emission peaks, pointing to the inherent complexity of these ecosystems (Rinne et al., 2007;
 752 Tagesson et al., 2012).

753
 754 **Figure 12. Site-year peak methane (CH₄) emission (a) and peak soil temperature (b) occur earlier in the season for sites**
 755 **with lower mean annual temperatures. (c) Gross primary productivity (GPP) tends to peak earlier in the season for**
 756 **warmer sites, though the trend is weak. All r^2 values are significant at $p < 0.001$. Each point represents a site-year of**
 757 **data.**

758 3.3.3 Uniqueness of tropical wetlands

759 Tropical wetlands typically do not experience the large swings in temperature and GPP that contribute to
760 CH₄ flux seasonality in temperate and northern sites. Indeed, the relatively constant high temperatures and high
761 GPP in tropical ecosystems may lead to the lower ratio between seasonal amplitude and peak CH₄ flux compared
762 with temperate and northern sites (Fig. 8b). Tropical flux sites have historically been under-studied, leading to a
763 lack of synthesized information about these ecosystems. FLUXNET-CH₄ has five tropical wetland sites (latitude
764 between 20° S and 20° N), and one tropical rice site, representing 13 site-years of data. These sites are especially
765 insightful as they provide the first estimates of CH₄ fluxes from tropical, large seasonal floodplain systems.
766

767 We found a broad range of annual CH₄ fluxes across tropical sites in FLUXNET-CH₄ Version 1.0. Annual
768 CH₄ flux emissions from two Southeast Asian flooded peat forests were relatively low, 0.01 ± 0.1 and 9.5 ± 0.6 g C
769 m⁻² yr⁻¹ for ID-PAG and MY-MLM, respectively, which is consistent with annual CH₄ fluxes measured at another
770 peat forest in Indonesia (Deshmukh et al., 2020). In contrast, mean annual CH₄ flux for a seasonally flooded swamp
771 in the Brazilian Pantanal region (BR-NPW) was over twice as high as MY-MLM, at 19.2 ± 2.5 g C m⁻² yr⁻¹.
772 Similarly high annual CH₄ fluxes were observed at the two Botswana swamp sites in the Okavango Delta ($51.7 \pm$
773 10.6 and 47.3 ± 3.7 g C m⁻² yr⁻¹ for BW-GUM and BW-NXR, respectively), one of which is seasonally inundated
774 and surrounded by grassland (BW-NXR) and the other is a permanently flooded lagoon covered in a floating
775 papyrus mat (BW-GUM). The relatively low fluxes found at the two Southeast Asian peat forest sites indicate that
776 these ecosystems may be smaller CH₄ sources than expected, given their location in the humid tropics. Even the
777 higher-emitting tropical sites in Brazil and Botswana are still well within the range of annual CH₄ flux typical in
778 cooler latitudes (Fig. 1).

779 In addition to having highly variable CH₄ flux magnitudes, the tropical sites differ from each other in their
780 seasonality. CH₄ flux hit a minimum around July for two sites (BW-GUM, latitude 18.965 °S and MY-MLM, latitude
781 1.46 °N), while CH₄ flux increased through July and the subsequent months for the other Botswana site, BW-NXR
782 (latitude 19.548 °S). Site ID-Pag (latitude 2.32 °S) had minimal seasonality, whereas the flooded forest site in Brazil
783 (BR-NPW, latitude 16.49 °S) had near-zero fluxes from approximately July to January, and consistently high fluxes
784 for the remainder of the year. The rice site PH-RiF (latitude 14.14 °N) had two annual CH₄ flux peaks, which is
785 consistent with some other rice sites and likely reflects management practices. Baseline CH₄ flux values also differed,
786 with the two Botswana sites having the highest off-season fluxes (29 and 133 nmol m⁻² s⁻¹ for BW-NXR and BW-
787 GUM, respectively, estimated by Timesat), MY-MLM having an intermediate baseline CH₄ flux (16 nmol m⁻² s⁻¹,
788 estimated by Timesat), and the remainder of the sites having essentially zero flux at baseline. While more tropical
789 wetland data will be needed to extract broad scale conclusions about these ecosystems, the six tropical sites in
790 FLUXNET-CH₄ provide an important starting point for synthesis studies and highlight tropical wetland CH₄
791 variability.

792

793 4.0 Data Availability

794 Half-hourly and daily aggregations are available for download at [https://fluxnet.org/data/fluxnet-ch4-](https://fluxnet.org/data/fluxnet-ch4-community-product/)
795 [community-product/](https://fluxnet.org/data/fluxnet-ch4-community-product/), along with a table containing site metadata compiled from Table B3. Variable descriptions and
796 units are provided in Table B1, and at <https://fluxnet.org/data/fluxnet-ch4-community-product/>. Each site has a unique
797 FLUXNET-CH₄ DOI as listed in Table B3. All site data used in this analysis are available under the CC BY 4.0
798 (<https://creativecommons.org/licenses/by/4.0/>) copyright policy (2 additional sites in FLUXNET-CH₄ are available
799 under the more restrictive Tier 2 data policy, <https://fluxnet.org/data/data-policy/>; these sites are not used in our
800 analysis). The individual site DOIs are provided below in Table 2. All seasonality parameters used in these analyses
801 are available at <https://doi.org/10.5281/zenodo.4672601>.

805

806

807 5.0 Conclusions

808 The breadth and scope of CH₄ flux data in the FLUXNET-CH₄ dataset make it possible to study the global
809 patterns of CH₄ fluxes, particularly for global freshwater wetlands which release a substantial fraction of
810 atmospheric CH₄. To help data users understand seasonal patterns within the dataset, we provide the first global
811 estimates of CH₄ flux patterns and predictors in CH₄ seasonality using freshwater wetland data. In the seasonality
812 analysis, we find that, on average, the seasonal increase in CH₄ emissions begins about three months earlier and lasts
813 about four months longer at the warmest sites compared with the coolest sites. We also find that the beginning of the
814 CH₄ emission season lags the beginning of seasonal soil warming by approximately one month, with almost no
815 instances of CH₄ emissions increasing before temperature increases. Additionally, roughly half the sites have CH₄
816 emissions increasing prior to GPP increase; highlighting the importance of substrate versus temperature limitations
817 on wetland CH₄ emissions. Furthermore, relative to warmer climates, wetland CH₄ emissions in cooler climates
818 increase faster in the warming season and decrease slower in the cooling season. This phenomenon has previously
819 been noted on a regional scale and we show that it persists at the global scale. Constraining the seasonality of CH₄
820 fluxes on a global scale can help improve the accuracy of global wetland models.

821 FLUXNET-CH₄ is an important new resource for the research community, but critical data gaps and
822 opportunities remain. The current FLUXNET-CH₄ dataset is biased towards sites in boreal and temperate regions,
823 which influence the relationships presented in our analyses. Tropical ecosystems are estimated to account for 64% of
824 potential natural CH₄ emissions (<30° N, Saunio et al., 2020) but only account for 13% of the FLUXNET-CH₄
825 sites in the dataset. Unsurprisingly, tropical sites in our network do not represent the range of bioclimatic wetland
826 conditions present in the tropics. Therefore, while maintaining flux towers in tropical ecosystems is challenging, it is
827 necessary to further constrain the global CH₄ cycle. Coastal wetlands are also poorly represented in FLUXNET-CH₄
828 even though there is evidence of substantial CH₄ emissions from these ecosystems, so better representation across
829 salinity gradients is warranted. Lastly, the average time series for FLUXNET-CH₄ Version 1.0 is relatively short,
830 only 3.7 site-years on average compared with 7.2 for CO₂ sites in FLUXNET (Pastorello et al., 2020). Adding
831 additional site-years of data from existing sites, as a complement to adding new sites, will increase the community's
832 ability to explain interannual variability in CH₄ emission and seasonality. Nevertheless, FLUXNET-CH₄ is an
833 important and unprecedented resource with which to diagnose and understand drivers of the global CH₄ cycle.

834 **Author contribution**

835 Kyle B. Delwiche oversaw the data release, performed the seasonality analysis, gathered metadata, and
836 prepared the manuscript with contributions from all co-authors. Sara Helen Knox gathered and standardized the
837 data, and gap-filled the CH₄ flux data. Avni Malhotra prepared the manuscript and gathered metadata. Etienne
838 Fluet-Chouinard did the representativeness analysis and prepared the manuscript. Gavin McNicol gathered data and
839 prepared the manuscript. Robert B. Jackson oversaw the data collection, processing, analysis, and release. Danielle
840 Christianson and You-Wei Cheah oversaw the FLUXNET-CH₄ dataset release on fluxnet.org. Dario Papale,
841 Eleonora Canfora, and Carlo Trotta did the data collection, curation, and pre-processing for all of the sites outside
842 North and South America. Remaining co-authors contributed eddy-covariance data to FLUXNET-CH₄ dataset
843 and/or participated in editing the manuscript.

844 **Competing interests**

845 The authors declare that they have no conflict of interest.

846 **Acknowledgements**

847 We acknowledge primary support from the Gordon and Betty Moore Foundation (Grant GBMF5439, “Advancing

1405 APPENDIX A

1406

1407

1408

1409 Figure A1: Peak methane (CH₄) flux timing versus peak gross primary productivity (GPP) timing (A) and peak soil
1410 temperature timing by day of year (B). Points represent site average and error bars represent standard deviations. Dotted
1411 line represents 1:1 relationship.

1412

1413 **APPENDIX B**

1414

1415 **Table B1: Data variable names, descriptions, and units**

1416 **FLUXNET-CH4 Data Variables**

1417 This webpage describes data variables and file formatting for the FLUXNET-CH4 Community Product.

1418 **1. Data Variable: Base names**

1419 Base names indicate fundamental quantities that are either measured or calculated/derived. They can also
 1420 indicate quantified quality information.

1421 Table 1. Base names for data variables

<i>Variable</i>	<i>Description</i>	<i>Units</i>
TIMEKEEPING		
TIMESTAMP_START	ISO timestamp start of averaging period, used in half-hourly data	YYYYMMDDHHMM
TIMESTAMP_END	ISO timestamp end of averaging period, used in half-hourly data	YYYYMMDDHHMM
TIMESTAMP	ISO timestamp used in daily aggregation files	YYYYMMDD
MET_RAD		
SW_IN	Shortwave radiation, incoming	W m ⁻²
SW_OUT	Shortwave radiation, outgoing	W m ⁻²
LW_IN	Longwave radiation, incoming	W m ⁻²
LW_OUT	Longwave radiation, outgoing	W m ⁻²

PPFD_IN	Photosynthetic photon flux density, incoming	$\mu\text{molPhoton m}^{-2} \text{ s}^{-1}$
---------	--	---

PPFD_OUT	Photosynthetic photon flux density, outgoing	$\mu\text{molPhoton m}^{-2} \text{ s}^{-1}$
----------	--	---

NETRAD	Net radiation	W m^{-2}
--------	---------------	-------------------

MET_WIND

USTAR	Friction velocity	m s^{-1}
-------	-------------------	-------------------

WD	Wind direction	Decimal degrees
----	----------------	-----------------

WS	Wind speed	m s^{-1}
----	------------	-------------------

HEAT

H	Sensible heat turbulent flux (with storage term if provided by site PI)	W m^{-2}
---	---	-------------------

LE	Latent heat turbulent flux (with storage term if provided by site PI)	W m^{-2}
----	---	-------------------

G	Soil heat flux	W m^{-2}
---	----------------	-------------------

MET_ATM

PA	Atmospheric pressure	kPa
----	----------------------	-----

TA	Air temperature	deg C
----	-----------------	-------

VPD	Vapor Pressure Deficit	hPa
-----	------------------------	-----

RH	Relative humidity, range 0-100	%
----	--------------------------------	---

MET_PRECIP

P	Precipitation	mm
---	---------------	----

PRODUCTS

NEE	Net Ecosystem Exchange	$\mu\text{molCO}_2 \text{ m}^{-2} \text{ s}^{-1}$
-----	------------------------	---

GPP	Gross primary productivity	$\mu\text{molCO}_2 \text{ m}^{-2} \text{ s}^{-1}$
-----	----------------------------	---

RECO	Ecosystem respiration	$\mu\text{molCO}_2 \text{ m}^{-2} \text{ s}^{-1}$
------	-----------------------	---

GASES

FCH4	Methane (CH ₄) turbulent flux (no storage correction)	$\text{nmolCH}_4 \text{ m}^{-2} \text{ s}^{-1}$
------	---	---

MET_SOIL

TS	Soil temperature	deg C
----	------------------	-------

WTD	Water table depth (negative values indicate below the surface)	m
-----	--	---

1423 2. Data Variable: Qualifiers

1424 Qualifiers are suffixes appended to variable base names that provide additional information about the
1425 variable. For example, the `_DT` qualifier in the variable label `GPP_DT` indicates that gross primary
1426 production (GPP) has been partitioned using the flux partitioning method from Lasslop et al. 2010.

1427 Multiple qualifiers can be added, and they must **follow the order in which they are presented here**.

1428 2.1. Qualifiers: General

1429 General qualifiers indicate additional information about a variable.

1430 · `_F` : Variable has been gap-filled by the FLUXNET-CH4 team. Gaps in meteorological variables
1431 (including air temperature (TA), incoming shortwave (SW_IN) and longwave (LW_IN) radiation, vapor
1432 pressure deficit (VPD), pressure (PA), precipitation (P), and wind speed (WS)) were filled with ERA-
1433 Interim (ERA-I) reanalysis data ((Vuichard and Papale 2015)). Other variables were filled using the MDS
1434 approach in REdDyProc (see Delwiche et al. 2020 for more details).

1435 · `_DT` : Variable acquired using the flux partitioning method from (Lasslop et al. 2010), with values
1436 estimated by fitting the light-response curve.

1437 · `_NT` : Variable acquired using the flux partitioning method from (Reichstein et al. 2005), with values
1438 estimated from night-time data and extrapolated to day time.

1439 · `_RANDUNC`: Random uncertainty introduced from several different sources including errors
1440 associated with the flux measurement system (gas analyzer, sonic anemometer, data acquisition system,
1441 flux calculations), errors associated with turbulent transport, and statistical errors relating to the location
1442 and activity of the sites of flux exchange (“footprint heterogeneity”) (Hollinger and Richardson 2005).

1443 · `_ANNOPTLM` : Gap-filled variable using an artificial neural net routine from Matlab with the
1444 Levenberg-Marquardt algorithm as the training function, and parameters optimized across runs (more
1445 detail in (Sara Helen Knox et al. 2016; Sara H. Knox et al. 2019)).

1446 · `_UNC` : Uncertainty introduced from ANNOPTLM gap-filling routine, as described in Knox et al.
1447 2016 and Knox et al. 2019.

1448 · `_QC` : Reports quality checks on FCH4 gap-filled data (`_ANNOPTLM`) based on length of data gap.
1449 1 = data gap shorter than 2 months, 3 = data gap exceeds 2 months which could lead to poor quality gap-
1450 filled data. Nondimensional.

1451

1452 2.2. Qualifiers: Positional (`_V`)

1453 Positional qualifiers are used to indicate relative positions of observations at the site. For FLUXNET-CH4,
1454 positional qualifiers are used to distinguish soil temperature probes for sites with more than one probe.
1455 Probe depths for each positional qualifier per site are included in the metadata file included with data
1456 download and also in Table B7 of Delwiche et al. 2020. For sites where the original database file release
1457 in Ameriflux, AsiaFlux, or EuroFlux contains multiple probes at the same `_V` depth, we average values
1458 and report only the average for each `_V` position. The one exception to this is site US-UAF where the
1459 original positional qualifier from the data we downloaded from Ameriflux had different depths for the

1460 same qualifier. We still averaged the probe data, so _V qualifiers from US-UAF represent an average of
1461 more than one depth.

1462 3.0 Missing data

1463 Missing data are reported using -9999. Data for all days in a leap year are reported.

**Data from ID-Pag spans 365 days from June 2016 to June 2017. Annual methane flux for each year is the sum of these 365 days, with uncertainty being calculated separately for each year.*

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
Year	Data year
Ann_Flux_g_C_m-2	Total annual methane flux (gC/m ²)
Ann_Flux_Uncertainty_g_C_m-2	Gap-filling and rancom uncertainty associated with annual flux (gC/m ²)
Mean_Soil_Temp_C	Annual mean soil temperature (degree C). For sites with multiple probes, we use the probe closest to the surface
Mean_Water_Table_Depth_m	Annual mean water table depth (m)

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
SITE_CLASSIFICATION	Site classification based on literature description of sites
UPLAND_CLASS	For upland sites, category of upland type
IGBP	International Geosphere–Biosphere Programme (IGBP) ecosystem surface classification
KOPPEN	Koppen climate zone abbreviation
MEAN_ANNUAL_TEMP_C_W	Mean annual precipitation from WorldClim2 Global Climate Data
ORLDCLIM	Mean annual precipitation from WorldClim2 Global Climate Data
MEAN_ANNUAL_PRECIP_M	Mean annual precipitation from WorldClim2 Global Climate Data
M_WORLDCLIM	Mean annual precipitation from WorldClim2 Global Climate Data
MOSS_BROWN	Presence/absence (1/0) brown moss. Presence/absence designated by Avni Malhotra using site-literature
MOSS_SPHAGNUM	Presence/absence (1/0) sphagnum moss. Presence/absence designated by Avni Malhotra using site-literature
AERENCHYMATOUS	Presence/absence (1/0) aerenchymatous vegetation. Presence/absence designated by Avni Malhotra using site-literature
ERI_SHRUB	Presence/absence (1/0) ericaceous shrubs. Presence/absence designated by Avni Malhotra using site-literature
TREE	Presence/absence (1/0) trees. Presence/absence designated by Avni Malhotra using site-literature
DOM_VEG	Dominant vegetation type in tower footprint. Dom_veg provided to Avni Malhotra by site personnel via sur
IN_SEASONALITY_ANALYSIS	Is site in freshwater wetland seasonality analysis? 1 = yes, 0 = no.

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
Mean_Air_Temp_C	Mean annual air temperature, calculated from flux tower variable TA_F (C)
Ann_Flux_g_CH4-C_m-2	Mean annual methane flux (g CH4-C/m2/year)
JFM_flux_g_CH4-C_m-2	Mean methane flux in January, February, March (gCH4-C/m2/year)
AMJ_flux_g_CH4-C_m-2	Mean methane flux in April, May, June (gCH4-C/m2/year)
JAS_flux_g_CH4-C_m-2	Mean methane flux in July, August, September (gCH4-C/m2/year)
OND_flux_g_CH4-C_m-2	Mean methane flux in October, November, December (gCH4-C/m2/year)
Mean_Air_Temp_stdev_C	Standard deviation of annual air temperature (C)
Ann_Flux_stdev_g_CH4-C_m-2	Standard deviation of annual methane flux (gCH4-C/m2/year)
JFM_flux_stdev_g_CH4-C_m-2	Standard deviation of methane flux in January, February, March (gCH4-C/m2/year)
AMJ_flux_stdev_g_CH4-C_m-2	Standard deviation of methane flux in April, May, June (gCH4-C/m2/year)
JAS_flux_stdev_g_CH4-C_m-2	Standard deviation of methane flux in July, August, September (gCH4-C/m2/year)
OND_flux_stdev_g_CH4-C_m-2	Standard deviation of methane flux in October, November, December (gCH4-C/m2/year)

Column Descriptions

SITE_ID

Site identification code as assigned by regional flux

Enhanced_Vegetation_Index_(EVI)	Enhanced vegetation index (unitless) from MOD13A3 (Didan 2015), 2001-2018 monthly data
Wong_Simple_Ratio_Water_Index_(SR WI)	Simple Ratio Water Index (unitless) from MOD09A1 (Vermote 2015), ~2001-2018 monthly data
Latent_Heat_(LE)	Latent heat in W m ⁻² from FLUXCOM (Jung et al., 2019), 2003-2013 monthly data
Mean_Annual_Temperature_(MAT)	Mean annual temperature (C) from BioClim (Fick & Hijman 2017), 2001-2018 monthly data

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
Year	Data year
Start_FCH4_(DOY)	Season start for elevated methane fluxes (DOY), point "f" in Figure 1
End_FCH4_(DOY)	Season end for elevated methane fluxes (DOY), point "h" in Figure 1
Base_value_FCH4_(nmolCH4/m2/s)	Baseline methane flux during non-elevated season (nmol CH4 /m2/ s), average of points "a" and "b" in Figure 1

Ampl_FCH4_(nmolCH4/m2/s)

Amplitude of methane flux during elevated flux season (nmol CH4/m2/s), difference between point "e" in Figure 1 and Base_value_FCH4

Peak_FCH4_(DOY)

Day of maximum elevated methane flux (DOY), point "g" in Figure 1

Peak_value_FCH4_(nmolCH4/m2/s)

Maximum value of methane flux (nmol CH4/m2/s), point "e" in Figure 1

Table B5-B Timesat output for FCH4, GPP_DT, TA, and TS (TS from shallowest probe at each site)

	SITE_ID	Year	Start_GPP_D T_(DOY)	End_GPP_ DT_(DOY)	Base_value_G PP_DT_(μ mol CO2/m2/s)	Ampl_GPP_D T_(μ molCO2/ m2/s)	Peak_GPP_D T_(DOY)	Peak_value_G PP_DT_(μ mol CO2/m2/s)

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
Year	Data year
Start_GPP_DT_(DOY)	Season start for elevated GPP_DT (DOY), point "f" in Figure 1
End_GPP_DT_(DOY)	Season end for elevated GPP_DT fluxes (DOY), point "h" in Figure 1
Base_value_GPP_DT_($\mu\text{molCO}_2/\text{m}^2/\text{s}$)	Baseline GPP_DT flux during non-elevated season ($\mu\text{molCO}_2/\text{m}^2/\text{s}$), average of points "a" and "b" in Figure 1

Ampl_GPP_DT_($\mu\text{molCO}_2/\text{m}^2/\text{s}$)

Peak_GPP_DT_(DOY)

Peak_value_GPP_DT_($\mu\text{molCO}_2/\text{m}^2/\text{s}$)

Amplitude of GPP_DT flux during elevated flux season ($\mu\text{mol CO}_2/\text{m}^2/\text{s}$), difference between point "e" in Figure 1 and Base_value_GPP_DT

Day of maximum elevated GPP_DT flux (DOY), point "g" in Figure 1

Maximum value of GPP_DT flux ($\mu\text{mol CO}_2/\text{m}^2/\text{s}$), point "e" in Figure 1

Table B5-C Timesat output for FCH4, GPP_DT, TA, and TS (TS from shallowest probe at each site)

Column Description

SITE_ID	Site identification code as assigned by regional flux data network
Year	Data year
Start_TA_(DOY)	Season start for elevated TA (DOY), point "f" in Figure 1
End_TA_(DOY)	Season end for elevated TA (DOY), point "h" in Figure 1
Base_value_TA_(C)	Baseline TA during non-elevated season (C), average of points "a" and "b" in Figure 1
Ampl_TA_(C)	Amplitude of TAduring elevated temperature season (C), difference between point "e" in Figure 1 and Base_value_TA
Peak_TA_(DOY)	Day of maximum elevated TA (DOY), point "g" in Figure 1
Peak_value_TA_(C)	Maximum value of TA (C) point "e" in Figure 1

Column Descriptions

SITE_ID Site identification code as assigned by regional flux data network

Year Data year

Probe_name Temperature probe name as given in data files

Soil_temp_depth_m Depth of soil temperature probe (m), with negative values being under the surface

Start_TS_(DOY) Season start for elevated TS (DOY), point "f" in Figure 1

End_TS_(DOY) Season end for elevated TS (DOY), point "h" in Figure 1

Base_value_TS_(C) Baseline TS during non-elevated season (C), average of points "a" and "b" in Figure 1

Ampl_TS_(C) Amplitude of TS during elevated temperature season (C), difference between point "e" in Figure 1 and Base_value_TS

Peak_TS_(DOY)
Peak_value_TS_(C)

Day of maximum elevated TS (DOY), point "g" in Figure 1
Maximum value of TS (C) point "e" in Figure 1

Table B6: Timesat output for all soil temperature probes

Column Descriptions

SITE_ID Site identification code as assigned by regional flux data
Year Data year
Probe_name Temperature probe name as given in data files

Soil_temp_depth_m	Depth of soil temperature probe (m), with negative values
Start_TS_(DOY)	Season start for elevated TS (DOY), point "f" in Figure 1
End_TS_(DOY)	Season end for elevated TS (DOY), point "h" in Figure 1
Base_value_TS_(C)	Baseline TS during non-elevated season (C), average of points
Ampl_TS_(C)	Amplitude of TS during elevated temperature season (C), difference between point "e" in Figure 1 and Base_value_TS
Peak_TS_(DOY)	Day of maximum elevated TS (DOY), point "g" in Figure 1
Peak_value_TS_(C)	Maximum value of TS (C) point "e" in Figure 1

Column Descriptions

SITE_ID	Site identification code as assigned by regional flux data network
Year	When relevant, information about time-span of probe location. If
Probe_name	Temperature probe name as given in data files
Soil_temp_depth_m	Depth of soil temperature probe (m), with negative values being under
Additional_notes	When relevant, additional information about site
