20 **Abstract.** From 2008 through 2019, a comprehensive research project, *SFB 754, Climate -*  
21 *Biogeochemistry Interactions in the Tropical Ocean*, was funded by the German Research Foundation  
22 to investigate the climate-biogeochemistry interactions in the tropical ocean with a particular emphasis  
23 on the processes determining the oxygen distribution. During three 4-year long funding phases, a  
24 consortium of more than 150 scientists conducted or participated in 34 major research cruises and  
25 collected a wealth of physical, biological, chemical, and meteorological data. A common data policy  
26 agreed upon at the initiation of the project provided the basis for the open publication of all data. Here  
27 we provide an inventory of this unique data set and briefly summarize the various data acquisition and  
28 processing methods used.

## 29 1 Introduction

30 The distribution of oxygen in the ocean interior is controlled by an intimate interplay of physics and  
31 biogeochemistry. Circulation and mixing transport oxygen from the near-surface where it is produced  
32 by photosynthesis and exchanged with the atmosphere into the ocean interior. Oxygen consumption  
33 occurs throughout the ocean and is essentially driven by bacterial respiration of organic matter. Both the  
34 supply and consumption of oxygen are sensitive to climate change in ways that are not fully understood.  
35 A central objective of the Collaborative Research Center 754 (Sonderforschungsbereich SFB 754,  
36 Climate - Biogeochemistry Interactions in the Tropical Ocean) was to better understand the observed  
37 changes in ocean oxygen distribution (see Figure 1) and thoroughly investigate the climate-  
38 biogeochemistry system in the tropical Atlantic and Pacific Oceans. The program was financed from  
39 2008 through 2019 by the German Research Foundation (DFG).

44

45 **Figure 1: The two working areas of the SFB 754 overlaid on the climatological content of dissolved oxygen on the potential density**  
46 **surface  $\sigma_{\theta}$  26.9 (between 200 and 500 m depth in tropical regions). The map is based on data from the World Ocean Atlas**  
47 **2018 (Garcia et al., 2018).**

48

49 Addressing the SFB 754 goals required a highly multi-disciplinary approach. The SFB 754 built upon  
50 the wide-ranging marine expertise available at the GEOMAR Helmholtz Centre for Ocean Research  
51 Kiel and Kiel University, both in Kiel, Germany. Biological, chemical and physical oceanography,  
52 sediment biogeochemistry, marine ecology, molecular microbiology, paleoceanography, geology, as  
53 well as climate and biogeochemical modelling all contributed to the project. The SFB 754 was  
54 organised in 18 highly interdisciplinary science sub-projects striving to answer the key questions of the  
55 project. An outreach sub-project complemented the scientific sub-projects with programs for pupils and  
56 the general public. A dedicated central data management team was hosted by the GEOMAR data  
57 management and supported and supervised the curation and publication of all data collected by the SFB  
58 754. The aim of this article is to describe and list the published observational data sets collected by the  
59 SFB 754 for easy access and find-ability.

## 60 **2 Observational and experimental program**

61 During the 12-year life-cycle the SFB 754 conducted or participated in a total of 34 research cruises on  
62 large research vessels (see Table 1 and Figures 2 and 3). Data from these cruises constitutes the bulk of  
63 the SFB 754 data. The three 4-year long phases allowed for the development and adaptation of the  
64 observational and experimental program. Questions arising from the data already collected were  
65 incorporated into new sub-projects for the subsequent project phases.

66 **Table 1: Cruises on large research vessels in chronological order.**

| Cruise-id                   | Vessel              | Start                            | End                              | Expocode     | Cruise Report DOI                                                                                           | Main Funding             |

86 the project (a: 2008-2011, b: 2012-2015, c: 2016-2019).

### 87 3 Data management

88 One of the first steps after the inception of the SFB 754 was the development and implementation of a  
89 common data policy (<https://oceanrep.geomar.de/47369>). Binding for all scientists of the SFB 754, it  
90 regulated how fully processed data sets should be curated, stored, distributed, and finally published, as  
91 well as the latency of this process. This data policy and its strict application is one of the reasons for the  
92 success of the SFB 754 with 421 peer reviewed publications at the time of writing.

93 The data management was based on two pillars: The data was stored for, and distributed among, the  
94 scientists of the SFB 754 within the Ocean Science Information System (OSIS,  
95 <https://www.sfb754.de/sfb754-osis>) of GEOMAR. OSIS allows for the storage of different versions of  
96 the data set from preliminary and raw data shortly after collection, over calibrated data to the final data  
97 ready for publication. In the final step the data was published and made freely available at the World  
98 Data Center PANGAEA (<https://www.pangaea.de>) or at other more specific data centers.  
99 Because of the diverse scientific fields and measurements involved, the rules of the data policy were  
100 quite generic. At the same time, an important goal was to ensure the timely exchange of data between  
101 the various research groups within the SFB 754. Within 3 months after data collection, meta-data for the  
102 measurements had to be entered into OSIS, and after 6 months initial versions had to be uploaded. The  
103 final publication of the data on PANGAEA was due 3 years after collection leaving sufficient time for  
104 analyses by members of the SFB 754. To support the adherence to the rules automatic reminders were  
105 sent by OSIS to the scientists responsible for the data sets. More than 1000 data sets have to date been  
106 published on PANGAEA (see <https://www.pangaea.de/?q=sfb754>  
107 listing), while a small number is still being processed and will be published in the near future. For easier  
108 accessibility, the data from the different scientific fields using different methods and instruments have  
109 been separated into data collections at PANGAEA (see Table 2). Some of the data sets have been  
110 published elsewhere on more specialized databases. These are explicitly mentioned in the text below.

111 **Table 2: Dataset collections at PANGAEA related to the descriptive sections. Abbreviations used are CTDO: Conductivity-  
112 Temperature-Depth - Oxygen, ADCP: Acoustic Doppler Current Profiler, UCTD: Underway Conductivity-Temperature-Depth,  
113 BIGO: Biogeochemical Observatory.**

## 115 4 Observational and experimental methods and data

116 During its 12-year existence, the SFB 754 used a large number of observational and experimental  
 117 methods to assess the physical and biogeochemical state of the tropical oceans and the interactions  
 118 between its components; these are briefly described here. Dataset collections have been created on  
 119 PANGAEA for each of the following subsections (see Table 2). Each collection on PANGAEA also  
 120 includes a pdf document with a summarizing table listing ancillary information and all relevant dataset  
 121 DOIs. Table 1 lists the research cruises with their start and end dates together with the DOIs of the  
 122 cruise reports where additional information about the data collected and methods used can be found.

## 123 **4.1 Physical Oceanography**

124 Measurements of physical parameters in the surface layer and throughout the water column were a core  
125 element of the observational program of the SFB 754. They delivered information on the physical  
126 processes that determine the water masses and their properties in the regions of interest and at the same  
127 time set conditions for the various biogeochemical processes that determine the oxygen distribution.

### 128 **4.1.1 Conductivity-Temperature-Depth-Oxygen (CTDO) measurements**

129 CTDO measurements were acquired on 32 of the major research cruises performed as part of the SFB  
130 754 or other projects (Krahmann and Mehrrens, 2021a; see Table 2 and supplementary Table S1).  
131 Seabird 911plus systems equipped with dual temperature-conductivity-oxygen sensors were employed.  
132 All systems had a 24-bottle water sampling rosette with 10 l Niskin bottles. On some cruises only 22  
133 bottles were mounted to accommodate a lowered Acoustic Doppler Current Profiler for deep ocean  
134 current observations. Water sampling, processing, and calibration followed GO-SHIP recommendations  
135 (Swift, 2010; McTaggart et al., 2010; Uchida et al., 2010) and included the recommended steps *Data*  
136 *Conversion, Sensor Time-Alignment, Creation of Bottle Files, Outlier Removal, Pressure Sensor*  
137 *Filtering, Conductivity Cell Thermal Mass Correction, Ship Roll Correction and Deck Offset*  
138 *Correction by Loop Editing*, as well as *Derivation of Calculated Properties*. After these steps,  
139 conductivity and oxygen readings were calibrated against values determined with salinometry (see  
140 section 4.1.4) and Winkler titration (see section 4.2.1), respectively. Finally, the downcast data was  
141 averaged over 1 dbar wide intervals. An independent upcast calibration was used to obtain calibrated  
142 CTDO values coincident with the discrete water samples. These values entered the bottle file described  
143 in section 4.2.

144 In addition to the CTDO measurements, basically all CTDO casts included either a Dr. Haardt or a  
145 Wetlabs FLNTU fluorometer for CHL-a fluorescence. Several other sensors, such as a Wetlabs CDOM  
146 fluorometer and turbidity sensor, a Wetlabs C-Star transmissometer, a Photosynthetically Active  
147 Radiation (PAR) sensor manufactured by Biospherical Instruments, or a Seabird/Satlantic Submersible  
148 Ultraviolet Nitrate Analyzer (SUNA) have been attached to the CTDO system on some of the cruises or  
149 casts, depending on the availability of the sensors and their pressure ratings. SUNA data was processed

150 following the procedures outlined in Sakamoto et al. (2009) and Sakamoto et al. (2017) and calibrated  
151 against Nitrate measurements from discrete bottle samples (see section 4.2.2). To CHL-a and CDOM  
152 fluorescence, turbidity, transmissometer beam attenuation, and PAR data only the manufacturer's  
153 calibration was applied in the published data sets. Details about the sensors used on each cruise can be  
154 found in the respective cruise reports (see Table 1).

#### 155 **4.1.2 Lowered Acoustic Doppler Current Profiler (LADCP) measurements**

156 LADCP measurements were performed on all research cruises that concentrated on open ocean areas  
157 (Krahmann and Mehrtens, 2021b; see Table 2 and supplementary Table S2) while on cruises that  
158 worked mostly in shallow waters, ocean current measurements by the shipboard ADCP (see section  
159 4.1.8) were deemed sufficient. GEOMAR used a two-instrument LADCP configuration with two  
160 Teledyne RDI 300 kHz workhorse ADCPs mounted in down- and up-looking positions. Data collection  
161 and processing was performed according to recommendations in the GO-SHIP manual (Thurnherr et al.,  
162 2010).

#### 163 **4.1.3 Moored instrument measurements**

164 Almost all long-term moored observations of the SFB 754 were conducted in the tropical Atlantic  
165 between the equator and 18° N, except for one mooring that was deployed in the tropical South Pacific  
166 (Hahn et al., 2021; see Table 2 and supplementary Table S3). Moorings were typically equipped with  
167 instruments recording pressure, temperature, conductivity, dissolved oxygen, and current velocity. The  
168 moorings at 17.6° N, 24.2° W which have been deployed in the same location for several periods were  
169 additionally equipped with biogeochemical sensors recording variables such as partial pressure of CO<sub>2</sub>  
170 (*p*CO<sub>2</sub>), fluorescence, and particle fluxes. Instruments with pressure, temperature, conductivity, and  
171 oxygen sensors were calibrated in situ immediately prior to and after a mooring deployment period by  
172 attaching them to the CTD frame during CTDO casts. Correction terms were then developed from the  
173 difference between the sensor readings and the calibrated CTDO data during several minute-long  
174 calibration stops. These correction terms were then applied to the full deployment periods. This ensured  
175 best data quality with recognition of potential sensor drifts and also allowed for the estimation of

176 calibration and measurement errors (Hahn et al., 2014; Bittig et al., 2018; Berx et al., 2019). Moored  
177 Acoustic Doppler Current Profiler bin depths were corrected using the sound speed at instrument depth  
178 following the approach by Shcherbina et al. (2005). Velocities were not corrected, but respective  
179 measurement errors were assumed as described in Hahn et al. (2014). For all instruments within a  
180 mooring that did not record pressure, full deployment pressure time series were estimated by linearly  
181 interpolating between the instruments having a pressure sensor.

#### 182 **4.1.4 Salinometry**

183 The conductivity sensors of the CTD were calibrated against IAPSO Standard SeaWater samples with  
184 known conductivities using Guildline Autosal B instruments. On all cruises two Autosals were available  
185 and used to measure between 100 and 1000 samples (typically 300–400 for a cruise or 4–5 per CTD  
186 cast). The procedures used for the calibration followed the recommendations in the GO-SHIP manual  
187 (Kawano, 2010). The results from the salinometer measurements are included in the source files for  
188 CTD data published on PANGAEA (Krahmann and Mehrtens, 2021a).

#### 189 **4.1.5 Autonomous Gliders**

190 Autonomous gliders were deployed during several cruises but also as stand-alone missions independent  
191 from large research vessels (Krahmann and Mehrtens, 2021c; see Table 2 and supplementary Table S4).  
192 Two different generations of Teledyne Webb Research Slocum gliders were used, G1 and G2. All  
193 gliders were equipped with Seabird CTD systems, G1 gliders with an unpumped and G2 gliders with a  
194 pumped version, respectively. An Aanderaa optode was present on all gliders to observe dissolved  
195 oxygen concentrations. Optical fluorescence and backscatter sensors manufactured by Wetlabs were  
196 also present on all gliders albeit in different configurations. They allowed the determination of CHL-a  
197 (excitation and emission wavelengths of 470 and 695 nm, respectively) and CDOM (excitation and  
198 emission wavelengths of 370 and 460 nm, respectively) concentrations and the turbidity (scattering  
199 wavelength of 470 nm) of the waters. All glider data was processed using a GEOMAR-developed  
200 software (Thomsen et al., 2016) resulting in gridded fields for all observed variables. During a small  
201 number of glider deployments, a Seabird/Satlantic SUNA Nitrate sensor was attached to a glider.

202 SUNA data was processed following the procedures outlined in Sakamoto et al. (2009) and Sakamoto et  
203 al. (2017) and calibrated against Nitrate measurements from nearby CTDO casts with discrete Nitrate  
204 measurements. Microstructure sensors were also attached to gliders on several deployments (see  
205 following section).

#### 206 **4.1.6 Ocean Turbulence Measurements**

207 Ocean turbulence measurement programs were carried out during 22 cruises to quantify the dissipation  
208 rate of turbulent kinetic energy and infer rates of turbulent mixing (Dengler and Mehrtens, 2021; see  
209 Table 2 and supplementary Table S5). The shipboard microstructure profiling systems (MSS) were  
210 manufactured by Sea & Sun Technology and consisted of a profiler (MSS90-D, S/N 26, 32, and 73), a  
211 winch having 500–1000 m of cable and a data interface. All profilers were equipped with three  
212 microstructure shear sensors, a fast-response temperature sensor (PF07), an acceleration sensor, and two  
213 tilt sensors as well as conductivity (Sea & Sun Tech.), temperature (Sea & Sun Tech.), pressure  
214 (Keller), turbidity (Seapoint), and oxygen sensors sampling with a lower response time. The profilers  
215 were optimized to sink at a rate of 0.5–0.6 m s<sup>-1</sup>. Standard processing procedures were used to  
216 determine the rate of kinetic energy dissipation of turbulence in the water column (see Schafstall et al.,  
217 2010).

218 Additionally, during several autonomous glider missions, a microstructure probe was mounted to the  
219 top of the gliders. These probes (MicroRider) were manufactured by Rockland Scientific and carried  
220 two microstructure shear and temperature sensors as well as pressure, accelerometer and tilt sensors.  
221 The data processing is detailed in Foltz et al. (2020).

#### 222 **4.1.7 Shipboard Acoustic Doppler Current Profiler (SADCP) measurements**

223 SADCP data were acquired on 33 of the research cruises (Krahmann and Mehrtens, 2021d; see Table 2  
224 and supplementary Table S6). On FS *Meteor*, FS *Maria S. Merian* and FS *Sonne II* two Teledyne RDI  
225 Ocean Surveyor systems with 38 and 75 kHz transmission frequency were used, while on NO *l'Atalante*  
226 a single 75 kHz system was used. All data was processed with a software package developed at  
227 GEOMAR following the GO-SHIP standards (Firing and Hummon, 2010). The data was subsequently

228 averaged over one-minute intervals, converted to a NetCDF based format and published. For a small  
229 number of cruises, the signal strength information of the SADCP data has been used to estimate the  
230 backscatter in the ocean. These data sets were processed following Mullison (2017) and published  
231 separately from the regular SADCP data (Krahmann and Mehrrens, 2021d; see Table 2 and  
232 supplementary Table S6).

#### 233 **4.1.8 Underway Conductivity-Temperature-Depth (UCTD) and Rapidcast measurements**

234 During the second funding phase (2012-2015) a new CTD system became available that could be  
235 deployed from a moving ship. First a Teledyne Oceanscience UCTD and later a Teledyne Oceanscience  
236 Rapidcast system were acquired and deployed successfully on several cruises (Krahmann and Mehrrens,  
237 2021e; see Table 2 and supplementary Table S7). They allowed for the sampling of water masses at  
238 high horizontal resolution (ranging from less than 1 km for the Rapidcast system to 10 km for deep  
239 UCTD casts) with good accuracy of the pressure, temperature, and conductivity sensors. Processing of  
240 the data involved mostly the fall-rate dependent correction of the thermal lag of the conductivity sensor  
241 and followed the approach described by Ullman and Hebert (2014). Subsequently the corrected data  
242 was calibrated against the calibrated coincident Thermosalinograph (see subsequent section) and the  
243 calibrated nearby CTD data. The typical accuracies of the final pressure, temperature, and salinity data  
244 are 1 dbar, 0.01 °C, and 0.01 g/kg, respectively.

#### 245 **4.1.9 Thermosalinograph (TSG) measurements**

246 For 32 SFB 754 cruises near-surface temperatures and salinities were collected using the ships'  
247 thermosalinograph systems. The four ships on which the major cruises were conducted were equipped  
248 with different systems with either one or two thermosalinographs in parallel or in alternating operating  
249 mode (Krahmann and Mehrrens, 2021f; see Table 2 and supplementary Table S8). All TSG data were  
250 cross-calibrated against the calibrated CTD data at the depth of the seawater intake for the TSG  
251 systems.

#### 252 **4.1.10 Argo Floats**

253 The SFB 754 also made a contribution to the global Argo float program (<https://argo.ucsd.edu>). In 2009,  
254 2011, and 2014 several floats equipped with additional Aanderaa oxygen sensors were deployed off  
255 Peru to study the effects of mesoscale eddies on the flow field and the water masses (Czeschel et al.,  
256 2018; Krahnann and Mehrtens, 2021g; see Table 2 and supplementary Table S9). A number of floats  
257 was deployed in the tropical Atlantic to accompany a tracer release experiment (see section 4.2.3).  
258 Additionally several of the cruises were used to deploy regular Argo floats (without oxygen sensor) on  
259 behalf of the German Hydrographic Office.

### 260 **4.2 Chemical Oceanography**

261 The chemical oceanography program was comprehensive and included a range of different  
262 measurements whose scope was adapted to the different research questions of the cruises. While on all  
263 cruises measurements were performed on water samples from the CTD/rosette additional measurements  
264 were made on some cruises on water pumped continuously along the route of the ship. All cruises  
265 conducted oxygen measurements, almost all conducted nutrient measurements, while 9 conducted  
266 measurements of transient tracers and the deliberately released tracer  $\text{CF}_3\text{SF}_5$ . In addition,  
267 measurements of stable and radiogenic isotopes, the inorganic carbon system, nitrous oxide ( $\text{N}_2\text{O}$ ),  
268 iodide, trace chemical species, and a range of other variables were conducted during the SFB 754. For a  
269 description of the not so frequently measured variables see the cruise reports (see Table 1).

#### 270 **4.2.1 Water sample oxygen measurements (Winkler titration)**

271 A number of discrete samples were taken on most CTDO casts with the objective of calibrating the  
272 CTDO oxygen sensor (Tanhua and Mehrtens, 2021; see Table 2 and supplementary Table S10). Almost  
273 never were the full 24 (or 22 on cruises on which the LADCP was in use) Niskin bottles sampled, as an  
274 adequate calibration of the CTDO sensor could be achieved with fewer values. Samples were taken in  
275 100 ml wide-necked WOCE glass bottles with well-defined volumes. Oxygen samples were taken  
276 immediately after the CTDO cast was finished and always directly after the sampling of transient  
277 tracers. The sample bottles were flushed with at least 3 times its volume and the samples were free of

278 air-bubbles. Immediately after sampling, the seawater samples were spiked from the bottom with the  
279 fixation solution. A significant fraction of the discrete samples were taken as duplicates or triplicates in  
280 order to quantify sampling and titration uncertainties.

281 The oxygen concentration was determined by Winkler titration within a minimum of 40 minutes and a  
282 maximum of 16 hours after sampling following GO-SHIP best practices (Langdon, 2010). Details of  
283 oxygen measurements can be found in the cruise reports (Table 1) of the individual cruises. For all  
284 cruises, we followed the standard procedures for compensating for impurities in the reagents and  
285 oxygen in the fixation solution. For a few cruises with very low oxygen concentrations we compensated  
286 for the sampling blank, i.e. contamination from air during sampling and fixation, and outgassing from  
287 the PVC Niskin bottles.

#### 288 **4.2.2 Nutrient measurements**

289 Nutrients were measured on-board for a sub-set of the cruises, and on another sub-set the samples were  
290 frozen for post-cruise processing in Kiel (Tanhua and Mehrtens, 2021; see Table 2 and supplementary  
291 Table S10). Nutrients measured on-board were performed with QuAAtro gas-segmented continuous  
292 flow analyzers (auto-analyzers) from SEAL Analytical. The exact methods used are listed in the cruise  
293 reports (see Table 1) and were normally: Nitrite and Nitrate – Q-068-05 Rev 11; Nitrite – Q-070-05 Rev  
294 6; Phosphate – Q-064-05 Rev 8; Silicate – Q-066-05 Rev 5. The precision of the nutrient measurements  
295 was calculated as the average of the standard deviation from the replicate measurements of samples, and  
296 are recorded in the cruise reports. For the majority of the cruises where nutrients were measured on-  
297 board, reference Material for Nutrients in Seawater (RMNS) from the General Environmental Technos  
298 (KANSO) Co., Ltd., Osaka/Japan were used. Normally, reference material samples were measured as  
299 triplicates at least once in every sampling run. For nutrient analysis we followed the GO-SHIP best  
300 practices for nutrient measurements (Hydes et al., 2010).

#### 301 **4.2.3 Transient Tracer measurements**

302 Three tracer release experiments were conducted during the SFB 754 using the artificial tracer  $\text{CF}_3\text{SF}_5$ ;  
303 two in the tropical North Atlantic, and one in the tropical South Pacific (Tanhua and Mehrtens, 2021;

304 see Table 2 and supplementary Table S10). The analytical technique for measuring this tracer is similar  
305 to that of the transient tracers CFC-12 and SF<sub>6</sub>. Both transient (i.e. CFC-12 and SF<sub>6</sub>) and released  
306 (CF<sub>3</sub>SF<sub>5</sub>) tracers were measured on 9 of the SFB 754 cruises. The tracers were measured using gas  
307 chromatograph / purge-and-trap techniques modified from Bullister and Weiss (1988). The sampling for  
308 CF<sub>3</sub>SF<sub>5</sub> was focused around the density where the tracer was released, whereas the transient tracers  
309 sampling covered the whole depth of the CTDO profiles. The sampling volume for transient tracers was  
310 around 200 ml, whereas the sampling volume for CF<sub>3</sub>SF<sub>5</sub> varied with time after injections (i.e. based on  
311 the expected concentration range) from 20 to 1000 ml.

#### 312 **4.2.4 Water column measurements of N<sub>2</sub>O**

313 Extensive discrete sampling for measurements of N<sub>2</sub>O was carried out on seven cruises during the time  
314 span of the SFB 754 (Tanhua and Mehrtens, 2021; see Table 2 and supplementary Table S10). Samples  
315 were collected with either the CTD/Rosette or a pump-CTD system (see Löscher et al., 2012; Kock et  
316 al., 2016) and measured directly on board or at the Chemical Oceanography department of GEOMAR.  
317 Samples were analysed by means of a headspace equilibration method coupled to gas chromatography  
318 with electron capture detection (for details, see Kock et al., 2016 and references therein).

#### 319 **4.2.5 Dissolved Silicate, Nitrate, and Nitrite Isotopes**

320 Seawater samples for stable isotopes measurements of dissolved silicate ( $\delta^{30}\text{Si}$ ), nitrate ( $\delta^{15}\text{NO}_3^-$ ) and  
321 nitrite ( $\delta^{15}\text{NO}_2^-$ ) were taken from the CTD/rosette on a number of SFB 754 cruises (Grasse et al., 2021;  
322 see Table 2 and supplementary Table S11). Samples for  $\delta^{30}\text{Si}$  were taken during M77/3, M77/4, M90,  
323 and M93 and immediately acidified to pH 2 after filtration (Ehlert et al., 2012; Grasse et al., 2013;  
324 Grasse et al., 2016). Sample preparation was according to the GEOTRACES  
325 (<https://www.geotraces.org>) protocol and samples for  $\delta^{30}\text{Si}$  were measured at GEOMAR on a Nu  
326 Plasma MC-ICP-MS (Nu Instruments<sup>TM</sup>, Wrexham, UK).  $\delta^{15}\text{NO}_3^-$  and  $\delta^{15}\text{NO}_2^-$  samples were taken  
327 during M77/3, M77/4, M90, M92 and M93. The samples were either preserved frozen or an azide  
328 treatment was applied depending on the nitrite concentration (Altabet et al., 2012; Bourbonnais et al.,

329 2015; Hu et al., 2016; Ryabenko et al., 2012). The isotopic composition of both N-species was  
330 measured using the Cd reduction/azide method (McIlvin and Altabet, 2005).

#### 331 **4.2.6 Radiogenic Isotopes**

332 Seawater samples for Rare Earth Element (REE) concentrations and neodymium (Nd) isotopes were  
333 taken during M77/3 and M77/4 off Peru (Grasse et al., 2012) and during M90 in the Panama Basin  
334 (Grasse et al., 2017; Grasse et al., 2021; see Table 2 and supplementary Table S12). Samples were taken  
335 with the CTD rosette and filtered through 0.45  $\mu\text{m}$  nitrocellulose acetate filters (Millipores) shortly after  
336 sampling. For analysis of Nd isotopes 20 l of seawater were collected for each sample and treated  
337 following GEOTRACES protocol (van de Flierdt et al., 2012). Nd isotope measurements were carried  
338 out on a Nu plasma MC-ICPMS as well as on a Thermo Scientific TIMS TRITON. The concentrations  
339 of dissolved REEs in seawater were measured with a SeaFAST online preconcentration system  
340 (Elemental Scientific Inc.) connected to an Agilent 7500ce quadrupole ICP-MS at GEOMAR (Hathorne  
341 et al., 2012).

#### 342 **4.2.7 Underway trace gas measurements**

343 Continuous measurements of the climate-relevant trace gases carbon dioxide ( $\text{CO}_2$ ), nitrous oxide  
344 ( $\text{N}_2\text{O}$ ), and carbon monoxide (CO) in the surface ocean and overlying atmosphere were conducted  
345 during 9 SFB 754 cruises (Arévalo-Martínez and Mehrtens, 2021; see Table 2 and supplementary Table  
346 S13) spanning the North, South and equatorial Atlantic, as well as the South and equatorial Pacific. To  
347 this end, laser spectroscopy-based gas analysers coupled to air-water equilibration chambers were used.  
348 For details of the analytical systems the reader is referred to the descriptions provided by Arévalo-  
349 Martínez et al. (2013) and Arévalo-Martínez et al. (2019). All trace gas measurements were quality-  
350 controlled to achieve the international standards for marine  $\text{CO}_2$  (Bender et al., 2002),  $\text{N}_2\text{O}$  (Bange et  
351 al., 2019), and atmospheric CO (Zellweger et al., 2019; to date there is no accepted standard for  
352 seawater measurements). The final quality-controlled data is available through the Surface Ocean  $\text{CO}_2$   
353 Atlas (SOCAT, <https://www.socat.info/>) and the Marine  $\text{CH}_4\text{-N}_2\text{O}$  database (MEMENTO,

354 <https://memento.geomar.de/>) as well as on PANGAEA (Arévalo-Martínez and Mehrtens, 2021; see  
355 Table 2 and supplementary Table S13).

#### 356 **4.2.8 Trace chemical species**

357 Trace metal clean sampling equipment was deployed on a sub-set of cruises (see Croot et al., 2021; see  
358 Table 2 and supplementary Table S14) to facilitate the observation of contamination prone chemical  
359 parameters. All trace metal sample collection, handling, and analysis was conducted in accordance with  
360 GEOTRACES protocols which have been updated through the SFB754 program (Cutter et al., 2014).  
361 For cruises with extensive trace metal work, the deployment of an over-pressured clean container on  
362 deck facilitated sampling and collection of trace metal and other contamination-prone samples at sea.  
363 For cruises from 2008 to 2013, PTFE-coated 8 l GO-FLO bottles (General Oceanics) were mounted on  
364 a Kevlar wire with sample handling and preservation as per Chever et al. (2015). From 2014 onwards,  
365 24 Ocean Test Equipment (OTE) samplers were deployed mounted on a powder coated sampling CTD  
366 (Sea-Bird SBE25) rosette using a Kevlar conducting cable with sample handling and preservation as per  
367 Rapp et al. (2019).

368 Prior to 2014, dissolved trace metal concentrations were largely determined by graphite furnace atomic  
369 absorption spectroscopy after offline pre-concentration as per Schlosser et al. (2018) with calibration of  
370 all elements via standard addition. Post 2014, dissolved trace metal samples were analysed via  
371 Inductively Coupled Plasma Mass Spectrometry after offline pre-concentration using a SEAFast  
372 system exactly as per Rapp et al. (2017). A number of trace metal isotopes were also analysed with  
373 forthcoming datasets expected to expand the limited available isotopic data for the Peruvian OMZ with  
374 analysis as per Chever et al. (2015) for Fe and Xie et al. (2019) for Cd.

375 In addition to dissolved trace metal concentrations, a number of redox sensitive trace species were  
376 quantified. These included Fe(II) and H<sub>2</sub>O<sub>2</sub> concentrations determined using flow injection analysis  
377 (Croot et al., 2019; Schlosser et al., 2018), and other Reactive Oxygen Species as per Wuttig et al.  
378 (2013). Metal-speciation was also explored through titrations to characterize metal-ligand interactions  
379 with analytical methods as per Baars and Croot (2015) for Co species, and Gledhill and Van Den Berg  
380 (1994) for Fe(III) species.

## 381 **4.3 Biological Oceanography**

382 Pelagic biological field work of varying extent was carried out during most cruises. Topics spanned  
383 from marine biogeochemistry and microbiology to zooplankton and nekton ecology, and methods  
384 included field observations as well as on-board incubations for microbial as well as metazoan metabolic  
385 rate determination and large-scale experimental set-ups with various treatments such as bioassays,  
386 shipboard mesocosms and a mesocosm experiment off Callao using the KOSMOS system.

### 387 **4.3.1 Particulate Organic Matter and Pigment Analysis**

388 Particulate organic matter (POM) distribution in the water column was on several cruises (Engel and  
389 Mehrtens, 2021; see Table 2 and supplementary Table S15) determined after filtration onto pre-  
390 combusted, acid-washed GF/F filters (Franz et al., 2012a). For particulate organic carbon (POC) and  
391 particulate nitrogen (PN), filters were exposed to fuming hydrochloric acid for 12 h to remove  
392 carbonate and subsequently dried (60 °C, 12 h). Analyses were carried out with a Euro EA elemental  
393 analyzer calibrated with an acetanilide standard. Particulate organic phosphorus (POP) collected on  
394 GF/F filters was determined colorimetrically as ortho-phosphate after potassium peroxydisulphate  
395 digestion following the method of Hansen and Koroleff (1999). Biogenic silica (BSi) was determined  
396 from material filtered onto cellulose acetate filters (0.8 µm), dissolved with 25 ml NaOH (0.1 M) at  
397 85 °C for 2h 15 min in a shaking water bath and analysed after cooling as Si(OH)<sub>4</sub> according to the  
398 method by Hansen and Koroleff (1999). Biogenic opal was calculated assuming a watercontent of  
399 ~10% (Mortlock and Fröhlich, 1989).

400 Samples for phytoplankton pigment concentrations were collected by filtration of seawater from the  
401 CTD/rosette through GF/F filters, and stored at -80 °C immediately after filtration. Pigments were  
402 extracted and analysed by High Performance Liquid Chromatography (HPLC) (Franz et al., 2012a).  
403 Seawater samples (4 ml) were collected for analyses of the phytoplankton community composition by  
404 flow cytometry to complement phytoplankton pigment data, fixed with hexamine/formalin solution and  
405 stored at -80 °C.

406 Transparent exopolymer particles (TEP) and Coomassie stainable particles were filtered under low  
407 pressure (< 150 mbar) onto 25 mm Nuclepore membrane filters (0.4 µm pore size, Whatman Ltd.) and

408 stained with Alcian Blue and Coomassie Brilliant Blue, respectively. Each filter was placed on the  
409 white side of a semi-transparent glass slide (Cytoclear©) and stored frozen at -20 °C until analysis. TEP  
410 and CSP were determined by microscopy and subsequent image analysis (Engel, 2009).

411 Export flux of was characterized using surface-tethered sediment traps (Engel et al., 2017), with Particle  
412 Interceptor-Traps (PIT) following Knauer et al. (1979). Each PIT had an inside diameter of 7 cm, an  
413 outside diameter of 7.6 cm and a height of 53 cm, leading to an aspect ratio of 7.5. PITs were covered  
414 with a baffle system consisting of smaller acrylic tubes attached to the top end and filled with a 0.2 µm  
415 filtered brine solution containing 50 g l<sup>-1</sup> sodium chloride to reduce drag-induced movement within the  
416 trap. For preservation, formalin (2% final concentration) was added to the brine solution.

### 417 **4.3.2 Dissolved Organic Matter, Cell Abundance, Extracellular Enzyme Rates, and** 418 **Bacterial Production**

419 For dissolved organic carbon (DOC) and total dissolved nitrogen (TDN), samples (20 ml) were  
420 collected in duplicate on a number of cruises (Engel et al., 2021; see Table 2 and supplementary Table  
421 S16), filtered through combusted (8 h, 500 °C) GF/F filters or through syringe filters (0.45 µm glass  
422 microfiber GD/X membrane, Whatman™) that were rinsed with 50 ml sample and filled into  
423 combusted (8 h, 500 °C) glass ampoules. Samples were acidified with 80 µl of 85 % phosphoric acid or  
424 20 µl of 30 % ultrapure hydrochloric acid, heat-sealed immediately and stored at 4 °C in the dark until  
425 analysis. DOC samples were analyzed by high-temperature catalytic oxidation (TOC-VCSH,  
426 Shimadzu), as described in more detail in Engel and Galgani (2016).

427 Samples for the analysis of dissolved amino acids (DAA, ~4 ml) and dissolved combined carbohydrates  
428 (DCHO, ~16 ml) were filtered through rinsed Acrodisc® 0.45 µm GHP membrane (Pall) in combusted  
429 vials (8 h, 500 °C) and stored at -20 °C, respectively. Prior to analysis DAA were hydrolysed using 6 N  
430 HCl at 100 °C for 20 h. Determination of DAA was carried on a 1260 HPLC system (Agilent),  
431 following the methods described by Lindroth and Mopper (1979) and Dittmar et al. (2009), with  
432 modifications as described in Engel and Galgani (2016). DCHO samples were desalted by membrane  
433 dialysis (1 kDa, Spectra Por) and hydrolysed using 1 M HCl for 20 h at 100 °C prior to analyses.  
434 Samples were analysed after Engel and Händel (2011) with a high-performance anion exchange

435 chromatography (HPAEC) (DIONEX ICS3000DC). More detail on molecular DOM composition may  
436 be found in Loginova et al. (2019) and Maßmig et al. (2020).

437 Bacterial abundance was determined by flow cytometry on a FACS Calibur (Becton Dickinson) after  
438 Gasol and Del Giorgio (2000) from 1.6 ml sample, fixed with 0.75  $\mu$ l 25 % glutaraldehyde on board and  
439 stored at -80 °C until analyses. To 400  $\mu$ l sample 10  $\mu$ l Flouresbrite® fluorescent beads (Polyscience,  
440 Inc.) and 10  $\mu$ l Sybr Green (Invitrogen) were added.

441 For the extracellular enzymes leucine aminopeptidase and  $\beta$ -glucosidase, potential hydrolytic rates were  
442 determined after Hoppe (1983). L-leucine-7-amido-4-methylcoumarin (Sigma Aldrich) and 4-  
443 methylumbelliferyl- $\beta$ -D-glucopyranoside (Acros Organics) were used as fluorescent substrate analogs  
444 and added in final concentrations of 1, 5, 10, 20, 50, 80, 100, and 200  $\mu$ mol l<sup>-1</sup> in 69 well plates  
445 (Costar). Afterwards 200  $\mu$ l sample were added and fluorescence was measured with a plate reader  
446 fluorometer (FLUOstar Optima, BMG labtech) (excitation: 355 nm; emission: 460 nm) after 0 and 12 h  
447 of incubation. For details about incubation conditions and subsequent calculations see Maßmig et al.  
448 (2020).

449 Bacterial production was determined by measuring the incorporation of labeled leucine (3H) that was  
450 added at a saturating final concentration of 20 nmol (specific activity 100 Ci mmol<sup>-1</sup>, Biotrend) in 1.5  
451 ml of sample (Kirchman et al., 1985; Smith and Azam, 1992). After 3 hours of incubation, samples  
452 were measured with a liquid scintillation counter (Hidex 300 SL, Triathaler™, FCI). For the estimation  
453 of incorporated carbon, a conversion factor of 1.5 kg C mol<sup>-1</sup> leucine was used (Simon and Azam,  
454 1989). For further details about incubation conditions, sample treatment and subsequent calculations see  
455 Maßmig et al. (2020).

456 FDOM samples were filtered through 0.2  $\mu$ m polyethersulfone syringe filters (CHROMAPHIL® Xtra  
457 PES-45/25) and stored into 15 ml combusted (450 °C, 8 h) amber-glass vials and at -20 °C.

458 FDOM was determined using 3D-Excitation-Emission-Matrix (EEM) fluorescence spectroscopy  
459 followed by parallel factor analysis (PARAFAC). EEM spectra were obtained using a Cary Eclipse  
460 Fluorescence Spectrophotometer (Agilent Technologies) within 230–455 nm excitation wavelength  
461 range in 5 nm intervals and within 290–700 nm emission wavelength range in 2 nm intervals. All  
462 FDOM samples were brought to the room temperature before analyses, the measurements were

463 performed under temperature-controlled conditions at 19 °C using Cary Single Cell Peltier Accessory  
464 (VARIAN). All the fluorescence measurements were performed at 0.2 s integration times and 5 nm slit  
465 width on both monochromators.

466 The 3D fluorescence spectra were corrected and analysed by PARAFAC (Stedmon and Bro, 2008),  
467 using “drEEM toolbox for MATLAB” after Murphy et al. (2013). The humification and biological  
468 indexes were calculated after (Zsolnay et al., 1999). CDOM samples were collected into combusted  
469 (450 °C, 8 h) 40 ml amber-glass vials. All samples were passed through 0.2 µm polyethersulfone  
470 syringe filters (CHROMAPHIL® Xtra PES-45/25, MACHEREY-NAGEL GmbH & Co.KG) before  
471 storage at 4 °C. Samples were processed within 1–90 days. The measurements were performed at room  
472 temperature (~19 °C) using Shimadzu® 1800 UV-VIS double-beam spectrophotometer within 230–750  
473 nm wavelength range against MilliQ water at 1 nm intervals. More details on the spectroscopic analyses  
474 may be found in Loginova et al. (2015, 2016, 2020).

### 475 **4.3.3 Microbial Oxygen Consumption, Nitrogen Transformation and Primary** 476 **Productivity Rates**

477 Dinitrogen (N<sub>2</sub>) and carbon (C) fixation rates were measured on 9 cruises (Löscher and Mehrrens,  
478 2021a; see Table 2 and supplementary Table S17) using shipboard incubation experiments,  
479 complemented with nutrient and oxygen manipulations. During cruises M77/3, M77/4, and M80/2, N<sub>2</sub>  
480 fixation was measured using the bubble addition method following Montoya et al. (1996). During  
481 M80/2 a novel method based on <sup>15</sup>N<sub>2</sub> gas pre-dissolution, which was developed by Mohr et al. (2010),  
482 was tested in parallel to the classic method. An underestimation of N<sub>2</sub> fixation rates by the classic  
483 method has been observed (Großkopf et al., 2012) and therefore the novel ‘pre-dissolution method’ was  
484 applied during the following cruises (M83/1, M90, M91, M93, M97, M104, M107). Single cell N<sub>2</sub>  
485 fixation rates to differentiate the contribution of different clades of N<sub>2</sub> fixers were measured using a  
486 NanoSIMS (Martinez-Perez et al., 2016). C fixation was determined using <sup>13</sup>C- bicarbonate additions  
487 (e.g. Grosskopf et al., 2012; Löscher et al., 2014) and heterotrophic C turnover was determined using  
488 <sup>13</sup>C- glucose additions (Löscher et al., 2014, 2016).

489 Potential rates for microaerobic respiration and aerobic organic matter degradation as a source of  
490 ammonia ( $\text{NH}_4^+$ ) in the Peruvian OMZ was assessed using an  $^{18}\text{O}_2$  labelling approach suitable for  
491 microaerobic respiration (Holtappels et al., 2014). Further, the effects of  $\text{O}_2$  depletion associated with  
492 marine snow particles on microbial respiration was explored by combining  $^{18}\text{O}_2$  labelling experiments  
493 with in-situ particle size analysis and modelling of aggregate-size dependent respiration (Kalvelage et  
494 al., 2015). Anammox, denitrification, and nitrification, as well as  $\text{N}_2\text{O}$  production rates were measured  
495 on several cruises (Kalvelage et al., 2011; Löscher et al., 2012; Callbeck et al., 2017; Bourbonnais et al.,  
496 2017; Frey et al., 2020; Löscher and Mehrrens, 2021b; see Table 2 and supplementary Table S18) using  
497 isotope fractionation studies,  $^{15}\text{N}$  tracer additions, and inhibitor studies.

#### 498 **4.3.4 Marine Microbial Diversity and Function**

499 In order to identify key groups of microbes for C, N, and  $\text{O}_2$  turnover, microbial metabolic rate  
500 measurements were complemented with analyses of metagenomes and metatranscriptomes from the  
501 Eastern Tropical South Pacific (ETSP) and Eastern Tropical North Atlantic (ETNA). In addition, key  
502 gene and transcript characterization and quantification for aerobic respiration (Kalvelage et al., 2015),  
503  $\text{N}_2$  fixation (Großkopf et al., 2012; Löscher et al., 2014, 2015, 2016, 2020), anammox, denitrification  
504 and nitrification (Kalvelage et al., 2013, Löscher et al., 2012, 2015, 2016) were carried out using Sanger  
505 sequencing and quantitative real time polymerase chain reactions (PCRs) as described in Löscher et al.,  
506 (2012, 2014). To assure high quality sampling of nucleic acids, sample filtration times did not exceed  
507 20 min and samples were shock-frozen in liquid  $\text{N}_2$  and stored at  $-80\text{ }^\circ\text{C}$  (e.g., Löscher et al., 2014).  
508 Early metagenomic and -transcriptomic analyses targeted an understanding of microbial communities in  
509 the surface waters above the OMZ, the oxyclines, OMZ core waters, and sulfidic anoxic waters, as  
510 summarized in Löscher et al. (2016) and were based on Pyrosequencing technology (e.g., Schunck et  
511 al., 2013; Desai et al., 2013). Due to the rapid advance in sequencing technologies, it was possible to  
512 generate more conclusive metagenomes for targeted studies on sulphur, N, and  $\text{O}_2$  cycling during  
513 M90–M93. Nine metagenomes were sequenced using Illumina HiSeq technology (Callbeck et al., 2018)  
514 from those cruises. On those datasets, genome assemblies and phylogenetic classifications were carried  
515 out to explore the role of a key microbial cluster, SUP05, and its role in OMZ sulphur and nitrogen

516 turnover. Metagenomes from the ETNA cruise M107 were sequenced in the context of the development  
517 of anoxic water masses in collaboration with the DFG-funded Cluster of Excellence ‘The Future Ocean’  
518 (Löscher et al., 2015). In addition to full metagenomes, targeted community studies were carried out  
519 using 16S rDNA amplicon sequencing sequenced on Illumina MiSeq sequencers from the same anoxic  
520 eddy in the ETNA and from the Peruvian OMZ (Löscher et al., 2015; Scholz et al., 2016). All published  
521 sequences were submitted to the National Center for Biotechnology Information’s archives (NCBI;  
522 <https://www.ncbi.nlm.nih.gov/>; see Table 2 and supplementary Table S19). Physical DNA libraries  
523 were generated, and subsamples are available on request from C. Löscher.

524 In addition to this mainly pelagic work, transcriptomes, and genomes of the denitrifying benthic  
525 foraminifera *Globobulimina turgida* and *G. auriculata* from the seasonally hypoxic Swedish Gullmar  
526 Fjord were analysed (Woehle and Roy et al., 2018). The obtained information was used to describe the  
527 foraminifera unique eukaryotic ability to denitrify and colonize low-oxygen environments. Sequences  
528 were submitted to the NCBI’s Sequence Read Archive (accession numbers SRR6202052 -  
529 SRR6202078) and to the transcriptome sequencing archive (accession numbers GGCE00000000 and  
530 GGCD00000000). The genome assembly was submitted to NCBI (draft genomes PIVH00000000-  
531 PIWH00000000; unassigned contigs: PJEL00000000). Furthermore, individually amplified 18S rRNA  
532 gene sequences of the two analysed foraminiferal species were submitted to GenBank (MG800664 to  
533 MG800667).

### 534 **4.3.5 Zooplankton and Particle Distribution**

535 A Hydrobios Multinet Midi with an aperture of 0.25 m<sup>2</sup> and 5 nets (mesh size 200 µm) was deployed  
536 for vertically stratified hauls on several cruises (Hausse et al., 2021a; see Table 2 and supplementary  
537 Table S20), mostly in paired day-night hauls to quantify diel vertical migration. Standard depths used  
538 for these deployments were 1000-600-300-200-100-0 m. On cruise M93, a Multinet Maxi (9 nets, 333  
539 µm mesh) was used instead. Samples were fixated in 4% formaldehyde in seawater solution, scanned at  
540 GEOMAR or at the Ocean Science Center Mindelo, Mindelo/Cape Verde, and analyzed using  
541 automated imaging software (Gorsky et al., 2010) allowing taxonomical classification as well as the  
542 estimation of taxon-specific biomass (Lehette and Hernández-León, 2006) and metabolic rates. Scanned

543 image data are available on EcoTaxa (<https://ecotaxa.obs-vlfr.fr/>; Picheral et al., 2017) upon request  
544 from R. Kiko and H. Hauss. Taxon-specific biomass and metabolic rate estimates are publicly available  
545 on PANGAEA (Kiko and Hauss, 2019; Kiko et al., 2020).

546 To expand the ecological knowledge on fragile organisms (such as giant rhizaria, medusae,  
547 ctenophores, and siphonophores) in situ imaging techniques were employed in addition to net sampling.  
548 An Underwater Vision Profiler 5 (UVP5; Picheral et al., 2010) was routinely mounted on the  
549 CTD/rosette during most SFB 754 cruises since 2012 (Kiko et al., 2021a; see Table 2 and  
550 supplementary Table S21). During the cruises in 2012 and 2013 a UVP5 was used that was kindly  
551 provided by the Laboratoire d’Océanographie de Villefranche-sur-Mer (France). The instrument consists  
552 of one down facing HD camera in a steel pressure case and two red LED lights which illuminate a 0.88  
553 to 0.93 l volume (depending on the actual set-up). During the downcast, the UVP5 takes 3–20 pictures  
554 of the illuminated field per second. For each picture, the particles are counted and sized immediately  
555 and the data is stored in the instrument for later analysis. Furthermore, images of particles with a  
556 size >500 µm are saved as separate “vignettes” - small cut-outs of the original picture - which allow for  
557 later, computer assisted, identification of these particles and their assignment into different particle,  
558 phyto-, and zooplankton groups. Since the UVP5 was integrated in the CTD and has its own pressure  
559 sensor, fine-scale vertical distribution of particles and major planktonic groups can be related to  
560 environmental data. UVP5 particle and zooplankton data from all cruises can be accessed on EcoTaxa  
561 (<https://ecotaxa.obs-vlfr.fr/>; Picheral et al., 2017). UVP5 particle data has undergone further quality  
562 controls since their first publication and were merged with data from other international collaborators to  
563 yield a global dataset. This dataset, to be found at <https://doi.org/10.1594/PANGAEA.924375>  
564 supersedes the previous UVP5 particle datasets and should be used for further research, whereas the  
565 original datasets are still available for reference.

#### 566 **4.3.6 Zooplankton Metabolic Rates**

567 Zooplankton metabolic rates (oxygen respiration and ammonium excretion) at different temperatures,  
568 oxygen, and carbon dioxide partial pressures (Kiko et al., 2015; 2016) were measured during three  
569 cruises (Kiko et al., 2021b; see Table 2 and supplementary Table S22). Zooplankton was collected by

570 different nets and the entire catch immediately transferred to 10 l beakers containing pre-cooled  
571 seawater. Diel vertical migrators were sampled at the surface at night. Individuals for respiration rate  
572 measurements were isolated immediately and maintained in filtered seawater for 1 to 13 hours at the  
573 chosen experimental temperature (13, 18, or 23 °C). Only animals appearing unharmed and fit were  
574 used for experiments. Water for the respiration and excretion rate trials was UV-treated, filtered over a  
575 0.2 µm sterile filter, and supplemented with antibiotics (25 mg l<sup>-1</sup> ampicillin and 25 mg l<sup>-1</sup>  
576 streptomycin). Subsequently, the water was bubbled with different Gas mixtures (N<sub>2</sub>, O<sub>2</sub>, CO<sub>2</sub>; see Kiko  
577 et al., 2016 for details) adjusted to represent different environmental *p*O<sub>2</sub> and *p*CO<sub>2</sub> levels. Incubation  
578 bottles (12 to 280 ml) were pre-filled with the respective incubation water and the animals quickly  
579 added, transferring as little water as possible. The incubation bottles were equipped with a PreSense  
580 oxygen microsensors and readout was conducted from the outside, using a fibre optic cable and a 4-  
581 or 10-channel Oxy-Mini (PreSens Precision Sensing GmbH, Regensburg, Germany). Incubations were  
582 conducted in the dark in 10 l water baths located inside temperature-controlled incubators. Experiments  
583 were generally conducted for a maximum of 16 hours to avoid microbial growth, which would have  
584 affected the ammonium measurements. Generally, three incubations were combined with one animal  
585 free control incubation, which served to estimate microbial background respiration and ammonium  
586 concentrations in these controls. As oxygen levels within the bottles declined, respiration rates could  
587 also be estimated at other than the pre-set conditions. After an acclimation phase of 1 hour, respiration  
588 rates were calculated for 1-hour intervals using a linear regression. The microbial background  
589 respiration rate was subtracted from the experimental incubation respiration rate to yield the animal's  
590 respiration rate. Generally, 1 or 15 ml water samples were taken at the end of the incubation to  
591 determine ammonium concentrations fluorometrically according to Holmes et al. (1999). Ammonium  
592 excretion rates were calculated as the difference between the incubation and animal-free controls.  
593 Animals used in the experiments were afterwards recovered, frozen at -80 °C and transported to the  
594 home laboratory, where their dry-weight was determined. The rates presented should be considered  
595 routine metabolic rates, as activity was not monitored continuously (Prosser, 1961). Please refer to Kiko  
596 et al. (2015, 2016) for further experimental details.

### 597 **4.3.7 Nutrient amendment experiments**

598 Bioassays with amendment of DIN, DIP, and various trace elements were conducted in short-term  
599 replicated bottle incubations to determine limiting elements for phytoplankton growth (Browning et al.,  
600 2017; Hauss et al., 2021b; see Table 2 and supplementary Table S23). Shipboard mesocosm  
601 experiments with a duration from 7 to 11 days were conducted on several cruises in the ETNA and  
602 ETSP and land-based on Cape Verde to determine the impact of N:P stoichiometry on the pelagic  
603 community (Franz et al., 2012b; Hauss et al., 2012; Czerny et al. 2016; Meyer et al., 2016) and  
604 dissolved organic compounds (Loginova et al., 2015; Engel et al., 2015). In austral summer 2017, a  
605 large-scale in situ mesocosm experiment was conducted off Callao (Peru) using the KOSMOS facilities.  
606 Deep water was injected into the mesocosms to simulate an upwelling event and the response of the  
607 planktonic ecosystem was monitored for 50 days (Bach et al., 2020).

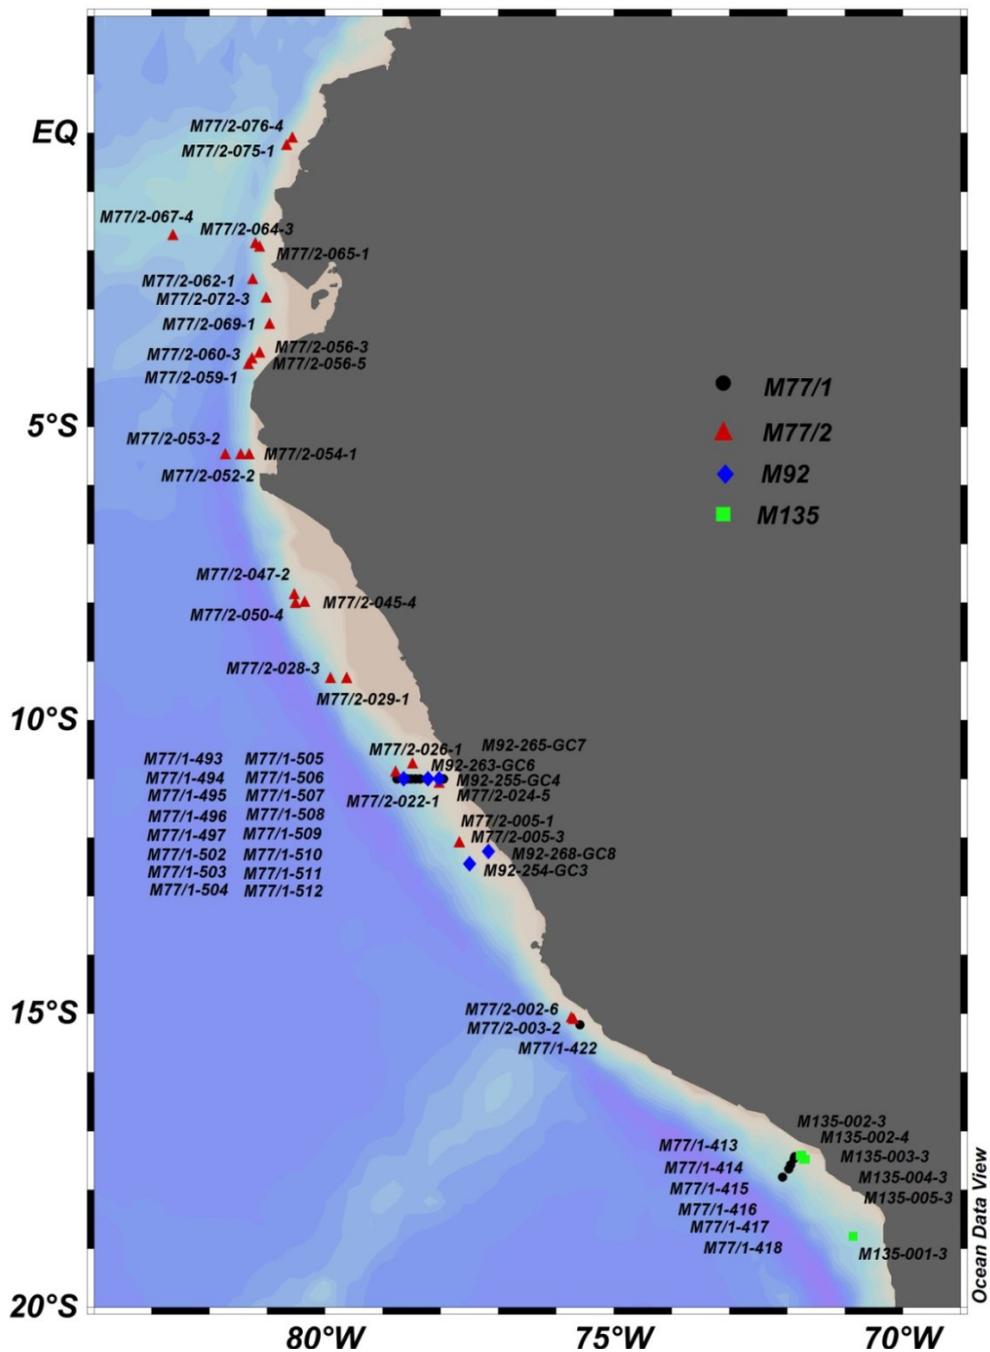

### 609 **4.4 Paleoceanography**

610 One of the objectives of the SFB 754 was the reconstruction of the factors controlling the intensity and  
611 the spatial extent of the OMZ in the Eastern Tropical Pacific, specifically off Peru, since the Last  
612 Glacial Maximum (21000 years ago). For the purpose of these paleoceanographic studies, long gravity  
613 cores were recovered during four scientific expeditions (M77/1, M77/2, M92, and M135; see Figure 4).  
614 During the cruises M77/1 and M77/2 in 2008, 51 sediment cores were retrieved below and in the centre  
615 of the OMZ, from  $\sim 17^\circ$  S to the equator (Pfannkuche et al., 2011; see Figure 4). Most of the records  
616 collected in the core of the OMZ (i.e.  $\sim 200$  to  $\sim 500$  m depth), from  $\sim 8$  to  $15^\circ$  S, show sedimentary  
617 discontinuities during the Holocene (last 11700 years), which preclude high resolution  
618 paleoceanographic reconstructions in this area (Erdem et al., 2016; Salvattecchi et al., 2014, 2016). Based  
619 on the information collected during M77/1 and M77/2 and also on the scientific literature, cruise M135  
620 aimed specifically at finding the most complete Holocene sequence in the Eastern Tropical South  
621 Pacific. For this purpose, a detailed paleoceanographic survey took place at  $\sim 17^\circ$  S, an area that is less  
622 affected by processes that can produce sediment discontinuities. Six sediment cores were retrieved, two

623 of which contained the most complete sediment sequences for the last 10000 years (Salvatteci et al.,  
624 2019).

625 Data from the gravity and piston cores taken during cruises M77/1, M77/2, M92, and M135 has been  
626 assembled by Salvatteci and Mehrrens (2021a; see Table 2 and supplementary Table S24). A piston  
627 corer was used on cruise M77/2 while on M77/1, M92, and M135 a long gravity corer was employed. In  
628 total 57 sediment cores were taken on the three cruises. The water depths of the sampling sites ranged  
629 from 144 to 2591 m; however, most of the cores were retrieved in the core of the OMZ, i.e. between  
630 ~200 and ~700 m depth. The average sediment recovery of the piston cores was 1168 cm. For the  
631 gravity cores, the average sediment recovery was 318 cm for M77/1 and 609 cm for M135. Up to date,  
632 these sediment cores have been used in 17 scientific publications that aim to understand climate and  
633 ocean variability and its effect on the OMZ at multiple timescales (Salvatteci and Mehrrens, 2021a; see  
634 Table 2 and supplementary Table S24). Age models (Salvatteci and Mehrrens, 2021b; see Table 2 and  
635 supplementary Table S25), X-Ray Fluorescence (XRF) measurements (Salvatteci and Mehrrens, 2021c;  
636 see Table 2 and supplementary Table S26), and other geochemical records (Salvatteci and Mehrrens,  
637 2021d; see Table 2 and supplementary Table S27) have been assembled and published. In addition, core  
638 tops of near sediment surface cores from multiple-corers (MUCs) have been used to establish local  
639 calibrations for several paleoproxies, such as redox-sensitive elements in foraminifera (i.e. Mn/Ca, I/Ca  
640 and Fe/Ca), foraminiferal assemblages, and stable Mo and N isotopes (Glock and Mehrrens, 2021; see  
641 Table 2 and supplementary Table S28).

642

643 Figure 4. Map of the Eastern Tropical South Pacific showing the location of the gravity cores and piston cores taken during  
644 cruises M77/1 (black circles), M77/2 (red triangles), M92 (blue diamonds) and M135 (green squares).

## 645 **4.5 Benthic fluxes and surface sediment sampling**

646 In the Peruvian upwelling area, benthic biogeochemical fieldwork focused on the FS *Meteor* cruises  
647 M77/1, M77/2, M92, M136, and M137. Off Mauritania, benthic investigations were mainly conducted  
648 on FS *Maria S. Merian* cruise MSM17/4 and FS *Meteor* cruise M107 (Sommer et al., 2021; see Table 2  
649 and supplementary Tables S29 to S35). Research questions addressed organic carbon degradation,  
650 associated element cycling, and solute fluxes in the benthic boundary layer in response to variable  
651 bottom water redox conditions and hydrodynamic forcing (e.g. Bohlen et al., 2011; Dale et al., 2014;  
652 Dale et al., 2016; Dale et al., 2019; Dale et al., 2021; Loginova et al., 2020; Lomnitz et al., 2016;  
653 Noffke et al., 2012; Plass et al., 2020; Schroller-Lomnitz et al., 2019; Sommer et al., 2016). Effects of  
654 variable bottom water conditions on seabed nutrient and trace metal release were studied during in situ  
655 and ex situ on-board sediment incubations and the analysis of pore water geochemistry. Further  
656 emphasis was placed on resolving the imprint of specific microbial processes and foraminiferal  
657 metabolic activity on element turnover and exchange across the sediment water interface (e.g. Glock et  
658 al., 2013, 2019, 2020; Gier et al., 2016, 2017; Scholz et al., 2016; 2017). The results were further  
659 interpreted using benthic numerical models (e.g. Bohlen et al., 2011; Dale et al., 2014, 2015, 2016,  
660 2017, 2019). The corresponding DOIs are listed in the supplementary Tables S29 to S35.

### 661 **4.5.1 In situ solute fluxes measured using the benthic flux lander BIGO**

662 Benthic solute fluxes of major elements traversing the Peruvian OMZ at 11° S and 12° S were  
663 determined based on data measured in situ using the two Biogeochemical Observatories BIGO I and  
664 BIGO II during FS *Meteor* cruises M77/1-2 (2008, 11° S; Pfannkuche et al., 2011; see also  
665 supplementary Table S29), M92 (2013, 12° S; Sommer et al., 2014; see also supplementary Table S31),  
666 M136 (2017, 12° S; Dengler and Sommer, 2017; see also supplementary Table S34) and M137 (2017,  
667 12° S; Sommer et al., 2019; see also supplementary Table S35). Solute fluxes along a zonal transect at  
668 18° N off Mauritania were determined during the FS *Maria S. Merian* cruise MSM17/4 in 2011  
669 (Pfannkuche, 2014; see also supplementary Table 30) and FS *Meteor* cruise M107 in 2014 (Sommer et  
670 al., 2015; see also supplementary Table S32). The landers are described in detail by Pfannkuche and

671 Linke (2003) and Sommer et al. (2008, 2009, 2016). Note that during the cruises M77/1-2 the landers  
672 were named BIGO and BIGO T instead of the usual terminology of BIGO I and BIGO II .

673 During all cruises the basic functioning principle of the BIGO type lander was the same. However, for  
674 some measurements and experiments the lander set-up was modified slightly. Details of the  
675 modifications are provided in cruise reports and specific publications. In brief, the BIGO lander  
676 contained two circular flux chambers (internal diameter 28.8 cm, area 651.4 cm<sup>2</sup>). BIGO T contained  
677 only one flux chamber, the second one was replaced by the underwater mass spectrometer TETHYS,  
678 operated by R. Camilli (Woods Hole Oceanographic Institution). A TV-guided launching system  
679 allowed smooth emplacement of the observatories at selected sites on the sea floor. Several hours after  
680 the observatories were placed on the sea floor the chambers were slowly driven into the sediment (~30  
681 cm h<sup>-1</sup>). During this initial time period, the water inside the flux chamber was periodically replaced with  
682 ambient bottom water. After the chamber was fully driven into the sediment, the chamber water was  
683 again replaced with ambient bottom water to flush out solutes that might have been released from the  
684 sediment during chamber insertion. The water volume enclosed by each benthic chamber was variable  
685 but typically ranged from 7 to 18 l. To determine benthic solute fluxes, four (M77/1, M77/2) or eight  
686 sequential water samples (M92, M107, M136, M137, MSM17/4) were removed periodically with glass  
687 syringes (volume of each syringe ~ 46 to 47 ml). The syringes were connected to the chamber using 1 m  
688 long Vygon tubes. Prior to deployment, these tubes were filled with distilled water and care was taken  
689 to avoid enclosure of air bubbles. An additional syringe water sampler (4 or 8 sequential samples) was  
690 used to monitor the ambient bottom water. The sampling ports for ambient bottom water were  
691 positioned about 30–60 cm above the sediment-water interface.

692 For the measurement of the dinitrogen/argon ratio (N<sub>2</sub>/Ar), CO<sub>2</sub> and/or dissolved inorganic carbon  
693 (DIC) concentrations on cruises M92, M107, M136, M137, and MSM17/4, water samples were pumped  
694 into four (M92, M107, MSM17/4) or eight (M136, M137) 750 mm long glass tubes with an internal  
695 diameter of 4.6 mm (volume ~12.5 ml) using self-constructed underwater peristaltic pumps. Prior to  
696 deployment, each glass tube was filled with distilled water that was completely replaced by the sample  
697 without dilution. Four (M92, MSM17/4) or eight tubes (M136, M137, M107) were used to sample each  
698 chamber and the ambient bottom water. During all cruises, the incubations at the sea floor were

699 conducted for time periods of at least 24 h and to up 48 h, defined as the time interval between insertion  
700 of the chamber into the sediment and filling of the last syringe . Immediately after retrieval of the  
701 observatories, the water samples were transferred to the on-board cool room for further sample  
702 processing.

703 Dissolved O<sub>2</sub> concentration in each chamber and in the ambient bottom water was measured using  
704 optodes (Aanderaa Systems; Tengberg et al., 2006). The precision of the sensors was better at lower  
705 concentrations ( $\pm 0.5 \mu\text{M}$ ) than at higher concentrations of 300–500  $\mu\text{M}$  ( $\pm 1 \mu\text{M}$ ). The effect of salinity  
706 on the measured O<sub>2</sub> concentration was corrected internally by the optode using a salinity of 35. O<sub>2</sub>  
707 concentrations were cross-calibrated with automated Winkler O<sub>2</sub> measurements in parallel water  
708 samples. For the calculation of the total oxygen uptake (TOU), the linear part of the O<sub>2</sub> time series after  
709 the start of the chamber incubation was used. In addition to O<sub>2</sub>, fluxes of nitrate (NO<sub>3</sub><sup>-</sup>), nitrite (NO<sub>2</sub><sup>-</sup>),  
710 ammonium (NH<sub>4</sub><sup>+</sup>), phosphate (PO<sub>4</sub><sup>3-</sup>), and silicic acid (H<sub>4</sub>SiO<sub>4</sub>) were measured routinely. During some  
711 lander deployments, further biogeochemical parameters such as sulphide (e.g. M92), dissolved organic  
712 matter (M136/M137), or trace metals (M136/M137) were measured.

713 Fluxes of routinely measured solutes were calculated from the linear increase or decrease of  
714 concentration versus time and the height of the water in each chamber. Starting with cruises M136 and  
715 M137, a logistic function in addition to linear regression was used to capture the occasional sigmoidal  
716 temporal trend of solutes.

717 The landers were also equipped to recover the surface layer of the incubated sediment (~10–15 cm),  
718 which serves as a check for sediment disruption during seafloor operations and chamber insertion. The  
719 sediment surface for most deployments during the cruises was intact and undisturbed. The sediment was  
720 routinely subsampled for geochemical pore water analysis and depending on the specific goals of the  
721 cruise for biological analyses (e.g. foraminifera, sulfur bacteria, bacterial metagenomic analyses, and  
722 viruses). Details of sampling and processing of water and sediment samples, as well as their  
723 geochemical analysis, are presented in the respective cruise reports and specific publications.

724 As indicated above, in addition to standard flux measurements of the natural system, during Meteor  
725 cruise M137 a series of in situ experiments was conducted. During these incubations, NO<sub>3</sub><sup>-</sup> and O<sub>2</sub>  
726 concentrations inside the benthic chamber were experimentally manipulated (cf. cruise report by

727 Sommer et al., 2019). During cruises M136 and M137, the BIGO lander was slightly modified to enable  
728 trace metal measurements in the benthic chambers and in the bottom water (cooperation with F. Scholz,  
729 GEOMAR). To determine gradients of nutrients and trace metals within the benthic boundary layer the  
730 BIGO was equipped with an extendable arm (cooperation with F. Scholz, GEOMAR). Subsequent to  
731 the placement of the lander on the seafloor the arm unfolded and allowed water sampling in several  
732 heights above the seafloor. Water samples were collected in appropriate sampling bags.

### 733 **4.5.2 Near-surface sediment coring**

734 Undisturbed sediment cores for the biogeochemical analysis of near surface sediment were retrieved  
735 using a multiple-corer (MUC) and using push-cores inserted into the sediment retrieved with the BIGO  
736 incubation chambers once on deck. The MUC was equipped with 6–8 Perspex liners 60 cm long with an  
737 internal diameter of 10 cm. The MUC was lowered into the sediment with a speed of 0.3 m s<sup>-1</sup> in all  
738 deployments. Once on the sea floor, the liners were pushed into the sediment under gravity by a set of  
739 lead weights. Penetration ranged from 10 to 50 cm depending on the sediment type. BIGO push-cores  
740 had a diameter of 10 cm and recovered around 5–20 cm of sediment. After retrieval, all cores were  
741 transferred to an on-board cool room set to the temperature of the bottom and processed immediately.  
742 Supernatant bottom water of the MUC cores was sampled and filtered for subsequent analyses. In  
743 general, at least one MUC and one BIGO sediment core was taken at the same site, but not necessarily  
744 on the same day. Sub-sampling for redox-sensitive parameters (e.g. dissolved Fe, nutrients) was mainly  
745 achieved by sectioning the sediment cores inside an argon filled glove bag. The sampling depth  
746 resolution increased from 0.5 or 1 cm at the surface to 4 cm at larger depths. Sediment samples were  
747 then spun in a refrigerated centrifuge at 4000 G for 20 min to separate the porewater from the  
748 particulates. Subsequently, the porewater samples were filtered (0.2 µm cellulose-acetate syringe filters)  
749 under argon. In sandy sediments (MSM17/4, M107), rhizone samplers were used to extract porewaters.  
750 All BIGO cores were sectioned either under argon or ambient atmosphere. Standard analytes measured  
751 in porewater included nutrients, trace metals, total alkalinity, major ions, and dissolved hydrogen  
752 sulphide.

### 753 **4.5.3 Metabolic rates of benthic microorganisms and their role in benthic N-cycling**

754 Denitrification and oxygen respiration rates of benthic microorganisms (i.e. foraminifera) were  
755 measured during one cruise to the Peruvian OMZ (M137) and one research trip to the Swedish Gullmar  
756 Fjord (Woehle and Roy, 2018; Glock et al., 2019). The rates were calculated from linear steady-state  
757 gradients of nitrous oxide or oxygen in glass microcapsules (after Høgslund et al., 2008; Piña-Ochoa et  
758 al., 2010; Glock et al., 2019). Abundances of living benthic foraminifera were determined on three  
759 cruises to the Peruvian OMZ (Mallon et al., 2012; Glock et al., 2013; Erdem et al., 2020). Total  
760 abundances and individual metabolic rates were used to upscale to the total contribution of foraminifers  
761 to benthic N-fluxes and nitrate storage (Glock et al., 2013; Glock et al., 2019). On M137, intracellular  
762 phosphate storage was also investigated (Glock et al., 2020).

## 763 **5 Data availability**

764 Data that has been submitted to the World Data Center PANGAEA (<https://www.pangaea.org>) is freely  
765 available and collection DOIs are listed in Table 2. A complete and up to date list of SFB 754 data  
766 available on PANGAEA can be obtained by entering ‘SFB754’ in the search field. Some of the data  
767 collected by the project has not been fully processed and thus has not yet been published. We expect  
768 this data to be available in the near future and have included references to it in the tables though the  
769 DOIs are not yet available.

770 Data that has been submitted to the database SOCAT (<https://www.socat.info>) is freely available.

771 Data that has been submitted to the database MEMENTO (<https://memento.geomar.de>) is freely  
772 available, but access has to be granted.

773 Data that has been submitted to the NCBI (<https://www.ncbi.nlm.nih.gov/>) is freely available.

774 Data and images that are archived on ExoTaxa (<https://ecotaxa.obs-vlfr.fr/>) are freely available, but  
775 access has to be granted.

## 776 **6 Conclusions**

777 The SFB 754 project was a milestone for the investigation of biogeochemical and physical interactions  
778 in the tropical oceans. The extended period of funding granted by the German Research Foundation  
779 allowed for the development of a highly interdisciplinary research program that has lead to a wealth of  
780 new insights documented in a large number of publications, theses, and presentations. The open access  
781 publication of the large number of different data sets collected during the project can be expected to  
782 form a lasting legacy well beyond the project itself. We anticipate and look forward to many more  
783 publications and projects that will build upon this unique basis.

## 784 **7 Author contribution**

785 Each of authors wrote subsections of the manuscript and provided data for the tables. GK combined the  
786 input and wrote the common sections. HM handled the data submissions to PANGAEA.

## 787 **8 Competing interests**

788 The authors declare that they have no conflict of interest.

## 789 **9 Acknowledgements**

790 We thank the Cape Verdean, Chilean, Ecuadorian, Moroccan, Peruvian, and Senegalese authorities for  
791 giving the permission to conduct studies in their territorial waters. We gratefully acknowledge the  
792 financial support for the “Sonderforschungsbereich 754: Climate-Biogeochemistry Interactions in the  
793 Tropical Ocean” by the DFG. The main support for the cruises M91 and MSM18/3 came through the  
794 BMBF-funded joint projects SOPRAN I-III (FKZ 03F0462, 03F0611, and 03F0662). Cruise SO243  
795 was mainly supported by the BMBF-funded project SO243 – ASTRA-OMZ (FKZ 03G0243A). Support  
796 for cruises ATA\_IFMGOMAR\_4, M80/1, MSM18/2, MSM22, M130, and M145 came also through  
797 the BMBF-funded joint projects NORDATLANTIK and RACE (FKZ 03F0443B and 03F0729D).

798 Cruises MSM22 and M105 received further support from the EU-funded project CARBOCHANGE  
799 (grant 264879).
