

Dear Oliver Bothe,

Thanks for your positive comments and suggestions. Please, find our answers below.

General comments

There is one suggestion for the future of the database. I would like to invite the authors to reconsider the general structure of the database and/or to provide a set of functions that allow an even easier interaction with the data than is already the case. Obviously, it is unlikely that there is a set of tools that accounts for all preferences of all potential users, and neither is it likely that there is a database structure that is intuitive even for the most inexperienced user. This suggestion originates from my struggles to access the data.

Accessing and querying any database is challenging for non-specialists but, as the reviewer acknowledges, it would be impossible to provide functions for all types of software and that addresses all the preferences that data users may have. To facilitate potential database users, we have created a set of “example queries” that are available along with the database files. While these 27 queries do not cover all potential needs of the researchers using the database, they provide a starting point. The existence of the example queries is mentioned in the README file available with the database in the data repository, but we will add text in the manuscript to make this clearer.

The structure of the database was agreed with the wider speleothem community as the most efficient way to capture the metadata and data available from speleothem records. A detailed description of the database and all its parameters is available in the paper describing the first version of the database (Atsawawanunt et al., 2018). We will make sure that this is clear in the text. Note that it is also possible to download the individual tables comprising the database, allowing a user to reconfigure this in any format they prefer.

Minor

Suggestion: Add a list of abbreviations and technical terms. From my point of view, a database and a database paper is of interest for a community that extends beyond the specialists in a field. Therefore it might be advisable to provide a table or an appendix with definitions of technical terms and abbreviations. Otherwise, already Figure 1 may overwhelm some potential users.

In this paper, we did not define all concepts presented in the current database structure because these are already defined in Atsawawaranunt et al., 2018. This publication is cited in the manuscript as the source to look at for a detailed description of the database (L170-172: “*The structure and contents of all tables except the new sisal_chronology table are described in detail in Atsawawaranunt et al. (2018a). Here, we focus on the new sisal_chronology table and on the changes that were made to other tables in order to accommodate this new table (See section 2.3).*”).

We are unsure as to whether providing that information again in the supplementary material of this paper would make things substantially different than referring to a paper previously published in the same journal. However, we will make it clear earlier in the manuscript that all concepts that appear in the database are defined in that publication and we hope that this will address the reviewer’s concern satisfactorily.

Line 16: The authors write here 294 and later 293. Obviously “cave sites” and “cave systems” may mean different things, but I would like to ask the authors to clarify.

We used cave sites and cave systems interchangeably but will change it to cave sites throughout.

Line 81: 10.5281/zenodo.3591197 is not a valid doi, i.e. the link is broken.

Thank you for spotting this. The link to the ensemble file is now working.

This occurs again at line 271.

Thank you for spotting this. This link is now working properly.

The doi in line 270 is not valid either.

Thank you for spotting this. This link is now working properly.

Finally, in section 6 (lines 273,274, 276) and in the supplementary materials there are a few dois given as links but missing the “doi.org”-part and therefore not working directly.

Thanks. We will revise the hyperlinks in the manuscript as well as in the supplementary material before submitting a revised version of this manuscript.

Line 96: “This is consistent” implies that there are differences to these previous approaches. If these differences can be summarised shortly, it may be helpful to detail them.

By “this is consistent” we mean that our approach is equivalent, in that it produces highly similar results (apart from small numerical differences

we expect due to the choice of random number generator and interpolation depths as well as, for COPRA the different programming language). We will clarify this in the revised document.

Provide a script to reproduce Figure 5. I would like to suggest to provide a script that reproduces Figure 5. Parts of this are already included in the GitHub repository for SISAL.AM, cf. the `plot_sisal_overview.R` script. However, the `final.plot` function is only partially doing this and the script does not run as it is. The reading of the input-files has two errors (that can be easily corrected).

We have updated the GitHub repository for SISAL.AM with a script to successfully produce figure 5 as requested by the reviewer: https://github.com/paleovar/SISAL.AM/tree/master/SISAL_plot_functions

Technicalities

Some of the following technicalities are purely subjective. Some are meant to capture already at this stage some of the annotations that will come because of Copernicus' copy editing efforts.

Line 22: Please rephrase the sentence in combination with the parentheses. I am also unsure whether the tense of the verb in the parentheses is correct.

We will rephrase this sentence to: "Speleothems are a rich terrestrial palaeoclimate archive that forms from infiltrating rainwater after it percolates through the soil, epikarst, and carbonate bedrock."

Line 23: I stumbled between the first and second sentence of the paragraph as I felt they were rather badly connected. But that is rather subjective.

We agree with this comment and we will revise these two sentences to: "Speleothems are a rich terrestrial palaeoclimate archive that forms from infiltrating rainwater after it percolates through the soil, epikarst, and carbonate bedrock. In particular, stable oxygen and carbon isotope ($\delta^{18}\text{O}$, $\delta^{13}\text{C}$) measurements made on speleothems have been widely used to reconstruct regional and local hydroclimate changes."

Line 25: Again subjectively, I felt there should already be a new paragraph here.

We agree with the reviewer and we will move the sentence starting with "The Speleothem Isotope Synthesis..." to a new paragraph.

Line 40: I assume it should read "pointed to the" instead of "pointed the".

We agree and we will apply this change.

Line 48: The authors use two different notations for COPRA; COPRA and copRa. It may be that copRa is meant only to refer to the implementation of COPRA, but that does not become clear. I invite the authors to either only use one notation or to clearly specify that copRa is COPRA for R. In this context, I also would invite the authors of copRa to make copRa publically available. Giving an official acronym to the author's COPRA implementation in R already suggests such an availability.

Indeed, copRa is the R implementation of COPRA created specifically for this paper. We will revise the text to make this clear.

As stated in the data availability section, this new copRa implementation is already publicly available at <https://github.com/paleovar/SISAL.AM>.

Similarly it would be nice, if the authors' updated version of StalAge could be made available. This may be already the case, then I missed the pointer. It may be that all what I am writing here is already fulfilled by Roesch (2020, <https://github.com/paleovar/SISAL.AM>). If that is the case then please put the link at all positions where it is relevant.

Yes, as stated in the data availability section, the modified version of StalAge is already publicly available at <https://github.com/paleovar/SISAL.AM>. We will add the links were appropriate in addition to the "data availability section" to make this clear.

Oh, and the link to github.com/paleovar/SISAL.AM given by the authors does not work.

Apologies, the correct link is <https://github.com/paleovar/SISAL.AM> (without the "a" of palaeo). We will correct the link in the manuscript.

Line 154: The authors mention the function *pchip* but not the package. I ask them to add the package and a citation for it. There may be other instances where this is necessary.

The *pchip* function comes from the signal R package, we will add this in the reference list.

We will provide the package name and a citation for it every time that an R function is mentioned in the manuscript.

Personal communications: If I remember correctly, Copernicus' editors are asking authors to provide the year of personal communication and also full names.

We will revise this to: “(Christoph Bronk Ramsey, personal communication, 2019).”

Similarly, the copy editors/typesetting editors are going to check for completeness of citations. I think I noted some missing information, e.g., the DOI for Rehfeld and Kurths (2014). Maybe the authors want to check all citations for completeness already at this stage.

Thanks for spotting this. We will revise all DOIs and references before submitting a revised version of the manuscript.

All links: please provide last accessed dates for all URLs.

We will do.

R packages: I did not check in detail - and I do not always follow this idea myself - but I think it would be nice if the authors could not only mention the R packages they use but also provide references for each of them. It may be that they already do this. I only noted that, e.g., for rBacon there is not a direct reference given, but maybe this is already fulfilled with the references in line 124. Another example is the mentioning of Hmisc on line 99.

We will make sure that all R packages that we used are cited were appropriate and that links are always copied where relevant.

There is an R package with rBacon. We mention it in the data availability section: “rBacon package (version 2.3.9.1) is available on CRAN (<https://cran.r-project.org/web/packages/rbacon/index.html>).” but we will also add its citation where appropriate in the text.

We will also cite the packages of Hmisc (L99) and pchip (L154) in the manuscript.

Software in general: The last comment, obviously, also applies to all other sorts of software, e.g., github-links in the manuscript. Similarly, the authors probably should also provide references for the zenodo-dois in the manuscript.

We will double check that all links are properly working before submitting a revised version of the manuscript. We will also properly cite the zenodo-dois mentioned in the manuscript.

Dear Jud W. Partin,

Thanks for your comments and suggestions. Indeed, data compilations are an enormous community-based effort that we believe will have a strong impact on how science is done. Please, find our answers below highlighted in blue.

Can you please describe in more detail how the 95% confidence intervals are calculated (line 227) in the SISAL chronologies? I'm not sure, but I think it is the 95% spread in the ages using all of the age models, i.e. the spread in the curves in Figure 5 a and b. If so, I wholeheartedly support this idea. If not, then please describe in more detail.

The 95% confidence intervals are the spread for each type of age model separately not the spread considering all of the age models. Specifically, the SISAL chronology table has three columns per age-depth model technique. The first is the median age-depth model and the other two are their corresponding 2 sigma confidence intervals. These confidence intervals have been calculated from the spread of the individual ensembles for each technique that support this approach (specifically, linear interpolation, linear regression, Bchron, Bacon, OxCal and copRa)) and the last 1000 have been kept – and made available – for further analyses. For StalAge we report the uncertainties of the returned age model which are internally calculated and based on iterative fits as well as dating uncertainty. Fig. 5a and 5b show the median age models for each technique (the mean for StalAge). Each of these lines has corresponding confidence intervals which are individually reported.

We have not attempted to merge all SISAL chronologies for any given entity. Different modelling approaches give stronger weighting to some age determinations, so averaging across several methods could yield age-depth relationships that are unrealistic and/or not robust compared to the available U-Th dates.

We will add a statement on how the uncertainties are obtained in the description of each age-depth model technique in section 2.1.

Lines 204-210 are hard to follow. (Author's comment: Please note that we have separated this comment from the paragraph above as it refers to different things).

Original text in L204-210 copied for reference: “The conception and the test of the R workflow, integrating all methods but OxCal, was outlined in Roesch and Rehfeld (2019) and includes automatized checks for the final chronologies except for OxCal. The quality control parameters obtained from OxCal were compared with the recommended values of Agreement Index (A) larger than 60 % and Convergence (C) larger than 95 %, in accordance with the guidelines in Bronk Ramsey (2008). In addition to both model agreement and P-Sequence convergence meeting these criteria, at least 90 % of individual dates had to have an acceptable Agreement and Convergence themselves. OxCal age-depth models failing to meet these criteria were not included in the SISAL chronology table.”

We acknowledge that this paragraph needs rewriting and we will add the following text instead:

“We used an automated approach to age-depth modelling in R because of the large number of records. Roesch and Rehfeld (2019) have described the basic workflow concept and tested it using all of the age-modelling approaches used here except OxCal. The basic workflow involves step-by-step inspection and formatting of the data for the different methods, and the use of pre-defined parameter choices specific to each method. Each age-modelling method is called sequentially. An error message is recorded in the log file if a particular age-modelling method fails, and the algorithm then progresses to the next method. If output is produced for a particular age-modelling method, these age models are checked for monotonicity. Finally, the output standardization routine writes out, for each entity and age-modelling approach, the median age model, the ensembles (if applicable) and information of which hiatuses and dates were used in the construction of the age models. These outputs are then added to the sisal-chronology table (Table 2). All functions are available at <https://github.com/paleovar/SISAL.AM> (last access: 23 July 2020) and CRAN (<https://cran.r-project.org/web/packages/rbacon/index.html>; last access: 31 January 2020).

The general approach for the OxCal age models was similar, and step-by-step details and scripts are provided in <https://doi.org/10.5281/zenodo.3586280> (Amirnezhad-Mozhdehi and Comas-Bru, 2019). The quality control parameters obtained from OxCal were compared with the recommended values of Agreement Index (A) larger than 60% and Convergence (C) larger than 95%, in accordance with the guidelines in Bronk Ramsey (2008), both for the overall model and for at least 90% of the individual dates. OxCal age-depth models failing to meet these criteria were not included in the sisal-chronology table (Table 2).”

We agree that the spread of the median age models is useful. However, we do not think it is useful to calculate cross-model uncertainties based on the medians/ensembles of all age models. As explained above, in many cases the resulting merged chronology would not be consistent with the available U-Th dates. However, we supply all the data (medians, uncertainties, ensembles) so that this could be done by individual researchers on an entity by entity basis. Medians and uncertainties are available in the database and ensembles are stored in zenodo: <http://doi.org/10.5281/zenodo.3816804> (Rehfeld et al., 2020).

Our approach does not penalize records with many dates. Usually, the better the spread in dates along a speleothem sample, the more constrained the age-depth model, and the lower the final uncertainty of the best-estimate median age model. However, it should be noted that this is not the case when there is a large number of conflicting U-Th dates with high analytical and correction uncertainties as the resulting age-depth model realisations will substantially differ amongst them.

For example, in Figure 5, there are a string of ages from 3400 – 3550 year BP that all follow each other. For this region of the $\delta^{18}\text{O}$ curve, there is fairly good agreement between the various age modeling techniques. Therefore, when all of those ages are viewed together, our confidence in the timing of any $\delta^{18}\text{O}$ excursion is less than that based on the error bars on each individual date (seen by less 'blur' in Figure 5c between the alternate age models). In other words, the multiple ages help to decrease our uncertainty to less than that of the analytical error bars on each U-Th dates. It's a bit like decreasing the signal to noise ratio by taking more measurements (by the square root of N). (Again SISAL may be doing this, but I'm not sure)

We agree with the reviewer that taking into account multiple chronologies for a given record provides more insights into the age-depth relationship. However, given that all the age models are consistent with the available dates, none of the individual chronologies should be discarded by default. Merging the chronologies obtained using different techniques to obtain "master chronologies for all the SISAL records would lead to a bias towards certain age-modelling approaches. For example, age models created using linear interpolation (successful 403 times) or Bchron (successful 420 times) would usually have a larger weight in a master chronology than Oxcal (successful 106 times) or linear regression (successful 182 times). Unless there is other information that suggests one age model type is better than others for a specific entity, all the chronologies should be considered equally likely.

To quantify the degree to which multiple age modeling techniques may reduce temporal uncertainty, I recommend that this manuscript includes a plot of the average of the analytical error in a record versus the average SISAL 95% chronology error in a record (i.e. average of 5b). Is the fit to that scatter plot a 1:1 line? Or is there a systematic reduction in the error across many records in the database b/c of time periods like 3400-3550 BP in Figure 5? Or do problematic areas, like unresolved hiatuses, compensate the reduction in errors for when the age model is tightly constrained? This would be an enlightening plot.

We do not expect a systematic reduction of the error as a result of the age-depth model techniques used and the data shows that the SISAL uncertainties ultimately depend on the uncertainties of the original U-Th dates and their spread/consistency. In any case, however, this would depend on the robustness of the approach used treat the uncertainties in each age-depth model.

As suggested by the reviewer, we will add a plot of the average analytical error per record vs the average SISAL chronology uncertainty as attached. The accompanying text will be:

“The published age-depth models of all speleothems are accessible in the original-chronology metadata table and our standardised age-depth models are available at the sisal-chronology table for 512 speleothems. Temporal uncertainties are now provided for 79% of the records in the SISAL database. This is a significantly larger number than in SISALv1b, where most age-depth models lacked temporal uncertainties. Most speleothem records show average U-Th age errors between 100-1,000 years (Figure 6), which are only slightly changed by using age-depth modelling software. Nevertheless, when comparing the mean uncertainties of the U-Th ages with those of their corresponding age-depth model, the slope between both parameters is smaller than one. This indicates that age-depth models tend to reduce uncertainties especially when dating errors are large while they increase uncertainties, when U-Th age errors are small.”

Please give more detail in the text of the principles used in your calculations for when the SISAL chronology decides that there is a hiatus in the record. While you reference Breitenbach, 2012, it would be good to review the guiding principles that SISAL is using in lines 83-86 in more detail to make the manuscript more self contained. Also, what happens if there is disagreement

among the various techniques about a hiatus – how does SISAL decide on a ‘yes’ or ‘no’ to split the record? Does majority rule??

Our age-depth model calculations use the U-Th dates and the depths of the hiatuses as entered in the database and which were provided by the researchers that produced the raw data and/or their publications.

We do not decide in our workflow whether there is (or should be) a hiatus in a section and therefore, all AM approaches use the same input data. For clarity, the input variables for the sisal chronologies are: depths of dating samples and isotopes, U-Th corrected ages and their uncertainties (if used to create the original or published age model), depth information of hiatuses if applicable, information on whether the speleothem was actively growing when collected and the year of collection. We did not attempt to assess whether the information provided by the data contributors/publications was correct. However, together with experts from the SISAL age modelling group we have checked whether the dates and hiatuses were visually consistent with the rest of the data.

We believe there is a misunderstanding as lines 83-86 refer to age reversals that occurred during the construction of the sisal chronologies instead of hiatuses:

“Major challenges arise through hiatuses (growth interruptions) and age reversals. In the classification of the reversals, we distinguish between tractable reversals (with overlapping confidence intervals) and non-tractable reversals (i.e., where the two-sigma-dating uncertainties do not overlap) following the definition of Breitenbach et al. (2012).”

We will rephrase this paragraph to clarify this point:

“Major challenges arise through hiatuses (growth interruptions) and age reversals. We developed a workflow to deal with records with known hiatuses that allowed the construction of age-depth models for 20% of the records with one or more hiatuses (Roesch and Rehfeld, 2019; details below for each age-depth modelling technique). Regarding the age reversals, we distinguish between tractable reversals (with overlapping confidence intervals) and non-tractable reversals (i.e., where the two-sigma-dating uncertainties do not overlap) following the definition of Breitenbach et al. (2012). Details such as the hiatus treatment and outlier age modification are recorded in a logfile created when running the age models. We followed the original author’s choices regarding date usage. If an age was marked as “not used” or “usage unknown”, we did not consider this in the construction of the new

chronologies except in OxCal, where dates with "usage unknown" were considered."

Details on how each technique tackled the hiatuses are copied below (with their corresponding line numbers):

Linear Interpolation: "Hiatuses are modelled following the approach of Roesch and Rehfeld (2019), where rather than modelling each segment separately, synthetic ages with uncertainties spanning the entire hiatus duration are introduced for use in age-depth model construction. These synthetic ages are removed after age-depth model construction. " (lines 100-104)

Linear Regression: "If hiatuses are present, the segments in-between were split at the depth of the hiatus without an artificial age. " (lines 110-111)

Bchron: "Since Bchron cannot handle hiatuses, we implemented a new workflow that adds synthetic ages with uncertainties spanning the entire hiatus duration (Roesch and Rehfeld, 2019), as performed with linear interpolation, StalAge and our implementation of COPRA. " (lines 116-118)

Bacon: "The R package rBacon can handle both outliers and hiatuses and apart from giving the median age-depth model, (...)." (lines 125-126)

Oxcal: "OxCal can deal with hiatuses and outliers and accounts for the non-uniform nature of the deposition process (Poisson process using the P-Sequence command). " (lines 134-136)

COPRA: " (...) we implemented a new workflow in R that adds artificial dates at the location of the hiatuses and prevents the creation of age reversals (Roesch and Rehfeld, 2019) as done with linear interpolation, StalAge and Bchron. " (lines 150-152)

StalAge: "The StalAge v1.0 R function has been updated to R version 3.4 and the default outlier and reversal checks were enabled to run automatically. Hiatuses cannot be entered in StalAge v1.0, but the updated version incorporates a treatment of hiatuses based on the creation of temporary synthetic ages following Roesch and Rehfeld (2019). " (lines 160-163)

SISALv2: A comprehensive speleothem isotope database with multiple age-depth models

1 Abstract:

2 Characterising the temporal uncertainty in palaeoclimate records is crucial for analysing past climate
3 change, for correlating climate events between records, for assessing climate periodicities, identifying
4 potential triggers, and to evaluate climate model simulations. The first global compilation of speleothem
5 isotope records by the SISAL (Speleothem Isotope Synthesis and Analysis) Working Group showed that
6 age-model uncertainties are not systematically reported in the published literature and these are only
7 available for a limited number of records (ca. 15%, $n = 107/691$). To improve the usefulness of the SISAL
8 database, we have (i) improved the database's spatio-temporal coverage and (ii) created new
9 chronologies using seven different approaches for age-depth modelling. We have applied these
10 alternative chronologies to the records from the first version of the SISAL database (SISALv1) and to new
11 records compiled since the release of SISALv1. This paper documents the necessary changes in the
12 structure of the SISAL database to accommodate the inclusion of the new age-models and their
13 uncertainties as well as the expansion of the database to include new records and the quality-control
14 measures applied. This paper also documents the age-depth model approaches used to calculate the new
15 chronologies. The updated version of the SISAL database (SISALv2) contains isotopic data from 691
16 speleothem records from 294 cave sites and new age-depth models, including age-depth temporal
17 uncertainties for 512 speleothems. SISALv2 is available at <http://dx.doi.org/10.17864/1947.242><http://doi.org/10.17864/1947.256> (Comas-Bru et al., ~~2020~~2020a).

21 1. Introduction

22 Speleothems (~~secondary cave carbonates form~~are a rich terrestrial palaeoclimate archive that forms from
23 infiltrating rainwater after it percolates through the soil, epikarst, and carbonate bedrock) ~~are a rich~~
24 ~~terrestrial palaeoclimate archive.~~ In particular, stable oxygen and carbon ~~isotopes~~isotope ($\delta^{18}\text{O}$, $\delta^{13}\text{C}$)
25 measurements made on speleothems have been widely used to reconstruct regional and local
26 hydroclimate changes.

The Speleothem Isotope Synthesis and Analyses (SISAL) Working Group is an international effort, under the auspices of Past Global Changes (PAGES), to compile speleothem isotopic records globally for the analysis of past climates (Comas-Bru and Harrison, 2019). The first version of the SISAL database (Atsawawaranunt et al., 2018a; Atsawawaranunt et al., 2018b) contained 381 speleothem records from 174 cave sites and has been used for analysing regional climate changes (Braun et al., 2019a; Burstyn et al., 2019; Comas-Bru and Harrison, 2019; Deininger et al., 2019; Kaushal et al., 2018; Kern et al., 2019; Lechleitner et al., 2018; Oster et al., 2019; Zhang et al., 2019). The potential for using the SISAL database to evaluate climate models was explored using an updated version of the database (SISALv1b; Atsawawaranunt et al., 2019) that contains 455 speleothem records from 211 sites (Comas-Bru et al., 2019).

SISAL is continuing to expand the global database by including new records (Comas-Bru et al., 2020a). Although most of the records in SISALv2 (79.7%: Figure 1a) have been dated using the generally very precise, absolute radiometric $^{230}\text{Th}/\text{U}$ dating method, a variety of age-modelling approaches were employed (Figure 1b) in constructing the original records. The vast majority of records provide no information on the uncertainty of the age-depth relationship. However, many of the regional studies using SISAL pointed to the limited statistical power of analyses of speleothem records because of the lack of temporal uncertainties. For example, these missing uncertainties prevented the extraction of underlying climate modes during the last 2k years in Europe (Lechleitner et al., 2018). To overcome this limitation, we have developed additional age-depth models for the SISALv2 records (Figure 2) in order to provide robust chronologies with temporal uncertainties. The results of the various age-depth modelling approaches differ because of differences in their underlying assumptions. We have used seven alternative methods: linear interpolation, linear regression, Bchron (Haslett and Parnell, 2008), Bacon (Blaauw, 2010; Blaauw and Christen, 2011; Blaauw et al., 2019), OxCal (Bronk Ramsey, 2008, 2009; Bronk Ramsey and Lee, 2013), COPRA (Breitenbach et al., 2012) and StalAge (Scholz and Hoffmann, 2011). Comparison of these different approaches provides a robust measure of the age uncertainty associated with any specific speleothem record.

2. Data and Methods

2.1 Construction of age-depth models: the SISAL chronology

We attempted to construct age-depth models for 533 entities in an automated mode. For eight records, this automated construction failed for all methods. For these records we provide manually constructed chronologies, where no age model previously existed, and added a note in the database with details on the construction procedure. Age models for 21 records were successfully computed but later dropped in

the screening process due to inconsistent information or incompatibility for an automated routine. In total, we provide ~~a new chronology~~additional chronologies for 512 speleothem records in SISALv2.

The SISAL chronology provides alternative age-depth models for SISAL records that are not composites (i.e., time-series based on more than one speleothem record), that have not been superseded in the database by a newer entity and which are purely $^{230}\text{Th}/\text{U}$ dated. We therefore excluded records for which the chronology is based on lamina counting, radiocarbon ages or a combination of methods. This decision was based on the low uncertainties of the age-depth models based on lamina counting and the challenge of reproducing age-depth models based on radiocarbon ages. We made an exception with the case of entity_id 163 (Talma et al., 1992), which covers two key periods, the Mid-Holocene and the Last Glacial Maximum, at high temporal resolution. In this case, we calculated a new SISAL chronology based on the provided $^{230}\text{Th}/\text{U}$ dates but did not consider the uncorrected ^{14}C ages upon which the original age-depth model is based. We also excluded records for which isotopic data is not available (i.e., entities that are part of composites) and entities that are constrained by less than three dates. Additionally, the dating information for 23 entities shows hiatuses at the top/bottom of the speleothem that are not constrained by any date. For these records, we partially masked the new chronologies to remove the unconstrained section(s). Original dates were used without modification in the age-depth modelling.

To allow a comprehensive cross-examination of uncertainties, seven age-depth modelling techniques were implemented here across all selected records. Due to the high number of records ($n = 533$), all methods were run in batch mode. A preliminary study, using the database version v1b demonstrated the feasibility of the automated construction and evaluation of age-depth models using a subset of records and methods (Roesch and Rehfeld, 2019). Further details on the evaluation of the updated age-depth models are provided in Section 3.2. The seven different methods are briefly described below. All methods assume that growth occurred along a single growth axis. For one entity, where it was previously known that two growth axes exist, we added an explanatory statement in the database. All approaches except StalAge produce Monte Carlo (MC) iterations of the age-depth models. We ~~provide~~aimed at providing 1,000 MC iterations for each new SISALv2 chronology (<https://doi.org/10.5281/zenodo.3591197>), in <http://doi.org/10.5281/zenodo.3816804> (Rehfeld et al., 2020) but this was not always possible because some records ($n=12$) yield a substantial number of non-monotonic ensembles that were not kept.

Major challenges arise through hiatuses (growth interruptions) and age reversals. ~~In~~We developed a workflow to deal with records with known hiatuses that allowed the classification ~~construction of age-depth models for 20% of the records with one or more hiatuses (Roesch and Rehfeld, 2019; details below for each age-depth modelling technique).~~ Regarding the age reversals, we distinguish between tractable

reversals (with overlapping confidence intervals) and non-tractable reversals (i.e., where the two-sigma-dating uncertainties do not overlap) following the definition of Breitenbach et al. (2012). ~~We developed a workflow to treat records with hiatuses (Roesch and Rehfeld, 2019; details below), which allowed the construction of age-depth models for 20% of the records with one or more hiatuses. Changes, Details~~ such as the hiatus treatment and outlier age modification, are recorded in a logfile created when running the age models. We followed the original author's choices ~~with regard to~~ regarding date usage. If an age was marked as "not used" or "usage unknown", we did not consider this in the construction of the new chronologies except in OxCal, where dates with "usage unknown" were considered.

1) **Linear Interpolation** (*lin_interp_age*) between radiometric dates. This is the classic approach for age-depth model construction for palaeoclimate archives and was used in 32.1% of the original age-depth models in SISALv2. Here, we extend this approach and calculate the age uncertainty by sampling the range of uncertainty of each $^{230}\text{Th}/\text{U}$ -age 2,000 times, assuming a Gaussian distribution. This approach is consistent with the implementation of linear interpolation in CLAM (Blaauw, 2010) and COPRA (Breitenbach et al., 2012). Linear interpolation was implemented in R (R Core Team, 2019), using the `approxExtrap()` function in the `Hmisc` package. We included an automated reversal check that increases the dating uncertainties until a monotonic age model is achieved, similar to that of StalAge (Scholz and Hoffmann, 2011). Hiatuses are modelled following the approach of Roesch and Rehfeld (2019), where rather than modelling each segment separately, synthetic ages with uncertainties spanning the entire hiatus duration are introduced for use in age-depth model construction. These synthetic ages are removed after age-depth model construction. Linear interpolation was applied to 80% (n=408/512) of the SISAL records for which new chronologies were developed.

2) **Linear Regression** (*lin_reg_age*) provides a single best fit line through all available radiometric ages assuming a constant growth rate. Linear regression was used in 6.7% of the original SISALv2 age models. As with linear interpolation, age uncertainties are based on randomly sampling the U-series dates to produce 2,000 age-depth models (i.e., ensembles). Temporal uncertainties are then given by the uncertainty of the median-based fit to each ensemble member. If hiatuses are present, the segments in-between were split at the depth of the hiatus without an artificial age. The method is implemented in R, using the `lm()` function from the base package. Linear regression was applied to 36% (n=185/512) of the SISAL records for which new chronologies were developed.

3) **Bchron** (*Bchron_age*) is a Bayesian method based on a continuous Markov processes (Haslett and Parnell, 2008) and available as an R package (Parnell, 2018). This method was originally used for only one speleothem record in SISALv2. Since *Bchron* cannot handle hiatuses, we implemented a new workflow

that adds synthetic ages with uncertainties spanning the entire hiatus duration (Roesch and Rehfeld, 2019), as performed with linear interpolation, StalAge and our implementation of COPRA. Bchron provides age-depth model ensembles of which we have kept the last 2,000. We calculate the age uncertainties from the spread of the individual ensembles. Here we use the function `bchron()` with `jitter.positions = true` to mitigate problems due to rounded-off depth values. This method has been applied to 83% (n=426/512) of the SISAL records for which new chronologies were developed.

4) **Bacon** (*Bacon_age*) is a semi-parametric Bayesian method based on autoregressive gamma-processes (Blaauw, 2010; Blaauw and Christen, 2011; Blaauw et al., 2019). It was used in three of the original chronologies in SISALv2. The R package *rBacon* can handle both outliers and hiatuses and apart from giving the median age-depth model, it also returns the Monte Carlo realisations (i.e. ensembles), from which the median age-depth model is calculated. During the creation of the SISAL chronologies, the existing *rBacon* package (version 2.3.9.1) was updated to improve the handling of stalagmite growth rates and hiatuses. We use this revised version, available on CRAN (<https://cran.r-project.org/web/packages/rbacon/index.html>), <https://cran.r-project.org/web/packages/rbacon/index.html>; last access date: 31 January 2020), to provide a median age-depth model and an ensemble of age-model realisations for 65% (n=335/512) of the SISAL records for which new chronologies were developed.

5) **OxCal** (*Oxcal_age*) is a Bayesian chronological modelling tool that uses Markov Chain Monte Carlo (Bronk Ramsey, 2009). This method was used in 4.1% of the original SISALv2 chronologies. OxCal can deal with hiatuses and outliers and accounts for the non-uniform nature of the deposition process (Poisson process using the P_Sequence command). Here we used the analysis module of OxCal version 4.3 with a default initial value of interpolation rate of 1 and an initial value of model rigidity (k) of $k_0=1$ with a uniform distribution from 0.01 to 100 for the range of k/k_0 ($\log_{10}(k/k_0)=(-2,2)$) (~~C.~~Christoph Bronk Ramsey, personal communication, 2019). The initial value of the interpolation rate determines the number of points between any two dates, for which an age will be calculated. We subsequently linearly interpolated the age-depth model to the depths of individual isotope measurements. ~~WereWhere~~ multiple dates are given for the same depth for any given entity, the date with the smallest uncertainty was used to construct the SISAL chronology. In case of asymmetric uncertainties in the dating table, the largest uncertainty value was chosen. We kept the last 2,000 realisations of the age-depth models for each entity. We calculate the age uncertainties from the spread of the individual ensembles. Details of the workflow used to construct these chronologies are available at Amirnezhad-Mozhdehi and Comas-Bru (2019). OxCal chronologies are available for 21% (n=106/512) of the SISAL records for which new chronologies were developed.

6) **COPRA** (*copRa_age*) is an approach based on interpolation-between-dates (Breitenbach et al., 2012) and was used for 9.7% of the original SISALv2 chronologies. COPRA is available as a Matlab package [in Rehfeld et al. \(2017\)](#) with a graphical user interface (GUI) that has interactive checks for reversals and hiatuses. The Matlab version can handle multiple hiatuses and (to some extent) layer-counted segments. However, age-reversals can occur near short-lived hiatuses. To overcome this, we implemented a new workflow in R that adds artificial dates at the location of the hiatuses and prevents the creation of age reversals (Roesch and Rehfeld, 2019) as done with linear interpolation, StalAge and Bchron. Additionally, we also incorporated an automated reversal check similar to that already embedded into StalAge (Scholz and Hoffmann, 2011). This R version, *copRa*, uses the default piecewise-cubic-hermite-interpolation (*pchip*) algorithm in R without consideration of layer counting. [We calculate the age uncertainties from the spread of the individual ensembles.](#) This approach was used for 76% (n= 389/512) of the SISAL records for which new chronologies were developed.

7) **StalAge** (*StalAge_age*) fits straight lines through three adjacent dates using weights based on the dating measurement errors (Scholz and Hoffmann, 2011). Age uncertainties are iteratively obtained through a Monte Carlo approach, but ensembles are not given in the output. StalAge was used to construct 13.1% of the original SISALv2 chronologies. The StalAge v1.0 R function has been updated to R version 3.4 and the default outlier and reversal checks were enabled to run automatically. Hiatuses cannot be entered in StalAge v1.0, but the updated version incorporates a treatment of hiatuses based on the creation of temporary synthetic ages following Roesch and Rehfeld (2019). In contrast to other methods, mean ages instead of median ages are reported for StalAge-[and the uncertainties are internally calculated and based on iterative fits considering dating uncertainties.](#) StalAge was applied to 62% (n=320/512) of the SISAL records for which new chronologies were developed.

2.2 Revised structure of the database

The data are stored in a relational database (MySQL), which consists of 15 linked tables: *site*, *entity*, *sample*, *dating*, *dating_lamina*, *gap*, *hiatus*, *original_chronology*, *d13C*, *d18O*, *entity_link_reference*, *references*, *composite_link_entity*, *notes* and *sisal_chronology*. Figure 3 shows the relationships between these tables and the type of each field (e.g. numeric, text). The structure and contents of all tables except the new *sisal_chronology* table are described in detail in Atsawawaranunt et al. (2018a). Here, we focus on the new *sisal_chronology* table and on the changes that were made to other tables in order to accommodate this new table (See section 2.3). Details of the fields in this new table are listed in Table 1.

Changes were also made to the dating table (*dating*) to accommodate information about whether a specific date was used to construct each of the age-depth models in the *sisal_chronology* table (Table 2).

We followed the original authors' decision regarding the exclusion of dates (i.e. because of high uncertainties, age reversals or high detrital content). However, some dates used in the original age-depth model were not used in the SISALv2 chronologies to prevent unrealistic age-depth relationships (i.e. age inversions). Information on whether a particular date was used for the construction of specific type of age-depth model is provided in the dating table, under columns labelled *date_used_lin_interp*, *date_used_lin_reg*, *date_used_Bchron*, *date_used_Bacon*, *date_used_OxCal*, *date_used_copRa* and *date_used_StalAge* (Table 2).

The dating and the sample tables were modified to accommodate the inclusion of new entities in the database. Specifically, the pre-defined options lists were expanded, options that had never been used were removed, and some typographical errors in the field names were corrected; these changes are listed in Table 3.

3. Quality Control

3.1 Quality control of individual speleothem records

The quality control procedure for individual records newly incorporated in the SISALv2 database is based on the steps described in Atsawawaranunt et al. (2018a). We have updated the Python database scripts to provide a more thorough quality assessment of individual records. Additional checks of the dating table resulted in modifications in the *230Th_232Th*, *230Th_238U*, *234U_238U*, *ini230Th_232Th*, *238U_content*, *230Th_content*, *232Th_content* and *decay constant* fields in the dating table for 60 entities. A summary of the fields that are both automatically and manually checked before uploading a record to the database is available in Appendix 1.

Analyses of the data included in SISALv1 (Braun et al., 2019a; Burstyn et al., 2019; Deininger et al., 2019; Kaushal et al., 2018; Kern et al., 2019; Lechleitner et al., 2018; Oster et al., 2019; Zhang et al., 2019) and SISALv1b (Comas-Bru et al., 2019) revealed a number of errors in specific records that have now been corrected. These revisions include, for example, updates in mineralogies (*sample.mineralogy*), revised coordinates (*site.latitude* and/or *site.longitude*) and addition of missing information that was previously entered as "unknown". The fields affected and the number of records with modifications are listed in Table 4. All revisions are also documented at Comas-Bru et al., 2020. (2020a).

3.2 ~~Quality~~Automation and quality control of the age-depth models in the SISAL chronology

~~The conception and the test of the R workflow, integrating all methods but OxCal, was outlined in Roesch and Rehfeld (2019) and includes automatized checks for the final chronologies except for OxCal. We used an automated approach to age-depth modelling in R because of the large number of records. Roesch and~~

Rehfeld (2019) have described the basic workflow concept and tested it using all of the age-modelling approaches used here except OxCal. The basic workflow involves step-by-step inspection and formatting of the data for the different methods, and the use of pre-defined parameter choices specific to each method. Each age-modelling method is called sequentially. An error message is recorded in the log file if a particular age-modelling method fails, and the algorithm then progresses to the next method. If output is produced for a particular age-modelling method, these age models are checked for monotonicity. Finally, the output standardization routine writes out, for each entity and age-modelling approach, the median age model, the ensembles (if applicable) and information of which hiatuses and dates were used in the construction of the age models. These outputs are then added to the `sisal` chronology table (Table 2). All functions are available at <https://github.com/paleovar/SISAL.AM> (last access: 23 July 2020) and CRAN (<https://cran.r-project.org/web/packages/rbacon/index.html>; last access: 31 January 2020).

The general approach for the OxCal age models was similar, and step-by-step details and scripts are provided in <https://doi.org/10.5281/zenodo.3586280> (Amirnezhad-Mozhdehi and Comas-Bru, 2019). The quality control parameters obtained from OxCal were compared with the recommended values of Agreement Index (A) > 60% and Convergence (C) > 95%, in accordance with the guidelines in Bronk Ramsey (2008). In addition to, both for the overall model agreement and P_Sequence convergence meeting these criteria, for at least 90% of the individual dates had to have an acceptable Agreement and Convergence themselves. OxCal age-depth models failing to meet these criteria were not included in the `SISAL` `sisal` chronology table. (Table 2).

An overview of the evaluation results for the age-depth models constructed in automated mode is given in Figure 4. Three nested criteria are used to evaluate them. Firstly, chronologies with reversals (Check 1) are automatically rejected (score -1). Secondly, the final chronology should flexibly follow clear growth rate changes (Check 2), such that 70% of the dates are encompassed in the final age-depth model within 4 sigma uncertainty (score +1). Thirdly, temporal uncertainties are expected to increase between dates and near hiatuses (Check 3). This criterion is met in the automated screening (score +1) if the Interquartile range (IQR) is higher between dates or at hiatuses than at dates. Only entities that pass all three criteria are considered successful. All age-depth models that satisfied Check 1 were also evaluated in an expert-based manual screening by ten people. If more than two experts agreed that an individual age-depth model was unreliable or inconsistencies, such as large offsets between the original age model and the dates marked as 'used', occurred, the model was not included in the `SISAL` chronology table. This automatic and expert-based quality control screening resulted in 2,138 new age-depth models constructed for 503 `SISAL` entities.

4. Recommendation for the use of SISAL chronologies

The original age-depth models for every entity are available in SISALv2. However, given the lack of age uncertainties for most of the records, we recommend considering the SISAL chronologies with their respective 95% confidence intervals whenever possible. No single age-depth modelling approach is successful for all entities, and we therefore recommend that all the methods for a specific entity are used together in visual and/or statistical comparisons. Depending on methodological choices, age-depth models compatible with the dating evidence can result in considerable temporal differences for transitions (Figure 5). For analyses relying on the temporal alignment of records (e.g. cross-correlation), age-depth model uncertainties should be considered using the ensemble of compatible age-depth models as described, e.g., in Mudelsee et al. (2012), Rehfeld and Kurths (2014) and Hu et al. (2017).

5. Overview of database contents

SISALv2 contains 353,976 $\delta^{18}\text{O}$ and 200,613 $\delta^{13}\text{C}$ measurements from 673 individual speleothem records and 18 composite records from 293 cave ~~systems~~sites (Table 5; Figure 2; Comas-Bru et al., ~~2020~~2020a). There are 20 records included in SISALv2 that are identified as being superseded and linked to the newer records; their original datasets are included in the database for completeness. This is an improvement of 235 records from SISALv1b (Atsawawaranunt et al., 2019; Comas-Bru et al., 2019; Table 6). SISALv2 represents 72% of the existing speleothem records identified by the SISAL Working Group and more than three times the number of speleothem records in the NCEI-NOAA repository (n = 210 as of November 2019), which is the one most commonly used by the speleothem community to make their data publicly available. SISALv2 also contains nine records that have not been published or are only available in PhD theses.

The published age-depth models of all speleothems are accessible in the *original_chronology* metadata table and our standardised age-depth models are available at the *sisal_chronology* table for 512 speleothems. Temporal uncertainties are now provided for 79% of the records in the SISAL database. This is a significantly larger number than in SISALv1b, where most age-depth models lacked temporal uncertainties. Most speleothem records show average U-Th age errors between 100-1,000 years (Figure 6), which are only slightly changed by using age-depth modelling software. Nevertheless, when comparing the mean uncertainties of the U-Th ages with those of their corresponding age-depth model, the slope between both parameters is smaller than one. This indicates that age-depth models tend to reduce uncertainties especially when dating errors are large while they increase uncertainties, when U-Th age errors are small.

This second version of the SISAL database has an improved spatial coverage compared to SISALv1 (Atsawawaranunt et al., 2018b) and SISALv1b (Figure 3; Atsawawaranunt et al., 2019). SISALv2 contains most published records from Oceania (80.2%), Africa (73.7%) and South America (77.6%), but improvements are still possible in regions like the Middle East (42.3%) and Asia (64.8%) (Table 6).

The temporal distribution of records for the past 2,000 years is good, with 181 speleothems covering at least one-third of this period and 84 records covering the entire last 2k (-68 to 2,000 years BP) with an average resolution of 20 isotope measurements in every 100-year slice (Figure 6a7a). There are 182 records that cover at least one-third of the Holocene (last 11,700 years BP) with 37 of these covering the whole period with at least one isotope measurement in every 500-year period (Figure 6b7b). There are 84 entities during the deglaciation period (21,000 to 11,700 years BP) with at least one measurement in every 500-year time period (Figure 6b7b). The Last Interglacial (130,000 to 115,000 years BP) is covered by 47 speleothem records that record at least one-third of this period with, on average, 25 isotope measurements at every 1,000-year time-slice (Fig. 6cFigure 7c).

This updated SISALv2 database now provides the basis not only for comparing a large number of speleothem-based environmental reconstructions on regional to a global scale, but also allows for comprehensive analyses of stable isotope records on various timescales from multi-decadal to orbital.

6. Data and code availability:

The database is available in SQL and CSV format from <http://dx.doi.org/10.17864/1947.242><https://dx.doi.org/10.17864/1947.256> (Comas-Bru et al., 20202020a). The code used for constructing the linear interpolation, linear regression, Bchron, Bacon, copRa and StalAge age-depth models is available at <https://github.com/palaeovar/SISAL-AM><https://github.com/paleovar/SISAL-AM> (last access: 23 July 2020). rBacon package (version 2.3.9.1) is available on CRAN (<https://cran.r-project.org/web/packages/rbacon/index.html>)<https://cran.r-project.org/web/packages/rbacon/index.html>; last access: 31 January 2020). The code used to construct the OxCal age-depth models and trim the ensembles output to the last 2,000 iterations is available at <https://doi.org/10.5281/zenodo.3586280><https://doi.org/10.5281/zenodo.3586280> (Amirnezhad-Mozhdehi and Comas-Bru, 2019). The ensembles are available at <https://doi.org/10.5281/zenodo.3591197><https://doi.org/10.5281/zenodo.3816804> (Rehfeld et al., 2020). The workbook used to submit data to SISAL ~~is available and the codes for its quality assessment are available at~~ <https://doi.org/10.5281/zenodo.3631403> (Atsawawaranunt and Comas-Bru, 2020). The ~~workbook is also available~~ as a supplementary document of Comas-Bru and Harrison (2019); ~~also available~~

at <https://10.5281/zenodo.3631403>. The codes for the quality control assessment of the data submitted to SISAL can be obtained from <https://10.5281/zenodo.3631403>. The codes to assess the dating table in SISALv2 are available at https://github.com/jensfohlmeister/QC_SISALv2_dating_metadata (last access: 23 July 2020) and https://github.com/jensfohlmeister/QC_SISALv2_dating_metadata and <https://10.5281/zenodo.3631443> <https://10.5281/zenodo.3631443> (Comas-Bru et al., 2020b). Details on the Quality Control assessments are available in the Supplementary material.

Author contributions:

LCB is the coordinator of the SISAL working group. LCB, SPH and KR designed the new version of the database. KR coordinated the construction of the new age-depth models except OxCal. All age-depth models except OxCal were run by CR and KR. LCB coordinated the construction of the OxCal age-depth models, which were run by SAM and LCB. LCB implemented the changes in the v2 of the database with the assistance of KA. SMA, YAB, AB, YB, MB, AC, MD, AD, BD, IGH, JH, NK, ZK, FAL, AL, BM, VFN, JO, CPM, NS, NS, BMW, SW and HZ coordinated the regional data collection and the age-model screening. SFMB, MB and DS provided support for COPRA, Bacon and StalAge, respectively. JF assisted in the Quality Control procedure of the SISAL database. Figures 1, 4 and 5 were created by CR and KR. Figures 2, 3 and 6 were created by LCB. All authors listed as “SISAL Working Group members” provided data for this version of the database and/or helped to complete data entry. The first draft of the paper was written by LCB with inputs by KR and SPH and all authors contributed to the final version.

Team list:

The following SISAL Working Group members contributed with ~~data~~[either data or age-modelling advice](#) to SISALv2: James Apaéstegui (Instituto Geofísico del Perú, Lima, Peru), Lisa M. Baldini (School of Health & Life Sciences, Teesside University, Middlesbrough, UK), Shraddha Band (Geoscience Department, National Taiwan University, No.1, Sec. 4, Roosevelt Road, Taipei 106, Taiwan), Maarten Blaauw (School of Natural and Built Environment, Queen's University Belfast, U.K.), Ronny Boch (Institute of Applied Geosciences, Graz University of Technology, Rechbauerstraße 12, 8010 Graz, Austria), Andrea Borsato (School of Environmental and Life Sciences, University of Newcastle, Callaghan 2308, NSW, Australia), Alexander Budsky (Institute for Geosciences, Johannes Gutenberg University Mainz, Johann-Joachim-Becher-Weg 21, 55128 Mainz, Germany), Maria Gracia Bustamante Rosell (Department of Geology and Environmental Science, University of Pittsburgh, USA), Sakonvan Chawchai (Department of Geology, Faculty of Science, Chulalongkorn University, Bangkok 10330, Thailand), Silviu Constantin (Emil Racovita Institute of Speleology, Bucharest, Romania and Centro Nacional de Investigación sobre la Evolución

344 Humana, CENIEH, Burgos, Spain), Rhawn Denniston (Department of Geology, Cornell College, Mount
 345 Vernon, IA 52314, USA), Virgil Dragusin (Emil Racovita Institute of Speleology, 010986, Strada Frumoasă
 346 31, Bucharest, Romania), Russell Drysdale (School of Geography, University of Melbourne, Melbourne,
 347 Australia), Oana Dumitru (Karst Research Group, School of Geosciences, University of South Florida, 4202
 348 E. Fowler Ave., NES 107, Tampa, FL 33620, USA), Amy Frappier (Department of Geosciences, Skidmore
 349 College, Saratoga Springs, New York, USA), Naveen Gandhi (Indian Institute of Tropical Meteorology, Dr.
 350 Homi Bhabha Road, Pashan, Pune-411008, India), Pawan Gautam (Centre for Earth, Ocean and
 351 Atmospheric Sciences, University of Hyderabad, India; now at Geological Survey of India, Northern Region,
 352 India), Li Hanying (Institute of Global Environmental Change, Xi'an Jiaotong University, China), Ilaria Isola
 353 (Istituto Nazionale di Geofisica e Vulcanologia, Pisa, Italy), Xiuyang Jiang (College of Geography Science,
 354 Fujian Normal University, Fuzhou 350007, China), Zhao Jingyao (Institute of Global Environmental Change,
 355 Xi'an Jiaotong University, China), Kathleen Johnson (Dept. of Earth System Science, University of
 356 California, Irvine, 3200 Croul Hall, Irvine, CA 92697 USA), Vanessa Johnston (Research Centre of Slovenian
 357 Academy of Sciences and Arts ZRC SAZU, Novi trg 2, Ljubljana, Slovenia), Gayatri Kathayat (Institute of
 358 Global Environmental Change, Xi'an Jiaotong University, China), Jennifer Klose (Institut für

Competing Interests:

The authors declare no competing interests.

Funding:

SISAL (Speleothem Isotopes Synthesis and Analysis) is a working group of the Past Global Changes (PAGES)
programme. We thank PAGES for their support for this activity. The design and creation of v2 of the
database was supported by funding to SPH from the ERC-funded project GC2.0 (Global Change 2.0:
Unlocking the past for a clearer future, grant number 694481) and the Geological Survey Ireland Short Call
2017 (Developing a toolkit for model evaluation using speleothem isotope data, grant number 2017-SC-
056) award to LCB. SPH and LCB acknowledge additional support from the ERC-funded project GC2.0 and
from the JPI-Belmont project “PALaeo-Constraints on Monsoon Evolution and Dynamics (PACMEDY)”
through the UK Natural Environmental Research Council (NERC). KR and DS acknowledge support by the
Deutsche Forschungsgemeinschaft (DFG, codes RE3994/2-1 and SCHO 1274/11-1).

Acknowledgements

SISAL (Speleothem Isotopes Synthesis and Analysis) is a working group of the Past Global Changes (PAGES)
programme. We thank PAGES for their support for this activity. We thank SISAL members who
contributed their published data to the database and provided additional information when necessary.
We thank all experts who engaged in the age-depth model evaluation. The authors would like to
acknowledge Avner Ayalon, Jordi López, Bahadur Singh Kotlia, ~~and~~ Dennis Rupprecht.

404 **List of Figures and Tables**

405 **Figure 1:** Summary of the dating information on which the original age-depth models are based
406 (a) and the original age-depth model types (b) present in SISALv2.
407

408

Figure 2: Cave sites included in the version 1, 1b and 2 of the SISAL database on the Global Karst Aquifer Map (WOKAM—project; Chen et al., 2017: <https://www.un-igrac.org/resource/world-karst-aquifer-map-wokam>; Goldscheider et al., 2020).

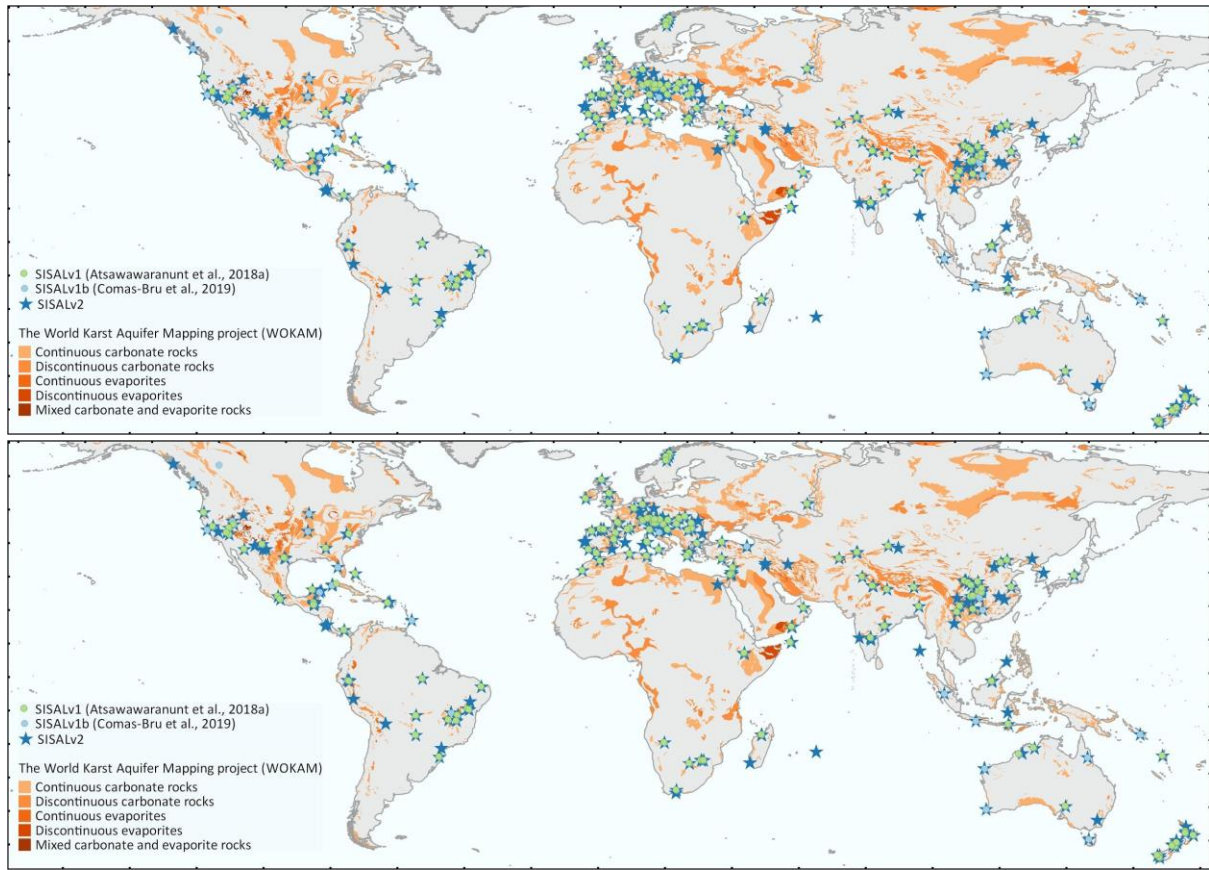

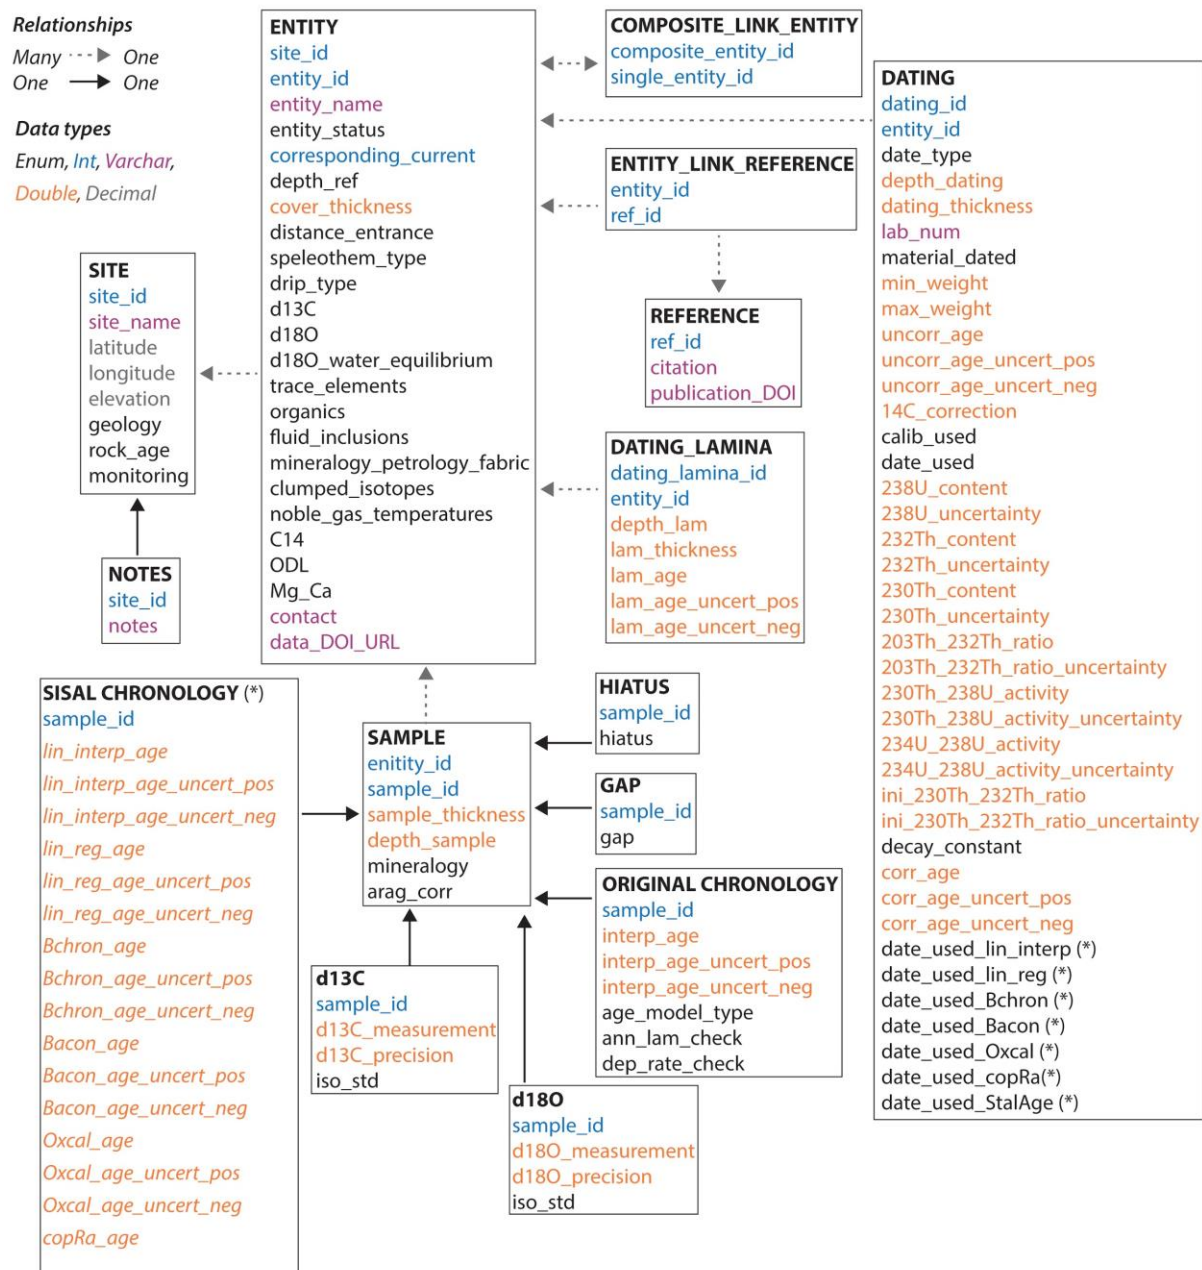

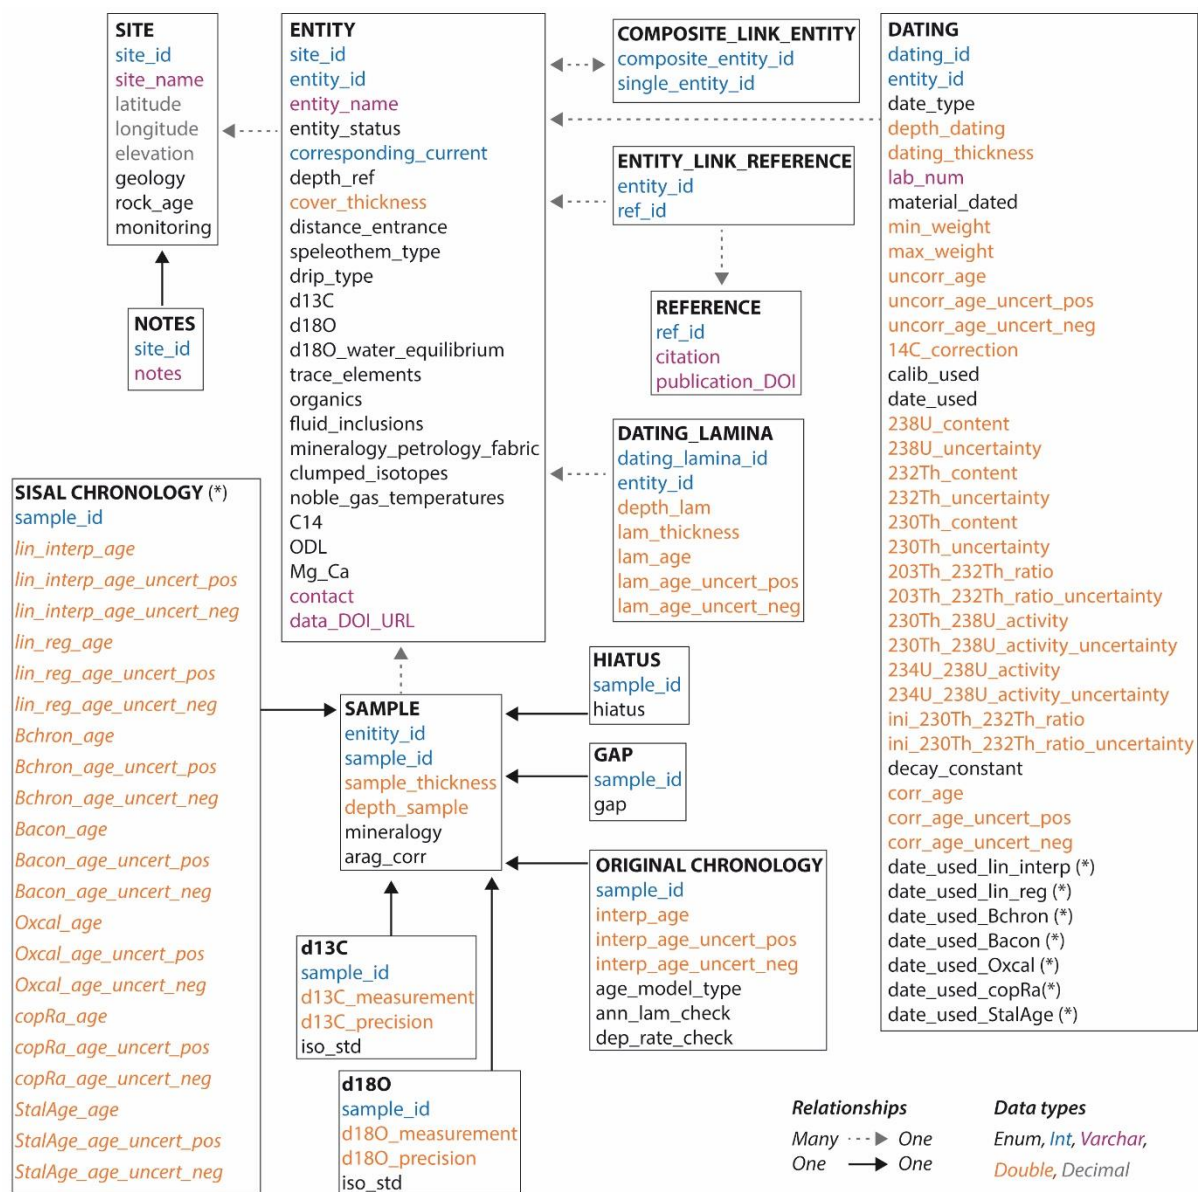

Figure 3: The structure of the SISAL database version 2. Fields and table marked with (*) refer to new information added to SISALv1b; see tables 1 and 2 for details. The colours refer to the format of that field: Enum, Int, Varchar, Double or Decimal. More information on the list of pre-defined menus can be found in Atsawawaranunt et al. (2018a).

425
426

Figure 4: Visual summary of quality control of the automated SISAL chronology construction. The evaluation of the age-depth models for each method (x-axis) is given for each entity (y-axis) that was considered for the construction (n=533). Black lines mark age-depth models that could not be computed. Age-depth models dropped in the automated or expert evaluation are marked by grey lines. Age-depth models retained in SISALv2 are scored from 1 (only one criterion satisfied) to 3 (all criteria satisfied) in shades of blue. For ~~504~~503 records alternative age-depth models with uncertainties are provided (green lines) in the “success” column.

435

Figure 5: Illustration of the impact of the age model choice on reconstructed speleothem chronology illustrated by the KNI-51-H speleothem record (entity_id 342; Denniston et al., 2013b). Panel (a) shows the median and mean age estimates for each downcore sample from the different age models; (b) shows the interquartile range (IQR) of the ages. Horizontal dashed lines show the depths of the measured dates; (c) shows the isotopic record using the different age models.

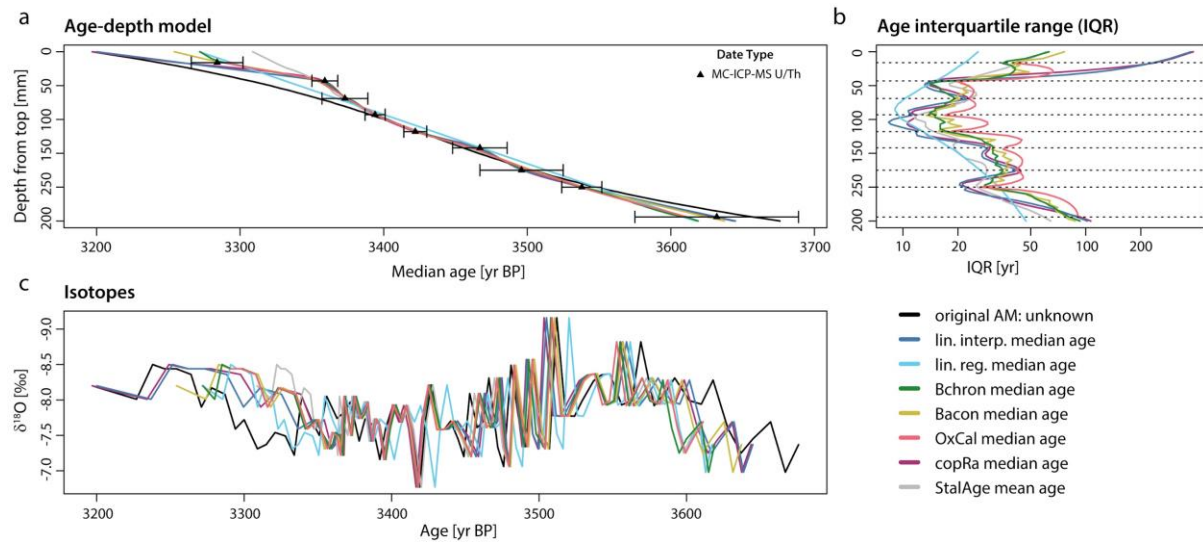

Figure 6

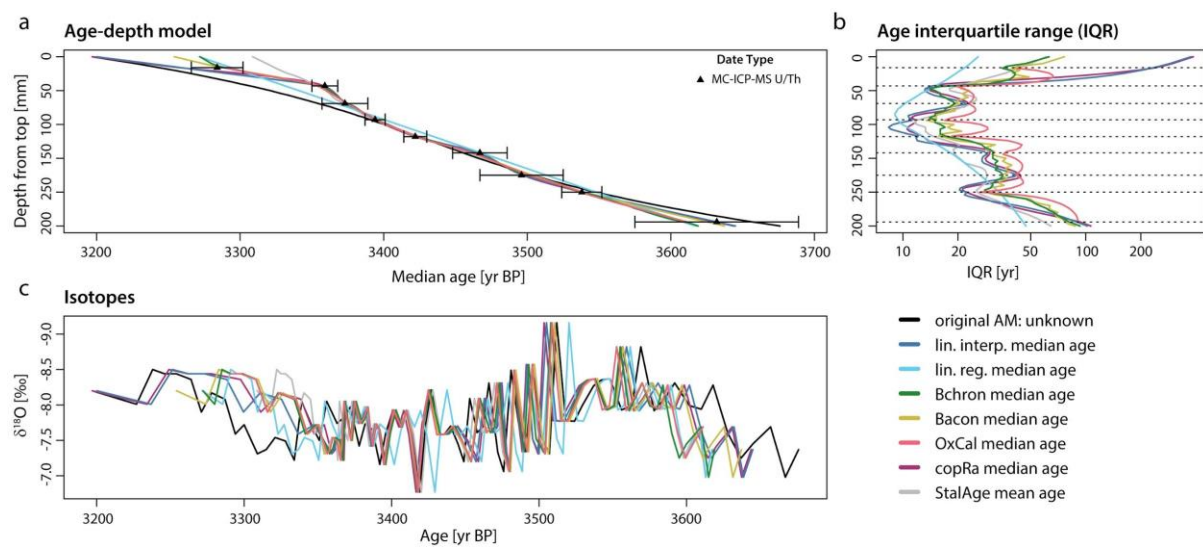

Figure 6: Scatter plot of average uncertainties in the sisal chronology table and U/Th mean dating uncertainties for each entity and age-depth model technique. The 1:1 line is shown in black.

Figure 7: Global and regional temporal coverage of entities in the SISALv2. (a) last 2,000 years with a bin size of 10 years; (b) last 21,000 years with a bin size of 500 years; (c) the period between 115,000 and 130,000 years BP with a bin size of 1,000 yrs. BP refers to “Before Present” where present is 1950 CE. Regions defined as in Table 7.

457
458

459 **Table 1:** Details of the `sisal_chronology` table. All ages in SISAL are reported as years BP (Before
460 Present) where present is 1950 CE.
461

Field label	Description	Format	Constraints
<i>sample_id</i>	Refers to the unique identifier for the sample (as given in the sample table)	Numeric	Positive integer
<i>lin_interp_age</i>	Age of the sample in years calculated with linear interpolation between dates	Numeric	None
<i>lin_interp_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with linear interpolation between dates	Numeric	Positive decimal
<i>lin_interp_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with linear interpolation between dates	Numeric	Positive decimal
<i>lin_reg_age</i>	Age of the sample in years calculated with linear regression	Numeric	None
<i>lin_reg_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with linear regression	Numeric	Positive decimal
<i>lin_reg_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with linear regression	Numeric	Positive decimal
<i>Bchron_age</i>	Age of the sample in years calculated with Bchron	Numeric	None
<i>Bchron_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with Bchron	Numeric	Positive decimal
<i>Bchron_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with Bchron	Numeric	Positive decimal
<i>Bacon_age</i>	Age of the sample in years calculated with Bacon	Numeric	None
<i>Bacon_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with Bacon	Numeric	Positive decimal
<i>Bacon_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with Bacon	Numeric	Positive decimal
<i>OxCal_age</i>	Age of the sample in years calculated with OxCal	Numeric	None
<i>OxCal_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with OxCal	Numeric	Positive decimal
<i>OxCal_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with OxCal	Numeric	Positive decimal
<i>copRa_age</i>	Age of the sample in years calculated with copRa	Numeric	None

<i>copRa_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with copRa	Numeric	Positive decimal
<i>copRa_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with copRa	Numeric	Positive decimal
<i>Stalage_age</i>	Age of the sample in years calculated with StalAge	Numeric	None
<i>Stalage_age_uncert_pos</i>	Positive 2-sigma uncertainty of the age of the sample in years calculated with StalAge	Numeric	Positive decimal
<i>Stalage_age_uncert_neg</i>	Negative 2-sigma uncertainty of the age of the sample in years calculated with StalAge	Numeric	Positive decimal

Table 2: Changes made to the Dating table to accommodate the new age models. These changes are marked with (*) in Figure 2.

Action	Field label	Description	Format	Constraints
Field added	<i>date_used_lin_age</i>	Indication whether that date was used to construct the linear age model	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_lin_reg</i>	Indication whether that date was used to construct the age model based on linear regression	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_Bchron</i>	Indication whether that date was used to construct the age model based on Bchron	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_Bacon</i>	Indication whether that date was used to construct the age model based on Bacon	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_OxCal</i>	Indication whether that date was used to construct the age model based on OxCal	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_copRa</i>	Indication whether that date was used to construct the copRa-based age model	Text	Selected from pre-defined list: "yes", "no".
Field added	<i>date_used_StalAge</i>	Indication whether that date was used to construct the age model based on StalAge	Text	Selected from pre-defined list: "yes", "no".

Table 3: Changes made to tables other than the *sisal_chronology* since the publication of SISALv1 (Atsawawaranunt et al., 2018a; Atsawawaranunt et al., 2018b).

Table name	Action	Field label	Reason	Format	Constraints
Dating	Removed “sampling gap” option	<i>date_type</i>	This option was never used	Text	Selected from pre-defined list
	“others” option changed to “other”	<i>decay_constant</i>	Correction of typo	Text	Selected from pre-defined list
	Added “other” option	<i>calib_used</i>	Option added to accommodate new entities	Text	Selected from pre-defined list
	Added “other” option	<i>date_type</i>	Option added to accommodate new entities	Text	Selected from pre-defined list
Sample	Added “other” option	<i>original_chronology</i>	Option added to accommodate new entities	Text	Selected from pre-defined list
	Added “other” option	<i>ann_lam_check</i>	Option added to accommodate new entities	Text	Selected from pre-defined list

Table 4: Summary of the modifications applied to records already in version 1 (Atsawawaranunt et al., 2018b) and version 1b (Atsawawaranunt et al., 2019) of the SISAL database. Mistakes in previous versions of the database were identified as outlined in the Supplementary material and through analysing the data for the SISAL publications.

Table 6: Percentage of entities uploaded to the different versions of the SISAL database with respect to the number of records identified by the SISAL working group as of November 2019. The number of identified records includes potentially superseded speleothem records. Regions are defined as: Oceania ($-60^{\circ} < \text{Lat} < 0^{\circ}$; $90^{\circ} < \text{Lon} < 180^{\circ}$); Asia ($0^{\circ} < \text{Lat} < 60^{\circ}$; $60^{\circ} < \text{Lon} < 130^{\circ}$); Middle East ($7.6^{\circ} < \text{Lat} < 50^{\circ}$; $26^{\circ} < \text{Lon} < 59^{\circ}$); Africa ($-45^{\circ} < \text{Lat} < 36.1^{\circ}$; $-30^{\circ} < \text{Lon} < 60^{\circ}$; with records in the Middle East region removed); Europe ($36.7^{\circ} < \text{Lat} < 75^{\circ}$; $-30^{\circ} < \text{Lon} < 30^{\circ}$; plus Gibraltar and Siberian sites); South America (S. Am; $-60^{\circ} < \text{Lat} < 8^{\circ}$; $-150^{\circ} < \text{Lon} < -30^{\circ}$); North and Central America (N./C. Am; $8.1^{\circ} < \text{Lat} < 60^{\circ}$; $-150^{\circ} < \text{Lon} < -50^{\circ}$)

Region	Version 1		Version 1b		Version 2	
	Entities	Sites	Entities	Sites	Entities	Sites
Oceania	47.7	36.7	56.8	51.0	80.2	69.4
Asia	36.2	28.8	41.1	33.3	64.8	48.5
