26   **Abstract.** This article presents a comprehensive hydrometeorological dataset collected over the
27   past two decades throughout the Cordillera Blanca, Peru. The data recording sites, located in the
28   upper portion of the Rio Santa valley, also known as the Callejon de Huaylas, span an elevation
29   range of 3738 - 4750 m a.s.l. As many historical hydrological stations measuring daily discharge
30   across the region became defunct after their installation in the 1950s, there was a need for new
31   stations to be installed and an opportunity to increase the temporal resolution of the streamflow
32   observations. Through inter-institutional collaboration the hydrometeorological network
33   described in this paper was deployed with goals to evaluate how progressive glacier mass loss
34   was impacting stream hydrology, and to better understand the local manifestation of climate
35   change over diurnal to seasonal and interannual time scales. The four automatic weather stations
36   supply detailed meteorological observations, and are situated in a variety of mountain
37   landscapes, with one on a high-mountain pass, another next to a glacial lake, and two in glacially
38   carved valleys. Four additional temperature and relative humidity loggers complement the
39   weather stations within the Llanganuco valley by providing these data across an elevation
40   gradient. The six streamflow gauges are located in tributaries to the Rio Santa and collect high
41   temporal resolution runoff data. The datasets presented here are available freely from
42   https://doi.org/10.4211/hs.506c1f66f87e4004b84e6af4097853a4 (Mateo et al., 2021). Combined,
43   the hydrological and meteorological data collected throughout the Cordillera Blanca enable
44   detailed research of atmospheric and hydrological processes in tropical high-mountain terrain.

1 Introduction

Glaciers and water resources in the Cordillera Blanca, Peru, have been under close observation for nearly a century. In the 1930s, an Austrian geographer from Universitat Innsbruck, Hans Kinzl, laid the groundwork for glaciological research in the region by surveying and mapping the glaciers and identifying other natural features in the mountainous landscape (Kaser and Osmaston, 2002). While the first systematic Peruvian effort to observe glacier tongue variations in the Cordillera Blanca was initiated in 1944 by Broggi (Petersen et al., 1969), glaciers as a source of security and water resources became the object of study in the subsequent decades. The Unidad de Glaciología e Hidrología (later Unidad de Glaciología y Recursos Hidricos (UGRH) of Electroperú S.A.) was initiated by the Corporación Peruana del Santa, a government company for energy development, and took on glacier and lake monitoring after many glacial lake outburst flooding (GLOF) events damaged communities downstream (Ames, 1998). GLOFs in 1941, 1945, and 1950 killed over 6000 people and destroyed a third of the Ancash district capital of Huaraz (Carey, 2010; Carey et al., 2012). Other glacier hazards have had detrimental impacts on the communities as well, including the 1970 avalanche, triggered by a massive earthquake, which killed approximately 6000 people and along with the debris flow it produced, covered the city of Yungay (Carey, 2010). Lliboutry, Morales and Schneider (1977) investigated two glaciers in the mountain range in relation to the danger they presented for flooding a downstream power plant. From the 1970s to the 1990s, a local Peruvian from Huaraz, Alcides Ames, provided many important contributions to the present knowledge of glaciers in the Cordillera Blanca while employed at UGRH, and after his retirement continued to dedicate much of his time to studying the glaciers and sharing his knowledge with other researchers (Ames et al., 1989; Hastenrath and Ames, 1995; Ames and Hastenrath, 1996; Ames, 1998; Kaser and Osmaston, 2002). In the 1980s, Georg Kaser, an Austrian geographer, began studying the Cordillera Blanca with a focus on the extent, causes, and possible consequences of the observed glacier retreat (Kaser and Osmaston, 2002). For many decades, much of the research in the region focused on developing better maps of the mountains and observing the marked glacier retreat in the tropics. Although the meteorological and hydrological stations installed by UGRH had been in place for nearly 40 years, it was not until the mid-1990s when studies began to assess water resources in the Cordillera Blanca, but with minimal focus on flooding and GLOFs (Kaser and Georges 1997; Mark and Seltzer, 2003).

The UGRH spent many years collecting an abundance of climatological, hydrological, and glaciological data, which was useful for future researchers, hydroelectric and mining companies, and other stakeholders throughout the Cordillera Blanca and its glaciers. Since the mid-1990s, most of the daily-resolution discharge data from the Rio Santa watershed has been cataloged and collected at a much-reduced number of sites by private energy companies who took over after Electroperu was privatized. The rapid turnover of the energy companies holding the discharge observations makes it difficult to track down all available historical data. Also, many of the hydrological stations have become defunct since they were installed in the 1950s,

96 creating a need for new stations to be installed for continuous monitoring of the region. A further
97 benefit of installing a new hydrological monitoring network in the 2000s was to significantly
98 increase the temporal resolution of the discharge observations.

99   Collaborating researchers from The Ohio State University, Bridgewater State University
100 and McGill University initiated a network of embedded environmental sensors in 2005. The
101 main goals of the instrument arrays were to evaluate how progressive glacier mass loss was
102 impacting stream hydrology, and to better understand the local manifestation of climate change
103 on the variability and controls of local weather phenomena over diurnal to seasonal and
104 interannual time scales. In order to create a sustainable network for continuous, long-term
105 observation, this project has been maintained in close collaboration with Peruvian researchers
106 and government agencies, as well as with other international scientists to leverage resources in
107 maintaining instruments, in exchange for openly sharing data.

108   The instrumentation for the data collection we present in this work was installed and
109 maintained under a collaborative work agreement ("convenio") formalized with the Peruvian
110 government agency overseeing the office in Huaraz (Peruvian Institute of Natural Resources
111 (INRENA) and the Autoridad Nacional del Agua (ANA)). This work agreement involved a
112 secondary collaboration with other international researchers who shared in installing and
113 calibrating the instrumentation. Specifically, Dr. Thomas Condom of the French Institut de
114 Recherche pour le Developpement (IRD) joined the agreement to install and maintain a series of
115 stream gauges logging water stage at 15-minute intervals. We also collaborated with the Austrian
116 research team of Dr. Irme Juen and Professor Georg Kaser from the Universitat Innsbruck,
117 Austria, who co-located a precipitation gauge with our weather station in Llanganuco. Further
118 details about the instrumentation are provided below.

119   Inter-institutional collaboration in this fashion has provided an effective partnership to
120 aid in maintaining the instrumentation over time, but also introduces challenges of logistical
121 coordination and data continuity. Visitation as non-resident international scientists to the field
122 sites has been feasible only one or two times annually. Thus, the Peruvians in our collaboration
123 have incorporated our instruments within their routine monitoring network. This has permitted
124 regular observations of stations and instruments to download data loggers, perform stream
125 discharge measurement to build a rating curve, and undertake a limited range of repair work.
126 However, limitations in local resources and manpower in Peru have often prevented recordings
127 of stage observation and discharge measurement to constrain rating curves. Likewise, having
128 multiple operators also increases some risk for data recovery errors. For instance, loggers that are
129 improperly relaunched after data downloads can jeopardize subsequent acquisitions. Having
130 more frequent site visits can allow for interventions, but also incurs increased risk of operator
131 error. Furthermore, Peruvian domestic political changes have disrupted the operations by
132 introducing different leadership, with altered operational priorities and resources, which directly
133 or indirectly interrupt the continuity of trained personnel responsible for data recovery and

134   preservation. Overcoming the many challenges of maintaining the instrumentation and
135   constructing rating curves has required regular cross-cultural communication, multiple and
136   annual visitation to the region. Likewise, the rating curves continue to be refined as additional
137   measurements are made.

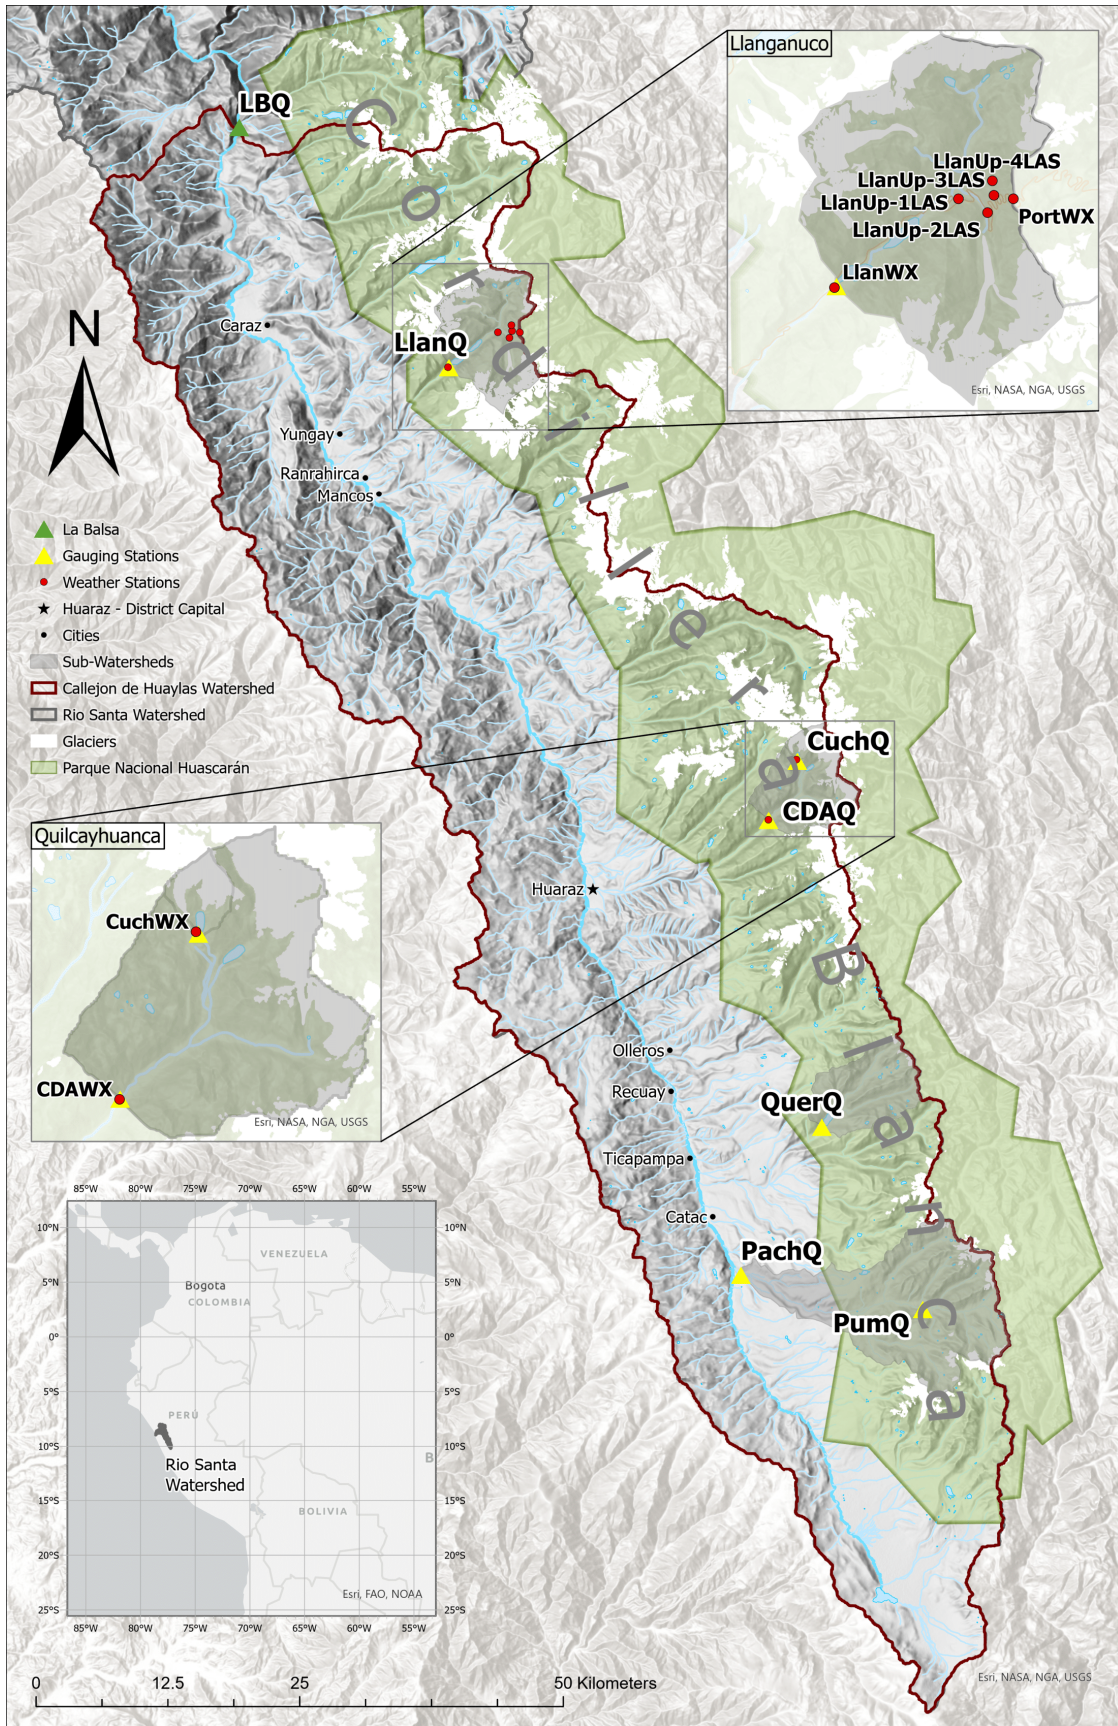
138   Our collaborative observations have provided important new insights into how the
139   hydroclimate of the region is changing on different scales. Updated discharge and climate
140   observations in specific glacier catchments documented important shifts in seasonal supply of
141   glacier storage to the Yanamarey catchment (Bury et al., 2011) as well as suggesting regional
142   thresholds in glacier melt provision (Mark et al., 2010). The discharge constraints also provided
143   important validation for a novel hydrochemical basin characterization method to quantify
144   proportionate glacier melt and groundwater contributions to streamflow in tributaries of varying
145   glacierized coverage (Baraer et al., 2009, 2015). Regionally, the gauge network provided the key
146   constraint for a model of time-progressive hydrograph evaluation that verified significantly that
147   the main catchment had already passed "peak water" in the wake of strong glacier recession
148   underway for multiple decades (Baraer et al., 2012). Our embedded temperature and humidity
149   loggers distributed over elevation and linked to weather stations in the Llanganuco valley have
150   revealed novel diurnal to seasonal variations in lapse rates linked to catchment-specific valley
151   wind dynamics validated with downscaled climate models (Hellstrom et al., 2017). These studies
152   demonstrate the importance of collecting in situ hydrometeorological data and indicate the need
153   for continued data collection in the high Andes (Condom et al., 2020).

154   In this paper, we document available data from the Cordillera Blanca area collected over
155   the past 15 years. It is separated into (i) meteorological data recorded by permanently installed
156   automatic temperature and relative humidity loggers (Lascars), or automatic weather stations,
157   and (ii) hydrological data consisting of stage and discharge data from multiple sub-catchments.
158   The data are stored in .csv extension format on Consortium of Universities for the Advancement
159   of Hydrologic Science, Inc. (CUAHSI) Hydroshare:
160   https://doi.org/10.4211/hs.506c1f66f87e4004b84e6af4097853a4 (Mateo et al., 2021). The data
161   collection consists of multiple time series of point observations from both meteorological and
162   hydrological measurement sites. These high-temporal resolution data provide detailed insight
163   into the complex hydro-meteorological system of the tropical Cordillera Blanca.

164   **2 Study Area - Cordillera Blanca**

165   The Rio Santa (Santa River) captures runoff from the western side of the glacierized
166   Cordillera Blanca and the eastern side of the non-glacierized Cordillera Negra, encompassing a
167   drainage area of 11636 km^2 at the outlet to the Pacific Ocean. While the headwaters of the Rio
168   Santa are found at Laguna Conococha at 4100 m above sea level (a.s.l.), the highest point in the
169   basin (and in Peru) is the summit of Huascaran at 6768 m a.s.l. The average slope of the entire
170   drainage basin is 20.6° and its average elevation is 3374 m a.s.l. calculated from a 3 m resolution

171   DEM of the region. The Rio Santa flows over 300 km northwest from its origin at Laguna
172   Conococha, an alpine lake at 4000 m a.s.l., to its outlet into the Pacific Ocean, near Chimbote.
173   The Callejon de Huaylas refers to the upper section of the Rio Santa, comprising approximately
174   4773 km^2 located above the Cañon del Pato 50 MW hydroelectric generation plant in Huallanca
175   (Figure 1). The Rio Santa basin is home to three other hydroelectric plants and provides water to
176   the expansive Chavimochic irrigation district near the coast (Mark and McKenzie, 2007). The
177   discharge on the Rio Santa has been carefully monitored since the Cañon del Pato dam began
178   operating in the 1950s, however, only one station near the dam remains active which is situated
179   slightly upstream at La Balsa (labeled as LBQ in Figure 1).

180   Figure 1.
181   Map of the Callejon de Huaylas showing the locations of the hydrological and meteorological
182   stations. (Base layers of the map originated from: © Esri, © NASA, © NGA, © USGS, © FAO,
183   © NOAA; all other layers were created and edited by authors of this article.)


185   Rio Santa discharge experiences a strong seasonal contrast with the lowest discharge
186   occurring between July and September, while peak discharge, nearly 20 times greater, typically
187   occurs in March. Calculated from daily streamflow observations between 1954 and 2015, mean
188   annual streamflow at La Balsa station on the Rio Santa, is 87 m^3s^{-1}, while the average annual
189   minimum discharge is 25 m^3s^{-1}, and the average annual maximum discharge is 445 m^3s^{-1}. The
190   Callejon de Huaylas is approximately 10% covered in ice (RGI Consortium, 2017), has an
191   average slope of 19° and an average elevation of 4055 m a.s.l. Glacial melt in the Rio Santa at La
192   Balsa provides 10-20% of the total annual discharge and may exceed 40% in the dry season
193   (Mark et al., 2005; Condom et al., 2012).

194   The climate of the Callejon de Huaylas is semi-arid and displays distinct precipitation
195   seasonality, with the wet season between October and May being responsible for 80% of the
196   800-1200 mm/year of precipitation (Baraer et al., 2009), and the dry season lasting from June to
197   September (Figure 2). As a localized example, the Llanganuco valley displays an average total of
198   8 mm during the dry season, and an average of total of 258 mm during the wet season months of
199   December, January, and February, based on monthly totals from 1953 to 2010 (Hellstrom et al.,
200   2017). Variations in river discharge are largely driven by seasonality of precipitation.
201   Temperature remains nearly constant in the outer tropics, with the annual variation in
202   temperature being smaller than diurnal variation (Kaser et al., 1990).

203   Figure 2.
204   A climograph from LlanWX in the Cordillera Blanca displaying the strong contrast in
205   precipitation between wet and dry seasons, while maintaining a steady temperature throughout
206   the entire year.

207
208   The geology in the Rio Santa basin is dictated by numerous tectonic and erosional
209   processes because the basin is situated along the active detachment fault of the Cordillera Blanca
210   (McNulty et al., 1998; Garver et al., 2005; Eddy et al., 2017). The highest peaks of the Cordillera

211 Blanca are composed largely of a granodiorite batholith intruded into a metamorphic unit that
212 includes hornfels, gneiss, and sulfide-rich lithologies, such as pyrite schist, phyllite, and pyrite-
213 bearing quartzite (Giovanni et al., 2010; Eddy et al., 2017). Granodiorite is found predominantly
214 in the northern portion of the range, while the southern portion of the range is made up of a
215 variety of metasediments, including quartzites and carbonates (Garver et al., 2005). The main
216 valley of the Rio Santa watershed is covered by recent sediment deposits, including alluvium,
217 landslide deposits, and glacial-fluvial fill. The impact of past and present glacier extent in the
218 topography is visible in geomorphic features throughout the range, including steep walled U-
219 shaped valleys, moraines, and proglacial lakes (Eddy et al., 2017).

220 **3 The Data**

221   In the following section, the data collected from the Cordillera Blanca are presented in
222 two collections. First, we provide a description of the meteorological stations and embedded
223 sensor network of Lascar data loggers, and then we present the time series data from the stations.
224 Second, we provide details of the setup and context of the discharge gauging station network,
225 and then conclude by presenting the time series of discharge data and general statistics from
226 them. The Figures A1, A2, and A3 in the Appendix, indicate missing data beyond 2020, however
227 due to travel restrictions over the past two years we have not been able to collect the up-to-date
228 measurements. Our intent is to sustain these hydrological and meteorological measurements into
229 the future once travel to the region is possible again. This future data will be available upon
230 request as it is collected.

231 **3.1 Meteorological Data**

232   The Servicio Nacional de Meteorología e Hidrología del Perú (SENAMHI) has operated
233 a relatively dense national network of meteorological stations since 1964. Air temperature is
234 provided as daily T_{max} and T_{min} (additionally measured at 07:00, 13:00 and 19:00 local time), and
235 precipitation is measured once a day. Some SENAMHI stations still provide daily temperature
236 and precipitation data through their web portal, providing data back to 1980
237 (https://www.senamhi.gob.pe/?&p=descarga-datos-hidrometeorologicos), but very few stations
238 within the Rio Santa Valley or Cordillera Blanca, Peru, remain active. Note that additional data
239 from SENAMHI are available upon request from the Swiss MeteoDat GmbH team through a
240 data portal (Schwarb et al. 2011, http://www.meteodat.ch/). In addition, the Universidad
241 Nacional Santiago Antúnez de Mayolo (UNASAM) has maintained a network of what was
242 originally 16 meteorological stations located at different elevations in the Cordillera Blanca
243 (Ancash district) since 2012. Monthly totals of precipitation data for the Rio Santa watershed
244 have been collected by Electroperú South America since 1953 although measurements were
245 interrupted in the mid-1990's with the privatization of the respective institutions when most of
246 the stations were abandoned and quality control was an issue (Kaser et al., 2003). More recent
247 installations of weather stations in the Cordillera Blanca have been mostly associated with short-

248   lived research projects typically lasting less than three years (Hofer et al., 2010; Georges and
249   Kaser, 2002). The hourly meteorological observations we describe below were collected
250   primarily from instrumentation we installed in two sub-catchments of the Rio Santa drainage
251   basin, Llanganuco, and Quilcayhuanca.

252   The Llanganuco valley is situated on the western side of the Cordillera Blanca across a
253   southwest (~240°) to northeast (~60°) axis with elevations ranging from 3400 m a.s.l. to 6746 m
254   a.s.l. Llanganuco is one of most glacierized valleys in the mountain range at 30% glacier
255   coverage, making it one of the most glacierized tropical valleys in the world. In the Llanganuco
256   catchment, our group has installed multiple weather stations dating back to 2007, although only
257   one remains active. This currently active station, labeled LlanWX, is located at 3835 m.a.s.l. near
258   the lower of the two largest valley lakes (Table 1).

259   Table 1.
260   This table provides general information about each meteorological station (WX) and lascar data
261   logger (LAS) location within the embedded sensor network. Dates with an asterisk in the "Period
262   of Operation" column indicate the station is operational.

Station	Station Valley	Elevation (m a.s.l.)	Period of Operation	Lascar Error Adjustment	Slope Angle (°)	Slope Aspect (°)	Temporal Resolution
Cuchillacocha - CuchWX	Quilcayhuanca	4642	2013-2020*	--	0	NA	30-min
Casa de Agua - CDAWX	Quilcayhuanca	3924	2013-2019*	--	0	NA	30-min
Llanganuco - LlanWX	Ranrahirca	3835	2007-2019*	Yes	0	NA	60-min
Portachuelo - PortWX	Ranrahirca	4750	2006-2015	--	0	NA	60-min
LlanUp-1/1A LAS	Ranrahirca	3955	2006-2015; 2015-2020*	No	14	301	60-min
LlanUp-2/2A LAS	Ranrahirca	4122	2006-2014; 2015-2020*	No	33	259	60-min
LlanUp-3/3A LAS	Ranrahirca	4355	2006-2015; 2015-2020*	No	31	236	60-min
LlanUp-4/4A LAS	Ranrahirca	4561	2006-2015; 2018-2020*	Yes	33	225	60-min

263

264   The embedded sensor network (ESN), as described by Hellström et al. (2010) and
265   Hellström and Mark (2006), provides the in-situ meteorological data provided in the paper. In
266   July 2007 the first automatic weather station (AWS), LlanWX, was installed near the lower lake
267   in the Llanganuco valley to collect a continuous record of point measurements of air
268   temperature, wind speed, wind direction, relative humidity, and solar irradiance (Table 2). The
269   AWS shown in Figure 3A is located in an open area on the valley floor and is surrounded by
270   *Polylepis* trees. A lascar data logger was also hung at this site for static calibration. The site is
271   protected in Huascaran National Park, and the location was previously used by the University of
272   Innsbruck for precipitation measurements. The most significant wind obstructions are the steep
273   bedrock walls of the valley toward the northwest and southeast which exceed 1000 meters above
274   the valley floor. Northerly and southerly winds are occasionally recorded by LlanWX and are
275   likely caused by turbulence or lateral winds from the uneven heating of the valley walls. Winds
276   flow parallel to the axis of the valley during approximately 92% of the recorded time and are not
277   greatly obstructed by surface vegetation. The sensors for LlanWX were originally sourced from
278   the Onset Computer Corporation and logged with an Onset HOBO® data logger
279   (http://www.onsetcomp.com) until 2014 when these loggers were replaced with an Iridium®
280   satellite Data Garrison logger (http://www.upwardinnovations.com). A 102-mm diameter

281 radiation shield was used to reduce air temperature error caused by the sun except during the
282 following years: 2007, 2011-2014. During these years a separate data logger was used as the
283 primary source for air temperature and relative humidity observations. In 2013, our team
284 upgraded the station by replacing the wind sensors with two new units from Onset and a new
285 pyranometer from Apogee (http://www.apogeeinstruments.com/pyranometer) which exceeded
286 the 1277 Wm^{-2} maximum reading of the previous Onset sensors (Covert, 2016). The
287 observations from LlanWX are largely continuous since 2007, with data gaps occurring
288 occasionally between 2010 and 2014.

289 Table 2.
290 This table details the variables, sensors, and their accuracy which are collected at the
291 meteorological stations throughout the region.

Variable	Sensor	Accuracy	Unit
Air temperature	Onset HOBO S-THB-M002 Temperature RH Smart Sensor	± 0.2 °C	°C
Precipitation	Onset HOBO S-RGB-M002 0.2 mm Rainfall tipping bucket Smart Sensor	± 0.2 mm	mm
Relative humidity	Onset HOBO Temperature RH Smart Sensor: S-THB-M002	± 2.5 %	%
Wind speed	Onset HOBO S-WSB-M003 Wind Speed Smart Sensor	± 1.1 m/s	m/s
Wind direction	Onset HOBO S-WDA-M003 Wind Direction Smart Sensor	± 5 °	°
Incoming solar radiation	Onset HOBO S-LIN-M003 Solar Radiation Smart Sensor	± 10 W/m²	W/m²
Atmospheric pressure	Onset HOBO S-BPB-CM50 Smart Barometric Pressure Sensor	± 3.0 mb	mb

292

293   A second AWS, situated at Portachuelo (referred to as PortWX in Figure 1), was installed
294 in July 2006 on a high pass at the top of the Llanganuco valley (4742 m a.s.l.). The station was
295 situated on a steep, rocky ridge between the Llanganuco valley and the Vaqueria valley. There
296 were only wind obstructions to the north due to a steep rock wall within 10 m of the station
297 location. The AWS at Portachuelo had the same sensors as its counterpart, LlanWX, however
298 was lacking an air temperature and relative humidity sensor with a radiation shield until it was
299 installed in July 2015. Prior to this upgrade, these variables were recorded each hour by a Lascar
300 data logger part of the ESN discussed in the following section. The Portachuelo station was
301 stolen in 2015 after recording data for nine years; a replacement station installed in 2016 was
302 also stolen so the site was abandoned. Gaps in weather station data is plotted in Figure A1 of the
303 Appendix.

304 Figure 3.
305 The typical setup for the HOBO automatic weather station, shown here is the LlanWX station
306 near the lower lake in Llanganuco. Measurements include air temperature, humidity, wind speed
307 and direction, incoming solar radiation, and rainfall. Note also the two Lascars with different
308 radiation shields hanging from crossbar. Photographs taken by R. Hellström (Covert, 2016).

309

310   Smaller loggers measuring air temperature were installed in June 2005 to begin collecting
311 near surface temperatures to calculate lapse rates (Table 1). These data loggers were a series of 8
312 nickel sized iButton Thermochron® temperature loggers (Figure 3). Hellström et al. (2010)
313 demonstrated the effectiveness of using the Thermochron loggers for purposes of observing near
314 surface lapse rates within the Llanganuco valley between the elevations 3470 and 4740 m a.s.l.
315 (Covert, 2016). The ESN of iButtons was replaced in July 2006 with a more robust network of
316 Lascar El-USB2 data loggers (www.lascarelectronics.com) which were setup to measure air
317 temperature and relative humidity at one-hour intervals. Each Lascar logger is attached to a
318 custom-designed and locally crafted radiation shield made of a thin tin cone and two Styrofoam
319 pieces in order to reduce error caused by direct sunlight, as shown in Figure 3B. Figure 4 (from:

320   Covert, 2016) provides photos for a visual landscape context for each Lascar logger. Because the

321   LlanWX, LlanUp-4, and PortWX Lascar loggers are nearly entirely exposed to sunlight, the

322   recorded air temperature values in the dataset are higher than expected and contain greater error

323   than actual temperatures during the day (see section 4.1 for details). This Lascar network is still

324   recording hourly data. The Lascar network does not have any gaps in its time series; thus, it is

325   not included in the Appendix.

326   Figure 4.

327   Photos A-F show the locations of all Lascar dataloggers labeled by names matching Table 1.

328   Photographs taken by B. Mark and R. Hellström (Covert, 2016).

329
330   Quilcayhuanca contains two weather stations (Table 1) similar to the LlanWX station in
331   Llanganuco valley, the lower is located at 3924 m a.s.l. near an old river diversion station called
332   Casa de Agua (station referred to as CDAWX in Figure 1), and the upper is located at 4642 m
333   a.s.l. slightly above an alpine lake, Cuchillacocha (station referred to as CuchWX in Figure 1).
334   CDAWX collects all of the same variables as LlanWX (Table 2), is still active since its
335   installation in July 2013 and data are mostly continuous over this duration. CuchWX was also
336   installed in July 2013, is still presently active, and only has one data gap lasting longer than a
337   month (from November 2016 – June 2017). The data presented here conclude in 2020, but
338   ongoing data extensions will be provided through the repository.

3.1.1 Relative Humidity Error Correction for LlanWX

341   In 2006 and 2007 saturation of the humidity sensor at LLanWX resulted in relative
342   humidity values greater than 100% (as high as 110%) resulting from dust and condensation on
343   the humidity sensor and persisting during the wet season for periods of up to about 48 hours,
344   with periods of reasonable humidity values during drier periods. In light of data preservation,
345   these erroneously supersaturated values were simply replaced with 100% relative humidity; this
346   correction is referred to as "Lascar Error Adjustment" in Table 1. Note that the dew point was
347   equal to the air temperature for values of relative humidity 100% or greater, so no adjustment
348   was made for dew point. The humidity sensor was replaced in June 2007 and the correction was
349   no longer needed. Both the original and corrected values are retained in the LlanWX data file.
350   There was no similar humidity error observed for PortWX or any of the LAS sensors.

3.1.2 Radiation Error Correction for Lascar Temperature Loggers

352   A year-long comparison between the Lascar (Figure 5) and LlanWX AWS temperature
353   sensors indicated an expected error in the Lascar that was largely dependent on the time of day.
354   Variability in temperature bias due to solar radiative heating is likely caused by changes in solar
355   angle and cloud cover patterns, particularly during the dry season. It is well documented that
356   daytime temperature error rises on sunny days with calm wind and is reduced on windy and
357   cloudy days regardless of the season but is far more prominent during the dry season in the
358   tropical Andes (Georges and Kaser, 2002). It is important to note that snow cover, which can
359   create larger biases in temperature by reflected solar radiation, is minimal throughout the year at
360   the locations of the Lascars in this study. Over an entire month, nightly error was within the 0.5
361   °C resolution of the Lascar sensor. The occasional occurrence of greater nighttime error could be
362   caused by the sensor capturing longwave radiation emitted by the surface. The primary source of
363   consistent instrumentation error for air temperature measurements is the heating of radiation
364   shields from those locations exposed to direct sunlight, which required bias correction according
365   to Figure 5. We bias-corrected for radiation error using comparison with the LlanWX shielded
366   temperature and Lascar logger hanging next to it under the same exposure, including the
367   LlanWX, LlanUp-4 LAS, and PortWX station locations. We conducted this same comparison

368 when replacing Lascar sensors in 2015 and found no significant differences between old and new
369 sensors. Because solar radiation is the predominant source of error, corrections were only applied
370 to daylight hours between 07:00 to 19:00 (Covert, 2016). Future studies may consider thicker or
371 more encased radiation shields for temperature data loggers in tropical regions. Our group has
372 created and used a variety of styles of radiation shields as seen in Figure 5.
373
374 Figure 5.
375 Image A displays a Lascar data logger connected to its cone radiation shield. Two white
376 Styrofoam plates beneath the cone insulate the sensor from radiative heating. Image B shows the
377 radiation shields used on the AWS in comparison to the Lascar setup in image A. Image C shows
378 polylepis trees which are used to hide and shade Lascars in order to obtain accurate temperature
379 and relative humidity values. A comparison test between the Lascar setup and the AWS radiation
380 shield with no shading yielded the expected errors shown in graph D. Positive values indicate
381 that the Lascar reported a temperature higher than the AWS sensor. Photographs taken by R.
382 Hellström (Covert, 2016).

383
3.1.3 Data Gaps and Other Quality Control Checks

385   The most common reasons for gaps in weather data was either loss of sensors due to theft
386 or inability to access sensors because of logistical reasons, such as poor weather conditions or
387 human error during downloading or redeploying of sensors. In addition to corrections for solar
388 radiation heating and the relative humidity correction, humidity and temperature records were
389 assessed for accuracy and outliers removed if there were unrealistic deviations from the previous
390 24-hour trend of conditions within the valley. Most of these deviations occurred during time
391 intervals coincident with sensor deployment, battery replacement or data download, although
392 data (less than 1%) were also removed if there was a concern with the integrity of the sensor.
393 The four Lascar loggers were replaced or had new radiation shields installed in June 2015, and
394 likewise renamed in the dataset as LlanUp-1A, 2A, 3A, and 4A.

3.2 Hydrological Data

The La Balsa gauge (8.87° S, 77.82° W at 1880 m a.s.l.) (Duke Energy, Orazul Energy, Inkia Energy) near the diversion canal for the Cañon del Pato hydroelectric plant has a nearly complete record since 1954, acting as a long-term reference point for discharge on the Rio Santa at the base of the Callejon de Huaylas basin. Many other stream gauges and precipitation stations were put in place by the hydroelectric companies, however, due to the lack of maintenance these stations became unusable after the mid-1990's. In 2008, The Ohio State University, McGill University, IRD, and the Peruvian glaciology unit of ANA commenced a joint project to reinstitute a stream gauging network throughout the Cordillera Blanca (Baraer et al., 2012). Many of these redeployed stream gauges in sub-catchments of the Rio Santa are still in working condition and are continuing to be monitored.

The stream gauges comprise custom-designed and locally crafted steel stilling wells containing two Solinst leveloggers (Figure 6), with one measuring total pressure (water plus atmospheric), and the other measuring barometric pressure. The Model 3001 Solinst levelogger Edge has an accuracy of ± 0.05 kPa and a resolution of 0.002% Full Scale (FS) for pressure and a temperature accuracy of ± 0.05° C, and a temperature resolution of 0.003° C (www.solinst.com). Water level is continuously monitored at these gauges at a temporal resolution of 15-minutes by subtracting atmospheric pressure from the total pressure. The adjusted water level variable in the discharge datasets indicates the adjustment based on where the water level logger was located in the water column. This measurement is conducted in the field using a built-in meter stick at each gauging station. Many factors influence the uncertainty of discharge measurements, especially in smaller, turbid streams (McMillan et al., 2012). First, the Solinst levelogger instruments used have accuracies and resolutions provided by the company as a percentage of FS as indicated above. Second, we estimate a ± 2 mm variation in water stage due to the turbulent nature of the streams in the region. These streams have a variety of bed surfaces, ranging from weedy to rocky, and flat to rolling, which are constantly modified by high flows during each year. Each stage and discharge field measurement are influenced by these small to large changes in the stream bed and the timing and location at which the discharge is measured. Finally, stage-discharge rating curves inherently introduce variable amounts of error depending on high or low flows, and how frequently they are updated. Stage-discharge rating curves at all stations were established and verified by conducting discharge measurements using the velocity area method and salt dilution during high flows (Figure A2 and Table A1 in the Appendix). Prior to publishing this dataset, one updated rating curve was fitted for all the data at each site, helping standardize the measurements and uncertainty in the data. All rating curves developed from discharge measurements in the field are assessed by their fit and significance to a quadratic function. All rating curves display R^2 values above 0.85, except for Cuchillacocha, which provides an R^2 value of 0.71. This slightly lower R^2 value at Cuchillacocha is likely due to the under-representation of high flows in the field measurements, and overall lower flow volumes recorded at this site. Uncertainties (using standard error at 95% uncertainty intervals)

434 were calculated for all rating curves, indicating average error ranging from ± 3–20% for low
435 flows, and ± 4–70% during high flows. These error values are standard when using a stage-
436 discharge rating curve as described in Kiang et al. (2018), and McMillan et al. (2012). Rating
437 curves can be further constrained, and their variation better understood with the addition of more
438 high flow discharge point measurements (McMillan et al., 2010; Coxon et el., 2014).
439 Unavailable data is denoted by "NA" in the dataset. Linear interpolation of missing data was
440 only calculated for missing periods of less than 1 hour, coinciding with the time the leveloggers
441 were being downloaded in the field. Other than these short periods of interpolated data, the
442 datasets provided consist of raw data. Gaps of missing streamflow data are plotted in Figure A3
443 in the Appendix.

444 Figure 6.
445 Figure 6 illustrates the design of the stilling wells used to collect total pressure (water +
446 barometric) and barometric pressure. The photograph shows the stilling well and the insert tube
447 containing the pressure data loggers.

448
449   The stream gauges that were installed in 2008 and 2009 and which are continuing to
450 collect discharge are Casa de Agua, Cuchillacocha, Pachacoto, Llanganuco, and Querococha
451 (Figure 1). The Pumapampa gauge went out of commission in 2016 but is also included in this
452 dataset (Table 3). These stream gauges have variable lengths of record due to periods of missing
453 data, but still provide valuable streamflow information in a region where stream records are
454 limited. As shown in the map (Figure 1), two pairs of these stream gauges are located at different
455 points along the same Rio Santa tributary in their respective sub-catchments: Pumapampa and
456 Pachacoto in the Pachocoto valley; and Cuchillacocha and Casa de Agua in the Quilcayhuanca
457 valley. All discharge measurements are calculated from rating curves containing a minimum of
458 eight, point measurements throughout all times of the year. As mentioned above, rating curves

459 are not directly provided in this data paper because they are variable in nature as we collect new
460 discharge measurements in the field. The following two subsections provide a brief overview and
461 summary for each gauging station, organized by general location in the Cordillera Blanca,
462 moving from the southern end of the mountain range to the northern. Note that all glacier
463 coverage is calculated from RGI 6.0 (RGI Consortium, 2017).

464 Table 3.
465 This table provides geographical information about each of the hydrological gauging stations.
466 Elevations are recorded at bank of stream. Note that all glacier coverage is calculated from RGI
467 6.0 (RGI Consortium, 2017). Dates with an asterisk in the "Period of Operation" column indicate
468 the station is operational.

Station	Station Valley	Latitude	Longitude	Elevation (m a.s.l.)	Period of Operation	Contributing Area (km²)	Percent basin covered in ice (%)
Cuchillacocha - CuchQ	Quilcayhuanca	-9.41	-77.35	4631	2008-2019*	4.1	60.49
Casa de Agua - CDAQ	Quilcayhuanca	-9.46	-77.37	3948	2009-2019*	66.9	24.78
Pumapampa - PumQ	Pachacoto	-9.88	-77.24	4287	2008-2016	58.1	8.33

469

470 **3.2.1 The southern Cordillera Blanca**

471 The Pumapampa catchment encompasses 58 km^2 with about 8% being covered by
472 glaciers (Table 3). Pumapampa gauge (referred to as PumQ in Figure 1) is located at 4287 m
473 a.s.l., below Nevado Pastoruri at the southern end of the Cordillera Blanca. This stream gauge is
474 situated in a channel through a low-lying meadow, where wet-season flow exceeds bankfull
475 stage, causing inaccuracies in high discharge measurements. Most notably, a series of values in
476 late-February 2014 indicated a peak discharge of 25 m^{3}s^{-1}, well above extremes measured from
477 the rating curve. It was determined that during this period the leveloggers were overrun by water
478 and measurements became unreliable solely during this flooding event. Outside of this event,
479 discharge at Pumapampa is consistently within the measured values on the rating curve. Mean
480 annual streamflow (averaged from three years of data missing less than one-month during the
481 entire year) at this stream gauge was 2.3 m^{3}s^{-1} and a specific discharge of 1248 mm a^{-1}. Mean
482 streamflow during the dry season (May through September) in Pumapampa was 1 m^{3}s^{-1}, while
483 the mean streamflow during the wet season (October through April) was 2.9 m^{3}s^{-1}. Highest mean
484 monthly streamflow occurred in March 2014 with an average of 5.3 m^{3}s^{-1} (Figure 7).

485 The Pachacoto gauge (referred to as PachQ in Figure 1) measures discharge 19 km
486 downstream from Pumapampa, at 3738 m a.s.l., just above its confluence with the Rio Santa.
487 Streamflow at Pachacoto is significantly greater than Pumapampa as it is the drainage point for a
488 larger area of 202 km^2, 5% of which is covered by glaciers. The mean annual streamflow at
489 Pachacoto was 3.2 m^{3}s^{-1}, averaged from the seven near-complete years of data, with a calculated
490 specific discharge of 499 mm a^{-1}. Dry season runoff accounted for approximately 20% of the

491   annual streamflow by volume, while the majority of the remaining wet season runoff occurred

492   during February and March.

493   Streamflow at another tributary catchment in the southern Cordillera Blanca is recorded

494   at the Querococha gauge (referred to as QuerQ in Figure 1) at 4005 m a.s.l., located 100 m

495   downstream of Querococha lake and defining a drainage area of 63 km^2, 1.5% of which is

496   glacierized. This drainage collects from two sub-catchments, one of which is entirely glacier-

497   free, while the other contains rapidly receding ice masses including the Yanamarey glacier.

498   Using five years of complete data, the mean annual streamflow at this gauging station was

499   calculated to be 1.4 m^3s^{-1} and the specific discharge was 702 mm a^{-1}. The streamflow from this

500   gauge is somewhat regulated by Querococha, the second largest lake in the Cordillera Blanca.

501   This catchment has featured many previous research studies and many other instruments

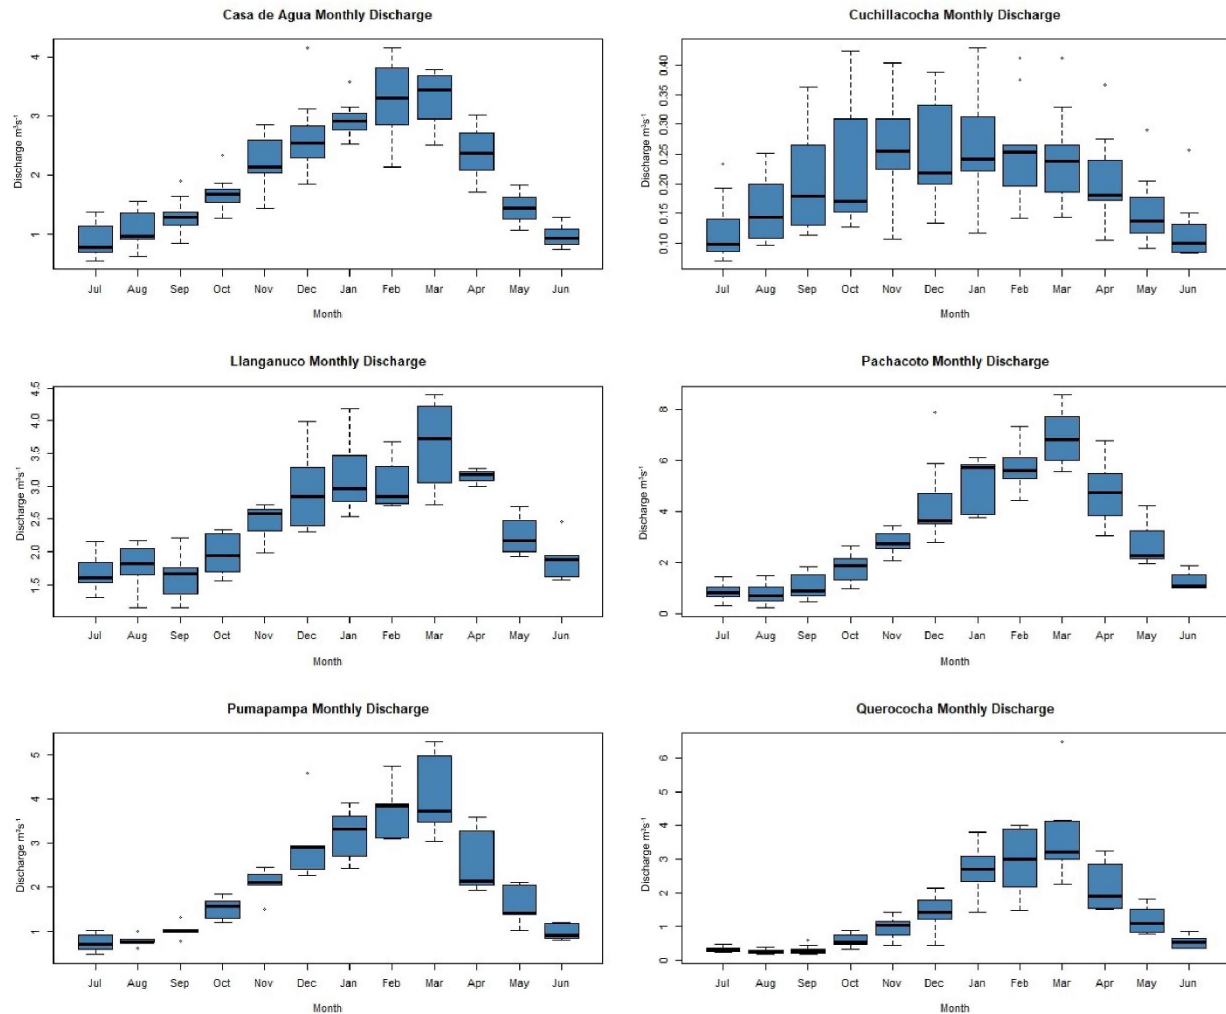
502   throughout the basin are still consistently monitored by ANA.

503   Figure 7.

504   Figure 7 shows the monthly discharge, in m^3s^{-1}, at each of the gauging stations described in this

505   study calculated from all complete months of data for each station. The strong seasonal pattern is

506   clearly visible at most of the stream gauges.

507


3.2.2 The central and northern Cordillera Blanca

509   Another catchment that contains two streamflow gauges is Quilcayhuanca, a valley
510 directly above the region's most populous city, Huaraz. The higher elevation stream gauge is
511 Cuchillacocha (referred to as CuchQ in Figure 1) which is situated at 4631 m a.s.l. and measures
512 discharge below a high-alpine lake and two cirque glaciers encompassing a drainage area of 4
513 km^2 (with 61% of the basin covered in ice). This station displays a noticeably different discharge
514 pattern throughout the year than the lower gauging stations which collect greater runoff.
515 Cuchillacocha discharge is not defined by a strong wet-dry season fluctuation, instead displaying
516 more variability each month and rising to peak values much earlier in the wet season than other
517 stream gauges. The average streamflow values at this location are also an order of magnitude
518 lower than other gauging stations due to the small drainage area it collects from (Figure 7).

519   The stream gauge located at a lower elevation in the Quilcayhuanca valley is Casa de
520 Agua (referred to as CDAQ in Figure 1) at 3948 m a.s.l. This gauging station is found near a

521 channel cut in the stream, in a large meadow, where water was previously rerouted for
522 agricultural purposes. This gauge collects drainage from an area of 67 km^2 below the confluence
523 of two upper catchments, Cuchillacocha and Cayesh, well above the city of Huaraz (3100 m
524 a.s.l.). From this drainage point in the watershed, the basin is approximately 25% glacierized.
525 The mean annual streamflow, calculated from six complete years of data at Casa de Agua, was 2
526 m^{3}s^{-1}, with a specific discharge of 943 mm a^{-1}.

527 The last streamflow gauge still recording data, Llanganuco (referred to as LlanQ in
528 Figure 1), is named after the valley it is located in and is positioned at 3850 m a.s.l., below two
529 valley lakes and a catchment area of 87 km^2, 30% of which is currently glacierized. The mean
530 annual streamflow, calculated from three complete years of data, was 2.3 m^{3}s^{-1}, with a specific
531 discharge of 835 mm a^{-1}. A stream gauge has been in commission at Llanganuco on and off for
532 68 years, beginning as a gauge for UGRH and hydroelectric companies and later, after the
533 original station became defunct, a site for our new, higher temporal resolution network of
534 gauges.

4 Data availability

536 The datasets presented here are available freely from
537 https://doi.org/10.4211/hs.506c1f66f87e4004b84e6af4097853a4 (Mateo et al., 2021). The
538 hydrological and meteorological data from the Cordillera Blanca have been used in short
539 segments in previous studies (Baraer et al., 2012; Baraer et al., 2015). Data availability varies
540 from station to station depending on location of loggers and instrumental errors which caused
541 periods of time to lapse without data being recorded. These datasets represent a majority of the
542 streamflow and meteorological data collected by our research group over the past two decades
543 collected at a high temporal resolution of 15-30 minutes. These include point discharge
544 measurements and short-time periods of 1-minute temporal resolution meteorological
545 measurements. The data provided here concludes in 2020, however future data collected by these
546 stations will be added to an updated version of the repository as future field seasons occur and
547 the effort to provide hydrometeorological data to the scientific community will continue at all of
548 the involved universities and institutions.

5 Conclusions

550 The Cordillera Blanca in the tropical Andes of Peru is a unique, high mountain region
551 where high resolution meteorological and hydrological time series observations collected from a
552 network of instruments over the past two decades have been compiled in a new dataset. The
553 region has been the focus of glacier monitoring efforts for nearly a century. While daily-to-
554 monthly time series of meteorological and hydrological observations have been recorded
555 discontinuously for nearly 70 years, there was no generalized sub-daily data monitoring until the
556 early 2000s. Maintaining this network of instruments recording high-temporal resolution data has

557   involved traveling to remote areas of the Cordillera Blanca, protecting the instruments from the
558   harsh weather conditions at high elevations, and concealing instruments to prevent theft. There is
559   also difficulty in developing long-term strategies because most funding agencies are focused on
560   short-term based projects and do not fund continuous monitoring and maintenance of data
561   collection networks. In the context of ongoing global climate change with variable localized
562   extremes, long-term monitoring of hydrometeorological variables is of utmost importance to
563   document and understand the changes that are occurring.

564   The datasets collected and described in this paper support investigations into climate
565   evolution, water resource availability, and hydrological changes across the Cordillera Blanca in
566   the past twenty-years. These datasets will also provide valuable, easy-to-access observations for
567   local water resource managers. This paper provides an overview of the variables which have
568   been measured and what is being made available as of 2021. Future measurements recorded in
569   the field will be made available as they are collected, to further build on the available hydro-
570   meteorological database in the Cordillera Blanca.

Author Contribution

EM prepared the manuscript with contributions from co-authors. EM, RH and MB curated the
data in preparation for this article. BGM acquired the initial funding for this international
research collaboration and instrumental network. All authors collaborated in fieldwork gathering
data and maintaining the instruments and dataloggers.

Competing Interests

The authors declare that they have no conflict of interest.

Acknowledgements

Funding for instrumentation, installation and field maintenance was provided by various
agencies and institutions associated with overlapping research projects and educational initiatives
through respective institutions. BGM acknowledges Ohio State University, National Science
Foundation (NSF #0752175 with REU supplement; NSF #1010384; NSF #1316432), National
Geographic Society, NASA (New Investigator Program), and US Fulbright (Award #4506).
