26 **Abstract.** This article presents a comprehensive hydrometeorological dataset collected over the
27 past two decades throughout the Cordillera Blanca, Peru. The data recording sites, located in the
28 upper portion of the Rio Santa valley, also known as the Callejon de Huaylas, span an elevation
29 range of 3738 - 4750 m a.s.l. As many historical hydrological stations measuring daily discharge
30 across the region became defunct after their installation in the 1950s, there was a need for new
31 stations to be installed and an opportunity to increase the temporal resolution of the streamflow
32 observations. Through inter-institutional collaboration the hydrometeorological network
33 described in this paper was deployed with goals to evaluate how progressive glacier mass loss
34 was impacting stream hydrology, and to better understand the local manifestation of climate
35 change over diurnal to seasonal and interannual time scales. The four automatic weather stations
36 supply detailed meteorological observations, and are situated in a variety of mountain
37 landscapes, with one on a high-mountain pass, another next to a glacial lake, and two in glacially
38 carved valleys. Four additional temperature and relative humidity loggers complement the
39 weather stations within the Llanganuco valley by providing these data across an elevation
40 gradient. The six streamflow gauges are located in tributaries to the Rio Santa and collect high
41 temporal resolution runoff data. The datasets presented here are available freely from
42 https://doi.org/10.4211/hs.059794371790407abd749576df8fd121 (Mateo et al., 2021).
43 Combined, the hydrological and meteorological data collected throughout the Cordillera Blanca
44 enable detailed research of atmospheric and hydrological processes in tropical high-mountain
45 terrain.

1 Introduction

Glaciers and water resources in the Cordillera Blanca, Peru, have been under close observation for nearly a century. In the 1930s, an Austrian geographer from Universitat Innsbruck, Hans Kinzl, laid the groundwork for glaciological research in the region by surveying and mapping the glaciers and identifying other natural features in the mountainous landscape (Kaser and Osmaston, 2002). While the first systematic Peruvian effort to observe glacier tongue variations in the Cordillera Blanca was initiated in 1944 by Broggi (Petersen et al., 1969), glaciers as a source of security and water resources became the object of study in the subsequent decades. The Unidad de Glaciología e Hidrología (later Unidad de Glaciología y Recursos Hidricos (UGRH) of Electroperú S.A.) was initiated by the Corporación Peruana del Santa, a government company for energy development, and took on glacier and lake monitoring after many glacial lake outburst flooding (GLOF) events damaged communities downstream (Ames, 1998). GLOFs in 1941, 1945, and 1950 killed over 6000 people and destroyed a third of the Ancash district capital of Huaraz (Carey, 2010; Carey et al., 2012). Other glacier hazards have had detrimental impacts on the communities as well, including the 1970 avalanche, triggered by a massive earthquake, which killed approximately 6000 people and along with the debris flow it produced, covered the city of Yungay (Carey, 2010). Lliboutry, Morales and Schneider (1977) investigated two glaciers in the mountain range in relation to the danger they presented for flooding a downstream power plant. From the 1970s to the 1990s, a local Peruvian from Huaraz, Alcides Ames, provided many important contributions to the present knowledge of glaciers in the Cordillera Blanca while employed at UGRH, and after his retirement continued to dedicate much of his time to studying the glaciers and sharing his knowledge with other researchers (Ames et al., 1989; Hastenrath and Ames, 1995; Ames and Hastenrath, 1996; Ames, 1998; Kaser and Osmaston, 2002). In the 1980s, Georg Kaser, an Austrian geographer, began studying the Cordillera Blanca with a focus on the extent, causes, and possible consequences of the observed glacier retreat (Kaser and Osmaston, 2002). For many decades, much of the research in the region focused on developing better maps of the mountains and observing the marked glacier retreat in the tropics. Although the meteorological and hydrological stations installed by UGRH had been in place for nearly 40 years, it was not until the mid-1990s when studies began to assess water resources in the Cordillera Blanca, but with minimal focus on flooding and GLOFs (Kaser and Georges 1997; Mark and Seltzer, 2003).

The UGRH spent many years collecting an abundance of climatological, hydrological, and glaciological data, which was useful for future researchers, hydroelectric and mining companies, and other stakeholders throughout the Cordillera Blanca and its glaciers. Since the mid-1990s, most of the daily-resolution discharge data from the Rio Santa watershed has been cataloged and collected at a much reduced number of sites by private energy companies who took over after Electroperu was privatized. The rapid turnover of the energy companies holding the discharge observations makes it difficult to track down all available historical data. Also, many of the hydrological stations have become defunct since they were installed in the 1950s,

96 creating a need for new stations to be installed for continuous monitoring of the region. A further
97 benefit of installing a new hydrological monitoring network in the 2000s was to significantly
98 increase the temporal resolution of the discharge observations.

99   Collaborating researchers from The Ohio State University, Bridgewater State University
100 and McGill University initiated a network of embedded environmental sensors in 2005. The
101 main goals of the instrument arrays were to evaluate how progressive glacier mass loss was
102 impacting stream hydrology, and to better understand the local manifestation of climate change
103 on the variability and controls of local weather phenomena over diurnal to seasonal and
104 interannual time scales. In order to create a sustainable network for continuous, long term
105 observation, this project has been maintained in close collaboration with Peruvian researchers
106 and government agencies, as well as with other international scientists to leverage resources in
107 maintaining instruments, in exchange for openly sharing data.

108   The instrumentation for the data collection we present in this work was installed and
109 maintained under a collaborative work agreement ("convenio") formalized with the Peruvian
110 government agency overseeing the office in Huaraz (Peruvian Institute of Natural Resources
111 (INRENA) and the Autoridad Nacional del Agua (ANA)). This work agreement involved a
112 secondary collaboration with other international researchers who shared in installing and
113 calibrating the instrumentation. Specifically, Dr. Thomas Condom of the French Institut de
114 Recherche pour le Developpement (IRD) joined the agreement to install and maintain a series of
115 stream gauges logging water stage at 15 minute intervals. We also collaborated with the Austrian
116 research team of Dr. Irme Juen and Professor Georg Kaser from the Universitat Innsbruck,
117 Austria, who co-located a precipitation gauge with our weather station in Llanganuco. Further
118 details about the instrumentation are provided below.

119   Inter-institutional collaboration in this fashion has provided an effective partnership to
120 aid in maintaining the instrumentation over time, but also introduces challenges of logistical
121 coordination and data continuity. Visitation as non-resident international scientists to the field
122 sites has been feasible only one or two times annually. Thus, the Peruvians in our collaboration
123 have incorporated our instruments within their routine monitoring network. This has permitted
124 regular observations of stations and instruments to download data loggers, perform stream
125 discharge measurement to build a rating curve, and undertake a limited range of repair work.
126 However, limitations in local resources and manpower in Peru have often prevented recordings
127 of stage observation and discharge measurement to constrain rating curves. Likewise, having
128 multiple operators also increases some risk for data recovery errors. For instance, loggers that are
129 improperly relaunched after data downloads can jeopardize subsequent acquisitions. Having
130 more frequent site visits can allow for interventions, but also incurs increased risk of operator
131 error. Furthermore, Peruvian domestic political changes have disrupted the operations by
132 introducing different leadership, with altered operational priorities and resources, which directly
133 or indirectly interrupt the continuity of trained personnel responsible for data recovery and

134 preservation. Overcoming the many challenges of maintaining the instrumentation and
135 constructing rating curves has required regular cross-cultural communication, multiple and
136 annual visitation to the region. Likewise, the rating curves continue to be refined as additional
137 measurements are made.

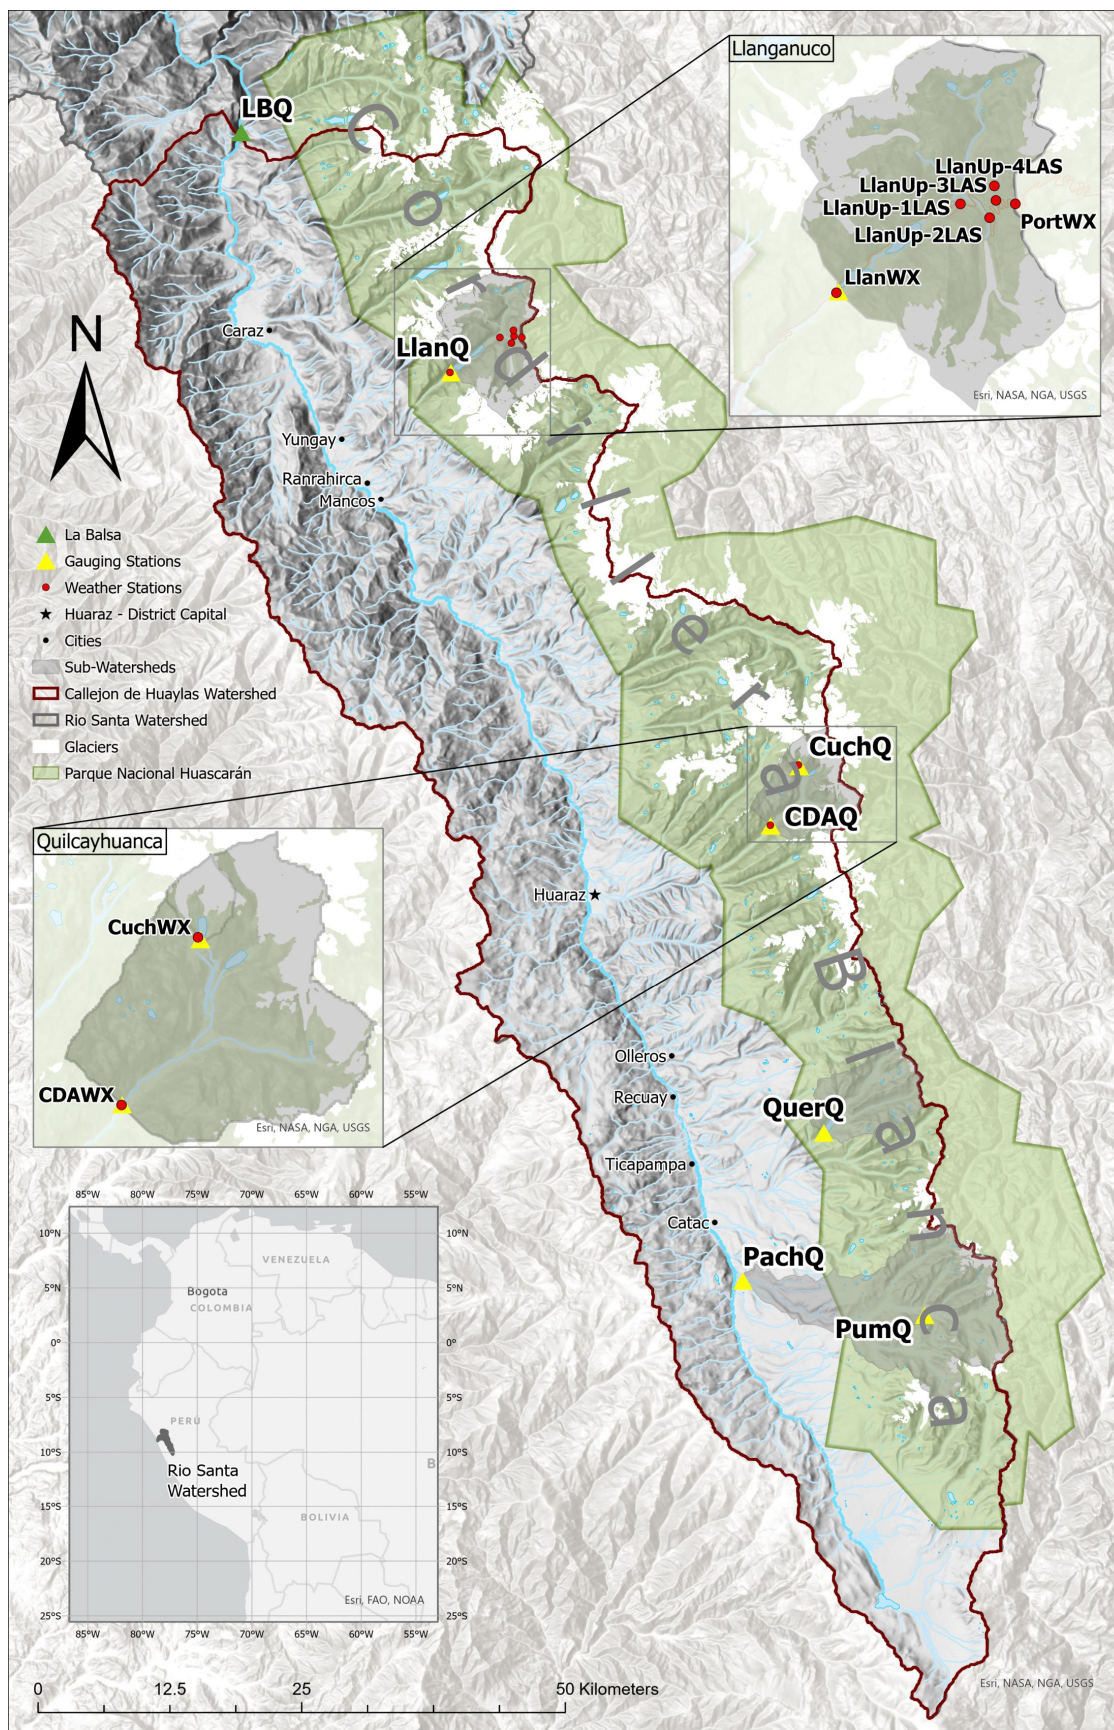
138   Our collaborative observations have provided important new insights into how the
139 hydroclimate of the region is changing on different scales. Updated discharge and climate
140 observations in specific glacier catchments documented important shifts in seasonal supply of
141 glacier storage to the Yanamarey catchment (Bury et al., 2011) as well as suggesting regional
142 thresholds in glacier melt provision (Mark et al., 2010). The discharge constraints also provided
143 important validation for a novel hydrochemical basin characterization method to quantify
144 proportionate glacier melt and groundwater contributions to streamflow in tributaries of varying
145 glacierized coverage (Baraer et al., 2009, 2015). Regionally, the gauge network provided the key
146 constraint for a model of time-progressive hydrograph evaluation that verified significantly that
147 the main catchment had already passed "peak water" in the wake of strong glacier recession
148 underway for multiple decades (Baraer et al., 2012). Our embedded temperature and humidity
149 loggers distributed over elevation and linked to weather stations in the Llanganuco valley have
150 revealed novel diurnal to seasonal variations in lapse rates linked to catchment-specific valley
151 wind dynamics validated with downscaled climate models (Hellstrom et al., 2017). These studies
152 demonstrate the importance of collecting in situ hydrometeorological data and indicate the need
153 for continued data collection in the high Andes (Condom et al., 2020).

154   In this paper, we document available data from the Cordillera Blanca area collected over
155 the past 15 years. It is separated into (i) meteorological data recorded by permanently installed
156 automatic temperature and relative humidity loggers (Lascars), or automatic weather stations,
157 and (ii) hydrological data consisting of stage and discharge data from multiple sub-catchments.
158 The data are stored in .csv extension format on Consortium of Universities for the Advancement
159 of Hydrologic Science, Inc. (CUAHSI) Hydroshare:
160 https://doi.org/10.4211/hs.059794371790407abd749576df8fd121 (Mateo et al., 2021). The data
161 collection consists of multiple time series of point observations from both meteorological and
162 hydrological measurement sites. These high-temporal resolution data provide detailed insight
163 into the complex hydro-meteorological system of the tropical Cordillera Blanca.

164 **2 Study Area - Cordillera Blanca**

165   The Rio Santa (Santa River) captures runoff from the western side of the glacierized
166 Cordillera Blanca and the eastern side of the non-glacierized Cordillera Negra, encompassing a
167 drainage area of 11636 km^2 at the outlet to the Pacific Ocean. While the headwaters of the Rio
168 Santa are found at Laguna Conococha at 4100 m above sea level (a.s.l.), the highest point in the
169 basin (and in Peru) is the summit of Huascaran at 6768 m a.s.l.. The average slope of the entire
170 drainage basin is 20.6° and its average elevation is 3374 m a.s.l. calculated from a 3 m resolution

171   DEM of the region. The Rio Santa flows over 300 km northwest from its origin at Laguna
172   Conococha, an alpine lake at 4000 m a.s.l., to its outlet into the Pacific Ocean, near Chimbote.
173   The Callejon de Huaylas refers to the upper section of the Rio Santa, comprising approximately
174   4773 km^2 located above the Cañon del Pato 50 MW hydroelectric generation plant in Huallanca
175   (Figure 1). The Rio Santa basin is home to three other hydroelectric plants and provides water to
176   the expansive Chavimochic irrigation district near the coast (Mark and McKenzie, 2007). The
177   discharge on the Rio Santa has been carefully monitored since the Cañon del Pato dam began
178   operating in the 1950s, however, only one station near the dam remains active which is situated
179   slightly upstream at La Balsa (labeled as LBQ in Figure 1).

180   Figure 1.
181   Map of the Callejon de Huaylas showing the locations of the hydrological and meteorological
182   stations. (Base layers of the map originated from: © Esri, © NASA, © NGA, © USGS, © FAO,
183   © NOAA; all other layers were created and edited by authors of this article.)


185   Rio Santa discharge experiences a strong seasonal contrast with the lowest discharge
186   occurring between July and September, while peak discharge, nearly 20 times greater, typically
187   occurs in March. Calculated from daily streamflow observations between 1954 and 2015, mean
188   annual streamflow at La Balsa station on the Rio Santa, is 87 m^3s^{-1}, while the average annual
189   minimum discharge is 25 m^3s^{-1}, and the average annual maximum discharge is 445 m^3s^{-1}. The
190   Callejon de Huaylas is approximately 10% covered in ice (RGI Consortium, 2017), has an
191   average slope of 19° and an average elevation of 4055 m a.s.l.. Glacial melt in the Rio Santa at
192   La Balsa provides 10-20% of the total annual discharge and may exceed 40% in the dry season
193   (Mark et al., 2005; Condom et al., 2012).

194   The climate of the Callejon de Huaylas is semi-arid and displays distinct precipitation
195   seasonality, with the wet season between October and May being responsible for 80% of the
196   800-1200 mm/year of precipitation (Baraer et al., 2009), and the dry season lasting from June to
197   September (Figure 2). As a localized example, the Llanganuco valley displays an average total of
198   8 mm during the dry season, and an average of total of 258 mm during the wet season months of
199   December, January, and February, based on monthly totals from 1953 to 2010 (Hellstrom et al.,
200   2017). Variations in river discharge are largely driven by seasonality of precipitation.
201   Temperature remains nearly constant in the outer tropics, with the annual variation in
202   temperature being smaller than diurnal variation (Kaser et al., 1990).

203   Figure 2.
204   A climograph from LlanWX in the Cordillera Blanca displaying the strong contrast in
205   precipitation between wet and dry seasons, while maintaining a steady temperature throughout
206   the entire year.

207
208   The geology in the Rio Santa basin is dictated by numerous tectonic and erosional
209   processes because the basin is situated along the active detachment fault of the Cordillera Blanca
210   (McNulty et al., 1998; Garver et al., 2005; Eddy et al., 2017). The highest peaks of the Cordillera

Blanca are composed largely of a granodiorite batholith intruded into a metamorphic unit that includes hornfels, gneiss, and sulfide-rich lithologies, such as pyrite schist, phyllite, and pyrite-bearing quartzite (Giovanni et al., 2010; Eddy et al., 2017). Granodiorite is found predominantly in the northern portion of the range, while the southern portion of the range is made up of a variety of metasediments, including quartzites and carbonates (Garver et al., 2005). The main valley of the Rio Santa watershed is covered by recent sediment deposits, including alluvium, landslide deposits, and glacial-fluvial fill. The impact of past and present glacier extent in the topography is visible in geomorphic features throughout the range, including steep walled U-shaped valleys, moraines, and proglacial lakes (Eddy et al., 2017).

3 The Data

In the following section, the data collected from the Cordillera Blanca are presented in two collections. First, we provide a description of the meteorological stations and embedded sensor network of Lascar data loggers, and then we present the time series data from the stations. Second, we provide details of the setup and context of the discharge gauging station network, and conclude by presenting the time series of discharge data and general statistics from them.

3.1 Meteorological Data

The Servicio Nacional de Meteorología e Hidrología del Perú (SENAMHI) has operated a relatively dense national network of meteorological stations since 1964. Air temperature is provided as daily T_{max} and T_{min} (additionally measured at 07:00, 13:00 and 19:00 local time), and precipitation is measured once a day. Some SENAMHI stations still provide daily temperature and precipitation data through their web portal, providing data back to 1980 (https://www.senamhi.gob.pe/?&p=descarga-datos-hidrometeorologicos), but very few stations within the Rio Santa Valley or Cordillera Blanca, Peru, remain active. Note that additional data from SENAMHI are available upon request from the Swiss MeteoDat GmbH team through a data portal (Schwarb et al. 2011, http://www.meteodat.ch/). In addition, the Universidad Nacional Santiago Antúnez de Mayolo (UNASAM) has maintained a network of what was originally 16 meteorological stations located at different elevations in the Cordillera Blanca (Ancash district) since 2012. Monthly totals of precipitation data for the Rio Santa watershed have been collected by Electroperú South America since 1953 although measurements were interrupted in the mid-1990's with the privatization of the respective institutions when most of the stations were abandoned and quality control was an issue (Kaser et al., 2003). More recent installations of weather stations in the Cordillera Blanca have been mostly associated with short-lived research projects typically lasting less than three years (Hofer et al., 2010; Georges and Kaser, 2002). The hourly meteorological observations we describe below were collected primarily from instrumentation we installed in two sub-catchments of the Rio Santa drainage basin, Llanganuco, and Quilcayhuanca.

247   The Llanganuco valley is situated on the western side of the Cordillera Blanca across a
248 southwest (~240°) to northeast (~60°) axis with elevations ranging from 3400 m a.s.l. to 6746 m
249 a.s.l. Llanganuco is one of most glacierized valleys in the mountain range at 30% glacier
250 coverage, making it one of the most glacierized tropical valleys in the world. In the Llanganuco
251 catchment, our group has installed multiple weather stations dating back to 2007, although only
252 one remains active. This currently active station, labeled LlanWX, is located at 3835 m.a.s.l. near
253 the lower of the two largest valley lakes (Table 1).

254 Table 1.
255 This table provides general information about each meteorological station (WX) and lascar data
256 logger (LAS) location within the embedded sensor network.

Station	Elevation (m a.s.l.)	Period of Operation	Lascar Error Adjustment	Slope Angle (°)	Slope Aspect (°)	Temporal Resolution
Cuchillacocha - CuchWX	4642	2013-Present	--	0	NA	30-min
Casa de Agua - CDAWX	3924	2013-Present	--	0	NA	30-min
Llanganuco - LlanWX	3835	2007-Present	Yes	0	NA	60-min
Portachuelo - PortWX	4750	2006-2015	--	0	NA	60-min
LlanUp-1/1A LAS	3955	2006-2015; 2015-Present	No	14	301	60-min
LlanUp-2/2A LAS	4122	2006-2014; 2015-Present	No	33	259	60-min
LlanUp-3/3A LAS	4355	2006-2015; 2015-Present	No	31	236	60-min
LlanUp-4/4A LAS	4561	2006-2015; 2018-Present	Yes	33	225	60-min
Portachuelo LAS	4767	2007-2015	Yes	9	180	60-min

258   The embedded sensor network (ESN), as described by Hellström et al. (2010) and
259 Hellström and Mark (2006), provides the in-situ meteorological data provided in the paper. In
260 July 2007 the first automatic weather station (AWS), LlanWX, was installed near the lower lake
261 in the Llanganuco valley to collect a continuous record of air temperature, wind speed, wind
262 direction, relative humidity, solar irradiance, and soil temperature/moisture (Table 2). The AWS
263 shown in Figure 3A is located in an open area on the valley floor and is surrounded by *Polylepis*
264 trees. A lascar data logger was also hung at this site for static calibration. The site is protected in
265 Huascaran National Park, and the location was previously used by the University of Innsbruck
266 for precipitation measurements. The most significant wind obstructions are the steep bedrock
267 walls of the valley toward the northwest and southeast which exceed 1000 meters above the
268 valley floor. Northerly and southerly winds are occasionally recorded by LlanWX, and are likely
269 caused by turbulence or lateral winds from the uneven heating of the valley walls. Winds flow
270 parallel to the axis of the valley during approximately 92% of the recorded time and are not
271 greatly obstructed by surface vegetation. The sensors for LlanWX were originally sourced from
272 the Onset Computer Corporation and logged with an Onset HOBO® data logger
273 (http://www.onsetcomp.com) until 2014 when these loggers were replaced with an Iridium®
274 satellite Data Garrison logger (http://www.upwardinnovations.com). A 102-mm diameter
275 radiation shield was used to reduce air temperature error caused by the sun except during the
276 following years: 2007, 2011-2014. During these years a separate data logger was used as the
277 primary source for air temperature and relative humidity observations. In 2013, our team
278 upgraded the station by replacing the wind sensors with two new units from Onset and a new
279 pyranometer from Apogee (http://www.apogeeinstruments.com/pyranometer) which exceeded
280 the 1277 Wm^{-2} maximum reading of the previous Onset sensors (Covert, 2016). The

281 observations from LlanWX are largely continuous since 2007, with data gaps occurring
282 occasionally between 2010 and 2014.

283 Table 2.
284 This table details the variables, sensors, and their accuracy which are collected at the
285 meteorological stations throughout the region.

Variable	Sensor	Accuracy	Unit
Air temperature	Onset HOBO S-THB-M002 Temperature RH Smart Sensor	± 0.2 °C	°C
Precipitation	Onset HOBO S-RGB-M002 0.2 mm Rainfall tipping bucket Smart Sensor	± 0.2 mm	mm
Relative humidity	Onset HOBO Temperature RH Smart Sensor: S-THB-M002	± 2.5 %	%
Wind speed	Onset HOBO S-WSB-M003 Wind Speed Smart Sensor	± 1.1 m/s	m/s
Wind direction	Onset HOBO S-WDA-M003 Wind Direction Smart Sensor	± 5 °	°
Incoming solar radiation	Onset HOBO S-LIN-M003 Solar Radiation Smart Sensor	± 10 W/m²	W/m²
Atmospheric pressure	Onset HOBO S-BPB-CM50 Smart Barometric Pressure Sensor	± 3.0 mb	mb
Soil temperature	Onset HOBO S-TMB-M002 12-bit Temperature Smart Sensor	± 0.2 °C	°C

286

287   A second AWS, situated at Portachuelo (referred to as PortWX in Figure 1), was installed
288 in July 2006 on a high pass at the top of the Llanganuco valley (4742 m a.s.l.). The station was
289 situated on a steep, rocky ridge between the Llanganuco valley and the Vaqueria valley. There
290 were only wind obstructions to the north due to a steep rock wall within 10 m of the station

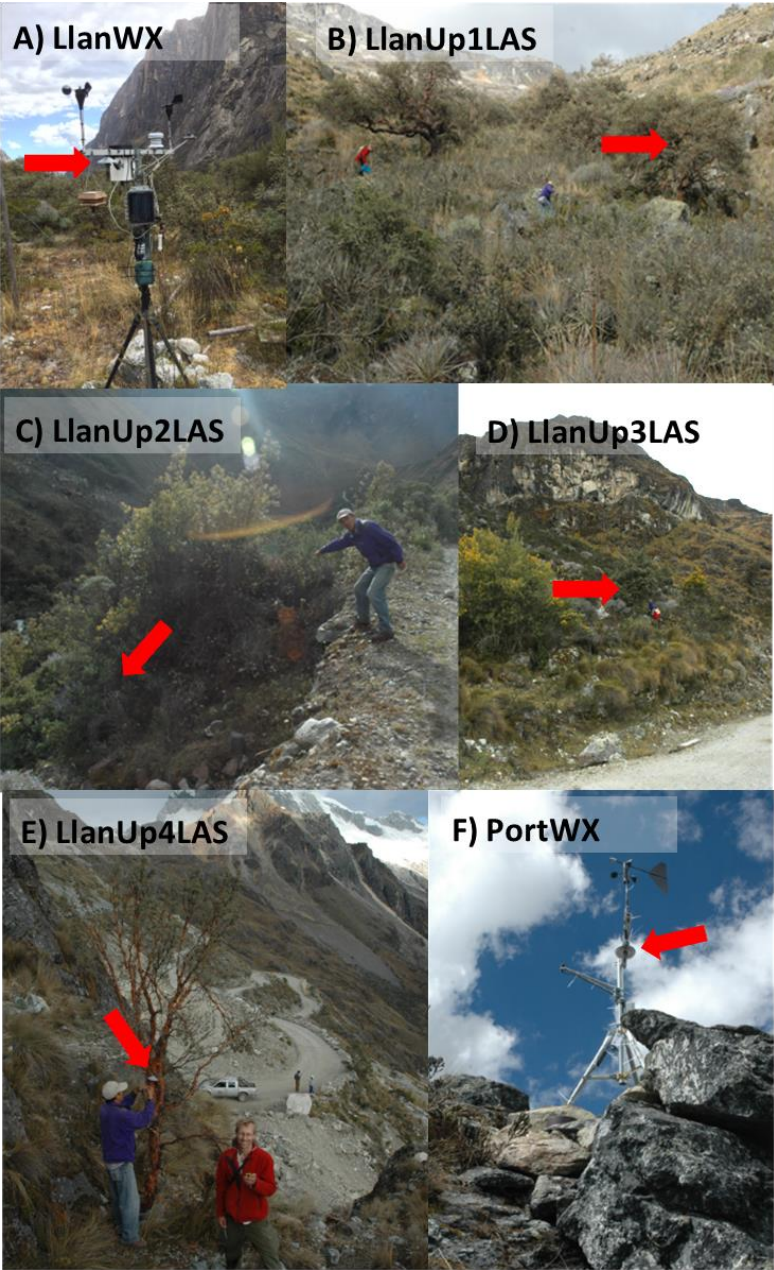
291   location. The AWS at Portachuelo had the same sensors as its counterpart, LlanWX, however
292   was lacking an air temperature and relative humidity sensor with a radiation shield until it was
293   installed in July 2015. Prior to this upgrade, these variables were recorded each hour by a Lascar
294   data logger part of the ESN discussed in the following section. The Portachuelo station was
295   stolen in 2015 after recording data for nine years; a replacement station installed in 2016 was
296   also stolen so the site was abandoned.

297   Figure 3.
298   The typical setup for the HOBO automatic weather station, shown here is the LlanWX station
299   near the lower lake in Llanganuco. Measurements include: air temperature, humidity, wind speed
300   and direction, incoming solar radiation, rainfall, and soil temperature and soil moisture at -10cm.
301   Note also the two Lascars with different radiation shields hanging from crossbar. Photographs
302   taken by R. Hellström (Covert, 2016).

303

304   Smaller loggers measuring air temperature were installed in June 2005 to begin collecting
305   near surface temperatures to calculate lapse rates (Table 1). These data loggers were a series of 8
306   nickel sized iButton Thermochron® temperature loggers (Figure 3). Hellström et al. (2010)
307   demonstrated the effectiveness of using the Thermochron loggers for purposes of observing near
308   surface lapse rates within the Llanganuco valley between the elevations 3470 and 4740 m a.s.l.
309   (Covert, 2016). The ESN of iButtons was replaced in July 2006 with a more robust network of
310   Lascar El-USB2 data loggers (www.lascarelectronics.com) which were setup to measure air
311   temperature and relative humidity at one-hour intervals. Each Lascar logger is attached to a
312   custom-designed and locally crafted radiation shield made of a thin tin cone and two Styrofoam
313   pieces in order to reduce error caused by direct sunlight, as shown in Figure 3B. Figure 4 (from:
314   Covert, 2016) provides photos for a visual landscape context for each Lascar logger. Because the
315   LlanWX, LlanUp-4, and PortWX Lascar loggers are nearly entirely exposed to sunlight, the
316   recorded air temperature values in the dataset are higher than expected and contain greater error

317 than actual temperatures during the day (see section 4.1 for details). This Lascar network is still
318 recording hourly data.

319 Figure 4.
320 Photos A-F show the locations of all Lascar dataloggers labeled by names matching Table 1.
321 Photographs taken by B. Mark and R. Hellström (Covert, 2016).


322

323   Quilcayhuanca contains two weather stations (Table 1) similar to the LlanWX station in
324 Llanganuco valley, the lower is located at 3924 m a.s.l. near an old river diversion station called
325 Casa de Agua (station referred to as CDAWX in Figure 1), and the upper is located at 4642 m

326   a.s.l. slightly above an alpine lake, Cuchillacocha (station referred to as CuchWX in Figure 1).
327   CDAWX collects all of the same variables as LlanWX (Table 2), is still active since its
328   installation in July 2013 and data are mostly continuous over this duration. CuchWX was also
329   installed in July 2013, is still presently active, and only has one data gap lasting longer than a
330   month (from November 2016 – June 2017).

331   3.1.1 Relative Humidity Error Correction for LlanWX

332

333   In 2006 and 2007 saturation of the humidity sensor at LLanWX resulted in relative
334   humidity values greater than 100% (as high as 110%) resulting from dust and condensation on
335   the humidity sensor and persisting during the wet season for periods of up to about 48 hours,
336   with periods of reasonable humidity values during drier periods. In light of data preservation,
337   these erroneously supersaturated values were simply replaced with 100% relative humidity; this
338   correction is referred to as "Lascar Error Adjustment" in Table 1. Note that the dew point was
339   equal to the air temperature for values of relative humidity 100% or greater, so no adjustment
340   was made for dew point. The humidity sensor was replaced in June 2007 and the correction was
341   no longer needed. Both the original and corrected values are retained in the LlanWX data file.
342   There was no similar humidity error observed for PortWX or any of the LAS sensors.

343   3.1.2 Radiation Error Correction for Lascar Temperature Loggers

344   A year-long comparison between the Lascar (Figure 5) and LlanWX AWS temperature
345   sensors indicated an expected error in the Lascar that was largely dependent on the time of day.
346   Variability in temperature bias due to solar radiative heating is likely caused by changes in solar
347   angle and cloud cover patterns, particularly during the dry season. It is well documented that
348   daytime temperature error rises on sunny days with calm wind and is reduced on windy and
349   cloudy days regardless of the season but is far more prominent during the dry season in the
350   tropical Andes (Georges and Kaser, 2002). It is important to note that snow cover, which can
351   create larger biases in temperature by reflected solar radiation, is minimal throughout the year at
352   the locations of the Lascars in this study. Over an entire month, nightly error was within the 0.5
353   °C resolution of the Lascar sensor. The occasional occurrence of greater nighttime error could be
354   caused by the sensor capturing longwave radiation emitted by the surface. The primary source of
355   consistent instrumentation error for air temperature measurements is the heating of radiation
356   shields from those locations exposed to direct sunlight, which required bias correction according
357   to Figure 5. We bias-corrected for radiation error using comparison with the LlanWX shielded
358   temperature and Lascar logger hanging next to it under the same exposure, including the
359   LlanWX, LlanUp-4 LAS, and PortWX station locations. We conducted this same comparison
360   when replacing Lascar sensors in 2015 and found no significant differences between old and
361   new sensors. Because solar radiation is the predominant source of error, corrections were only
362   applied to daylight hours between 07:00 to 19:00 (Covert, 2016).
363

364 Figure 5.
365 Image A displays a Lascar data logger connected to its cone radiation shield. Two white
366 Styrofoam plates beneath the cone insulate the sensor from radiative heating. Image B shows the
367 radiation shields used on the AWS in comparison to the Lascar setup in image A. Image C shows
368 polylepis trees which are used to hide and shade Lascars in order to obtain accurate temperature
369 and relative humidity values. A comparison test between the Lascar setup and the AWS radiation
370 shield with no shading yielded the expected errors shown in graph D. Positive values indicate
371 that the Lascar reported a temperature higher than the AWS sensor. Photographs taken by R.
372 Hellström (Covert, 2016).

373

374

375
376
3.1.3 Data Gaps and Other Quality Control Checks

378   The most common reasons for gaps in data was either loss of sensors due to theft or
379 inability to access sensors because of logistical reasons, such as poor weather conditions or
380 human error during downloading or redeploying of sensors. In addition to corrections for solar
381 radiation heating and the relative humidity correction, humidity and temperature records were
382 assessed for accuracy and outliers removed if there were unrealistic deviations from the previous
383 24-hour trend of conditions within the valley. Most of these deviations occurred during time
384 intervals coincident with sensor deployment, battery replacement or data download, although
385 data (less than 1%) were also removed if there was a concern with the integrity of the sensor.
386 The four Lascar loggers were replaced or had new radiation shields installed in June 2015, and
387 likewise renamed in the dataset as LlanUp-1A, 2A, 3A, and 4A.

3.2 Hydrological Data

389   The La Balsa gauge (8.87° S, 77.82° W at 1880 m a.s.l.) (Duke Energy, Orazul Energy,
390 Inkia Energy) near the diversion canal for the Cañon del Pato hydroelectric plant has a nearly

391 complete record since 1954, acting as a long-term reference point for discharge on the Rio Santa
392 at the base of the Callejon de Huaylas basin. Many other stream gauges and precipitation stations
393 were put in place by the hydroelectric companies, however, due to the lack of maintenance these
394 stations became unusable after the mid-1990's. In 2008, The Ohio State University, McGill
395 University, IRD, and the Peruvian glaciology unit of ANA commenced a joint project to
396 reinstitute a stream gauging network throughout the Cordillera Blanca (Baraer et al., 2012).
397 Many of these redeployed stream gauges in sub-catchments of the Rio Santa are still in working
398 condition and are continuing to be monitored.

399   The stream gauges comprise custom-designed and locally crafted steel stilling wells
400 containing two Solinst leveloggers (Figure 6), with one measuring total pressure (water plus
401 atmospheric), and the other measuring barometric pressure. The Model 3001 Solinst levelogger
402 Edge has an accuracy of ± 0.05 kPa and a resolution of 0.002% Full Scale (FS) for pressure and
403 a temperature accuracy of $\pm 0.05°$ C, and a temperature resolution of $0.003°$ C
404 (www.solinst.com). Water level is continuously monitored at these gauges at a temporal
405 resolution of 15-minutes by subtracting atmospheric pressure from the total pressure. The
406 adjusted water level variable in the discharge datasets indicates the adjustment based on where
407 the water level logger was located in the water column. This measurement is conducted in the
408 field using a built-in meter stick at each gauging station. Rating curves at all stations were
409 established and verified by conducting discharge measurements using the velocity area method.
410 Unavailable data is denoted by "NA" in the dataset. Linear interpolation of missing data was
411 only calculated for missing periods of less than 1 hour, coinciding with the time the leveloggers
412 were being downloaded in the field. Other than these short periods of interpolated data, the
413 datasets provided consist of raw data.

414 Figure 6.
415 Figure 6 illustrates the design of the stilling wells used to collect total pressure (water +
416 barometric) and barometric pressure. The photograph shows the stilling well and the insert tube
417 containing the pressure data loggers.

418
419   The stream gauges that were installed in 2008 and 2009 and which are continuing to
420 collect discharge are Casa de Agua, Cuchillacocha, Pachacoto, Llanganuco, and Querococha
421 (Figure 1). The Pumapampa gauge went out of commission in 2016 but is also included in this
422 dataset (Table 3). These stream gauges have variable lengths of record due to periods of missing
423 data, but still provide valuable streamflow information in a region where stream records are
424 limited. As shown in the map (Figure 1), two pairs of these stream gauges are located at different
425 points along the same Rio Santa tributary in their respective sub-catchments: Pumapampa and
426 Pachacoto in the Pachocoto valley; and Cuchillacocha and Casa de Agua in the Quilcayhuanca
427 valley. All discharge measurements are calculated from rating curves containing a minimum of
428 eight point measurements throughout all times of the year. Rating curves are not directly
429 provided in this data paper because they are variable in nature as we collect new discharge
430 measurements in the field. Rating curves are available upon request. The following two
431 subsections provide a brief overview and summary for each gauging station, organized by
432 general location in the Cordillera Blanca, moving from the southern end of the mountain range to
433 the northern. Note that all glacier coverage is calculated from RGI 6.0 (RGI Consortium, 2017).

434 Table 3.
435 This table provides geographical information about each of the hydrological gauging stations.
436 Note that all glacier coverage is calculated from RGI 6.0 (RGI Consortium, 2017).

Station	Latitude	Longitude	Elevation (m a.s.l.)	Period of Operation	Contributing Area (km²)	Percent basin covered in ice (%)
Cuchillacocha - CuchQ	-9.41	-77.35	4631	2008-Present	4.1	60.49
Casa de Agua - CDAQ	-9.46	-77.37	3948	2009-Present	66.9	24.78
Pumapampa - PumQ	-9.88	-77.24	4287	2008-2016	58.1	8.33
Pachacoto - PachQ	-9.85	-77.4	3738	2008-Present	202.3	4.95
Llanganuco - LlanQ	-9.07	-77.65	3850	2008-Present	86.9	30.32
Querococha - QuerQ	-9.72	-77.33	4005	2008-Present	62.9	1.53

437

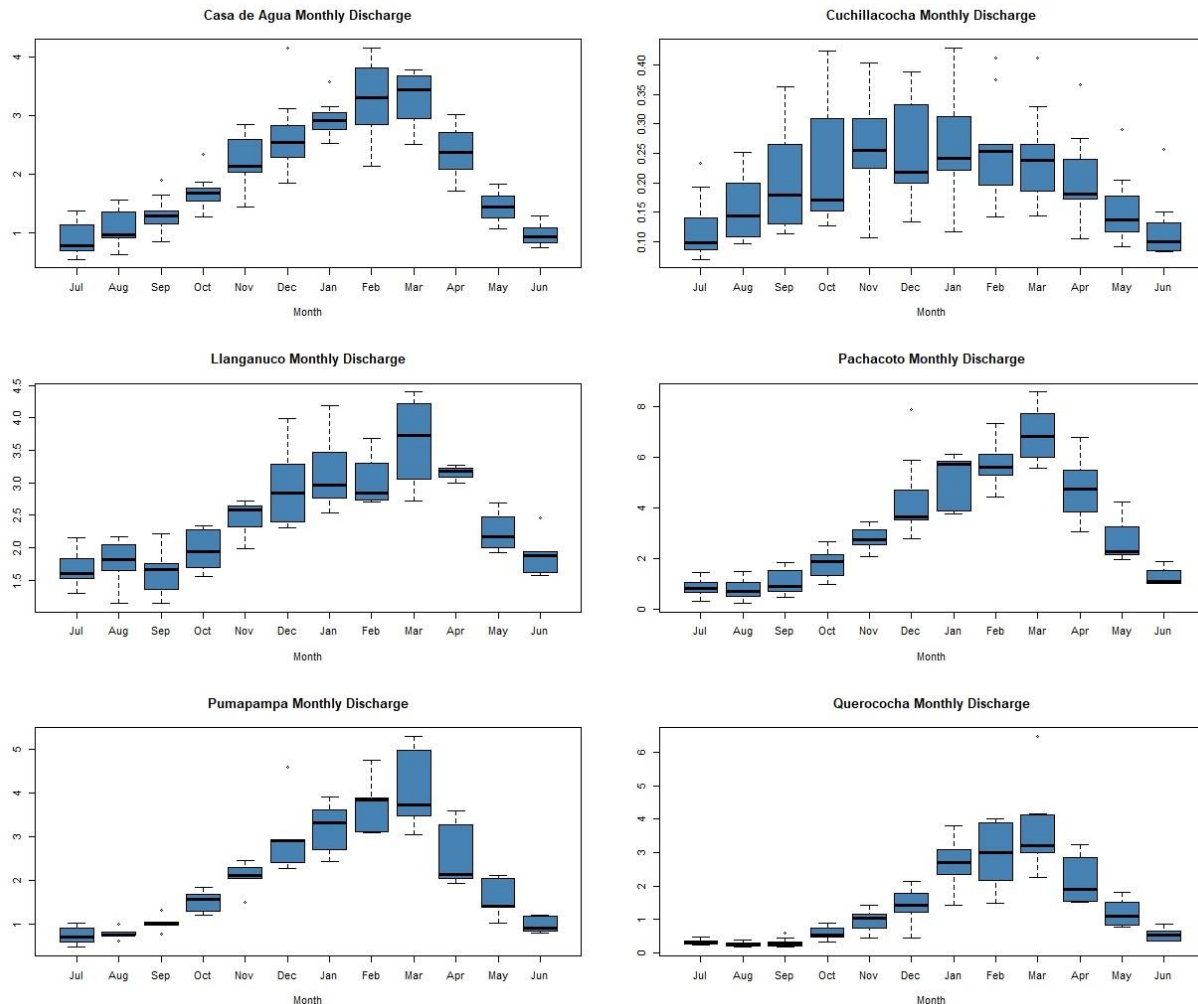
438 **3.2.1 The southern Cordillera Blanca**

439   The Pumapampa catchment encompasses 58 km^2 with about 8% being covered by
440   glaciers (Table 3). Pumapampa gauge (referred to as PumQ in Figure 1) is located at 4287 m
441   a.s.l., below Nevado Pastoruri at the southern end of the Cordillera Blanca. This stream gauge is
442   situated in a channel through a low-lying meadow, where wet-season flow exceeds bankfull
443   stage, causing inaccuracies in high discharge measurements. Most notably, a series of values in
444   late-February 2014 indicated a peak discharge of 25 m^{3}s^{-1}, well above extremes measured from
445   the rating curve. It was determined that during this period the leveloggers were overrun by water
446   and measurements became unreliable solely during this flooding event. Outside of this event,
447   discharge at Pumapampa is consistently within the measured values on the rating curve. Mean
448   annual streamflow (averaged from three years of data missing less than one-month during the
449   entire year) at this stream gauge was 2.3 m^{3}s^{-1} and a specific discharge of 1248 mm a^{-1}. Mean
450   streamflow during the dry season (May through September) in Pumapampa was 1 m^{3}s^{-1}, while
451   the mean streamflow during the wet season (October through April) was 2.9 m^{3}s^{-1}. Highest mean
452   monthly streamflow occurred in March 2014 with an average of 5.3 m^{3}s^{-1} (Figure 7).

453   The Pachacoto gauge (referred to as PachQ in Figure 1) measures discharge 19 km
454   downstream from Pumapampa, at 3738 m a.s.l., just above its confluence with the Rio Santa.
455   Streamflow at Pachacoto is significantly greater than Pumapampa as it is the drainage point for a
456   larger area of 202 km^2, 5% of which is covered by glaciers. The mean annual streamflow at
457   Pachacoto was 3.2 m^{3}s^{-1}, averaged from the seven near-complete years of data, with a calculated
458   specific discharge of 499 mm a^{-1}. Dry season runoff accounted for approximately 20% of the
459   annual streamflow by volume, while the majority of the remaining wet season runoff occurred
460   during February and March.

461   Streamflow at another tributary catchment in the southern Cordillera Blanca is recorded
462   at the Querococha gauge (referred to as QuerQ in Figure 1) at 4005 m a.s.l., located 100 m
463   downstream of Querococha lake and defining a drainage area of 63 km^2, 1.5% of which is
464   glacierized. This drainage collects from two sub-catchments, one of which is entirely glacier-
465   free, while the other contains rapidly receding ice masses including the Yanamarey glacier.
466   Using five years of complete data, the mean annual streamflow at this gauging station was
467   calculated to be 1.4 m^{3}s^{-1} and the specific discharge was 702 mm a^{-1}. The streamflow from this
468   gauge is somewhat regulated by Querococha, the second largest lake in the Cordillera Blanca.
469   This catchment has featured many previous research studies and many other instruments
470   throughout the basin are still consistently monitored by ANA.

471   Figure 7.
472   Figure 7 shows the monthly discharge, in m^{3}s^{-1}, at each of the gauging stations described in this
473   study calculated from all complete months of data for each station. The strong seasonal pattern is
474   clearly visible at most of the stream gauges.

475


3.2.2 The central and northern Cordillera Blanca

477   Another catchment that contains two streamflow gauges is Quilcayhuanca, a valley
478 directly above the region's most populous city, Huaraz. The higher elevation stream gauge is
479 Cuchillacocha (referred to as CuchQ in Figure 1) which is situated at 4631 m a.s.l. and measures
480 discharge below a high-alpine lake and two cirque glaciers encompassing a drainage area of 4
481 km^2 (with 61% of the basin covered in ice). This station displays a noticeably different discharge
482 pattern throughout the year than the lower gauging stations which collect greater runoff.
483 Cuchillacocha discharge is not defined by a strong wet-dry season fluctuation, instead displaying
484 more variability each month and rising to peak values much earlier in the wet season than other
485 stream gauges. The average streamflow values at this location are also an order of magnitude
486 lower than other gauging stations due to the small drainage area it collects from (Figure 7).

487   The stream gauge located at a lower elevation in the Quilcayhuanca valley is Casa de
488 Agua (referred to as CDAQ in Figure 1) at 3948 m a.s.l. This gauging station is found near a
489 channel cut in the stream, in a large meadow, where water was previously rerouted for

490   agricultural purposes. This gauge collects drainage from an area of 67 km^2 below the confluence
491   of two upper catchments, Cuchillacocha and Cayesh, well above the city of Huaraz (3100 m
492   a.s.l.). From this drainage point in the watershed, the basin is approximately 25% glacierized.
493   The mean annual streamflow, calculated from six complete years of data at Casa de Agua, was 2
494   m^{3}s^{-1}, with a specific discharge of 943 mm a^{-1}.

495   The last streamflow gauge still recording data, Llanganuco (referred to as LlanQ in
496   Figure 1), is named after the valley it is located in and is positioned at 3850 m a.s.l., below two
497   valley lakes and a catchment area of 87 km^2, 30% of which is currently glacierized. The mean
498   annual streamflow, calculated from three complete years of data, was 2.3 m^{3}s^{-1}, with a specific
499   discharge of 835 mm a^{-1}. A stream gauge has been in commission at Llanganuco on and off for
500   68 years, beginning as a gauge for UGRH and hydroelectric companies and later, after the
501   original station became defunct, a site for our new network of gauges.

4 Data availability

503   The datasets presented here are available freely from
504   https://doi.org/10.4211/hs.059794371790407abd749576df8fd121 (Mateo et al., 2021). The
505   hydrological and meteorological data from the Cordillera Blanca have been used in short
506   segments in previous studies (Baraer et al., 2012; Baraer et al., 2015). Data availability varies
507   from station to station depending on location of loggers and instrumental errors which caused
508   periods of time to lapse without data being recorded. These datasets represent a majority of the
509   streamflow and meteorological data collected by our research group over the past two decades
510   collected at a high temporal resolution of 15-30 minutes. These include point discharge
511   measurements and short-time periods of 1-minute temporal resolution meteorological
512   measurements. The data provided here will be added to as future field seasons occur and the
513   effort to provide hydrometeorological data to the scientific community will continue at all of the
514   involved universities and institutions.

5 Conclusions

516   The Cordillera Blanca in the tropical Andes of Peru is a unique, high mountain region
517   where high resolution meteorological and hydrological time series observations collected from a
518   network of instruments over the past two decades have been compiled in a new dataset. The
519   region has been the focus of glacier monitoring efforts for nearly a century. While daily-to-
520   monthly time series of meteorological and hydrological observations have been recorded
521   discontinuously for nearly 70 years, there was no generalized sub-daily data monitoring until the
522   early 2000s. Maintaining this network of instruments recording high-temporal resolution data has
523   involved traveling to remote areas of the Cordillera Blanca, protecting the instruments from the
524   harsh weather conditions at high elevations, and concealing instruments to prevent theft. There is
525   also difficulty in developing long-term strategies because most funding agencies are focused on
526   short-term based projects and do not fund continuous monitoring and maintenance of data

527   collection networks. In the context of ongoing global climate change with variable localized
528   extremes, long-term monitoring of hydrometeorological variables is of utmost importance to
529   document and understand the changes that are occurring.

530   The datasets collected and described in this paper support investigations into climate
531   evolution, water resource availability, and hydrological changes across the Cordillera Blanca in
532   the past twenty-years. These datasets will also provide valuable, easy-to-access observations for
533   local water resource managers. This paper provides an overview of the variables which have
534   been measured and what is being made available as of 2021. Future measurements recorded in
535   the field will be made available as they are collected, to further build on the available hydro-
536   meteorological database in the Cordillera Blanca.

537   **Author Contribution**

538   EM prepared the manuscript with contributions from co-authors. EM, RH and MB curated the
539   data in preparation for this article. BGM acquired the initial funding for this international
540   research collaboration and instrumental network. All authors collaborated in fieldwork gathering
541   data and maintaining the instruments and dataloggers.

542   **Competing Interests**

543   The authors declare that they have no conflict of interest.

544   **Acknowledgements**

545   Funding for instrumentation, installation and field maintenance was provided by various
546   agencies and institutions associated with overlapping research projects and educational initiatives
547   through respective institutions. BGM acknowledges Ohio State University, National Science
548   Foundation (NSF #0752175 with REU supplement; NSF #1010384; NSF #1316432), National
549   Geographic Society, NASA (New Investigator Program), and US Fulbright (Award #4506).
