10 **Abstract.** The retrieval of solar induced chlorophyll fluorescence (SIF) from space is a relatively new  
11 advance in Earth observation science, having only become feasible within the last decade. Interest in SIF  
12 data has grown exponentially, and the retrieval of SIF and the provision of SIF data products has become  
13 an important and formal component of spaceborne Earth observation missions. Here, we describe the global  
14 Level 2 SIF Lite data products for the Greenhouse Gases Observing Satellite (GOSAT), the Orbiting  
15 Carbon Observatory-2 (OCO-2), and OCO-3 platforms, which are provided for each platform in daily  
16 netCDF files. We also outline the methods used to retrieve SIF and estimate uncertainty, describe all the  
17 data fields, and provide users the background information necessary for the proper use and interpretation  
18 of the data, such as considerations of retrieval noise, sun-sensor geometry, the indirect relationship between  
19 SIF and photosynthesis, and differences among the three platforms and their respective data products. OCO-  
20 2 and OCO-3 have the highest spatial resolution spaceborne SIF retrievals to date, and the target and  
21 snapshot area mode observation modes of OCO-2 and OCO-3 are unique. These modes provide hundreds  
22 to thousands of SIF retrievals at biologically diverse global target sites during a single overpass, and provide  
23 an opportunity to better inform our understanding of canopy-scale vegetation SIF emission across biomes.

## 24 1 Introduction

25 Chlorophyll fluorescence is light that is emitted from chlorophyll after the absorption of photosynthetically  
26 active radiation (PAR), which covers the spectral range of roughly 400 to 700 nm and corresponds to the  
27 range of light visible to the human eye (Müller, 1874). The fluorescence emission occurs in the range of  
28 ~650 to 800 nm during the light reaction of photosynthesis, where energy absorbed by leaf pigments is  
29 converted into the chemical energy that is needed by the dark reactions for fixing atmospheric carbon

30 dioxide into sugars. The absorption of a photon by chlorophyll excites an electron, and the excitation energy  
31 has three main pathways: photochemistry, non-photochemical quenching or heat, and chlorophyll  
32 fluorescence. Most of the excitation energy is used for photochemistry when vegetation is not stressed, but  
33 at all times only a small fraction (~0.5-2%) is emitted as chlorophyll fluorescence (Porcar-Castell et al.,  
34 2014; Maxwell and Johnson, 2000).

35  
36 Chlorophyll fluorescence has been a research tool for studying photosynthesis for nearly 150 years (Müller,  
37 1874), but only recently have spaceborne retrievals of solar induced chlorophyll fluorescence (SIF) been  
38 realized (Guanter et al., 2007; Joiner et al., 2011; Frankenberg et al., 2011b). The number of spaceborne  
39 platforms from which SIF can be retrieved continues to grow, and the SIF temporal record continues to  
40 lengthen. Spaceborne SIF data has generated much excitement in a plethora of fields within the biological,  
41 biogeochemical cycle, climate, and Earth system science communities. Chlorophyll fluorescence has long  
42 been a key component of the plant physiological and ecophysiological research communities (Maxwell and  
43 Johnson, 2000) and has traditionally been studied *in vivo* at the subcellular level and *in situ* using pulse  
44 amplitude-modulated (PAM) fluorometry (Schreiber et al., 1986).

45  
46 Most recently, remote sensing techniques have enabled the canopy and ecosystem-level retrieval of SIF  
47 from towers, aircraft, and satellites. The evolution in our ability to retrieve SIF infrequently at the leaf-level  
48 to frequent canopy-level retrievals across regional to global scales continues to greatly advance our  
49 understanding of plant and ecosystem function and carbon cycling.

50  
51 Here, we describe, compare, and discuss the Level 2 SIF Lite version 9 (v9) data produced from the  
52 Greenhouse Gases Observing Satellite (GOSAT; <http://dx.doi.org/10.22002/D1.8771>) and Level 2 SIF Lite  
53 version 10 (v10) data from the Orbiting Carbon Observatory-2 (OCO-2) and OCO-3 (OCO-2 Science Team  
54 et al., 2020; OCO-3 Science Team et al., 2020). Our data description goes beyond previous documentation  
55 and publications via our description of the SIF Lite files and our presentation and comparison of the SIF  
56 data from the three platforms. Also, our discussions on SIF are intended to help the data user community  
57 to access and apply the data for scientific research and prevent misinterpretation.

58

59

## 60 **2 Satellite platforms**

61 The retrieval of SIF from space requires high spectral resolution and a high signal-to-noise ratio (SNR) as  
62 solar Fraunhofer lines are very narrow and SIF is a relatively weak signal (Frankenberg et al., 2011b).  
63 Coincidentally, the spaceborne spectrometers that have been used for retrieving Earth's atmospheric carbon  
64 dioxide and methane concentrations include spectral channels covering Fraunhofer lines in the vicinity of  
65 the oxygen A-band where atmospheric mass is retrieved with high spectral resolution ( $< 0.2$  nm), enabling  
66 SIF retrievals with a mean single measurement precision around  $\sim 0.5$  W/m<sup>2</sup>/sr/ $\mu$ m. Thus, the retrieval of  
67 SIF from space has been pioneered by the atmospheric science community (Guanter et al., 2007; Joiner et  
68 al., 2011; Frankenberg et al., 2011b), and spaceborne SIF retrievals and data products have historically been  
69 a by-product of missions that have aimed to monitor Earth's atmospheric trace gases.

### 70 **2.1 GOSAT**

71 GOSAT (aka Ibuki) was developed by the Japan Aerospace Exploration Agency (JAXA) and launched in  
72 January 2009. In fact, the first global satellite SIF observations came from GOSAT (Joiner et al., 2011;  
73 Frankenberg et al., 2011b). Onboard the satellite is the greenhouse gas observation sensor (TANSO-FTS),  
74 which has a spectral resolution of 0.012 nm ( $0.2$  cm<sup>-1</sup>). The sensor has four bands: 0.758-0.775  $\mu$ m, 1.56-  
75 1.72  $\mu$ m, 1.92-2.08  $\mu$ m, and 5.56-14.3  $\mu$ m. It has a sun synchronous, descending orbit with an overpass  
76 time of 13:00  $\pm$  15 minutes at the equator, a three-day repeat cycle, and a circular footprint of  $\sim 82$  km<sup>2</sup> per  
77 sounding ( $\sim 10$  km diameter) (Kuze et al., 2009).

### 78 **2.2 OCO-2 and OCO-3**

79 OCO-2 is a NASA satellite that was launched in July 2014, and OCO-3 is a duplicate of the OCO-2 grating  
80 spectrometer attached to the Japanese Experimental Module Exposed Facility (JEM-EF) on the  
81 International Space Station (ISS) in May 2019 (Eldering et al., 2019). Each platform houses a three-channel  
82 grating spectrometer with a spectral resolving power of  $\lambda/\Delta\lambda > 17,000$  (Crisp et al., 2017; Eldering et al.,  
83 2019) centered around the following wavelengths: an oxygen-A band at 0.765  $\mu$ m and carbon dioxide bands  
84 at 1.61  $\mu$ m and 2.06  $\mu$ m. The swath widths are  $\sim 10$  km with eight measurements across-track. The spatial  
85 resolution at nadir is slightly different for OCO-2 and OCO-3, about 1.3 km  $\times$  2.25 km and 1.6 km  $\times$  2.2  
86 km (across  $\times$  along track), respectively.

87

88 OCO-2 has a 98.8 minute orbit with a 1:36 PM nodal crossing time and a 16-day ground-track repeat cycle  
89 (Crisp et al., 2017). The ISS has a precessing low-inclination orbit that allows OCO-3 to view Earth at  
90 absolute latitudes less than  $\sim 52^\circ$ . The ISS orbits the Earth  $\sim 15.5$  times a day and data acquisition is halted  
91 during ISS maintenance and docking, thus overpass times, revisit periods, and data availability are relatively

92 irregular. Validation of the OCO-2 SIF retrievals was conducted by Sun et al. (2017) by comparing OCO-  
93 2 SIF to coordinated airborne measurements using the Chlorophyll Fluorescence Imaging Spectrometer  
94 (Frankenberg et al., 2018).

### 95 **2.3 Observation Modes**

96 GOSAT observation modes are described as Observation Mode 1 Sunshine (OB1D), Observation Mode 2  
97 Sunshine (OB2D), and Specific Observation Mode Sunshine (SPOD). OB1D is the routine observation  
98 mode, whereas OB2D is a non-routine mode in which the thermal-infrared observation and pointing  
99 mechanism is stopped during low power supply. Over land, SPOD is a target observation mode designed  
100 to observe specific sites. The TANSO-FTS sensor has a setting for low, medium, and high gain. The  
101 medium gain data is recommended for scenes that are bright, such as deserts. Since the data used for SIF  
102 retrievals are filtered to exclude bright scenes due to deserts, ice, snow, and cloud cover, the high gain data  
103 is used for SIF retrievals.

104  
105 Nadir, glint, target, and transition observation modes are common to each OCO platform. The OCO-2 target  
106 mode provides repeated spatial sampling of a given target, such as an emission source or tower site. Target  
107 mode data for OCO-2 is absent from the v10 SIF Lite files, but will be included in the v11 update.

108  
109 The OCO-3 target mode is a sequence of adjacent and partially overlapping segments that allow for  
110 increased spatial sampling. The target modes for both platforms provide over  $10^3$  soundings. OCO-3 has an  
111 additional observation mode using its pointing mirror assembly (PMA), which allows for snapshot area  
112 mapping (SAM) of targets of interest. SAMs are a series of scans of a target that are nearly adjacent and  
113 can cover an area of  $\sim 80$  km<sup>2</sup> in about 2 minutes. The SAMs and their target locations, which include  
114 volcanoes, various vegetation land cover types, and point sources of fossil fuel emissions, can be viewed at  
115 <https://ocov3.jpl.nasa.gov/sams/index.php>. Target and SAM mode scans are prioritized and scheduled  
116 several days in advance of an overpass of the ISS over the target (Taylor et al., 2020).

117  
118 The target and SAM observation modes offer unique, spatially resolved acquisition of a target during a  
119 single overpass at different sun-sensor geometries as solar illumination is relatively fixed during overpasses  
120 and soundings are acquired over a range of viewing angles as the sensors pass over their targets. For SIF  
121 applications, these measurements can be averaged to obtain SIF estimates with a reduced standard error or  
122 binned by sun-sensor geometries to investigate the effect of observation geometry on the retrieved SIF  
123 values, as we demonstrate below.

## 124 **3 Data description**

### 125 **3.1 SIF Lite file structure and content**

126 Level 2 data is ungridded (vector) data that contains geophysical variables that are of interest and use to the  
127 broader scientific community and is at same spatial and temporal resolution of the Level 0 and Level 1  
128 data., Level 0 data which are data obtained as-is from the sensor (Level 0) to which and ancillary  
129 information, such as radiometric and geometric calibration coefficients and georeferencing parameters, is  
130 appended to Level 0 data to form (Level 1 data.), such as radiometric and geometric calibration coefficients  
131 and georeferencing parameters. Level 3 products refer to gridded (raster) data, which can be found at  
132 <https://climatesciences.jpl.nasa.gov/sif/download-data/level-3/>.

133

134 The annual and monthly spatial distribution of the GOSAT and OCO Level 2 data for the globe and the  
135 continental United States are presented in Figures 1 and 2 for visualization. These data are produced by the  
136 OCO-2 and OCO-3 projects at the Jet Propulsion Laboratory (Frankenberg et al., 2014), quality controlled  
137 by NASA’s Making Earth System dData rRecords for Use in Research Environments (MEaSURES) SIF  
138 team, and are publicly available on the NASA Goddard Earth Sciences Data and Information Services  
139 Center (GES-DISC) website (<https://disc.gsfc.nasa.gov/>). Recent efforts by the OCO and MEaSURES team  
140 have focused on harmonizing the processing pipeline, attributes, and file structures of the GOSAT and OCO  
141 SIF products (Parazoo et al., 2019). Here, we present a first analysis of these harmonized products and  
142 demonstrate for the user community their key commonalities and differences.

143

144 The ungridded Level 2 SIF Lite data are provided in netCDF-4 format and contain information for each  
145 sounding from which a SIF retrieval was made. For each of the three satellite platforms, there is one file  
146 for each day in which there is at least one sounding and each file contains information for all soundings  
147 acquired on that day, including all measurement modes (glint, nadir, target). The SIF Lite files can be read  
148 by, but are not limited to, MATLAB, Python, R, and Julia using their respective netCDF4 or HDF5 libraries.  
149 The filename convention is, using the filename “oco2\_LtSIF\_200201\_20210129t071949z.nc4” as an  
150 example, platform (oco2), data product (LtSIF), date (YYMMDD), and file creation date (YYYYMMDD)  
151 and time (tHHMMSS). The SIF Lite netCDF global attributes, dimensions, variables, and variable groups  
152 are described below and listed in Table1.

#### 153 **3.1.1 Global attributes and dimensions**

154 The global attributes provide file-level metadata information, the most important of which for data users  
155 are the citation, contact information, and the time range of the data in the file. The times listed in the global

156 attributes can be used in instances where the file names may have been changed. A netCDF dimension is  
157 an integer that specifies the shape of the multi-dimensional variables, and these are also described in Table  
158 1. For the OCO-2 and OCO-3 data, there are dimensions for the footprint vertices (*vertex\_dim*) and across-  
159 track footprint (*footprint\_dim*), which are not applicable for GOSAT. The polarization dimension  
160 (*polarization\_dim*) is used for GOSAT's P and S polarizations. The only variable dimension is the  
161 *sounding\_dim*, which is the number of soundings in the file.

### 162 3.1.2 Variables

163 The primary variables of interest in the SIF Lite files are the *SIF*, *Daily\_SIF*, and *SIF\_Uncertainty* variables,  
164 which are available for SIF retrievals at 757 nm and 771 nm and estimated SIF at 740 nm. The variables  
165 for GOSAT differ from those of OCO-2 and OCO-3 in that GOSAT has two polarizations, P and S, and  
166 thus retrieval-related variables are provided as a two-dimensional (2D) array.

### 167 3.1.3 Variable groups

168 Most of the variables have been grouped, as listed in Table 1. The ungrouped, root-level variables are those  
169 that are most used and some of these variables are duplicated in the *Geolocation* and *Science* groups. The  
170 *Cloud* group contains cloud and surface albedo variables from the L2ABP product, which are used in the  
171 assignment of the quality flag. The *Geolocation* group contains variables related to the geolocation of the  
172 sounding footprint, sun-sensor geometry, altitude, and acquisition time. GOSAT sounding footprints are  
173 circular and have a radius of 5 km, in contrast to the OCO-2 and OCO-3 soundings, which are rhomboidal  
174 and are described with coordinates for each of their four vertices. Thus, the GOSAT SIF Lite files do not  
175 contain the footprint latitude and longitude vertices, whereas the OCO-2/3 SIF Lite files do.

176  
177 The *Metadata* group houses variables with sounding-level metadata information, including build version  
178 of the data, unique orbit and sounding identifiers, and measurement mode.

179  
180 The *Meteo* group contains meteorological forecast variables, which were obtained from the GEOS-5 FP-IT  
181 3h forecast (Lucchesi, 2015) and are provided as-is without validation. The *Offset* group is a collection of  
182 variables of the bias/offset adjustments and statistics. These include mean, median, and standard deviations  
183 of the adjusted and unadjusted SIF values separated by cross-track footprint. These data are reported on a  
184 grid of signal level bins with a range of 3.0-229.0 W/m<sup>2</sup>/sr/μm and follows the SIF bias correction scheme  
185 outlined by Frankenberg et al. (2011b).

## 186 3.2 Quality flag criteria and rationale

187 The Quality\_Flag variable indicates the quality of the data for each sounding as being *best* (0), *good* (1), or  
188 *failed* (2). We recommend using a combination of *best* and *good* for scientific analysis. The criteria for the  
189 *best* and *good* quality flags are listed in Table 2, and soundings that do not meet either set of criteria are  
190 flagged as *failed*. The rationale for the criterion is as follows: reduced chi-square ( $\chi^2$ ) thresholds exclude  
191 fits that do not well represent the spectrum; continuum level radiance excludes scenes with brightness that  
192 is too high or low; solar zenith angle ( $\theta$ ) excludes retrievals with extreme solar zenith angles, which are  
193 more likely affected by rotational Raman scattering; and the O<sub>2</sub> and CO<sub>2</sub> thresholds exclude most cloudy  
194 scenes.

## 195 4 Methods

### 196 4.1 SIF retrieval

197 The SIF values provided in the SIF Lite files are based on spectral fits covering Fraunhofer lines, as SIF  
198 reduces the fractional depth of the Fraunhofer lines (Plascyk, 1975). The SIF retrieval methodologies are  
199 fully explained by Frankenberg et al. (2011b, a) and SIF is retrieved using the identical method for GOSAT  
200 and the OCO platforms at 757 nm and 771 nm. In brief, the main retrieval quantity in the retrieval state  
201 vector is the fractional contribution of SIF to the continuum level radiance, or relative fluorescence  
202 (SIF\_Relative\_757nm and SIF\_Relative\_771nm). The absolute SIF values (SIF\_757nm and SIF\_771nm)  
203 are generated during post-processing in W/m<sup>2</sup>/sr/μm.  
204

205 It is important to note that although the SIF values have traditionally been loosely labeled as being retrieved  
206 at 757 nm and 771 nm, the retrieval fit windows used to produce the SIF Lite data is centered at 758.7 and  
207 770.1 for OCO-2 and OCO-3, and at 758 and 771 for GOSAT. However, we retain the 757 and 771  
208 nomenclature to remain consistent with previous publications and to avoid confusion. We estimated SIF at  
209 740 nm for each sounding using both retrieval windows as described in more detail below.

### 210 4.2 SIF retrieval uncertainty

211 The determination of single sounding retrieval uncertainty is covered in great detail by Sun et al. (2018)  
212 and Frankenberg et al. (2014), and is provided in the SIF Lite files as SIF\_Uncertainty\_740nm,  
213 SIF\_Uncertainty\_757nm, and SIF\_Uncertainty\_771nm. Briefly, these values are the 1-sigma ( $\sigma$ ) estimated  
214 single sounding measurement precision and represent the random component of the retrieval errors. It is  
215 derived through standard least-square fitting by evaluating the error covariance matrix:  
216

217  $S_e = (K^T S_0 K)^{-1}$  (1)

218

219 where  $K$  is the Jacobian matrix of the least-squares fit, and  $S_0$  is the measurement error covariance matrix  
 220 and characterizes the instrument noise per detector pixel.

221

222 For the OCO-2/3 data, the uncertainty for SIF757 usually ranges between 0.3 and 0.5 W/m<sup>2</sup>/sr/μm, or ~15-  
 223 50% of the absolute SIF value. Uncertainties for SIF771 are slightly higher due to less fluorescence and a  
 224 relatively less reduction in the fractional depth of the radiance at 771 nm. Uncertainty for SIF740 is  
 225 calculated from using the general formula for error propagation and the partial derivatives for the  
 226 uncertainties for SIF757 and SIF771:

227

228  $SIF_{Uncertainty_{740}} = 0.5 \cdot \sqrt{((1.5 \cdot SIF_{Uncertainty_{757}})^2 + (2.25 \cdot SIF_{Uncertainty_{771}})^2)}$  (2)

229

### 230 4.3 SIF 740 nm and intersensor comparisons

231 The spectral window in which SIF retrievals are made depends on the wavelength bands of the platform.  
 232 Assuming the spectral shape of SIF is known and invariant, one can convert SIF to a standard reference  
 233 wavelength. Here, we use 740 nm as a reference as it corresponds to the 2<sup>nd</sup> SIF peak and is not as strongly  
 234 affected by chlorophyll re-absorption as red SIF, thus showing a relatively stable shape at wavelengths  
 235 above 740 nm (Magney et al., 2019; Parazoo et al., 2019). The differences in the retrieval windows  
 236 complicate the comparison of SIF retrievals from different sensors, thus it is useful to provide SIF at a well-  
 237 defined reference wavelength.

238

239 Although the range of the wavelengths used to retrieve SIF from the various sensors is small (740-771 nm),  
 240 absolute fluorescence can vary greatly depending on the spectral window used to retrieve SIF (Joiner et al.,  
 241 2013; Köhler et al., 2018; Sun et al., 2018). However, reference far-red SIF emission spectra at the leaf  
 242 level indicates that far-red fluorescence spectral shapes are consistent across species (Magney et al., 2019).  
 243 Thus, we provide an estimate of absolute SIF<sub>740</sub> (SIF\_740nm) in the GOSAT and OCO-2/3 SIF Lite files  
 244 derived from the empirical relationship between SIF at 740 nm and SIF at 758.7 nm and 770.1 nm (denoted  
 245 as 757 nm and 771 nm; Eq. 1). The rationale for including SIF<sub>740</sub> in the SIF Lite files is to allow for more  
 246 consistent and robust comparisons of SIF and SIF-based analyses across sensors (Parazoo et al., 2019), and  
 247 to reduce the retrieval error by a factor of  $\sqrt{2}$  (Sun et al., 2018). We stress that the reported SIF740 values  
 248 are not retrieved, but are estimated under the assumption that the spectral shape of SIF is invariant.

249

$$SIF_{740} = 0.5 \cdot (1.5 \cdot SIF_{757} + 2.25 \cdot SIF_{771}) \quad (3)$$

251

252 The ratios used in Eq. 1 were based on leaf level measurements conducted by Magney et al. (2019), however  
253 we observed a median ratio of 1.45 from OCO-2 over vegetated areas for 2015-2019 (Figure S1). The  
254 reason for this difference has not yet been discerned and requires further analysis, but the small potential  
255 bias introduced by the use of the empirical ratio does not infringe on the utility of the  $SIF_{740}$  data.

#### 256 **4.4 Bias/offset correction**

257 Biases in retrieved SIF can occur due to uncertainties in the exact instrument line-shape per footprint or  
258 slight uncertainties in detector linearity. To correct for biases, we use reference targets that are non-  
259 fluorescent surfaces barren of vegetation, similar to the method described by Frankenberg (2011b). In short,  
260 the background signal over reference targets is subtracted from all relative SIF values. We calculate the  
261 background signal for each day as mean SIF over all barren surfaces within a 31-day window centered on  
262 the current day for GOSAT and a three-day window for OCO-2/3. These windows were chosen to obtain a  
263 robust background signal given their respective spatial-temporal resolution. Here, we identify barren  
264 surfaces using a combination of the MODIS MCD12Q1 land cover data product (Friedl and Sulla-Menashe,  
265 2019) and the Vegetation Photosynthesis Model (VPM) (Xiao et al., 2004; Zhang et al., 2017) from the  
266 year 2018. The native spatial resolution of these data sets is 500 m, but we aggregated the data to a global  
267 0.20-degree grid so that the barren surface reference targets had a coarser resolution than the soundings.  
268 We classified barren surfaces as those grid cells which were 100% barren and/or snow and ice by  
269 MCD12Q1 and had zero (0) annual gross primary production as estimated by VPM. We also excluded  
270 coastal grid cells that overlapped with water using a global coastline shapefile and a buffer.

#### 271 **4.5 Daily average SIF and the daily correction factor**

272 We provide an estimate of daily average SIF (Daily\_SIF), which is instantaneous SIF scaled entirely upon  
273 the geometry of incoming solar radiation over a day. Instantaneous SIF is the absolute value of SIF for any  
274 given sounding and is a strong function of the illumination of the canopy at that instant in time. The  
275 differences in the illumination geometry of soundings at different overpass times and latitudes complicate  
276 direct comparisons of SIF at different points of Earth's surface and comparisons of SIF to other data that  
277 are more temporally coarse, such as daily estimates of GPP.

278

279 Downwelling solar radiation scales linearly with  $\cos(\theta)$  under clear sky conditions when ignoring Rayleigh  
280 scattering and gas absorption. As described by Frankenberg et al. (2011b) and Köhler et al. (2018), a first  
281 order approximation of daily average SIF ( $SIF_{Daily}$ ) can be written as:

$$282 \quad SIF_{Daily} = SIF_{t_0} \cdot \frac{1}{\cos(\theta(t_0))} \cdot \int_{t=t_0-12h}^{t=t_0+12h} \cos(\theta(t)) \cdot H(\cos(\theta(t))) dt \quad (4)$$

283 where  $SIF_{t_0}$  is absolute instantaneous SIF,  $\theta(t_0)$  is the solar zenith angle  $\theta$  at the time of measurement  $t_0$   
284 with a heaviside function  $H$  to zero out negative values of  $\cos(\theta)$ , and the integral is computed  
285 numerically in 10-min time steps ( $dt$ ). In terms of the SIF Lite file variable names, this equation can be  
286 written for SIF at any wavelength as  $Daily\_SIF = SIF \cdot daily\_correction\_factor$ .

## 287 **5 Discussion**

### 288 **5.1 Scaling of SIF to GPP**

289 We should note that SIF is, to first order, only a proxy for the electron transfer rate in the light reaction of  
290 photosystem II. However, SIF is oblivious to the light-independent reactions that fix  $CO_2$ . Nevertheless,  
291 many studies have reported on the linearity of SIF and GPP at bi-weekly or monthly timescales and at  
292 coarse spatial resolutions (Verma et al., 2017; Doughty et al., 2019; Yang et al., 2015). The seasonality of  
293 SIF and GPP tend to match well at such coarse temporal resolutions because both SIF and GPP are driven  
294 by changes in canopy structure, the amount chlorophyll in the canopy, and the amount of sunlight  
295 (photosynthetically active radiation; PAR) being absorbed by canopy chlorophyll ( $APAR_{chl}$ ) (Magney et  
296 al., 2020; Doughty et al., 2021; Dechant et al., 2019). The SIF-GPP relationship can also become more  
297 linear at the canopy scale due to the contribution of total canopy SIF by sunlit, shaded, stressed, and non-  
298 stressed leaves (Magney et al., 2019). SIF and GPP have an indirect relationship through non-  
299 photochemical quenching and the electron transport rate (Porcar-Castell et al., 2014; Gu et al., 2019), which  
300 can sometimes simultaneously downregulate photosynthesis and SIF, as has been seen in evergreen  
301 needleleaf ecosystems, but not always (Magney et al., 2019).

302  
303 At the leaf level, GPP saturates before SIF in response to APAR, such that we could see increased SIF  
304 without any response in GPP at high levels of APAR (Gu et al., 2019). Conversely, vegetation stress can  
305 cause a near or total cessation of GPP via stomatal closure with little or no change in SIF. This decoupling  
306 has been seen at the leaf scale during forced stomatal closure of deciduous tree species (Marrs et al., 2020)  
307 and a one-month drought experiment with Eastern cottonwood (*Populus deltoides*) (Helm et al., 2020).  
308 However, these studies and others of deciduous vegetation and croplands have repeatedly found a better  
309 correlation between SIF and APAR than SIF and GPP (Yang et al., 2018; Miao et al., 2018). For SIF to be

310 a reliable proxy of APAR,  $SIF_{yield}$  (ratio of SIF to APAR) would need to remain constant. For a detailed  
311 inquiry into SIF and photosynthesis, see Porcar-Castell et al. (2014), and a review of SIF remote sensing  
312 applications and challenges from the leaf, tower, and satellite scale by Magney et al. (2020) and Mohammed  
313 et al. (2019).

## 314 **5.2 Negative SIF values**

315 Data users are likely to find negative SIF values, which are due to retrieval noise, but these values should  
316 generally not be discarded. The one-sigma uncertainty in retrieved SIF values ( $SIF\_Uncertainty$ ) can be  
317 substantial, but negative values are plausible in a retrieval sense although not in physical terms (actual SIF  
318 emission cannot be negative). Discarding negative values will introduce a high bias when averaging.  
319 Nevertheless, extremely negative values may indicate a problem with the retrieval. We recommend the  
320 following guidelines for filtering negative SIF values: accept if  $SIF + 2\text{-}\sigma$  uncertainty  $\geq 0$ ; questionable if  
321  $SIF + 2\text{-}\sigma$  uncertainty  $< 0$  and  $SIF + 3\text{-}\sigma$  uncertainty  $\geq 0$ ; and reject if  $SIF + 3\text{-}\sigma$  uncertainty  $< 0$ . These  
322 thresholds have not been incorporated into the  $Quality\_Flag$  variable of the SIF Lite data.

## 323 **5.3 Sun-sensor geometry**

324 Users of SIF data from any source should be aware that sun-sensor geometry plays a role in the absolute  
325 values of SIF, in addition to vegetation canopy characteristics (Joiner et al., 2020; Köhler et al., 2018).  
326 Absolute SIF values increase rapidly when the phase angle approaches  $0^\circ$  (when the sun and sensor are  
327 aligned), but the effect of sun-sensor geometry has been shown to be small when the phase angle is greater  
328 than  $20^\circ$  (Köhler et al., 2018; Doughty et al., 2019). Thus, retrieved SIF values from target or SAM mode  
329 scans during a single overpass can vary greatly despite homogeneous vegetation cover due to changing sun-  
330 sensor geometries during data acquisition. Figure 3 illustrates the phase angle and  $SIF_{757}$  for a SAM  
331 acquired over the Amazon rainforest, where the vegetation canopy is very homogenous. The figure also  
332 illustrates how the phase angle changes during an OCO-3 SAM scan and that the sun-sensor geometries for  
333 each individual swath are rather distinct from each other (Figure 3a). Mean SIF for each swath is also  
334 distinctively different (Figure 3b), despite that the canopy was experiencing the same illumination geometry  
335 and environmental conditions during the two minutes in which this SAM was acquired. The effect of sun-  
336 sensor geometry is also illustrated in Figure 4, which shows the relationship between SIF for individual  
337 OCO-2 soundings and phase angle for two target scans in the Amazon. A distinctive change in the absolute  
338 values of retrieved SIF were observed due to sun-sensor geometry.

#### 339 **5.4 Averaging over space and time to reduce retrieval uncertainty**

340 There are two main challenges to working with all spaceborne SIF data: 1) the inherently large uncertainties  
341 for individual soundings due to retrieval noise, and 2) the effect of differences in sun-sensor geometry on  
342 retrieved SIF values. Thus, we advise against using single soundings for analysis. However, averaging  
343 soundings across space and time can reduce the retrieval noise by a factor of  $1/\sqrt{n}$ , with  $n$  being the number  
344 of soundings comprising the average (Frankenberg et al., 2014). For platforms with a wide swath, like the  
345 TROPospheric Monitoring Instrument (TROPOMI), the effect of sun-sensor geometry can be accounted  
346 for by averaging soundings for a point of interest over the entire repeat cycle (16-days for TROPOMI) as  
347 demonstrated by Doughty et al. (2019, 2021). In the case of OCO-2/3, as we demonstrate in Figure 3 and  
348 in Braghieri et al. (2021), soundings can be grouped by phase angle and then averaged to reduce retrieval  
349 uncertainty. Thus, retrieval uncertainty and sun-sensor geometry effects can be substantially minimized.  
350 For GOSAT, we recommend averaging SIF retrieved from both the P and S polarizations, as demonstrated  
351 in Figure 5.

352  
353 Users should also keep in mind that when conducting analyses at large spatial scales, gridding the data prior  
354 to analysis is largely unnecessary as the ungridded Level 2 data can be used directly (Doughty et al., 2019).  
355 Doing so will allow the users to retain sounding-level information that may aid in the interpretation of the  
356 results, which would otherwise be lost when merely gridding the SIF values. For instance, as demonstrated  
357 by Doughty et al. (2019), ungridded Level 2 SIF data was used to calculate mean SIF for the entire Amazon  
358 Basin at different phase angles to show that the seasonality of SIF in the Amazon Basin was consistent  
359 across sun-sensor geometries. Such an analysis would not have been possible with gridded data because  
360 after gridding it is impossible to group the data by sounding-level attributes, such as phase angle or cloud  
361 fraction.

#### 362 **5.5 The use of SIF at 740, 757, and 771 nm**

363 It is important to note that in areas where the SIF signal is near zero, the use of SIF at 757 nm would be  
364 more appropriate as the SIF signal is stronger at this wavelength. In areas where vegetation is sparse or  
365  $SIF_{\text{yield}}$  is low due to vegetation responses to environmental conditions or canopy leaf physiology, SIF at  
366 771 nm could be within the noise range due to its relatively far distance from the far-red peak at 740 nm.  
367 In these cases, we advise the use of SIF at 757 nm. Since SIF at 771 nm is used to compute SIF at 740 nm  
368 in the SIF Lite files, diligence should likewise be used when using SIF at 740 nm in analyses.

## 369 5.6 Comparison of GOSAT, OCO-2, and OCO-3

370 OCO-3 SIF has been shown to have a very high correlation ( $r > 0.9$ ) with OCO-2 (Taylor et al., 2020).  
371 Here, we present the first comparisons between GOSAT and OCO-2 Level 2 data. Currently, there are not  
372 enough coincident soundings for GOSAT and OCO-3 to provide a robust analysis but given that OCO-2  
373 and OCO-3 compare very well, we expect a comparison between GOSAT and OCO-3 to mimic the findings  
374 from our GOSAT and OCO-2 comparison.

375  
376 Although the data records for GOSAT and OCO-2 overlap six years, only a small percentage of soundings  
377 flagged as best quality and cloud free from GOSAT and OCO-2 overlap on the same day (Figure 5a).  
378 Despite this filter, the mean SIF values may differ widely on the same day due to differences in overpass  
379 time (and thus solar illumination angle and environmental conditions), viewing geometry, and the number  
380 of OCO-2 soundings comprising the mean. We progressively filtered the data as illustrated in Figure 5 to  
381 ensure the soundings were of a vegetated land surface, had similar sun-sensor geometries, environmental,  
382 and atmospheric conditions, and that the temperature was high enough for photosynthesis to occur as  
383 indicated by the temperature\_skin variable in the SIF Lite data.

384  
385 We found that the correlation and slope improved with more conservative filtering of the data, and that the  
386 comparison between GOSAT SIF and OCO-2 SIF were reasonable. However, it is important to note that  
387 any comparison between GOSAT and OCO data will inevitably be affected by spatial sampling bias, as the  
388 swath width for both OCO platforms is smaller than the diameter of the GOSAT sounding footprints (Figure  
389 6; left footprints). Also, it could be the case that only a small portion of the GOSAT footprint is sampled  
390 by OCO (Figure 6; right footprints). Our filter of  $\geq 10$  OCO-2 soundings within a GOSAT footprint aimed  
391 to reduce this potential sampling bias in addition to reducing the uncertainty of the OCO-2 SIF retrievals.  
392 It must also be remembered that in this comparison, we do not have the luxury to average several GOSAT  
393 soundings to reduce the uncertainty as we did with OCO-2, so the uncertainties of the GOSAT SIF is much  
394 higher than that for OCO-2.

395  
396 Upon a more detailed comparison of GOSAT and OCO-2 SIF at 740 nm, 757 nm, and 771 nm using the  
397 strictest filter we applied in Figure 5f, we found  $SIF_{740}$  from the two platforms to have higher correlations  
398 than for  $SIF_{757}$  and  $SIF_{771}$  alone (Figure 7). We also noticed that GOSAT and OCO-2 soundings most  
399 frequently overlap in the boreal winter, which corresponds to a period of little or no photosynthesis at mid  
400 and high latitudes (Figures S2 and S3). Thus, the direct comparison of GOSAT and OCO-2 SIF is severely  
401 restricted by the relatively infrequent overlap of the two platforms during the growing season.

402

403 In addition to the sounding level comparisons, we found mean annual SIF<sub>757</sub> for GOSAT and OCO-2 to  
404 compare reasonably well at the global scale during the boreal summer (Figure 8). The relatively large  
405 differences in SIF illustrated at the gridcell level in Figure 8c are due to differences in the spatial and  
406 temporal sampling of the two platforms. We presented the comparison here at 4.0-degree spatial  
407 resolution to improve the sampling by GOSAT (Fig. 1a).

408

## 409 **5.7 Collocating Soundings with their Targets**

410 Currently, the target and SAM soundings are not collated to the target to which they correspond, but  
411 variables will be added to upcoming versions (e.g., v11) of the SIF Lite files that will collocate the target  
412 and SAM soundings with their intended target site. For OCO-3, some of the target sites are in close  
413 proximity to each other and thus a target site may fall within the scan of another target. For these sites, users  
414 may also want to check scans that were intended for target sites adjacent to their target of interest. The  
415 OCO-3 targets, the dates of their scans, and scan maps are available at  
416 <https://ocov3.jpl.nasa.gov/sams/index.php>. A list of target locations for OCO-2 and OCO-3 are available in  
417 Table S1 and Table S2, respectively.

## 418 **6 Conclusions**

419 Here, we have presented and described the Level 2 SIF Lite files for GOSAT, OCO-2, and OCO-3, which  
420 have been standardized in the same netCDF format to maximize their interoperability and accessibility by  
421 the data user community and allow for intersensor comparisons. Users of remote sensing data are more  
422 accustomed to using Level 3 gridded data for analyses, but we incentivize data users to also exploit the  
423 Level 2 data we have presented in the SIF Lite files. The OCO-2 and OCO-3 platforms provide the highest  
424 spatial resolution spaceborne SIF data, and the target and SAM observation modes are unique to these  
425 platforms. The observation scheme for the OCO platforms allow for time series to be constructed for the  
426 target locations, and the repeated target and SAM scans allow for the investigation of the directionality and  
427 escape of SIF at varying sun-sensor geometries across many biomes in different seasons.

428

429 We have demonstrated how users can break target and SAM observations into phase angles for analysis  
430 and have described how the effect of sun-sensor geometry and retrieval noise can be mitigated through the  
431 averaging of the data. The OCO platforms also provide a rich resource for the validation of radiative transfer  
432 models, which is currently underutilized. Upcoming spaceborne platforms with frequent revisits and/or  
433 high spatial resolution, such as the European Space Agency's FLuorescence EXplorer (FLEX) and NASA's

434 Geostationary Carbon Cycle Observatory (GeoCarb), are expected to further our understanding of changes  
435 in vegetation structure and function (Drusch et al., 2016; Polonsky et al., 2014; Moore et al., 2018).

## 436 **7 Data availability**

437 OCO SIF Lite files can be found at NASA Goddard Earth Sciences (GES) Data and Information Services  
438 Center (DISC) at <https://disc.gsfc.nasa.gov/datasets/>. OCO-2 SIF Lite files can be accessed at  
439 <https://doi.org/10.5067/XO2LBBNPO010>, and OCO-3 data can be accessed at  
440 <https://doi.org/10.5067/NOD1DPPBCXSO>. GOSAT SIF Lite files can be accessed at  
441 <http://dx.doi.org/10.22002/D1.8771>.

## 442 **8 Author contributions**

443 RD and CF conceived this manuscript. TK prepared and provided the data and RD performed the  
444 analysis. RD prepared the manuscript with contributions from all co-authors.

## 445 **9 Competing interests**

446 The authors declare that they have no conflict of interest.

## 447 **10 Acknowledgements**

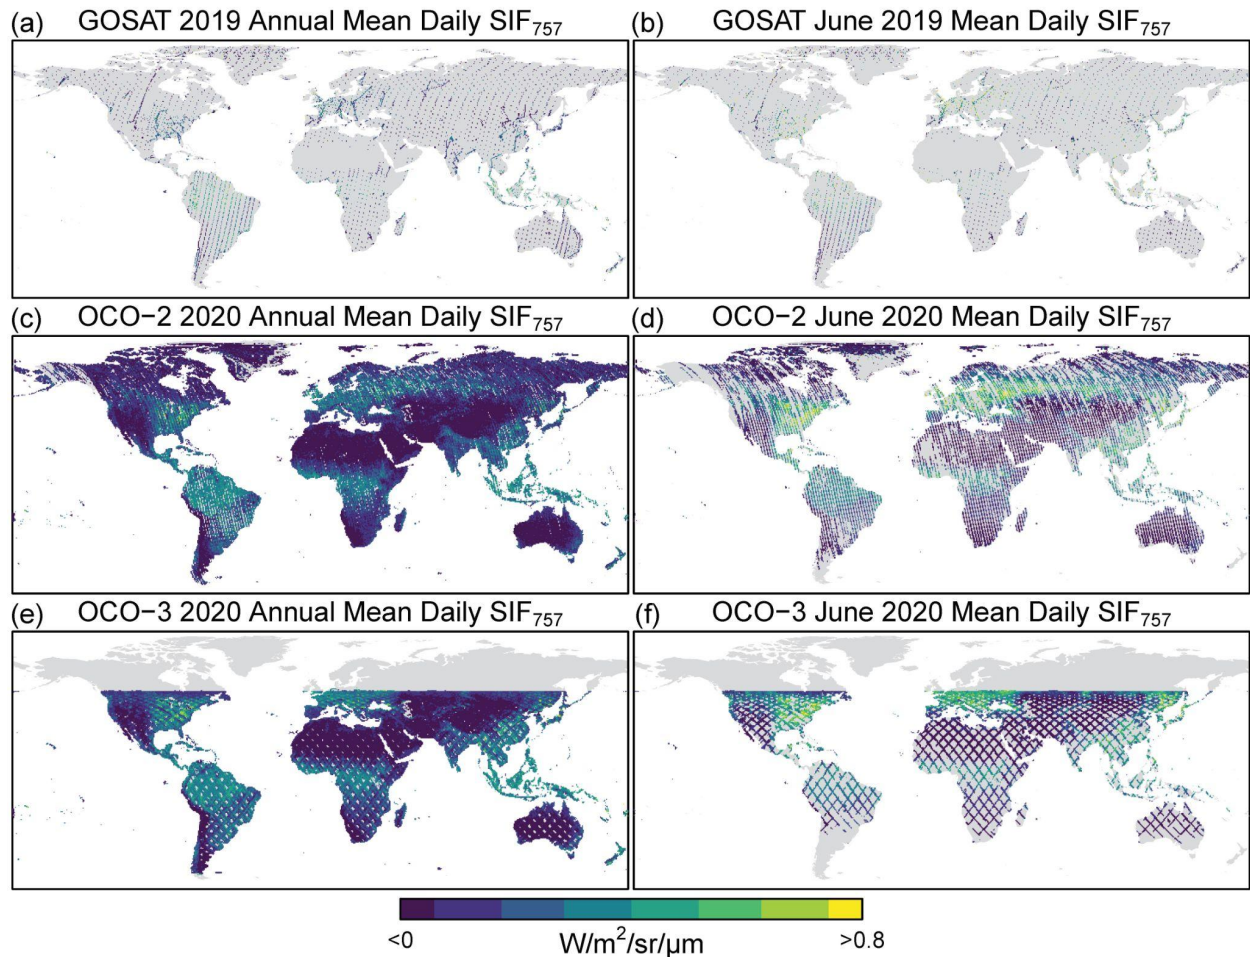

448 We thank Lan Dang for helping to process the GOSAT data, Annmarie Eldering for helping coordinate the  
449 publication of the SIF Lite files at the GES-DISC, and Yi Yin for publishing the GOSAT data on the Caltech  
450 data repository. Part of this research was carried out at the Jet Propulsion Laboratory, California Institute  
451 of Technology, under a contract with the National Aeronautics and Space Administration. Reference herein  
452 to any specific commercial product, process or service by trade name, trademark, manufacturer or otherwise  
453 does not constitute or imply its endorsement by the United States Government or the Jet Propulsion  
454 Laboratory, California Institute of Technology.

## 455 **11 Financial support**

456 This research was supported by NASA Making Earth System data Records for Use in Research  
457 Environments (MEaSUREs) Program (NNN12AA01C) and the NASA OCO Science Team  
458 (80NSSC18K0895).

460

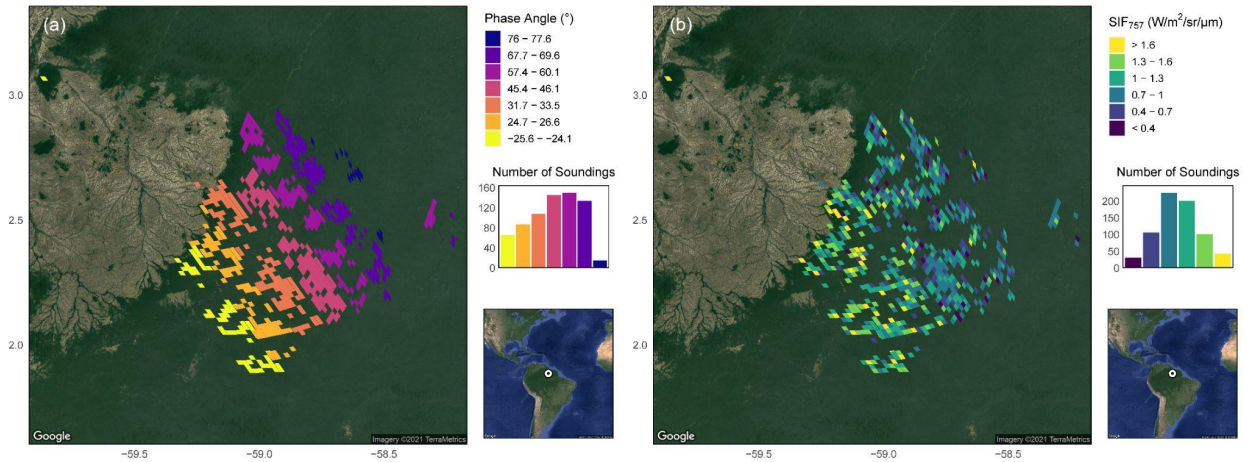

461  
 462 **Figure 1. Annual 2020 and June 2020 Mean Daily SIF<sub>757</sub> for GOSAT, OCO-2, and OCO-3.** The  
 463 annual and monthly nadir-mode coverage of GOSAT, OCO-2, and OCO-3 is presented here as mean daily  
 464 SIF at 757 nm (SIF<sub>757</sub>) at a gridded resolution of 0.5° for visualization. Included are soundings from all  
 465 measurement modes flagged as best and good quality and clear of clouds. At nadir, the diameter of the  
 466 GOSAT soundings is ~10 km, and the widths of the OCO-2 and OCO-3 swaths are about 10 km and 13  
 467 km, respectively. Thus, the data gaps shown here are larger than depicted and are not to scale.  
 468

474

475 **Figure 3. Phase angle and SIF757 for an OCO-3 SAM mode scan over the Amazon Rainforest in**  
 476 **Guyana.** OCO-3 SAMs are composed of several scans of a target whereby the eight-sounding wide  
 477 segment is offset adjacent to the previous scan. Each segment has a distinctive, small range of phase  
 478 angles as seen in (a). SIF has higher values at lower phase angles, which is apparent in (b) where the  
 479 higher SIF values occur for the soundings in the southwestern portion of the SAM where phase angles are  
 480 lowest.

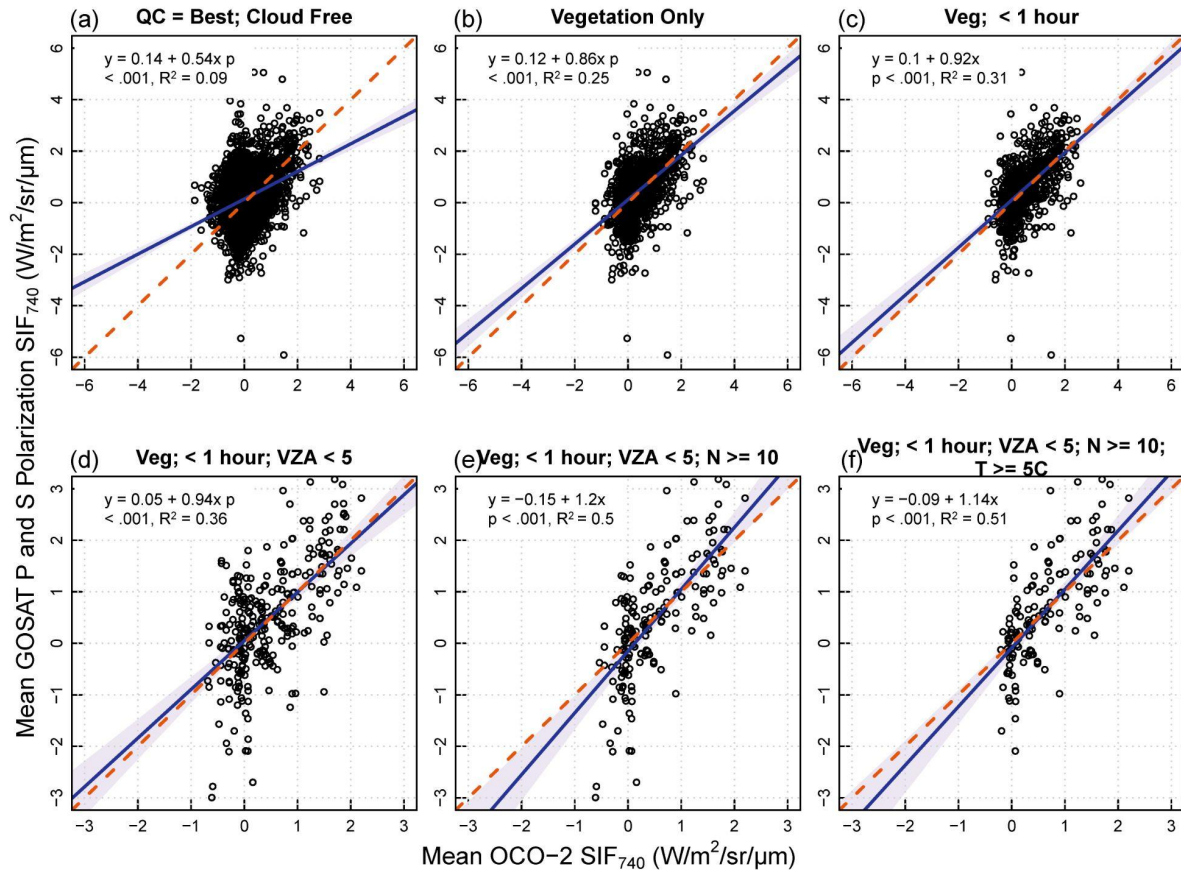

481

482

483

484 **Figure 4. Absolute phase angle and SIF757 for an OCO-2 target mode scan over evergreen**  
 485 **broadleaf forest in Manaus, Brazil.** As this figure demonstrates, retrieved SIF values increase as the  
 486 phase angle approaches 0 degrees.

487

488

489 **Figure 5. Relationships of SIF740 from OCO-2 and GOSAT using progressively conservative data**

490 **filters and Deming regression.** X-axis values are the mean of all OCO-2 soundings (~1.3 km × by 2.25

491 km) that fall within the corresponding GOSAT sounding footprint (~10 km in diameter). Y-axis values

492 represent the mean of SIF retrieved from P and S polarizations for a single GOSAT sounding. Six years

493 of data (2015-2020) were used to identify soundings that overlapped on the same day. (a) Soundings

494 flagged as best quality and cloud free. (b) Same as (a) but filtered as being over vegetation using the

495 IGBP flag in the OCO-2 SIF Lite file. (c) Same as (b) but filtered for data that was acquired from GOSAT

496 and OCO-2 within one hour of each other. (d) Same as (c) but with viewing zenith angles (VZA) < 5° for

497 both platforms. (e) Same as (d) but with number (N) of OCO-2 soundings within a GOSAT sounding

498 being ≥ 10. (f) Same as (e) but with skin temperature ≥ 5 °C.

499

**Table 1. Level 2 GOSAT, OCO-2, and OCO-3 SIF Lite netCDF File Global Attributes, Dimensions, and Variables.** Units for SIF and continuum level radiance variables are  $W/m^2/sr/\mu m$ , geolocation variables are in decimal degrees, angles are in degrees, and the units for the meteorological variables are in the table below. For GOSAT, data is provided for both the P and S polarizations as a two-dimensional array. \* denotes the variable or dimension is only applicable to OCO-2 and OCO-3, and \*\* denotes that the dimension is only applicable to GOSAT. Note that there are different MeasurementMode and OrbitID descriptions for GOSAT, and that some root-level variables are duplicated in the Geolocation and Science group.

<b>Global Attributes</b>	
date_time_coverage	UTC time string of the first and last observation
day_of_year_coverage	Same as date_time_coverage, but with day-of-year
InputCollectionLabel	Collection label of the L2 data products used to create the file
InputBuildID	Build ID of the L2 data products used to create the file
InputPointers	String with names of all input products and auxiliary data used to create the file
<b>Dimensions (length of dimension)</b>	
sounding_dim (variable)	Number of soundings in the file
footprint_dim (8) *	Number of OCO-2/3 across-track footprints
vertex_dim (4) *	Number of footprint corner coordinates
signalbin_dim (227)	Number of entries in the signal histogram arrays in the Offset group
statistics_dim (2)	Array dimension in the Mean and Median SIF values of the Offset group; adjusted and unadjusted values
polarization_dim (2) **	Array dimension of the polarization for GOSAT; P and S polarization
<b>Root Level Variables</b>	
Daily_SIF_740nm	Daily Corrected Solar induced chlorophyll fluorescence at 740 nm: $Daily\_SIF\_740nm = SIF\_740 * /Science/daily\_correction\_factor$
Daily_SIF_757nm	Daily Corrected Solar induced chlorophyll fluorescence at 757 nm: $Daily\_SIF\_757nm = /Science/sif\_757nm * /Science/daily\_correction\_factor$
Daily_SIF_771nm	Daily Corrected Solar induced chlorophyll fluorescence at 771 nm: $Daily\_SIF\_771nm = /Science/sif\_771nm * /Science/daily\_correction\_factor$
Delta_Time	Timestamp (seconds since 1 January 1990)
Latitude	Center latitude of the measurement
Latitude_Corners *	Corner latitude of the measurement
Longitude	Center longitude of the measurement
Longitude_Corners *	Corner longitude of the measurement
Quality_Flag	0 = best (passes quality control + cloud fraction = 0.0); 1 = good (passes quality control); 2 = bad (failed quality control); -1 = not investigated

SAz	Azimuth angle between the solar direction as defined by the sounding location, and the sounding local north
SIF_740nm	Solar induced chlorophyll fluorescence at retrieved wavelength: $SIF_{740nm} = 0.75 * (/Science/sif_{757nm} + 1.5*/Science/sif_{771nm})$
SIF_Uncertainty_740nm	Uncertainty computed from continuum level radiance at 740 nm: $SIF_{Uncertainty_{740}} = 0.75 * ((/Science/sif_{757nm})^2 + (1.5*/Science/sif_{771nm})^2)^{(1/2)}$
SZA	Solar zenith angle is the angle between the line of sight to the sun and the local vertical
VAz	Azimuth angle between line of sight and local north
VZA	Sensor zenith angle is the angle between the line of sight to the sensor and the local vertical
<u>Variable/Group Name</u>	<u>Description</u>
<b>Cloud Group Variables</b>	
cloud_flag_abp	Indicator of whether the sounding contained clouds: 0 - Classified clear, 1 - Classified cloudy, 2 - Not classified, all other values undefined; not used in SIF Lite processing
co2_ratio	Ratio of CO2 retrieved in weak and strong CO2 band (value near 1 indicate scattering free scene)
delta_pressure_abp	Retrieved-predicted surface pressure from ABO2, usable as cloud screener; not used in SIF Lite processing
o2_ratio	Ratio of retrieved and predicted O2 column
surface_albedo_abp	Surface albedo (Lambertian equivalent) as retrieved in the ABO2 preprocessor at 760nm; not used in SIF processing
<b>Geolocation Group Variables</b>	
altitude	Surface altitude of observed footprint
footprint_latitude_vertices *	Latitude corner coordinates of the sounding location
footprint_longitude_vertices *	Longitude corner coordinates of the sounding location
latitude	Center latitude of the measurement
longitude	Center longitude of the measurement
sensor_azimuth_angle	Azimuth angle between line of sight and local north
sensor_zenith_angle	Sensor zenith angle is the angle between the line of sight to the sensor and the local vertical
solar_azimuth_angle	Azimuth angle between the solar direction as defined by the sounding location, and the sounding local north
solar_zenith_angle	Solar zenith angle is the angle between the line of sight to the sun and the local vertical
time_tai93	Timestamp (seconds since 1 January 1993)
<b>Metadata Group Variables</b>	
BuildID	The ID of the Build, including the software version that created this product
CollectionLabel	The Collection Label of the Build, including the software version that created this product

FootprintID *	OCO-2 footprint identifier (1-8), identifying the 8 independent OCO-2 spatial samples per frame
MeasurementMode	OCO-2/3: Instrument Measurement Mode, 0=Nadir, 1=Glint, 2=Target, 3=AreaMap, 4=Transition; users might consider separating these for analysis GOSAT: Instrument Measurement Mode, 0=OB1D (FTS obs. mode I, sunlit), 1=OB2D (FTS obs mode II, sunlit), 2=SPOD (FTS specific obs. mode, sunlit); users might consider separating these for analysis
OrbitID	Orbit Identifier: Start Orbit Number (OCO-2) or Start Solar Day (OCO-3) of observation GOSAT: Orbit Identification String ("NominalDay OrbitOfDay StartPathNumber-StopPathNumber")
SoundingID	Unique Identifier for each sounding
<b>Meteo (Meteorological) Group Variables</b>	
specific_humidity	Specific humidity at surface layer at the sounding location, interpolated from GEOS-5 FP-IT inst3_3d_asm_Nv field QV (specific_humidity); kg/kg
surface_pressure	Surface pressure at the sounding location; interpolated from GEOS-5 FP-IT inst3_3d_asm_Nv field PS (surface_pressure); Pa
temperature_skin	Skin temperature at the sounding location; interpolated from GEOS-5 FP-IT inst3_2d_asm_Nx field TS (surface_skin_temperature); K
temperature_two_meter	Two-meter temperature at the sounding location; interpolated from GEOS-5 FP-IT inst3_2d_asm_Nx field T2M (2-meter_air_temperature); K
vapor_pressure_deficit	Vapor pressure deficit at the sounding location (2m) (ECMWF forecast); Pa
wind_speed	Surface wind speed at sounding location; interpolated from GEOS-5 FP-IT inst3_2d_asm_Nx field U10M and inst3_2d_asm_Nx field V10M (10-meter_eastward_wind, 10-meter_northward_wind); m/s
<b>Offset Group Variables</b>	
SIF_Mean_757nm	Mean Solar Induced Fluorescence at 757nm (by footprint, for adjusted and unadjusted values)
SIF_Mean_771nm	Mean Solar Induced Fluorescence at 771nm (by footprint, for adjusted and unadjusted values)
SIF_Median_757nm	Median Solar Induced Fluorescence at 757nm (by footprint, for adjusted and unadjusted values)
SIF_Median_771nm	Median Solar Induced Fluorescence at 771nm (by footprint, for adjusted and unadjusted values)
SIF_Relative_Mean_757nm	Mean relative Solar Induced Fluorescence at 757nm (by footprint, for adjusted and unadjusted values)
SIF_Relative_Mean_771nm	Mean relative Solar Induced Fluorescence at 771nm (by footprint, for adjusted and unadjusted values)
SIF_Relative_Median_757nm	Median relative Solar Induced Fluorescence at 757nm (by footprint, for adjusted and unadjusted values)
SIF_Relative_Median_771nm	Median relative Solar Induced Fluorescence at 771nm (by footprint, for adjusted and unadjusted values)

SIF_Relative_SDev_757nm	Standard deviation of relative Solar Induced Fluorescence at 757nm (by footprint, for adjusted and unadjusted values)
SIF_Relative_SDev_771nm	Standard deviation of relative Solar Induced Fluorescence at 771nm (by footprint, for adjusted and unadjusted values)
signal_histogram_757nm	Signal level histogram for 757 nm radiances
signal_histogram_771nm	Signal level histogram for 771 nm radiances
signal_histogram_bins	Radiance level offset histogram bins
<b>Science Group Variables</b>	
continuum_radiance_757nm	Continuum Level Radiance at 757 nm
continuum_radiance_771nm	Continuum Level Radiance at 771 nm
daily_correction_factor	Correction factor to estimate daily average SIF from instantaneous SIF (using pure geometric incoming light scaling)
IGBP_index *	IGBP Index
SIF_757nm	Offset-Adjusted Solar Induced Chlorophyll Fluorescence at 757nm
SIF_771nm	Offset-Adjusted Solar Induced Chlorophyll Fluorescence at 771nm
SIF_Relative_757nm	Relative Solar Induced Fluorescence at 757 nm
SIF_Relative_771nm	Relative Solar Induced Fluorescence at 771 nm
SIF_Unadjusted_757nm	Solar Induced Chlorophyll Fluorescence at 757nm, no offset adjustment
SIF_Unadjusted_771nm	Solar Induced Chlorophyll Fluorescence at 771nm, no offset adjustment
SIF_Unadjusted_Relative_757nm	Solar Induced Chlorophyll Fluorescence at 757nm in fractions of continuum level, no offset adjustment
SIF_Unadjusted_Relative_771nm	Solar Induced Chlorophyll Fluorescence at 771nm in fractions of continuum level, no offset adjustment
SIF_Uncertainty_757nm	One-Sigma Statistical Uncertainty in Solar Induced Chlorophyll Fluorescence at 757nm
SIF_Uncertainty_771nm	One-Sigma Statistical Uncertainty in Solar Induced Chlorophyll Fluorescence at 771nm
sounding_land_fraction	Percentage of land surface type within the sounding
sounding_qual_flag	Sounding Quality Flag: 0 = good, 1 = bad

527

528 **Table 2. Criterion of quality flags *best* and *good* for the Level 2 GOSAT, OCO-2, and OCO-3 data.**

529 Soundings that do not meet either set of criteria are flagged as *failed* (2).

Quality_Flag = 0 ( <i>best</i> )	Quality_Flag = 1 ( <i>good</i> )
$28 \leq \text{continuum radiance @757nm} \leq 195$ [W/m <sup>2</sup> /sr/μm]	$28 \leq \text{continuum radiance @757nm} \leq 195$ [W/m <sup>2</sup> /sr/μm]
$\chi^2 @ 757\text{nm} \leq 2.0$	$\chi^2 @ 757\text{nm} \leq 3.0$
$\chi^2 @ 771\text{nm} \leq 2.0$	$\chi^2 @ 771\text{nm} \leq 3.0$

$0.85 \leq O_2 \text{ ratio} \leq 1.5$	$0.85 \leq O_2 \text{ ratio} \leq 1.5$
$0.5 \leq CO_2 \text{ ratio} \leq 4.0$	$0.5 \leq CO_2 \text{ ratio} \leq 4.0$
$\theta_{\text{sun}} \leq 80^\circ$ for GOSAT; $\theta_{\text{sun}} \leq 70^\circ$ for OCO-2/3	$\theta_{\text{sun}} \leq 80^\circ$ for GOSAT; $\theta_{\text{sun}} \leq 70^\circ$ for OCO-2/3
Land Fraction = 100%	Land Fraction $\geq 80\%$
