14 **Abstract.** China's forests rank fifth in the world by area and cover a broad climatic
15 gradient from cold-temperate to tropical zones, and play a key role in the global carbon
16 cycle. Studies on forest soil respiration (R_s) are increasing rapidly in China over the last
17 two decades, but the resulting R_s data need to be summarized. Here, we compile a
18 comprehensive dataset of R_s in China's undisturbed forest ecosystems from literatures
19 published up to December 31, 2018, including monthly R_s and the concurrently measured
20 soil temperature (N=8317), mean monthly R_s (N=5003), and annual R_s (N=634).
21 Detailed plot information was also recorded, such as geographical location, climate factors,
22 stand characteristics, and measurement description. We examine some aspects of the
23 dataset – R_s equations fitted with soil temperature, temperature sensitivity (Q_{10}), monthly
24 variations and annual effluxes in cold-temperate, temperate, subtropical and tropical

25 zones. We hope the dataset will be used by the science community to provide a better
26 understanding of carbon cycle in China's forest ecosystems and reduce uncertainty in
27 evaluating of carbon budget at the large scale. The dataset is publicly available at
28 <https://doi.pangaea.de/10.1594/PANGAEA.943617> (Sun et al. 2021).

29

30 **Keywords:** Soil carbon flux, Carbon cycle, Temperature sensitivity, Forest, China

31 **1 Introduction**

32 Soil respiration (*Rs*) refers to the total amount of CO₂ released by undisturbed soil,
33 including autotrophic respiration and heterotrophic respiration, the former from plant
34 roots and their microbial symbionts, and the latter from microorganisms decomposing
35 litter and soil organic matter. As the second-largest terrestrial carbon flux, the recent
36 estimations of global annual *Rs* (80–98 Pg C year⁻¹) are above ten percent of the
37 atmospheric carbon pool (750 Pg C) (Bond-Lamberty and Thomson, 2010b;
38 Hashimoto et al., 2015; Raich et al., 2002; Warner et al., 2019), thus accelerating soil
39 respiration rates with climate warming have a strong potential to influence atmospheric
40 CO₂ levels. It is thus important to understand better soil respiration dynamics and
41 response to climate changes.

42 Forest area in China ranks fifth in the world (FAO, 2020) and covers a broad climatic
43 gradient, including cold-temperate, temperate, subtropical and tropical zones. In China,
44 most *Rs* measurements began only after 2001 (Chen et al., 2010), but have rapidly
45 increased during the last 20 years (Jian et al., 2020). Several studies have summarized
46 annual *Rs* in China's forest ecosystems, but with the small samples (e.g., N=50 in
47 Zheng et al., 2010; N=62 in Chen et al., 2008; N=120 in Zhan et al., 2012; N=139 in
48 Song et al., 2014). Yu et al. (2010) established a geostatistical model with a total of 390
49 monthly *Rs* data from different ecosystems in China. With 1782 monthly *Rs* in forest

50 ecosystems across China, Jian et al. (2020) analyzed the spatial patterns and temporal
51 trends from 1961 to 2014. However, amounts of R_s data are still unexploited, because
52 they were only displayed in the forms of monthly dynamics in the original papers' figures.
53 R_s data at a subannual timescales are important for upscaling global R_s (Jian et al.,
54 2018), which may derive different conclusions and deserve further exploration (Huang
55 et al., 2020).

56 The lack of the large-scale and observation-driven R_s data is a main constraining factor
57 in quantifying regional- to global-scale carbon budget (Bond-Lamberty and Thomson,
58 2010a; Rayner et al., 2005). R_s data and concurrently measured temperature thus
59 provide not only a solid base to understand the critical factors influencing R_s , but the
60 opportunity to better simulate R_s at the large scale. We attempted to compile a complete
61 forest R_s dataset at different temporal scales in China, and analyze temperature
62 sensitivity (Q_{10}), monthly and annual R_s in cold-temperate, temperate, subtropical and
63 tropical zones.

64 **2 Data and methods**

65 **2.1 Data sources**

66 The terms of “soil respiration”, “soil carbon (or CO₂) efflux”, or “soil carbon (or CO₂)
67 emission” were searched from publications before 2018 in the China Knowledge
68 Resource Integrated Database (<http://www.cnki.net/>), China Science and Technology
69 Journal Database (<http://www.cqvip.com>), ScienceDirect (<http://www.sciencedirect.com/>),
70 ISI Web of Science (<http://isiknowledge.com/>), and Springer Link
71 (<http://link.springer.com/>). Means, minimums and maximums of soil respiration during
72 the observation periods were usually given in these published studies, and monthly
73 patterns of soil respiration rates and the corresponding temperature were frequently
74 shown with figures. WEBPLOTDIGITIZER, a graphic digitizing software, was used to

75 take data from figures when values were not reported in the text (Burda et al., 2017).

76 **2.2 Data collection criteria**

77 The following criteria were used to ensure data consistency and accuracy: i) *Rs* was
78 measured in the field without obvious disturbances or manipulation experiments, e.g.
79 fire, cutting, nitrogen addition treatments, etc. ii) Forested swamps and commercial
80 plantations (e.g. orchard, rubber, etc.) were not examined. iii) *Rs* was measured either
81 by static chamber/gas chromatography (GC) or by dynamic chamber/infrared gas
82 analyzers (IRGA, model Li-6400, Li-8100, Li-8150 (LI-COR Inc., Lincoln, Nebraska,
83 USA)), which are the most popular methods and provide methodological consistency
84 (Sun et al., 2020; Wang et al., 2011; Yang et al., 2018; Zheng et al., 2010).

85 Based on these criteria, a total of 10288 monthly soil respiration data and 634 annual
86 soil respiration data were assembled from 568 publications. Meanwhile, the related
87 information was recorded, including geographical location (province, study site, latitude,
88 longitude and elevation), climate (mean annual temperature and mean annual
89 precipitation), stand description (forest type, origin, age, density, mean tree height and
90 diameter at breast height), measurement regime (method, time, frequency, collar area,
91 height and numbers) (Table 1). There were 155 study sites from 28 provinces in China
92 (18.61–52.86° N, 84.91–129.08° E, 7–4200 m) (Fig. 1). This forest region encompasses a
93 large gradient of climate regimes, mean annual temperature ranging from -5.4 to 23.8 °C
94 and mean annual precipitation ranging from 105 to 3000 mm. The observation years were
95 from 2000 until 2018.

96 **2.3 Data verification**

97 Soil temperature as a main influencing factor, was usually concurrently measured with
98 *Rs*. Monthly dynamics of *Rs* and soil temperature at 5 cm depth (T_5) and/or 10 cm depth

99 (T_{10}) were shown with figures in many literatures. In this study, most of the R_s data (~82%)
100 and the concurrent T_5 and/or T_{10} were extracted with WEBPLOTDIGITIZER, others (e.g.,
101 minimum, maximum) were directly given in the original papers. To verify the accuracy of
102 the digital software, the means (R_s , T_5 , T_{10}) averaged from the extracted data were
103 compared with the corresponding means directly given in the original papers (Fig. S1).
104 The Root Mean Square Errors (RMSE) of R_s , T_5 and T_{10} were $0.09 \mu\text{mol m}^{-2} \text{s}^{-1}$, $0.35 \text{ }^\circ\text{C}$
105 and $0.44 \text{ }^\circ\text{C}$, respectively, and the coefficients of determination (R^2) were all larger than
106 0.99, indicating that the accuracy of WEBPLOTDIGITIZER is excellent. Moreover, the
107 data from the same authors and different sources (e.g. master or Ph. D. dissertation and
108 journal article) has been carefully cross-checked and supplemented.

109 **2.4 Monthly and annual soil respiration calculation**

110 Long-term continuous R_s could be monitored with infrared gas analyzers (e.g., Li-8100,
111 Li-8150), but there are few published studies of such continuous data (Bond-Lamberty et
112 al., 2020; Tu et al., 2015; Wu et al., 2014; Yu et al., 2011). The observation frequency
113 was 1–12 days per month—high during the growing season, but low in winter. R_s was
114 measured throughout the day (16%) or at representative time, e.g., 9:00 a.m.–11:00 a.m.
115 (45%), 9:00 a.m.–12:00 a.m. (22%), etc., which had been validated to be close to the
116 diurnal mean value (Xu and Qi, 2001; Yan et al., 2006; Yang et al., 2018; Yao et al., 2011;
117 You et al., 2013; Zheng et al., 2010). Annual soil carbon efflux was integrated with soil
118 respiration model (i.e. integration method) or interpolated the average soil respiration rate
119 between sampling dates (i.e. interpolation method) (Shi et al., 2014). Finally, monthly R_s
120 and annual soil carbon efflux were converted to the common unit of $\mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$
121 and $\text{g C m}^{-2} \text{ year}^{-1}$, respectively (Bond-Lamberty and Thomson, 2010a).

122 **2.5 Statistical analysis**

123 Monthly and annual R_s were averaged arithmetically in cold-temperate, temperate,

124 subtropical and tropical zones. Independent-Samples T Tests (2 groups) and One-Way
125 ANOVA (≥ 3 groups) at the $P = 0.05$ significance level were used to test the differences
126 among different forest types in the same climate zone and among the same forest type
127 in different climate zones. Temperature sensitivity (Q_{10}) is defined as the factor by
128 which R_s is multiplied when temperature increases by $10\text{ }^\circ\text{C}$ (Davidson and Janssens,
129 2006; Lloyd and Taylor, 1994), which is usually calculated with the van't Hoff equation
130 ($R_s = ae^{\beta T}$ & $Q_{10} = e^{10\beta}$), where R_s is soil respiration rate ($\mu\text{mol m}^{-2} \text{s}^{-1}$), T is temperature
131 ($^\circ\text{C}$). All statistical analyses were performed with SPSS Statistics 21 (SPSS Inc.,
132 Chicago, USA).

133 **3 Results**

134 **3.1 Relationship between soil respiration rate and soil temperature**

135 Temperature is often the main factor determining soil respiration rates. The samples of
136 the paired R_s & T_5 and R_s & T_{10} were 6341 (69%) and 2878 (31%) in the dataset,
137 respectively. There were significantly exponential relationships of R_s with T_5 and T_{10}
138 in forest ecosystems across China, which could explain about 48% and 52% of the R_s
139 variations, respectively (Fig. S2). The exponential correlations were all significant in
140 four climatic zones ($R^2 = 0.23\text{--}0.93$) (Fig. 2). RMSEs in cold-temperate and temperate
141 zones ($1.52\text{--}1.67\ \mu\text{mol m}^{-2} \text{s}^{-1}$) were larger than those in subtropical and tropical zones
142 ($1.04\text{--}1.32\ \mu\text{mol m}^{-2} \text{s}^{-1}$), except the smallest RMSE from T_{10} in cold-temperate zone
143 ($0.42\ \mu\text{mol m}^{-2} \text{s}^{-1}$).

144 Q_{10} could be calculated with the exponential equations between R_s and soil
145 temperature. At the national scale, the Q_{10} values in China's forest ecosystems from T_5
146 ($-16.51\text{--}33.58\text{ }^\circ\text{C}$) and T_{10} ($-16.40\text{--}33.46\text{ }^\circ\text{C}$) were 2.05 and 2.17, respectively. The Q_{10}
147 was the largest in cold-temperate zone (T_5 : 3.74 & T_{10} : 3.32), secondary in temperate

148 zone (T_5 : 2.69 & T_{10} : 3.00), and the smallest in subtropical zone (T_5 : 2.15 & T_{10} : 2.20)
149 and tropical zone (T_5 : 2.28 & T_{10} : 1.63).

150 **3.2 Monthly dynamics of soil respiration**

151 Monthly R_s appeared as a single-peak curve (Fig. 3), which derived from the similar
152 years in cold-temperate (2003–2016), temperate (2002–2018), subtropical (2000–2017)
153 and tropical zones (2003–2015). The largest values occurred in August (4.18–4.36
154 $\mu\text{mol m}^{-2} \text{s}^{-1}$) in cold-temperate and temperate zones, larger than the largest values in
155 July (3.58–3.83 $\mu\text{mol m}^{-2} \text{s}^{-1}$) in subtropical and tropical zones. The lowest values
156 occurred in January in cold-temperate (0.20 $\mu\text{mol m}^{-2} \text{s}^{-1}$), temperate (0.49 $\mu\text{mol m}^{-2}$
157 s^{-1}), subtropical (1.10 $\mu\text{mol m}^{-2} \text{s}^{-1}$) and tropical zones (1.62 $\mu\text{mol m}^{-2} \text{s}^{-1}$). Monthly
158 variations were largest in cold-temperate and temperate zones, secondary in subtropical
159 zone, and smallest in tropical zone.

160 Annual mean R_s in January–December from low to high was cold-temperate (1.63
161 $\mu\text{mol m}^{-2} \text{s}^{-1}$), temperate (1.93 $\mu\text{mol m}^{-2} \text{s}^{-1}$), subtropical (2.47 $\mu\text{mol m}^{-2} \text{s}^{-1}$) and
162 tropical zones (2.57 $\mu\text{mol m}^{-2} \text{s}^{-1}$). Meanwhile, annual soil carbon emissions were
163 calculated with the annual mean R_s : 621.91 g C $\text{m}^{-2} \text{yr}^{-1}$ in cold-temperate zone, 733.31
164 g C $\text{m}^{-2} \text{yr}^{-1}$ in temperate zone, 937.15 g C $\text{m}^{-2} \text{yr}^{-1}$ in subtropical zone, and 973.35 g C
165 $\text{m}^{-2} \text{yr}^{-1}$ in tropical zone. Soil carbon emissions in growing season (May–October) and
166 winter (November–April) accounted for 85% and 15% in cold-temperate zone, 80%
167 and 20% in temperate zone, 69% and 31% in subtropical zone, 61% and 39% in tropical
168 zone. Subtropical and tropical zones still keep high soil respiration rates in November–
169 April, which is the main source of their larger annual soil carbon emissions.

170 **3.3 Annual soil carbon effluxes**

171 There were 634 annual soil carbon effluxes, and most of the observations were

172 conducted in subtropical zone (61%) and temperate zone (32%) (Fig. 4). The spanning
173 years were 2003–2014 in cold-temperate zone, 2000–2018 in temperate zone, 2002–
174 2017 in subtropical zone and 2003–2017 in tropical zone. The annual soil carbon
175 effluxes ranged from 260.10 g C m⁻² yr⁻¹ to 2058.00 g C m⁻² yr⁻¹ in China's forest
176 ecosystems, and the mean was 851.88±12.75 g C m⁻² yr⁻¹. The annual soil carbon
177 effluxes increased with the increasing of mean annual temperature and precipitation at
178 the national scale (Fig. S3). Mean annual soil carbon emissions in tropical, subtropical,
179 temperate and cold-temperate zones were 1042.01±68.55, 928.91±16.68,
180 697.85±16.39 and 684.29±61.81 g C m⁻² yr⁻¹, respectively. The former two was
181 significantly higher than the latter two, but the differences were not significant between
182 tropical and subtropical zones, and between temperate and cold-temperate zones. The
183 differences were not significant for evergreen broadleaf forest (EBF), evergreen
184 needleleaf forest (ENF) and deciduous needleleaf forest (DNF) among different
185 climate zones. Deciduous broadleaf forest (DBF) in temperate (748.59±25.18 g C m⁻²
186 yr⁻¹) and subtropical zones (755.41±58.26 g C m⁻² yr⁻¹) was similar, both of which were
187 larger than that in cold-temperate zone (284.20±21.36 g C m⁻² yr⁻¹). Broadleaf and
188 needleleaf mixed forest in subtropical zone (977.35±43.56 g C m⁻² yr⁻¹) had
189 significantly higher emissions than that in temperate zone (733.44±45.29 g C m⁻² yr⁻¹).

190 Evergreen forests were usually larger than deciduous ones in the same climatic zone,
191 for example, ENF (866.98±63.74 g C m⁻² yr⁻¹) and DNF (734.56±83.67 g C m⁻² yr⁻¹)
192 in cold-temperate zone, ENF (699.96±32.77 g C m⁻² yr⁻¹) and DNF (555.15±24.19 g C
193 m⁻² yr⁻¹) in temperate zone, EBF (1073.50±26.44 g C m⁻² yr⁻¹) and DBF (755.41±58.26

194 g C m⁻² yr⁻¹) in subtropical zone. Broad-leaved forests showed significantly larger
195 annual fluxes than coniferous forests in temperate zone (DBF: 748.59±25.18 g C m⁻²
196 yr⁻¹ vs. DNF: 555.15±24.19 g C m⁻² yr⁻¹) and subtropical zone one (EBF:
197 1073.50±26.44 g C m⁻² yr⁻¹ vs. ENF: 717.50±17.61 g C m⁻² yr⁻¹). However, DNF
198 (734.56±83.67 g C m⁻² yr⁻¹) was larger than DBF (284.20±21.36 g C m⁻² yr⁻¹) in cold-
199 temperate zone, which was from high-latitude Great Xing'an Mountains (~51° N) and
200 high-altitude Gongga Mountain (2800–2950 m), respectively. Additionally, bamboo is
201 a special type in subtropical areas, exhibiting the highest soil carbon emissions
202 (1133.55±42.74 g C m⁻² yr⁻¹).

203 **4 Discussion**

204 **4.1 Temperature sensitivity (Q_{10}) of soil respiration**

205 Q_{10} is a key parameter in modelling the effects of climate warming on soil carbon
206 release. The Q_{10} calculated with the exponential equations of T_5 and T_{10} were 2.05 and
207 2.17 at the national scale (Fig. S2), which were lower than the averaged Q_{10} from
208 different studies in the syntheses of China's forest ecosystems (T_5 : 2.28–2.51 and T_{10} :
209 2.74–3.00, Peng et al., 2009; Song et al., 2014; Xu et al., 2015; Zheng et al., 2009) and
210 global forest ecosystems (T_5 : 2.55–2.70 and T_{10} : 3.01–3.31, Wang et al., 2010 a; b).
211 Our results were close to the Q_{10} of 2 commonly used in many biogeochemical models
212 (e.g., Cox et al., 2000; Sampson et al., 2007) and the mean Q_{10} of 2.11 estimated with
213 inverse modeling in forest soils across China (Zhou et al., 2009).

214 Temperature was the most important limiting factor for soil microbial activity and
215 root growth in cold regions, thus, R_s was more sensitive to temperature changes (Lloyd
216 and Taylor, 1994; Peng et al., 2009; Zheng et al., 2009; Zheng et al., 2020). The Q_{10}

217 increased from tropical zone to cold-temperate zone in this study, and varied from 1.63
218 to 3.74. Soil temperature at the depth of 5 cm and 10 cm could only explain 29% and
219 23% of the R_s variations and RMSEs were $1.09 \mu\text{mol m}^{-2} \text{s}^{-1}$ and $1.13 \mu\text{mol m}^{-2} \text{s}^{-1}$ in
220 tropical zone, respectively (Fig. 2d). The difference of the mean R_s between tropical
221 moist forests ($1260 \text{ g C m}^{-2} \text{ yr}^{-1}$) and tropical dry forests ($673 \text{ g C m}^{-2} \text{ yr}^{-1}$) was about
222 2-fold (Raich and Schlesinger, 1992), indicating that soil moisture might play more
223 important roles.

224 **4.2 Comparisons of monthly and annual soil carbon effluxes**

225 The lowest monthly R_s occurred in January, and the largest values occurred in August
226 in cold-temperate and temperate zones and in July in subtropical and tropical zones
227 (Fig. 3). Similarly, monthly R_s of global terrestrial ecosystems reached their minima in
228 February and peaked in July and August (Hashimoto et al., 2015; Raich et al., 2002).
229 Due to the limitation of low temperature, winter observations of R_s were relatively
230 fewer in the cold-temperate and temperate zones. The R_s in winter (November–April)
231 was usually assumed to account for 20% of the total annual R_s (Geng et al., 2017; Yang
232 and Wang, 2005), which was in agreement with the proportion in temperate zone, but
233 greater than 15% in cold-temperate zone.

234 Annual soil carbon emission had been synthesized in forest ecosystems across China,
235 and the mean was $745.34 \text{ g C m}^{-2} \text{ yr}^{-1}$ (Zheng et al., 2010), $764.11 \text{ g C m}^{-2} \text{ yr}^{-1}$ (Zhan
236 et al., 2012), $917.73 \text{ g C m}^{-2} \text{ yr}^{-1}$ (Song et al., 2014) and $975.50 \text{ g C m}^{-2} \text{ yr}^{-1}$ (Chen et
237 al., 2008), and the mean of $851.88 \text{ g C m}^{-2} \text{ yr}^{-1}$ in the present study was in the mid-
238 range. The mean annual R_s in China's forest ecosystems was slightly lower than the
239 mean R_s of $990.00 \text{ g C m}^{-2} \text{ yr}^{-1}$ in global forest ecosystems (Chen et al., 2010). Warner
240 et al. (2019) modelled global R_s and found that the smallest and greatest annual soil
241 carbon emissions were in deciduous needleleaf forest (Mean= $344.10 \text{ g C m}^{-2} \text{ yr}^{-1}$) and

242 evergreen broadleaf forest (Mean=1310.47 g C m⁻² yr⁻¹), respectively. Compared with
243 the predicted annual *Rs*, deciduous needleleaf forest in cold-temperate (Mean=734.56
244 g C m⁻² yr⁻¹) and temperate zones (Mean= 555.15 g C m⁻² yr⁻¹) had larger values, but
245 those of evergreen broadleaf forest in subtropical (Mean=1073.50 g C m⁻² yr⁻¹) and
246 tropical zones (Mean=1065.09 g C m⁻² yr⁻¹) were lower (Fig. 4).

247 Mean annual soil carbon emissions from 634 annual *Rs* and 5003 mean monthly *Rs*
248 were 684.29 and 621.91 g C m⁻² yr⁻¹ in cold-temperate zone, 697.85 and 733.31 g C m⁻²
249 yr⁻¹ in temperate zone, 928.91 and 937.15 g C m⁻² yr⁻¹ in subtropical zone, and
250 1042.01 and 973.35 g C m⁻² yr⁻¹ in tropical zone (Fig. 4 and Fig. 3). The differences
251 between the directly averaged annual *Rs* and the accumulative mean monthly *Rs* were
252 smallest in tropical zone (-8.24 g C m⁻² yr⁻¹), secondary in temperate zone (-35.46 g C
253 m⁻² yr⁻¹), and largest in cold-temperate and tropical zones (62.38–68.66 g C m⁻² yr⁻¹).
254 From Fig. 4 we could also found that the standard errors in tropical and temperate zones
255 (~16 g C m⁻² yr⁻¹) were smaller those in cold-temperate and tropical zones (~65 g C m⁻²
256 yr⁻¹). Mean annual soil carbon emissions in temperate, subtropical and tropical
257 ecosystems were 745 g C m⁻² yr⁻¹, 776 g C m⁻² yr⁻¹ and 1286 g C m⁻² yr⁻¹ at the global
258 scale, respectively (Bond-Lamberty and Thomson, 2010a), which were comparable
259 with our results.

260 4.3 Improvements of the dataset

261 *Rs* measurements were mainly from Li-8100 (47%) and Li-6400 (33%), secondary
262 from gas chromatography (18%), and Li-8150 only accounted for 2%. The differences
263 of the four common measurement methods had been proved to be small (~10%) (Wang
264 et al., 2011; Yang et al., 2018; Zheng et al., 2010). The sample sizes of annual *Rs* were
265 50–139 (Chen et al., 2008; Song et al., 2014; Zhan et al., 2012; Zheng et al, 2010) and

266 634 in the current study, and increased above 4-fold. The global soil respiration
267 database (SRDB-V5) collected 523 undisturbed annual R_s in China's forest ecosystems
268 (Jian et al., 2021), but all methods were included, e.g. alkali absorption, gas
269 chromatography and various infrared gas analyzers. Alkali absorption method could
270 underestimate R_s (Chen et al., 2008; Jian et al., 2020). The total samples of mean
271 monthly R_s were 5003, which was much larger than the other dataset's monthly
272 samples of 1782 in China's forest ecosystems (Jian et al., 2020; Steele and Jian, 2018).
273 Additionally, we extended the dataset with the digital software
274 (WEBPLOTDIGITIZER) from the monthly dynamics figures of the original papers,
275 including the paired R_s & T_5 (N=6341) and R_s & T_{10} (N=2878). Predicting soil
276 respiration from soil temperature has gained extensive acceptance (Shi et al., 2014; Song
277 et al., 2014; Sun et al., 2020). These data could be used to establish the large-scale soil
278 respiration equation and acquire the key parameters of carbon cycle. Compared with the
279 above-mentioned monthly or annual databases, this study collected all available R_s data
280 at different time scales. Fig. S4 showed the length of the individual time series from
281 the different sites, the high frequencies were 12 months (38%), 6–7 months (20%) and
282 13–24 months (15%). Bamboo forests were seldom considered in the previous
283 databases (Chen et al., 2008; Steele and Jian, 2018; Zhan et al., 2012; Zheng et al.,
284 2010), which exhibited the highest soil carbon emissions (Mean=1133.55 g C m⁻² yr⁻¹,
285 Fig. 4). With the area increasing at a high rate of 3.1% per year (Song et al., 2017),
286 bamboo forests would play an important role in regional and even national carbon cycle.
287 It's worth noting that the R_s studies were fewer in the regions of latitude larger than 48°
288 (~2%) or elevation higher than 3000 m (~4%). The potentially under-represented forest
289 types might affect the evaluation of temperature sensitivity of soil respiration and
290 annual soil carbon emission at the regional and national scale.

291 **5 Data availability**

292 The soil respiration dataset in China's forest ecosystems used to produce the results in
293 this study is free to the public for scientific purposes and can be downloaded at
294 <https://www.pangaea.de/tok/788910d8d3ae0a415c7bad2e7025a3f16f042a1b> (Sun et
295 al. 2021).

296 **6 Conclusions**

297 In this study, we reviewed the *Rs*-related literatures and collected in situ *Rs*
298 measurements with common infrared gas analyzers (i.e. Li-6400, Li-8100, Li-8150) or
299 gas chromatography to assemble a comprehensive and uniform dataset of China's
300 forest ecosystems at different time scales. Besides the *Rs* data directly given in the
301 original papers, the monthly patterns of *Rs* and the concurrently measured soil
302 temperature at 5 cm and/or 10 cm depth in the figures were digitized. Meanwhile, we
303 have made a preliminary analysis of the data. The results showed that soil temperature
304 could explain 22.5%–93.4% of the *Rs* variations. Temperature sensitivity (Q_{10}) was
305 about 2.05–2.17 at the national scale, increasing from 1.63 in tropical zone to 3.74 in
306 cold-temperate zone. Monthly *Rs* showed a single-peak curve, and the largest values
307 occurred in August (4.18–4.36 $\mu\text{mol m}^{-2} \text{s}^{-1}$) in cold-temperate and temperate zones,
308 larger than the largest values in July (3.58–3.83 $\mu\text{mol m}^{-2} \text{s}^{-1}$) in subtropical and
309 tropical zones. Mean annual soil carbon emissions decreased from tropical (1042.01 g
310 $\text{C m}^{-2} \text{yr}^{-1}$), subtropical (928.91 g $\text{C m}^{-2} \text{yr}^{-1}$), temperate (697.85 g $\text{C m}^{-2} \text{yr}^{-1}$) to cold-
311 temperate zones (684.29 g $\text{C m}^{-2} \text{yr}^{-1}$). This study provides basic data and scientific basis
312 for quantitative evaluation of soil carbon emissions from forest ecosystems in China.

313 **Author contributions.** BJ designed the soil respiration dataset and searched the papers
314 until 2018. HS and BJ collected and digitized soil respiration data and compiled the

315 associated information. HS and BJ prepared the manuscript. ZX provided many useful
316 suggestions and reviewed the paper.

317 **Competing interests.** The authors declare that they have no conflict of interest.

318 **Acknowledgements.** We are grateful to the scientists who contributed their work to
319 the dataset. We thank Ben Bond-Lamberty and four anonymous reviewers for their
320 constructive comments and improvements to this manuscript. This work was supported
321 by the National Natural Science Foundation of China (32071592) and the National Key
322 Research and Development Program of China (2017YFC0503906).

506 that are not applicable.

Column	Description	Unit	Numbe	Range
ID	Unique identification number of each record	N/A	11297	1–11297
Province	Province location of study site	N/A	28	N/A
Study site	Name of study site	N/A	155	N/A
Latitude	Latitude (N) of study site	°	208	18.61–52.86
Longitude	Longitude (E) of study site	°	218	84.91–129.08
Elevation	Altitude of study site	m	329	7–4200
MAT	Mean annual temperature	°C	122	-5.4–23.8
MAP	Mean annual precipitation	mm	180	105–3000
Forest type	Forest community characterized by the dominant tree species, or the ecological similarities (e.g. life form and biotope)	N/A	180	N/A
Origin	Stand origin was classified into planted and natural (i.e. secondary, primary) forests	N/A	4	N/A
Age	Stand age, estimated from historical records or dominant tree rings in natural forest, defined since planting in planted forest	years	769	2–400
DBH	Mean diameter at breast height	cm	610	2.40–51.96
H _{tree}	Mean tree height	m	538	2.50–48.00
Density	Stem density and/or canopy coverage	trees ha ⁻¹	548	209–17000,0.23–0.98
Instrument	Measurement instrument of R_s , i.e. gas chromatography, infrared gas analyzers (Li-6400, Li-8100, Li-8150)	N/A	4	N/A
Time	Observation time of R_s per day (Beijing time)	Hour:Minute	749	0:00–23:00
Frequency	Observation frequency of R_s , i.e. days per month	days	961	0.5–31
Area	Observation area of R_s , i.e. area of soil collar or base	cm ²	976	50–2500
Height	Height of soil collar or chamber	cm	828	4–50
Replication	Numbers of soil collar or chamber	N/A	968	1–768
Date	Observation month of R_s per year	Year-Month	10288	2000-01–2018-03
R_s	Soil respiration rate, monthly means or a few values per month	$\mu\text{mol m}^{-2} \text{s}^{-1}$	10288	0.01–11.84
T_5	Soil temperature at 5 cm depth concurrently measured with R_s	°C	6341	-16.51–33.58
T_{10}	Soil temperature at 10 cm depth concurrently measured with R_s	°C	2878	-16.40–33.46
Mode	The ways to obtain R_s data, 1. extracted with WEB PLOTDIGITIZER, 2. directly given in the original study	N/A	2	1–2
Period	Period of annual soil carbon efflux	Year-Month	631	2001-01–2018-03
Annual R_s	Annual soil carbon efflux	$\text{g C m}^{-2} \text{ year}^{-1}$	634	260.10–2058.00
Method	Method to calculate annual soil carbon efflux, i.e. integration method and/or interpolation method	N/A	3	N/A
Reference	Data sources	N/A	568	N/A

507

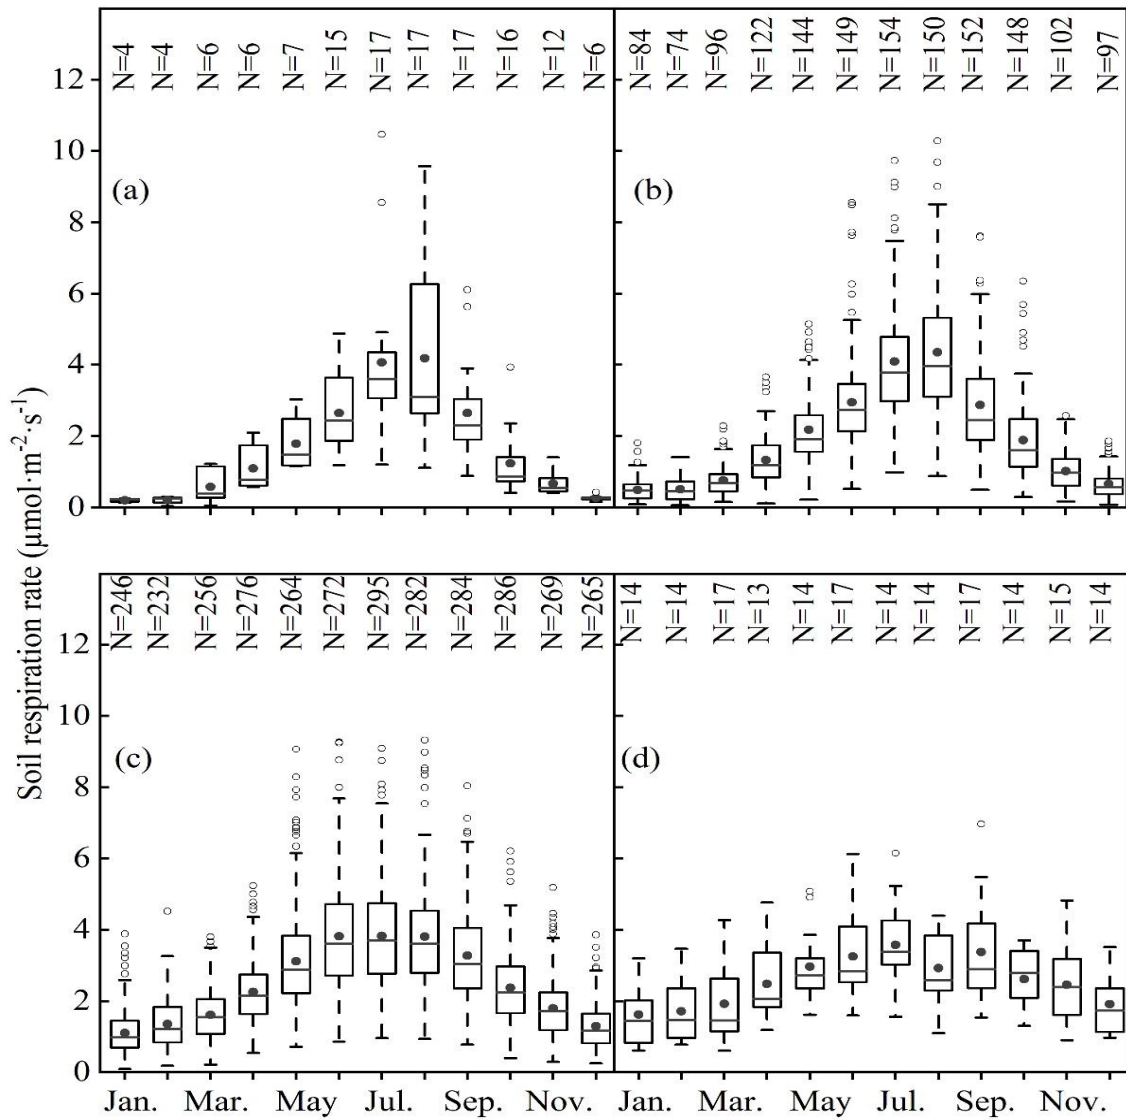

508 **Figure 1.** Distribution of study sites used to develop the forest soil respiration dataset

509 in China.

510

511 **Figure 2.** Exponential relationships of forest soil respiration rates with soil temperature
 512 at 5 cm depth and 10 cm depth in cold-temperate (a), temperate (b), subtropical (c) and
 513 tropical zones (d). P value below 0.01 was described by **. RMSE: Root Mean Square
 514 Error.

515 **Figure 3.** Monthly patterns of forest soil respiration rates in cold-temperate (a),
 516 temperate (b), subtropical (c) and tropical zones (d). Solid circle: mean value; Solid
 517 horizontal line: median; Box: 25th to 75th percentiles; Whisker: 1.5 times interquartile
 518 range; Open circle: data points beyond the whiskers. The samples per month were listed
 519 in the upper part of the figure.

520 **Figure 4.** Comparisons of annual soil carbon effluxes (mean \pm standard error) among
 521 different forest types across China in cold-temperate (a), temperate (b), subtropical (c)
 522 and tropical zones (d). Lowercase letters are the comparisons of different forest types
 523 in each climatic zone, while capital letters are the comparisons of the same forest type
 524 in different climatic zones. The samples were listed in the upper part of the figure, and
 525 the samples larger than 3 were compared. EBF: evergreen broadleaf forest, DBF:
 526 deciduous broadleaf forest, ENF: evergreen needleleaf forest, DNF: deciduous
 527 needleleaf forest, MF: broadleaf and needleleaf mixed forest and BB: Bamboo forest.
