19

20 **Abstract.** The China-Pakistan Economic Corridor (CPEC) is one of the flagship projects of  
21 the One Belt One Road Initiative, which faces threats from water shortage and mountain  
22 disasters in the high-elevation region, such as glacial lake outburst floods (GLOFs). An up-to-  
23 date high-quality glacial lake dataset with parameters such as lake area, volume and type,  
24 which is fundamental to water resource and flood risk assessments, and predicting glacier-  
25 lake evolutions, is still largely absent for the entire CPEC. This study describes a glacial lake  
26 dataset for the CPEC using a threshold-based mapping method associated with rigorous  
27 visual inspection workflows. This dataset includes (1) multi-temporal inventories for 1990,  
28 2000, and 2020 produced from 30 m resolution Landsat images, and (2) a glacial lake  
29 inventory for the year 2020 at 10 m resolution produced from Sentinel-2 images. The results  
30 show that, in 2020, 2234 lakes were derived from the Landsat images, covering a total area of  
31  $86.31 \pm 14.98 \text{ km}^2$  with a minimum mapping unit of 5 pixels ( $4500 \text{ m}^2$ ), whereas 7560 glacial  
32 lakes were derived from the Sentinel-2 images with a total area of  $103.70 \pm 8.45 \text{ km}^2$  with a  
33 minimum mapping unit of 5 pixels ( $500 \text{ m}^2$ ). The discrepancy shows that Sentinel-2 is able to  
34 detect a significant quantity of smaller lakes than Landsat due to its finer spatial resolution.  
35 Glacial lake data in 2020 was validated by Google Earth-derived lake boundaries with a  
36 median ( $\pm$ standard deviation) difference of  $7.66 \pm 4.96 \%$  for Landsat-derived product and  
37  $4.46 \pm 4.62 \%$  for Sentinel-derived product. The total number and area of glacial lakes from  
38 consistent 30 m resolution Landsat images remain relatively stable despite a slight increase  
39 from 1990 to 2020. A range of critical attributes have been generated in the dataset, including  
40 lake types and mapping uncertainty estimated by an improved Hanshaw's equation. This  
41 comprehensive glacial lake dataset has potential to be widely applied in studies on water  
42 resource assessment, glacial lake-related hazards, glacier-lake interactions, and is freely  
43 available at <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022).

## 44 1 Introduction

45 Glaciers in High-mountain Asia (HMA) play a crucial role in regulating climate, supporting  
46 ecosystems, modulating the release of freshwater into rivers, and sustaining municipal water  
47 supplies (Wang et al., 2019; Viviroli et al., 2020), agricultural irrigation, and hydropower  
48 generation (Pritchard, 2019; Nie et al., 2021). Most HMA glaciers are losing mass in the  
49 context of climate change (Brun et al., 2017; Maurer et al., 2019; Shean et al., 2020;  
50 Bhattacharya et al., 2021), therefore, unsustainable glacier melt and the passing of peak water  
51 are reducing the hydrological role of glaciers (Huss and Hock, 2018) and impacting  
52 downstream ecosystem services, agriculture, hydropower and other socioeconomic values  
53 (Carrivick and Tweed, 2016; Nie et al., 2021). The present and future glacier changes not  
54 only impact water supply for downstream area but also alter the frequency and intensity of  
55 glacier-related hazards, such as glacier lake outburst floods (GLOFs) (Nie et al., 2018;  
56 Rounce et al., 2020; Zheng et al., 2021), and rock and ice avalanches (Shugar et al., 2021).  
57 Global glacial lake number and total area both increased between 1990 and 2018 in response  
58 to glacier retreat and climate change (Shugar et al., 2020), affecting the allocation of  
59 freshwater resource. The Indus is globally the most important and vulnerable water tower unit  
60 where glaciers, lakes and reservoir storage contribute about two-thirds of the water supply  
61 (Immerzeel et al., 2020). Ice-marginal lakes store  $\sim 1\%$  of total ice discharge in Greenland and  
62 accelerate lake-terminating ice velocity by  $\sim 25\%$  (Carrivick et al., 2022). An increasing

63 frequency and risk of GLOFs (Nie et al., 2021; Zheng et al., 2021) is threatening Asian  
64 population and infrastructures in the mountain ranges, such as the China-Pakistan Economic  
65 Corridor (CPEC), as a flagship component of One Belt One Road Initiative (Battamo et al.,  
66 2021; Li et al., 2021). The northern section of the CPEC passes through Pamir, Karakoram,  
67 Hindu Kush and Himalaya mountains where droughts and glacier-related hazards are frequent  
68 and severe (Hewitt, 2014; Bhambri et al., 2019; Pritchard, 2019), threatening local people,  
69 the existing, under-construction and planned infrastructures, such as highways, hydropower  
70 plants and railways. Understanding the risk posed by water shortage and glacier-related  
71 hazards is a critical step to sustainable development for the CPEC.

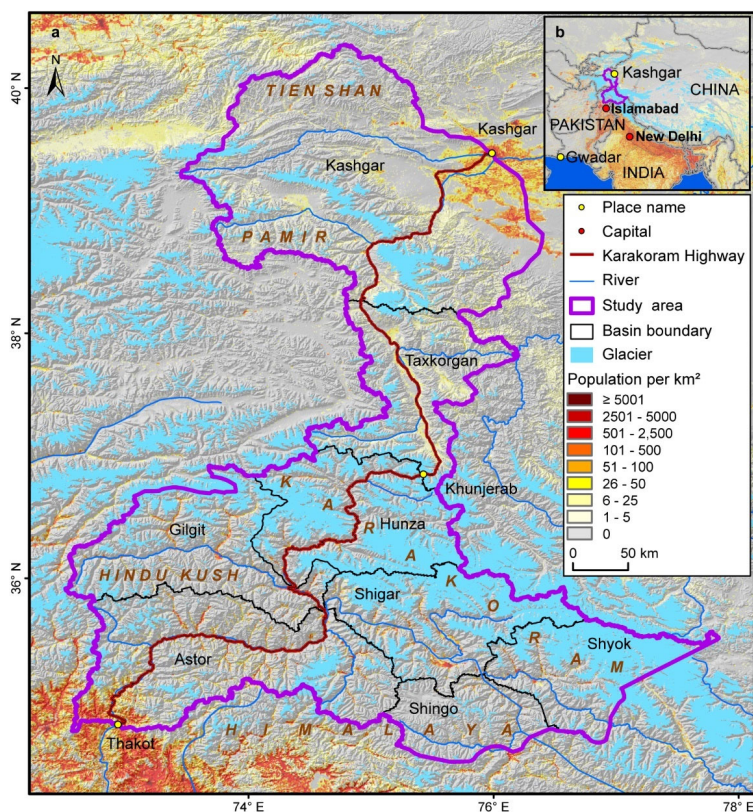

72 Glacial lake inventories with a range of attributes benefit water resource assessment and  
73 disaster risk assessment related to glacial lake (Wang et al., 2020; Carrivick et al., 2022), and  
74 contribute to predicting glacier-lake evolution and cryosphere-hydrosphere interactions under  
75 climate change (Nie et al., 2017; Brun et al., 2019; Maurer et al., 2019; Carrivick et al., 2020;  
76 Liu et al., 2020). Remote sensing is the most viable way to map glacial lakes and detect their  
77 spatio-temporal changes in the high-elevation zones where in situ accessibility is extremely  
78 low (Huggel et al., 2002; Quincey et al., 2007). Studies in glacial lake inventories using  
79 satellite observations have been heavily conducted at regional scales recently, such as in the  
80 Tibetan Plateau (Zhang et al., 2015), the Himalaya (Gardelle et al., 2011; Nie et al., 2017),  
81 the HMA (Wang et al., 2020; Chen et al., 2021), the Tien Shan (Wang et al., 2013), the  
82 Alaska (Rick et al., 2022), the Greenland (How et al., 2021) and the northern Pakistan  
83 (Ashraf et al., 2017). However, the latest glacial lake mapping in 2020 is still absent along the  
84 CPEC. Among existing studies, Landsat archival images are the most widely used due to their  
85 multi-decadal record of earth surface observations, reasonably high spatial resolution (30 m),  
86 and publicly available distribution (Roy et al., 2014). Freely available Sentinel-2 satellite  
87 images show a better potential than Landsat in glacial lake mapping and inventories due to  
88 their higher spatial resolution (10 m) and a global coverage, but have only been available  
89 since late 2015 (Williamson et al., 2018; Paul et al., 2020). Glacial lake inventories using  
90 Sentinel-2 images are relatively scarce at regional scales, and studies of the latest glacial lake  
91 mapping as well as comparisons of glacial lake dataset derived from Sentinel-2 and Landsat  
92 observations are still lacking.

93 Discrepancies between various glacial lake inventories (Zhang et al., 2015; Shugar et al.,  
94 2020; Wang et al., 2020; Chen et al., 2021; How et al., 2021) result from differences in  
95 mapping methods, minimum mapping units, definition of glacial lakes, time periods, data  
96 sources and other factors. For example, manual vectorization method was widely adopted at  
97 the earlier stage for its high accuracy. However, it is time-consuming associated with high  
98 labor intensity and is only practical at regional scales (Zhang et al., 2015; Wang et al., 2020).  
99 Automated and semi-automated lake mapping methods, such as multi-spectral index  
100 classification (Gardelle et al., 2011; Nie et al., 2017; Zhang et al., 2018; How et al., 2021),  
101 have been developed to improve the efficiency of glacial lake inventories using optical  
102 images, although manual modification is often unavoidable to assure the quality of lake data  
103 impacted by cloud cover, mountain shadows, seasonal snow cover and frozen lake surfaces  
104 (Sheng et al., 2016; Wang et al., 2017, 2018). Backscatter images from Synthetic Aperture  
105 Radar (SAR) (Wangchuk and Bolch, 2020; How et al., 2021) were used to remove the impact  
106 of cloud cover for lake mapping. Besides, other approaches such as hydrological sink

107 detection using DEM (How et al., 2021) and land surface temperature-based detection  
108 method (Zhao et al., 2020) were also used for lake inventories. Different classification  
109 methods impact the results of lake mapping and monitoring. So far, we are lacking a unified  
110 standard for the classification system of glacial lakes (Yao et al., 2018). Existing  
111 classification systems are generally used for their individual research purposes, mainly based  
112 on the relative positions of glacial lakes and glaciers, the supply conditions of glaciers, and  
113 the attributes of dams. In addition to different classification standards, the same type of  
114 glacial lakes may also have different names given by different scholars. For example, ice-  
115 marginal (Carrivick and Quincey, 2014; Carrivick et al., 2020), ice-contact (Carrivick and  
116 Tweed, 2013) and proglacial (Nie et al., 2017) lakes all represent glacial lakes sharing the  
117 boundary with glaciers. Glacier lakes in currently available datasets have been traditionally  
118 categorized by their spatial relationship with upstream glaciers (Gardelle et al., 2011; Wang  
119 et al., 2020; Chen et al., 2021), and classification attributes considering the formation  
120 mechanism and the properties of dams are rare or incomplete in the CPEC (Yao et al., 2018;  
121 Li et al., 2020). Dam type classification of glacial lakes provides a crucial attribute for  
122 glacier-lake interactions and risk assessment (Emmer and Cuñin, 2021). Therefore, an up-to-  
123 date glacial lake dataset with critical, quality-assured parameters (e.g. lake area, volume and  
124 type) is necessary.

125 This study aims to (1) present an up-to-date glacial lake dataset in the CPEC in 2020 using  
126 both Landsat 8 and Sentinel-2 images to accurately document its detailed lake distribution;  
127 (2) present two historical glacial lake datasets for the CPEC to show extent in 1990 and 2000  
128 using consistent 30-m Landsat images to reveal glacial lake changes at three time periods  
129 (1990, 2000 and 2020); and (3) generate a range of critical attributes for glacial lake  
130 inventories to benefit studies on water resource evaluation, risk assessment of GLOFs, glacier  
131 –lake evolution modeling in the HMA.

133  
 134 **Figure 1.** Location of the study area associated with distribution of glaciers (RGI Consortium, 2017),  
 135 mountains, basins and population (Rose et al., 2021) (a), and its location within the CPCE (b).  
 136

137 The northern part of the CPEC is selected as the study area (Figure 1). The CPCE,  
 138 originating from Kashgar of the Xinjiang Uygur Autonomous region, China and extending to  
 139 Gwadar Port, Pakistan (Ullah et al., 2019; Yao et al., 2020), is connecting China and Pakistan  
 140 via the only Karakoram Highway. The study area covers all the drainage basins along  
 141 Karakoram Highway starting from Kashgar and ending at Thakot, with a total area of ~125,000  
 142 km<sup>2</sup>. The upper Indus basins beyond the Pakistani-administrated border are excluded in this  
 143 study due to spatial coverage of the CPCE. The entire study area is divided into eight sub-  
 144 basins, covering most of the Karakoram with the highest elevation up to 8611 m, western  
 145 Himalaya and Tien Shan, eastern Hindu Kush and Pamir Mountains. The 9710 glaciers in the  
 146 study area cover a total area of 17,447 km<sup>2</sup> and nearly 60% of glaciers are distributed in the  
 147 Karakoram (5818 glaciers with a total area of 14,067.52 km<sup>2</sup>) (RGI Consortium, 2017). Most  
 148 glaciers in the western Himalaya and eastern Hindu Kush are losing mass in the context of

带格式的: 字体: 非加粗

149 climate change (Kääb et al., 2012; Yao et al., 2012; Brun et al., 2017; Shean et al., 2020;  
150 Hugonnet et al., 2021), whereas the glaciers in the eastern Karakoram and Pamir have shown  
151 unusually little changes, including unchanged, retreated, advanced and surged glaciers (Hewitt,  
152 2005; Kääb et al., 2012; Bolch et al., 2017; Brun et al., 2017; Shean et al., 2020; Nie et al.,  
153 2021). The spatially heterogeneous distribution and changes of glaciers are primarily explained  
154 as a result of differences in the dominant precipitation-bearing atmospheric circulation patterns  
155 that include the winter westerlies the Indian summer monsoon, their changing trends and their  
156 interactions with local extreme topography (Yao et al., 2012; Azam et al., 2021; Nie et al.,  
157 2021).

### 158 **3 Data sources**

159 Both Landsat and Sentinel-2 images have been employed to map glacial lakes between 1990  
160 and 2020 in the CPEC (Figure 2). A total number of 71 Landsat Thematic Mapper  
161 (TM), Thematic Mapper Plus (ETM+) and Landsat 8 Operational Land Imager (OLI) images  
162 with a consistent spatial resolution of 30 m were downloaded from the United States  
163 Geological Survey Global Visualization Viewer (GloVis, <https://glovis.usgs.gov/>) to be used  
164 to create glacial lake inventories in 1990, 2000 and 2020. High-quality Landsat-5 images  
165 around 2010 are insufficient to cover the entire study area, so we were unable to map lakes in  
166 2010 due to Landsat-7's scan-line corrector errors and significant cloud covers. In addition,  
167 39 Sentinel-2 images (23 scenes in 2020) were downloaded from Copernicus Open Access  
168 Hub (<https://scihub.copernicus.eu/>) to produce the 10-m resolution glacial lake inventory in  
169 2020. All images used in this study have been orthorectified before download, but we still  
170 find that one Sentinel-2 image was not well matched with Landsat images, leading to the  
171 discrepancy between the two glacial lake datasets. We manually georeferenced the shifted  
172 image to minimize the difference between Sentinel and Landsat derived glacial lakes.

173 Cloud and snow covers heavily affect the usability of optical satellite images (Wulder et  
174 al., 2019) and their availability in the entire study area, so we took advantage of the images  
175 acquired before and after each of the baseline years 1990, 2000 and 2020 to construct the  
176 glacial lake inventories. Only 4 images in 1990 (the largest covering the study area), 16  
177 images in 2000 and 23 images in 2020 were used for matching baseline year. Spatially, high-  
178 quality images in given baseline years were preferentially chosen, or we selected one or more  
179 alternative images acquired in adjacent years to delineate glacial lakes by removing the effect  
180 of cloud and snow covers. To minimize the impact of intra-annual changes of glacial lakes,  
181 most of used images (82% for Sentinel-2 and 75% for Landsat) were acquired from August to  
182 October in the given baseline year with cloud coverage of <20% for each image. For some  
183 specific scenes where cloud cover exceeded the threshold of 20%, we selected more than one  
184 image to remedy the effect of cloud contamination (Nie et al., 2010, 2017; Jiang et al., 2018).

185 Other datasets used include the Randolph Glacier Inventory version 6.0 (Pfeffer et al.,  
186 2014; RGI Consortium, 2017) and the Glacier Area Mapping for Discharge from the Asian  
187 Mountains (GAMDAM) glacier inventory (Sakai, 2019). These two glacier datasets were  
188 used to determine glacial lake types, such as ice-contact, ice-dammed and unconnected-  
189 glacier-fed lakes. The Shuttle Radar Topography Mission Digital Elevation Model (SRTM  
190 DEM) at a 1-arc second (30 m) resolution (Jarvis et al., 2008) was employed to extract the  
191 altitudinal characteristics of the glacial lakes. The absolute vertical accuracy of the SRTM

带格式的: 字体: (中文) 宋体, 非加粗

192 DEM is 16 m (90%) (Rabus et al., 2003; Farr et al., 2007). We also applied other published  
 193 glacial lake datasets for comparative analysis. They include the glacial lake inventories of  
 194 HMA in 1990 and 2018 downloaded from <http://doi.org/10.12072/casnw.064.2019.db> (Wang  
 195 et al., 2020), the Third Pole region in 1990, 2000 and 2010 publicly shared at  
 196 <http://en.tpdatabase.cn/> (Zhang et al., 2015), the Tibet Plateau from 2008 to 2017 accessed at  
 197 <https://doi.org/10.5281/zenodo.3700282> (Chen et al., 2021), and the entire world in 1990,  
 198 2000 and 2015 provided at [https://nsidc.org/data/HMA\\_GLI/versions/1](https://nsidc.org/data/HMA_GLI/versions/1) (Shugar et al.,  
 199 2020). In addition, field survey data collected between 2017 and 2018 were also used to assist  
 200 in lake mapping and glacial lake type classification.  
 201

 203 inventories. The bubble size indicates the available high-quality image number.  
 204

## 205 4 Glacial lake inventory methods

### 206 4.1 Definition of glacial lakes

207 We consider a glacial lake as one that formed as a result of modern or ancient glaciation.  
 208 Contemporary glacial lakes are easily recognized using a combination of glacier inventories  
 209 and remote sensing images. Ancient glacial lakes can be identified from periglacial  
 210 geomorphological characteristics, including moraine remnants and U-shaped valleys that are  
 211 discernible from satellite observations (Post and Mayo, 1971; Westoby et al., 2014; Nie et al.,  
 212 2018; Martín et al., 2021). A 10-km buffering distance of RGI 6.0 glacier boundaries that has  
 213 been widely used in previous studies (Zhang et al., 2015; Wang et al., 2020), was created to  
 214 help mapping glacial lakes. A few glacial lakes in the study area (a total of 84 lakes for  
 215 Sentinel-2 dataset and 55 lakes for Landsat dataset in 2020) beyond the buffering zone,  
 216 located near buffering boundaries, were intentionally included due to clear evidence of  
 217 glaciation (Figure 3). Landslide-dammed lakes (Chen et al., 2017) in the buffering  
 218 zone were excluded in our inventories because of their irrelevance to glaciation. All glacial  
 219 lakes in the study area were mapped according to our definition. We were able to implement  
 220 this definition by carefully leveraging the spectral properties of glacial lakes and the  
 221 periglacial geomorphological features that are often evident in remote sensing images (see  
 222 more in sections 4.3 and 4.4).  
 223

224  
 225 **Figure 3.** The 10-km buffer zone of RGI 6.0 glacier boundaries (a) and Sentinel-derived glacial lakes  
 226 located near buffering boundary within the study area (b).  
 227

228 **4.2 Interactive lake mapping**

229 A human-interactive and semi-automated lake mapping method (Wang et al., 2014; Nie et al.,  
 230 2017, 2020) was adopted to accurately extract glacial lake extents using Landsat and  
 231 Sentinel-2 images, based on the Normalized Difference Water Index (NDWI) (Mcfeeters,  
 232 1996). The NDWI uses the green and near infrared bands and is calculated by the following  
 233 equation:

234 
$$NDWI = \frac{Band_{Green} - Band_{NIR}}{Band_{Green} + Band_{NIR}} \quad (1)$$

235 where the green band and near infrared band were provided by both Landsat and Sentinel  
 236 multispectral images.

237 Specifically, the method calculated the NDWI histogram based on the pixels with each  
 238 user-defined and manually-drawn region of interest. The NDWI threshold that separates lake  
 239 surface from land was interactively determined by screening the NDWI histogram against the  
 240 lake region in the imagery (Wang et al., 2014; Nie et al., 2020). This way, the determined  
 241 NDWI threshold can be well-tuned to adapt various spectral conditions of the studied glacier  
 242 lakes. The raster lake extents segmented by the thresholds were then automatically converted  
 243 to vector polygons. We first completed the glacial lake inventory in 2020 using this  
 244 interactive mapping method, and the 2020 inventory was then used as a reference to facilitate  
 245 the lake mapping for other periods.

246 The minimum mapping unit (MMU) was set to 5 pixels for both Landsat (0.0045 km<sup>2</sup>) and  
 247 Sentinel-2 images (0.0005 km<sup>2</sup>) in this study. MMU determines the total number and area of  
 248 glacial lakes in the dataset, and varies in the previous studies, such as 3 pixels (Zhang et al.,  
 249 2015), 6 pixels (Wang et al., 2020), or 9 pixels (Chen et al., 2021) for a regional scale, or 55  
 250 pixels (Shugar et al., 2020) for a global scale. While a smaller threshold leads to a large  
 251 quantity of lakes mapped, it also generates larger mapping noises or uncertainties.

252 Considering this signal-noise balance and our focus on identifying prominent glacier lake  
253 dynamics in the study area, we opted to use 5 pixels as the MMU for both Landsat and  
254 Sentinel-2 images.

255 Several procedures were taken to assure the quality assurance and quality control for lake  
256 mapping, including 1) visual inspection and modification using the threshold-based mapping  
257 method for each lake according to Landsat, Sentinel-2 and Google Earth high-resolution  
258 images overlaying preliminarily lake boundary extraction at the given time period; 2) time  
259 series check for Landsat-derived glacial lake datasets from 1990 and 2020, and cross-check  
260 between Landsat and Sentinel-2-derived lake dataset in 2020 to reduce errors of omission and  
261 commission; 3) topological validation of glacial lake mapping, such as repeated removal,  
262 elimination of small sliver polygons; and 4) logical check for lake types between two  
263 classification systems of glacial lakes. False lake extents resulting from cloud or snow cover,  
264 lake ice, and topographic shadows (Nie et al., 2017, 2020) were modified using previous  
265 semi-automated mapping method based on alternative images acquired in adjacent years.  
266 Those procedures were time-consuming, but helped to minimize the effect of cloud and snow  
267 covers, lake mapping errors, and to maximize the quality of the produced lake product and  
268 the derived glacial lake changes.

#### 269 4.3 Classification of glacial lakes

270 Two glacial lake classification systems (GLCS) have been established based on relationship  
271 of interaction between glacial lakes and glaciers as well as lake formation mechanism and  
272 dam material properties. In the first GLCS (GLCS1), glacial lakes were classified into four  
273 types based on their spatial relationship to upstream glaciers: supraglacial, ice-contact,  
274 unconnected-glacier-fed lakes, and non-glacier-fed lakes according to Gardelle et al. (2011)  
275 and Carrivick et al. (2013). Alternatively, combining the formation mechanism of glacial  
276 lakes and the properties of natural dam features, glacial lakes were classified into five  
277 categories (herein named GLCS2) modified from Yao's classification system (2018):  
278 supraglacial, end-moraine-dammed, lateral-moraine-dammed, glacial-erosion lakes and ice-  
279 dammed lakes. Subglacial lakes were excluded due to the mapping challenge from spectral  
280 satellite images alone. Characterization and examples for each type are provided in [Table](#)  
281 [1](#) and [Table 2](#). Individual glacial lakes were categorized to the specific types  
282 for each GLCS according to available glacier inventory data, geomorphological and spectral  
283 characteristics interpreted from Landsat, Sentinel and Google Earth images. The synergy of  
284 these two GLCSs is beneficial to predicting glacier-lake evolutions and providing  
285 fundamental data for water resource and glacial lake disaster risk assessment.

**Table 1.** Classification system of glacial lake types (GLCS1) according to the relationship between glacial lakes and glaciers (© Google Earth 2019). Glacier outlines are from RGI 6.0 (RGI Consortium, 2017), and the yellow marker represents target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris.  Case location: 35°43'49.74" N 76°13'53.88" E			
Ice-contact	Lakes dammed by moraine, ice or bedrock, supplied by glacial meltwater and shared boundary with glaciers.  Case location: 39°09'32.40" N 73°43'12.00" E			
Unconnected-glacier-fed	Lakes currently supplied by upstream glacial meltwater but disconnected with glaciers.  Case location: 35°47'60.00" N 72°55'15.60" E			
Non-glacier-fed	Lakes formed by glaciology, dammed by moraine or bed rock, and currently not supplied by glacial meltwater.  Case location: 34°50'39.99" N 74°48'29.31" E			

291

292 **Table 2.** Classification system of glacial lake types (GLCS2) according to the formation mechanism of  
 293 glacial lakes and dam material properties (© Google Earth 2019). Glacier outlines from RGI 6.0 (RGI  
 294 Consortium, 2017), and the yellow marker represents target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris.  Case location: 36°46'7.39" N 74°20'7.59" E			
End-moraine-dammed	Lakes formed behind moraines as a result of glacier retreat and downwasting.  Case location: 35°42'50.40" N 73°09'57.60" E			
Lateral-moraine-dammed	Lakes formed behind lateral glacial moraine ridges and dammed by debris, different from ice-dammed glacial lake.  Case location: 38°28'45.62" N 75°20'52.30" E			
Glacial-erosion	Lakes formed in depressions created by glacial over-deepening. Bedrock dam dominates, partially superimposed by top moraine in rugged terrain. Dams are unclear in the satellite images.  Case location: 35°55'55.56" N 73°38'20.13" E			
Ice-dammed	Lakes formed behind glaciers, dammed by glacier ices (partially covered by debris on the top).  Case location: 35°28'31.32" N 77°30'46.81" E			

295

296 4.4 Attributes of glacial lake data

297 A total of 18 attribute fields were input into our glacial lake datasets (Table 3). They  
 298 include lake location (longitude and latitude), lake elevation (centroid elevation), orbital  
 299 number of the image source, image acquisition date, lake area, lake perimeter, lake types of the  
 300 two GLCSs, mapping uncertainty, lake water volume and the country, sub-basin, and mountain  
 301 range associated with the lake. Amongst the attributes, lake location was calculated based on

带格式的: 字体: 非加粗

302 the centroid of each glacial lake polygon associated with the DEM, N represents northing and  
 303 E represents easting. Orbital number of the image source was filled with the corresponding  
 304 satellite image, with the codes expressed as “PxxxRxxx” or “Txxxxx”, where P and R indicate  
 305 the path and row for Landsat image and T represents the tile of Sentinel-2 image associated  
 306 with 5 digit code of military grid reference system. SceneID indicated identifying information  
 307 of image source for Landsat or Sentinel-2, consisted of the orbital number, sensor ID and  
 308 acquisition date (YYYYMMDD) for Landsat image, or the orbital number and acquisition date  
 309 (YYYYMMDD) for Sentinel-2 image. Area and perimeter were automatically calculated based  
 310 on glacial lake extents. Lake water volume was estimated by area-volume empirical equation  
 311 (Cook and Quincey, 2015). Lake types were attributed using the characterization and  
 312 interpretation marks described in Section 4.3. Mapping uncertainty was estimated using our  
 313 modified equation which will be introduced in section 4.5 and appendix tutorial. Located  
 314 country, sub-basin and mountain range of each glacial lake was identified by overlapping the  
 315 geographic boundaries of countries, basins and mountain ranges.

316  
 317

**Table 3.** Attributes of glacial lake dataset.

Field Name	Type	Description	Note
FID or OBJECTID	Object ID	Unique code of glacial lake	Number
Shape	Geometry	Feature type of glacial lake	Polygon
Latitude	String	Latitude of the centroid of glacial lake polygon	Degree minute second
Longitude	String	Longitude of the centroid of glacial lake polygon	Degree minute second
Elevation	Double	Elevation of the centroid of glacial lake polygon	Unit: meter above sea level
SceneID	String	Scene ID of image source for Landsat or Sentinel-2	PxxxRxxx_xxxYYYYMMDD or Txxxxx_YYYYMMDD
ACQDATE	String	Acquisition date of source image	YYYYMMDD
GLCS1	String	The first classification system of glacial lakes based on relationship of interaction between glacial lakes and glaciers	Supraglacial, Ice-contact, Unconnected-glacier-fed, None-glacier-fed

Field Name	Type	Description	Note
GLCS2	String	The second classification system of glacial lakes based on lake formation mechanism and dam material properties	Supraglacial, End-moraine-dammed, Lateral-moraine-dammed, Glacial-erosion and Ice-dammed
Basin	String	Basin name where glacial lake locates in	
Mountain	String	Mountain name where glacial lake locates in	
Country	String	Country name where glacial lake locates in	
Perimeter	Double	Perimeter of glacial lake boundary	Unit: meter
Area	Double	Area of glacial lake coverage	Unit: square meter
AreaUncer	Double	Area uncertainty of glacial lake mapping estimated based on modified Hanshaw's equation (2014)	Unit: square meter
Operator	String	Operator of glacial lake dataset	Muchu, Lesi
Examiner	String	Examiner of glacial lake dataset	Yong, Nie
Volume	Double	Water volume of glacial lake estimated by area-volume empirical equation	Unit: cubic meter

## 319 4.5 Error and uncertainty assessment

### 320 4.5.1 Improved uncertainty estimating method

321 We modified Hanshaw's (2014) equation that had been used to calculate lake-area mapping  
322 uncertainty. Lake perimeter and displacement error are widely used to estimate the  
323 uncertainty of glacier and lake mapping from satellite observation (Carrivick and Quincey,  
324 2014; Hanshaw and Bookhagen, 2014; Wang et al., 2020). Hanshaw and Bookhagen (2014)  
325 proposed an equation to calculate the error of area measurement by the number of edge pixels  
326 of the lake boundary multiplied by half of a single pixel area. The number of edge pixels is  
327 simply calculated by the perimeter divided by the grid size. The equation is expressed as  
328 below:

$$329 \quad \text{Error}(1\sigma) = \frac{P}{G} \times 0.6872 \times \frac{G^2}{2} \quad (2)$$

$$330 \quad D = \frac{\text{Error}(1\sigma)}{A} \times 100\% \quad (3)$$

331 Where  $G$  is the cell size of the remote sensing imagery (10 m for Sentinel-2 image and 30 m  
332 for Landsat image).  $P$  is the perimeter of individual glacial lake (m), and the coefficient of  
333 0.6872 ( $1\sigma$ ), which means nearly 69% of the edge pixels are subject to errors (Hanshaw and  
334 Bookhagen, 2014), was chosen assuming that area measurement errors follow a Gaussian  
335 distribution. Relative error ( $D$ ) was calculated by equation 3, in which  $A$  is the area of an  
336 individual glacial lake.

337 In the original equation 2, the number of edge pixels varies by the shape of lake and is  
338 indicated by  $\frac{P}{G}$ . However, the pixels in the corner are double counted (Figure 4Figure 4). The  
339 total number of repeatedly calculated edge pixels equals the number of inner nodes.  
340 Therefore, we adjusted the calculation of the actual number of edge pixels as the maximum of  
341 edge pixels ( $\frac{P}{G}$ ) subtracting the number of inner nodes. Accordingly, the equation of  
342 uncertainty estimation for lake mapping is modified as below:

$$343 \quad \text{Error}(1\sigma) = \left(\frac{P}{G} - N_{\text{inner}}\right) \times 0.6872 \times \frac{G^2}{2} \quad (4)$$

344 Where  $N_{\text{inner}}$  is the number of inner nodes (inflection points) of each lake. The modified  
345 equation is also suitable for lakes with islands (as illustrated in Figure 4Figure 4b).

346 For polygons without islands (Figure 4Figure 4a), use the following equation:

$$347 \quad N_{\text{inner}} = \left(\frac{N_{\text{Total}} - 4 - 1}{2}\right) \quad (5)$$

348  $N_{\text{Total}}$  is the total number of nodes, including both the outer and inner.  $N_{\text{Total}}$  is calculated  
349 by the "Field Calculator" in ArcGIS, in some cases, it is necessary to remove the redundant  
350 nodes before calculating the total number of nodes (See the Appendix for more details). An  
351 inner node is a polygon vertex where the interior angle surrounding it is greater than 180  
352 degrees. An outer node is the opposite of the inner node, where the interior angle is less than  
353 180 degrees. We found that the outer nodes are usually four more than the inner nodes in our

带格式的: 字体: 非加粗

带格式的: 字体: 非加粗

带格式的: 字体: 非加粗

354 glacial lake dataset. The total nodes in ArcGIS contain one overlapping node to close the  
 355 polygon, meaning the endpoint is also the startpoint. This extra count was deleted in the  
 356 calculation (equation 5).

357 For polygons with island (Figure 4b) use the following equation:

$$358 \quad N_{Inner} = \left( \frac{N_{Total} - (N_{Island} + 1) \times 5}{2} \right) \quad (6)$$

359  $N_{Island}$  is the number of islands within each polygon. A calculation method of  $N_{Island}$  is  
 360 given in the Appendix.

361

363 **Figure 4.** Sketch of estimating the actual edge pixels for uncertainty calculation of individual glacial lake  
 364 (with (a) and without islands (b)).  
 365

#### 366 4.5.2 Validation of glacial lake mapping

367 A total of 89 glacial lakes were selected by stratified random sampling and manually digitized  
 368 based on the Google Earth images in circa 2020 with a spatial resolution of  $\sim 2$  m acquired  
 369 from WorldView, GeoEye, Pleiades etc. satellites to further validate the absolute error of our  
 370 glacial lake products in 2020 due to lacking of field measurements for glacial lakes in the  
 371 study area. During the sampling, we set a minimum lake area to be 4500 m<sup>2</sup> and a relative  
 372 difference between Landsat- and Sentinel-derived lake areas less than 18% (nearly equaling  
 373 to the average relative error of  $\pm 17.36\%$  for Landsat lake mapping) in order to minimize the  
 374 effect of lake changes from multi-temporal satellite observations in circa 2020. The 89  
 375 sample lakes range from 0.005 km<sup>2</sup> to 0.802 km<sup>2</sup> with a median (standard deviation) size of  
 376 0.047 $\pm$ 0.134 km<sup>2</sup> and a total area of 8.033 km<sup>2</sup> for Landsat-derived dataset, and range from  
 377 0.005 km<sup>2</sup> to 0.849 km<sup>2</sup> with a median (standard deviation) size of 0.045 $\pm$ 0.144 km<sup>2</sup> and a  
 378 total area of 8.447 km<sup>2</sup> for Sentinel-derived dataset.  
 379

## 380 5 Results

### 381 5.1 Glacier lake distribution and changes observed from Landsat

382 We mapped 2,234 glacial lakes for 2020 across the studied CPEC from Landsat-8 images,  
 383 with a total area of 86.31 $\pm$ 14.98 km<sup>2</sup> (Figure 5a and b). Unconnected-glacier-fed

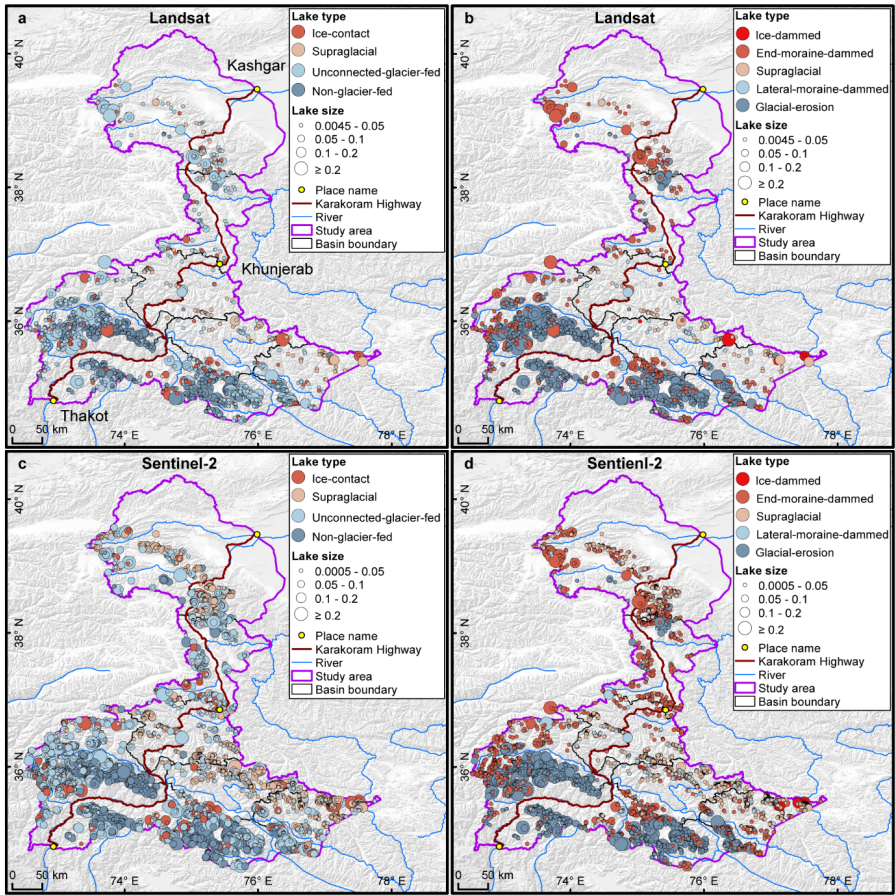

带格式的: 字体: 非加粗

带格式的: 字体: 非加粗

384 lakes are dominant in the first classification system, followed by non-glacier-fed lakes  
 385 (Figure 6) whereas glacial-erosion lakes dominate at both number (1478) and area  
 386 (57.02 km<sup>2</sup>) in the second classification system (Figure 7), followed by end-moraine-  
 387 dammed lakes and supraglacial lakes. Among the classified lakes, 137 are ice-contact lakes  
 388 and cover an area of 5.56 km<sup>2</sup>, implying a higher mean size of ice-contact lakes than  
 389 supraglacial lakes.

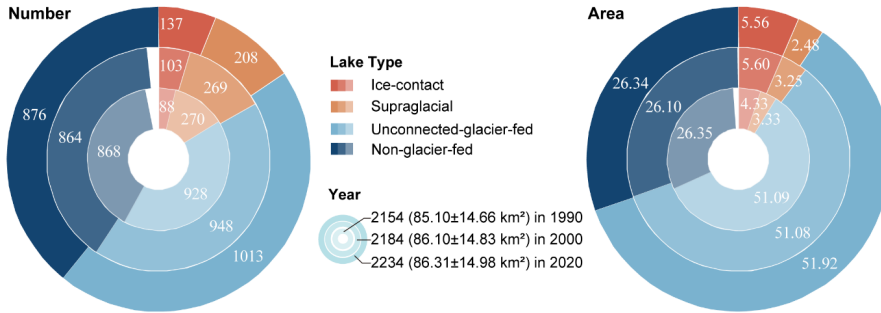

390

391  
 392 **Figure 5.** Distribution of glacial lakes in 2020 extracted from Landsat (a, b) and Sentinel-2 (c, d) images.  
 393 Panels a and c are classified by GLCS1, and GLCS2 for sub-graph b and d.

394

395

396 **Figure 6.** Number and area of different types of glacial lakes classified based on the condition of glacier  
 397 supply in the study area (GLCS 1). The outermost ring represents glacial lake data in 2020, middle ring for  
 398 2000 and innermost ring for 1990. Lake number and area in 2020 were selected as reference, meaning a  
 399 concept of "100 %" for a complete ring. Labeled values are scaled in degrees rather the radius of rings.  
 400

401

402 **Figure 7.** Number and area of different types of glacial lakes classified based on glaciation and nature of  
 403 dam in the study area (GLCS 2). The outermost ring represents glacial lake data in 2020, middle ring for  
 404 2000 and innermost ring for 1990. Lake number and area in 2020 were selected as reference, meaning a  
 405 concept of "100 %" for a complete ring. Labeled values are scaled in degrees rather the radius of rings.  
 406

407 The total number and area of glacial lakes in the study remain relatively stable with a  
 408 slight increase between 1990 and 2020, and the changes in count and area among various  
 409 types of glacial lakes vary substantially (Figure 6Figure 6 and Figure 7Figure 7). From 1990  
 410 to 2020, the total number of glacial lakes increased by 80 or 3.70%, while the area grew by  
 411 1.21 km<sup>2</sup> (or 1.42%). In GLCS1, unconnected-glacier-fed lakes have the largest increase in  
 412 number, followed by ice-contact and non-glacier-fed lakes, whereas supraglacial lakes  
 413 decreased by 62 in count. Ice-contact lakes expanded by 1.24 km<sup>2</sup> (equaling an increase of  
 414 26% in ice-contact lakes), contributed one third of the total area increase. Supraglacial lakes  
 415 decreased by 0.85 km<sup>2</sup> in area whereas the areas of unconnected-glacier-fed and non-glacier-  
 416 fed lakes remained stable as a result of disconnections from glaciers (Figure 6Figure 6). In  
 417 GLCS2, end-moraine-dammed lakes increased by 2.48 km<sup>2</sup> and contributed most of the  
 418 glacier lake area expansion, whereas supraglacial, ice-dammed and lateral-moraine-dammed

带格式的: 字体: 非加粗

带格式的: 字体: 12 磅, 非加粗

带格式的: 字体: 非加粗

419 lakes decreased slightly in both number and area. Glacial-erosion lakes accounted for the  
 420 maximum percentage (about 66% for both count and area) in each time period and remained  
 421 stable (Figure 7).

带格式的: 字体: 12 磅, 非加粗

## 422 5.2 Glacier lake distribution observed from Sentinel-2

423 Sentinel-derived results shows that there are 7,560 glacial lakes ( $103.70 \pm 8.45 \text{ km}^2$ ) in 2020  
 424 across the entire CPEC (Table 4) under a MMU of 5 pixels ( $500 \text{ m}^2$ ). Compared with  
 425 Landsat-derived product, glacial lakes from Sentinel-2 have similar spatial distribution  
 426 characteristics (Figure 5); meanwhile, a larger quantity of glacier lakes, with more  
 427 accurate boundaries and a greater total lake area, were generated from Sentinel-2 images  
 428 (Table 4). The smallest size class ( $0.0005\text{-}0.0045 \text{ km}^2$ ) contains the maximum lake number  
 429 (4,969) but the least lake area ( $7.73 \pm 2.62 \text{ km}^2$ ) (Table 4), which is not available in the  
 430 Landsat-derived lake data due to a coarser spatial resolution. In each size class, the overlap  
 431 ratios are greater than 85% in count and area, and there are also a higher number of larger  
 432 glacial lakes from Sentinel than that from Landsat images. The discrepancy is mainly  
 433 attributed to the inconsistency of spatial resolutions and image acquisition dates.

## 440 6 Discussions

### 441 6.1 Uncertainty and error of lake mapping

442 The uncertainty estimated from our improved equation shows that the relative error of  
 443 individual glacial lake decreases when lake size increases or cell size of remote sensing  
 444 images reduces (Lyons et al., 2013; Carrivick and Quincey, 2014) (Figure 8). Total  
 445 area errors of glacial lakes in study area are approximate  $\pm 14.98 \text{ km}^2$  and  $\pm 8.45 \text{ km}^2$  in 2020  
 446 for Landsat and Sentinel-2 dataset, respectively, and the average relative errors are  $\pm 17.36\%$   
 447 and  $\pm 8.15\%$ . Generally, small lakes have greater relative errors. For example, the mean  
 448 relative error is 35.38% for Landsat derived glacial lakes between  $0.0045$  and  $0.1 \text{ km}^2$  and  
 449 10.63% for glacial lakes greater than  $0.1 \text{ km}^2$ . The mean area error of Sentinel-derived glacial  
 450 lakes is almost one third of that extracted from Landsat images for glacial lakes of all or

带格式的: 字体: 非加粗

451 specific size groups. Because the relative error was estimated as a function of satellite image  
 452 spatial resolution and lake perimeter, the calculated error for large lake is proportionally  
 453 smaller than that of small lake (Salerno et al., 2012) and the error for Landsat-derived lake is  
 454 naturally greater than that of Sentinel-derived lake at the same size group.  
 455

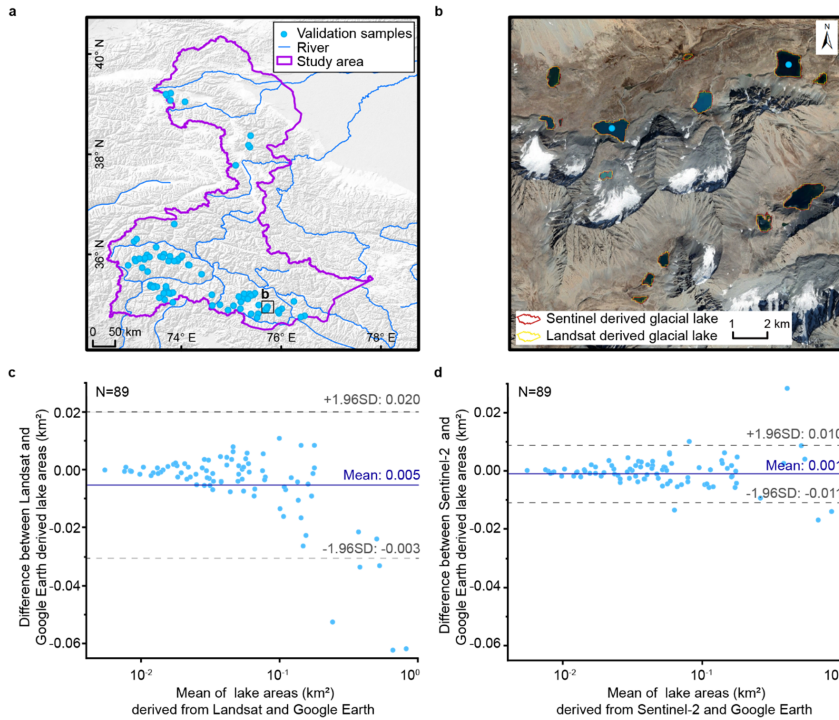

456 **Figure 8.** Estimated relative error for glacial lakes of all or specific size ranges in study area. Error  
 457 estimation is based on the modified equation and lake data extracted from Landsat (a) and Sentinel-2  
 458 images (b).  
 459

460  
 461 Our Landsat- and Sentinel-derived glacial lake dataset match well lake boundaries in Google  
 462 Earth higher resolution images (Figure 9). The mean difference in area is 0.005 km<sup>2</sup>  
 463 between Landsat and Google Earth derived lakes and 0.001 km<sup>2</sup> between Sentinel-2 and  
 464 Google Earth derived lakes, and major validation samples (84/89) are within the confidence  
 465 interval of 95%, indicating a high accuracy in lake mapping (Figure 9c and d). The  
 466 error of 89 sample lakes is 5.48% in total area between Landsat- and Google Earth-derived  
 467 data, and 0.61% for Sentinel- and Google Earth-derived data. The median ( $\pm$ standard  
 468 deviation) in discrepancy of individual lake area is 7.66 $\pm$ 4.96 % for Landsat- and Google  
 469 Earth-derived data, and 4.46 $\pm$ 4.62 % for Sentinel- and Google Earth-derived data. Our glacial  
 470 lake dataset shows a satisfactory mapping accuracy, although Sentinel-derived lake data  
 471 performs more accurate than those from Landsat images. We also validated the sampling  
 472 Landsat-derived 89 lakes by the existing Landsat-extracted lake data produced by Wang et al.  
 473 (2020). A total of 83 lakes are available in Wang's data with a mean difference of 0.005 km<sup>2</sup>

带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗

474 in lake area (Figure A8). This also shows an improvement of our lake product in contrast to  
 475 the existing dataset.

476  
 477 **Figure 9.** Distribution of the validation sample (a), visual comparison of glacial lakes derived from  
 478 Landsat and Sentinel-2 images overlaying Google Earth imagery (© Google Earth 2019) in a zoomed site  
 479 (b), and differences between our glacial lake product (mapped from Landsat and Sentinel-2 images) and  
 480 the validation reference (digitized from Google Earth images) (c and d). Distribution of validation samples  
 481 (a), comparison of glacial lakes derived from Landsat and Sentinel-2 overlaying Google Earth image (©  
 482 Google Earth 2019) in a zoomed site (b), and glacial lake product validated by Google Earth derived lake  
 483 boundaries (c and d).

484 6.2 Comparison of Sentinel-2 and Landsat derived products

485 Glacial lakes from Landsat and Sentinel-2 images have a high consistency in number and  
 486 area with overlap rates from approximately 86% to 94% for all lakes greater than 0.0045 km<sup>2</sup>  
 487 (Table 4 Table 4), indicating a good potential for coordinated utility with Landsat archived  
 488 observation (Figure 10 Figure 10). Lake extents extracted from Landsat and Sentinel images  
 489 match well for various types and sizes (Figure 10 Figure 10 and Figure 11 Figure 11, Table  
 490 4 Table 4). The best consistency rate reaches 94% for the glacial lakes between 0.1 km<sup>2</sup> and  
 491 0.2 km<sup>2</sup>. The difference in area of glacial lakes extracted from Landsat and Sentinel-2 images  
 492 generally lies within the uncertainty ranges.

带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗  
 带格式的: 字体: 非加粗

493  
 494 **Figure 10.** High consistency of lake extents extracted from Landsat and Sentinel-2 images. Lake types  
 495 shown include supraglacial (a), glacier-fed moraine-dammed (b), unconnected glacial-erosion lake without  
 496 glacier melt supply (c) and glacier-fed moraine-dammed lakes (d).

497  
 498 Spatial resolution of satellite images plays a primary role in the discrepancies in count and  
 499 area of glacial lakes extracted from Landsat (30 m) and Sentinel-2 (10 m) observations. Due  
 500 to a finer spatial resolution, Sentinel-2 images can extract more glacial lakes and more  
 501 accurate extents than those from Landsat images. We set the same 5 pixels as the MMU for  
 502 both Landsat and Sentinel-2 images, which corresponds to a minimum area of 0.0045 km<sup>2</sup>  
 503 and 0.0005 km<sup>2</sup>, respectively. The minimum mapping area results in generating nearly 5000  
 504 more lakes from Sentinel-2 images than from Landsat images, causing the greatest  
 505 discrepancy in number (Table 4 Table 4), such as Figure 11 Figure 11a. Small lakes such as  
 506 supraglacial lakes play an important role in analyzing glacier evolution and supraglacial  
 507 drainage systems (Liu and Mayer, 2015; Miles et al., 2018), implying a potential of our  
 508 dataset to be applied in studies of glacier-lake evolutions. Meanwhile, Sentinel-2 images are  
 509 able to depict boundaries of glacial lake with a lower uncertainty, as for some small islands  
 510 and narrow channels (Figure 11 Figure 11b and c) were mapped from Sentinel-2 imagery that  
 511 were unable to be detected in Landsat imagery.

512 In addition to the difference in image resolution, Different acquisition dates between  
 513 Sentinel-2 and Landsat images can also contribute to the discrepancy of those two glacial  
 514 lake datasets. Acquiring same-day images from the two sensors were not always possible due  
 515 to the impacts of cloud contaminations, topographic shadows, snow cover and revisit periods  
 516 (Williamson et al., 2018; Paul et al., 2020). As exemplified in Figure 11d, the mapped glacial  
 517 lake areas exhibit a substantial discrepancy, which is likely a joint consequence of both  
 518 sensor difference and actual glacier lake dynamics that occurred during this short period of  
 519 time. Glacial lakes are changing temporally in the context of climate and glacier changes. The  
 520 example is given to supraglacial lakes which showed considerable changes during a short-  
 521 period of time between the applied Landsat and Sentinel-2 images (Figure 11d). Despite our

带格式的: 字体: 非加粗

带格式的: 字体: (中文) Times New Roman, 非加粗

带格式的: 字体: (中文) Times New Roman, 非加粗

522 efforts of leveraging all available high-quality images, the overlap of acquisition dates  
 523 between Landsat and Sentinel-2 images for the same location is relatively low (only 7 scenes  
 524 of Sentinel-2 images or 112 glacial lakes in 2020) in this study area, and the consequential  
 525 temporal gaps led to a difference in the number and area of the derived glacial lakes.

 529

### 530 6.3 Comparison with previous similar dataset

531 An increasing number of glacier lake datasets have been released over the past years, and  
 532 most of them were produced from long-term Landsat archives. Regional glacial lake datasets  
 533 using Sentinel images are scarce. Lack of Sentinel-derived glacial lake data in the study area  
 534 makes it impossible to compare. Here we selected four available glacial lake datasets to  
 535 compare with our Landsat-derived dataset.

536 We provide the latest glacial lake dataset (in 2020) and the most long-term 30-m Landsat  
 537 observation (1990 to 2020) for this study, with a range of critical attributes including two  
 538 types of classification systems. Within the same study area, our 2020 glacial lakes appear to  
 539 be closest to the 2018 dataset produced by Wang et al. (2020), with the highest overlap of  
 540 greater than 9185% in areacount (Table 5-Table 5). In Wang et al. (2020), the minimum  
 541 mapping unit is 6 pixels so their dataset has a less lake quantity. However, their dataset  
 542 contains many large landslide-dammed lakes that are excluded in our glacial lake mapping.  
 543 As a result, their total glacier lake area is greater than ours. The overlapping rates between  
 544 Wang's glacial lakes (2020) in 1990 and ours are more than 7683% in areacount. However,  
 545 their results show a distinct increase of glacial lakes in number and area between 1990 and  
 546 2018 (Wang et al., 2020) whereas our data show a more stable change between 1990 and  
 547 2020. One possible reason is that manually delineating glacial lakes twice by different  
 548 operators during Wang's lake mapping (2020) exacerbates the errors of mapping. Another  
 549 reason is that their data contains landslide-dammed lakes that fluctuate greatly with time and

带格式的: 字体: 非加粗

550 expanded recently. One example is the Attabad Lake (Located at 36°18'22.33"N,  
 551 74°49'34.36"E).

552

556 **Note:** MMU represents the minimum mapping unit that is possible to enable a valid comparison between our product and each  
 557 of the third-party datasets. \* The MMU in the dataset of Zhang et al. (2015) is 3 pixels, finer than 5 pixels in our product, so a  
 558 MMU threshold of 5 pixels was used for this comparison. “% (%)” represents the ratios between the third-party dataset and  
 559 our product in count and area, respectively.

560 **Comparison of different glacial lake datasets sourced from Landsat images in the study area.**

2020 (2016-2020) Semi-automated 4500 (5) 2234 (86.31±14.98) — This study

Note: MMU represents minimum mapping units. The % represent the rate in area calculated by dividing individual glacial lake dataset by our Landsat-derived data greater than the same minimum lake size in the nearest baseline year respectively.

The second highest overlapping rate is approximate 54.59% for 2008 and 58% for 2017 in area count comparing with Chen's data (Chen et al., 2021). Similarly, a minimum mapping unit of 55 pixels (50000 m<sup>2</sup>) in Shugar et al.'s, dataset (2020) led to the lowest overlap with less than 43.24% in areacount and area. The dataset from Zhang et al. (2015) shows fewer glacial lakes in 1990 and 2000 even with a smaller MMU of 3 pixels. By inspecting their dataset, we attributed this anomalous discrepancy to a range of glacial lakes that were missing due to lack of thorough cross-check quality assurance during their manual delineation. Our Landsat derived glacial lake dataset has been visually cross-checked over three time periods after the step of threshold-based semi-automated lake mapping, and also been visually validated by Sentinel-2 derived glacial lakes. Through this series of quality assurance, we aim at delivering one of the most reliable multi-decadal glacial lake products for this study area.

Other factors, such as image quality and acquisition dates, mapping methods and quality assurance workflow, might also lead to the discrepancies between the glacial lake datasets. Despite such discrepancies, an increasing number of publically-shared datasets benefit potential users to select the most suitable one for their objectives. Herein, we provide an up-to-date glacial lake dataset derived from both Landsat and Sentinel-2 observations, which further increased the availability of glacial lake dataset for water resource and GLOFs risk assessment, predicting glacier-lake evolutions (Carrivick et al., 2020) in the context of climate change.

#### 6.4 Limitation and updating plan

We would like to acknowledge several limitations of our glacier lake dataset, largely due the availability of high quality satellite images in the study area and inadequate field survey data (Wang et al., 2020; Chen et al., 2021). First, it is unlikely to collect enough good-quality images within one calendar year for the entire study area due to high possibility of cloud or snow covers. Even though the capacity of repeat observations for Landsat-8 OLI and Sentinel-2 increased (Roy et al., 2014; Williamson et al., 2018; Wulder et al., 2019; Paul et al., 2020), the 2020 glacial lake dataset has to employ images acquired in adjacent years besides 2020. Most images used from Landsat and Sentinel-2 platforms were imaged in autumn, and some images taken between April and July and in November also were employed. Distribution and changes in glacial lakes primarily represent the characteristics between August and October. Glacial lakes evolve with time and space (Nie et al., 2017), and subtle inter- and intra-annual changes (Liu et al., 2020) for each time period were ignored. Second, field investigation data are limited due to low accessibility of high mountain environment in the study area, which restrained the accuracy in classifying the glacial lake types. Although very high-resolution Google Earth images were utilized to assist in lake type interpretation, occasional misclassification was unavoidable. We implemented two types of classification systems based on a careful utilization of glacier data, DEM, geomorphological features and expert knowledge. However, the lack of in situ survey prohibited a thorough validation of the glacial lake types. Third, the rigorous quality assurance and cross check after

603 semi-automated lake mapping assure the quality of our lake dataset but are still time and cost  
604 prohibitive. State-of-the-art mapping methods, such as deep learning method (Wu et al.,  
605 2020), Google Earth Engine cloud-computing (Chen et al., 2021) and synergy of SAR and  
606 optical images (Wangchuk and Bolch, 2020; How et al., 2021), would be used in the future to  
607 balance product accuracy and time cost.

608 The glacial lake dataset will be updated using newly collected Landsat and Sentinel  
609 images at a five-year interval or modified according to user feedbacks. The updated glacial  
610 lake dataset will continue to be released freely and publicly on the Mountain Science Data  
611 Center sharing platform.

## 612 **7 Data availability**

613 Our glacial lake dataset extracted from Sentinel-2 images in 2020 and Landsat observation  
614 between 1990 and 2020 are available online via the Mountain Science Data Center, the  
615 Institute of Mountain Hazards and Environment, the Chinese Academy of Sciences at  
616 <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022). The glacial lake dataset is  
617 provided in both ESRI shapefile format (total size of 22.6 MB) and the Geopackage format  
618 (version 1.2.1) with a total size of 9.2MB, which can be opened and further processed by  
619 open-source geographic information system software such as QGIS.

## 620 **8 Conclusions**

621 Glacial lake inventories of the entire China-Pakistan Economic Corridor in 2020 were  
622 provided based on Landsat and Sentinel-2 images using a threshold-based semi-automated  
623 mapping method. Both Landsat and Sentinel-2 derived glacial lake dataset show similar  
624 characteristics in spatial distribution and in the statistics of count and area. By contrast,  
625 glacial lake dataset derived from Sentinel-2 images with a spatial resolution of 10 m has a  
626 lower mapping error and more accurate lake boundary than those from 30 m spatial  
627 resolution Landsat images whereas Landsat imagery is more suitable to analyze spatial-  
628 temporal changes at a longer time scale due to its long-term archived observations at a  
629 consistent 30 m spatial resolution starting from the late 1980s.

630 Glacial lakes in the study area remain relatively stable with a slight increase in number and  
631 area between 1990 and 2020 according to Landsat observations. Our dataset reveals that 2154  
632 glacial lakes in 1990 covering  $85.1 \pm 14.66 \text{ km}^2$  increased to 2234 lakes with a total area of  
633  $86.31 \pm 14.98 \text{ km}^2$ . The same mapping method and rigorous workflow of quality assurance  
634 and quality control used in this study reduced the error in multi-temporal changes of glacial  
635 lakes.

636 The Hanshaw's error estimation method for pixel-based lake mapping was improved by  
637 removing repeatedly calculated edge pixels that vary with lake shape. Therefore, the newly  
638 proposed method reduces the estimated value of uncertainty from satellite observations. The  
639 average relative error is  $\pm 17.36\%$  for Landsat-derived product and  $\pm 8.15\%$  for product from  
640 Sentinel-2.

641 Our glacial lake dataset contains a range of critical parameters that maximize their  
642 potential utility for water resource and GLOFs risk evaluation, cryosphere-hydrological and  
643 glacier-lake evolution projection. The dual classification systems of glacial lake types were

644 developed and are very likely to attract broader researchers and scientists to use our datasets.  
645 In comparison with other existing glacial lake datasets, our products were created through a  
646 thorough consideration of lake types, cross checks and rigorous quality assurance, and will be  
647 updated and released continuously in the Mountain Science Data Center. As such, we expect  
648 that our glacial lake dataset will have significant value to cryospheric-hydrology research, the  
649 assessment of water resource and glacier-related hazards in the CPEC.

650  
651 **Appendix.** The appendix related to this article is available online.

652  
653 **Author contributions.** ML and YN conceived the study, ML, YN and XD performed data  
654 processing and analysis of the glacial lake inventory data, JW contributed to tool  
655 development and mapping methods, ML and YN wrote the manuscript. All authors reviewed  
656 and edited the manuscript before submission.

657  
658 **Competing interests.** The authors declare no conflict of interest.

659  
660 **Acknowledgements.**

661 We are grateful for the editor Kenneth Mankoff and three anonymous referees for their  
662 constructive comments that greatly help us to improve this manuscript. This study was  
663 supported by the second Tibetan Plateau Scientific Expedition and Research Program (grant  
664 2019QZKK0603), the National Natural Science Foundation of China (Grant Nos. 42171086,

667 Sciences and Engineering Research Council of Canada (Grant No. DG-2020-04207).

668  
669

670 **Appendix**

671 **Tutorial for Improved Uncertainty Estimating Method**

672  
673 The Hanshaw's equation was originally proposed for pixelated polygons (such as a polygon  
674 directly extracted from a remote sensing image), and performed more robustly than manually  
675 digitized polygons (where vertices do not necessarily follow the pixel edges). Our improved  
676 method also performs better for pixelated polygons. This tutorial is dedicated to helping  
677 implement our improved uncertainty estimation method.

678  
679 **Procedure of uncertainty estimating method (using ArcGIS (© ESRI) for example)**

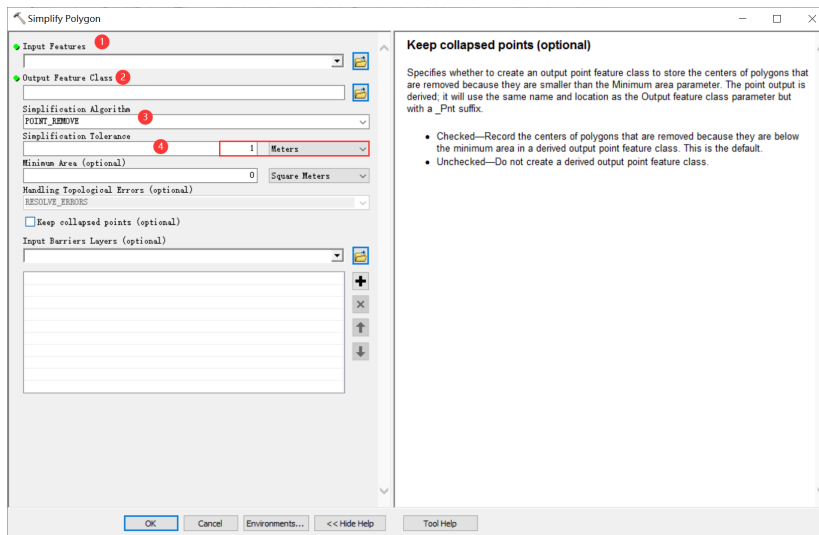

680 1. Removing redundant nodes (optional)

681 We found that a small proportion (~1%) of the pixelated lake polygons (directly extracted  
682 from satellite images) have redundant nodes, which affects the value of inner nodes. If no  
683 redundant nodes exist, this step can be skipped. Or, we recommend using the "Simplify  
684 Polygon" tool in ArcGIS to remove those nodes (Figure A1|Figure A1).

685 In the Simplify Polygon panel

- 686 • Input your dataset.  
687 • Set the output path and output file name.  
688 • Choose the simplification algorithm. We recommended "POINT\_REMOVE".  
689 • Set the tolerance of simplification algorithm. In this step, we need to ensure that the  
690 polygon boundaries remain unchanged after deleting redundant nodes. Generally, a  
691 tolerance of 1 meter will suffice, or you can adjust the threshold until your satisfaction.

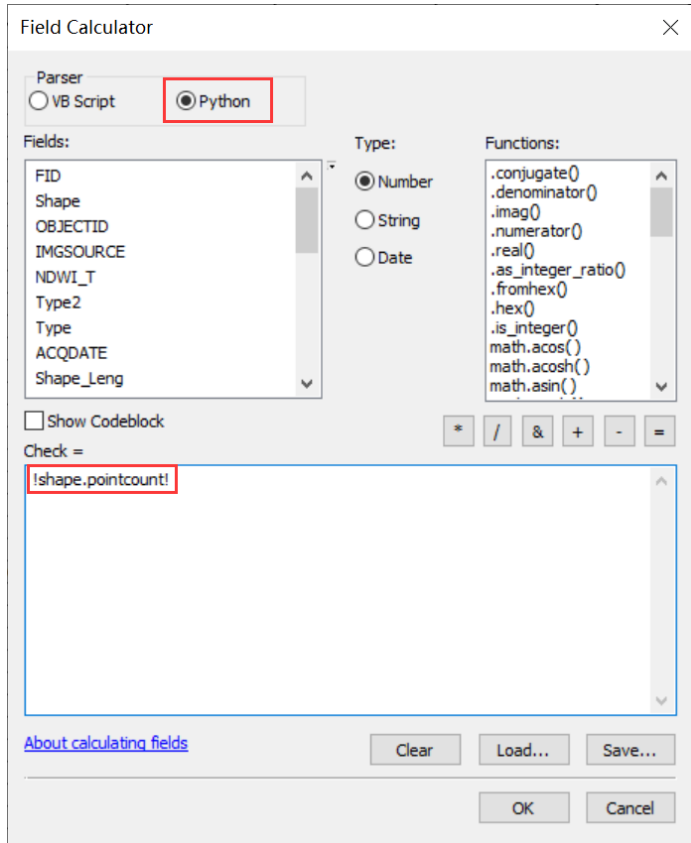

带格式的: 字体: 非加粗

692  
693 **Figure A1.** Input and option for Simplify Polygon in ArcGIS.  
694

- 695 2. Calculating the total number of nodes using ArcGIS (Figure A2):
- 696 • Add a new field in the attribute table of dataset.
- 697 • Open Field Calculator.
- 698 • Switch the parser to python mode, and enter the following code “!shape.pointcount!” in
- 699 the blue box to calculate the total number of nodes for each glacial lake boundary.

带格式的: 字体: 非加粗

700 **Figure A2.** Total node calculation in ArcGIS.

- 701
- 702
- 703 3. Calculating the number of inner nodes:

704

705 For polygons without islands (Figure A3), use the equation 5. An inner node is a

706 polygon vertex where the interior angle surrounding it is greater than 180 degrees. An outer

707 node is the opposite of the inner node, where the interior angle is less than 180 degrees. We

708 found that the outer nodes are usually four more than the inner nodes in our glacial lake

709 dataset. The total nodes in ArcGIS contain one overlapping node to close the polygon,

710 meaning the endpoint is also the startpoint. This extra count was deleted in the calculation

711 (equation 5).

带格式的: 字体: 非加粗

712

Figure A3. Sketch of outer and inner nodes of various glacial lakes without island.

713

714

715

716 For polygons with island (Figure A4) use the equation 6.

717

Figure A4. Sketch of outer and inner nodes for glacial lake with island.

718

719

720

721 We further specify the steps below to help implement equation 6.

722

723 Sept 1: detect the number of islands within each polygon.

724 • Convert the initial lake polygon to polyline using the “Feature To Line” tool (Figure

725 A5Figure A5).

带格式的: 字体: 非加粗

带格式的: 字体: 非加粗

Figure A5. Feature To Line tool in ArcGIS

726  
727  
728  
729

- Convert the polyline to generate a new polygon (Figure A6 Figure A6).

带格式的: 字体: 非加粗

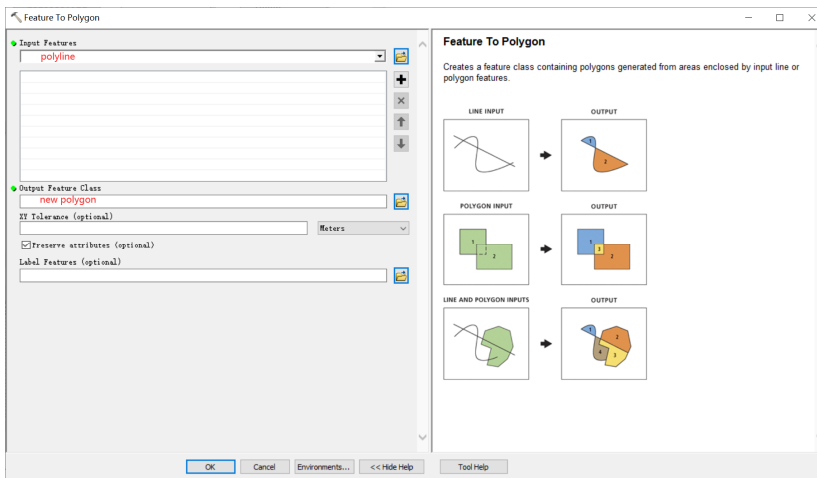

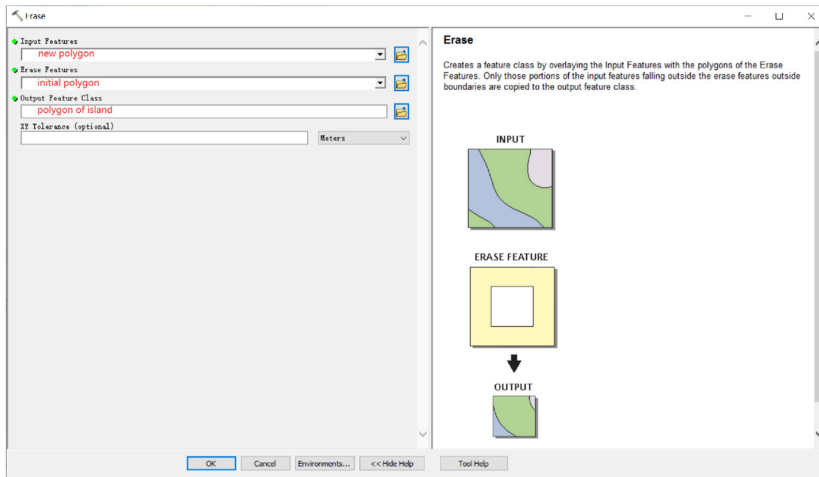

Figure A6. Feature To Polygon tool in ArcGIS

730  
731  
732  
733  
734

- Erase the new polygon by the initial polygon, which outputs the islands. Then we can count how many islands there are in each lake (Figure A7 Figure A7).

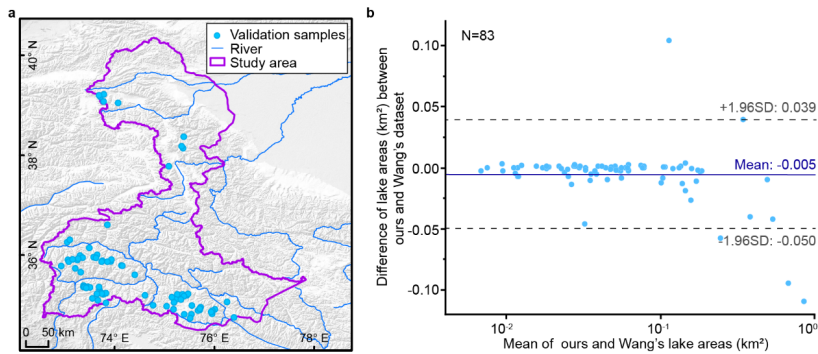

带格式的: 字体: 非加粗

735  
736 **Figure A7.** Erase tool in ArcGIS.  
737

738 Step 2: calculate the number of inner nodes for each polygon with island using equation 6.  
739

740 4. Calculating the uncertainty of lake mapping using equation 4.  
741

742 **Figure A8.** Distribution of validation samples (a) and comparison of glacial lakes (b) derived from our  
743 Landsat product in 2020 and Wang's lake data in 2018.
