20 **Abstract.** The China-Pakistan Economic Corridor (CPEC) is one of the flagship projects of
21 the One Belt One Road Initiative, which faces threats from water shortage and mountain
22 disasters in the high-elevation region, such as glacial lake outburst floods (GLOFs). An up-to-
23 date high-quality glacial lake dataset with parameters such as lake area, volume, and type,
24 which is fundamental to water resource and flood risk assessments, and predicting glacier-
25 lake evolutions, is still largely absent for the entire CPEC. This study describes a glacial lake
26 dataset for the CPEC using a threshold-based mapping method associated with rigorous
27 visual inspection workflows. This dataset includes (1) multi-temporal inventories for 1990,
28 2000, and 2020 produced from 30 m resolution Landsat images, and (2) a glacial lake
29 inventory for the year 2020 at 10 m resolution produced from Sentinel-2 images. The results
30 show that, in 2020, 2234 lakes were derived from the Landsat images, covering a total area of
31 86.31 ± 14.98 km² with a minimum mapping unit of 5 pixels (4500 m²), whereas 7560 glacial
32 lakes were derived from the Sentinel-2 images with a total area of 103.70 ± 8.45 km² with a
33 minimum mapping unit of 5 pixels (500 m²). The discrepancy shows that Sentinel-2 ~~is able~~
34 ~~to can~~ detect a significant quantity of smaller lakes than Landsat due to its finer spatial
35 resolution.
36 Glacial lake data in 2020 was validated by Google Earth-derived lake boundaries with a
37 median (\pm standard deviation) difference of 7.66 ± 4.96 % for Landsat-derived product and
38 4.46 ± 4.62 % for Sentinel-derived product. The total number and area of glacial lakes from
39 consistent 30 m resolution Landsat images remain relatively stable despite a slight increase
40 from 1990 to 2020. A range of critical attributes ~~have has~~ been generated in the dataset,
41 including lake types and mapping uncertainty estimated by an improved Hanshaw's equation.
42 This comprehensive glacial lake dataset has ~~the~~ potential to be widely applied in studies on
43 water resource assessment, glacial lake-related hazards, ~~and~~ glacier-lake interactions, and is
44 freely available at <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022).

45 1 Introduction

46 Glaciers in High-mountain Asia (HMA) play a crucial role in regulating climate, supporting
47 ecosystems, modulating the release of freshwater into rivers, and sustaining municipal water
48 supplies (Wang et al., 2019; Viviroli et al., 2020), agricultural irrigation, and hydropower
49 generation (Pritchard, 2019; Nie et al., 2021). Most HMA glaciers are losing mass in the
50 context of climate change (Brun et al., 2017; Maurer et al., 2019; Shean et al., 2020;
51 Bhattacharya et al., 2021), therefore, unsustainable glacier melt and the passing of peak water
52 are reducing the hydrological role of glaciers (Huss and Hock, 2018) and impacting
53 downstream ecosystem services, agriculture, hydropower and other socioeconomic values
54 (Carrivick and Tweed, 2016; Nie et al., 2021). The present and future glacier changes not
55 only impact ~~the~~ water supply for ~~the~~ downstream area but also alter the frequency and
56 intensity of glacier-related hazards, such as glacier lake outburst floods (GLOFs) (Nie et al.,
57 2018; Rounce et al., 2020; Zheng et al., 2021), and rock and ice avalanches (Shugar et al.,
58 2021). Global glacial lake number and total area both increased between 1990 and 2018 in
59 response to glacier retreat and climate change (Shugar et al., 2020), affecting the allocation of
60 freshwater resources. The Indus is globally the most important and vulnerable water tower
61 unit where glaciers, lakes, and reservoir storage contribute about two-thirds of the water
62 supply (Immerzeel et al., 2020). Ice-marginal lakes store ~1% of total ice discharge in

63 Greenland and accelerate lake-terminating ice velocity by ~25% (Carrivick et al., 2022). An
64 increasing frequency and risk of GLOFs (Nie et al., 2021; Zheng et al., 2021) is threatening
65 the Asian population and infrastructures in the mountain ranges, such as the China-Pakistan
66 Economic Corridor (CPEC), as a flagship component of One Belt One Road Initiative
67 (Battamo et al., 2021; Li et al., 2021). The northern section of the CPEC passes through
68 Pamir, Karakoram, Hindu Kush, and Himalaya mountains where droughts and glacier-related
69 hazards are frequent and severe (Hewitt, 2014; Bhambri et al., 2019; Pritchard, 2019),
70 threatening local people, the existing, under-construction and planned infrastructures, such as
71 highways, hydropower plants, and railways. Understanding the risk posed by water shortage
72 and glacier-related hazards is a critical step toward sustainable development for the CPEC.

73 Glacial lake inventories with a range of attributes benefit water resource assessment and
74 disaster risk assessment related to glacial lakes (Wang et al., 2020; Carrivick et al., 2022),
75 and contribute to predicting glacier-lake evolution and cryosphere-hydrosphere interactions
76 under climate change (Nie et al., 2017; Brun et al., 2019; Maurer et al., 2019; Carrivick et al.,
77 2020; Liu et al., 2020). Remote sensing is the most viable way to map glacial lakes and detect
78 their spatio-temporal changes in the high-elevation zones where in situ accessibility is
79 extremely low (Huggel et al., 2002; Quincey et al., 2007). Studies in glacial lake inventories
80 using satellite observations have been heavily conducted at regional scales recently, such as
81 in the Tibetan Plateau (Zhang et al., 2015), the Himalaya (Gardelle et al., 2011; Nie et al.,
82 2017), the HMA (Wang et al., 2020; Chen et al., 2021), the Tien Shan (Wang et al., 2013),
83 the Alaska (Rick et al., 2022), the Greenland (How et al., 2021) and the northern Pakistan
84 (Ashraf et al., 2017). However, the latest glacial lake mapping in 2020 is still absent along the
85 CPEC. Among existing studies, Landsat archival images are the most widely used due to their
86 multi-decadal record of earth surface observations, reasonably high spatial resolution (30 m),
87 and publicly available distribution (Roy et al., 2014). Freely available Sentinel-2 satellite
88 images show a better potential than Landsat in glacial lake mapping and inventories due to
89 their higher spatial resolution (10 m) and a global coverage, but have only been available
90 since late 2015 (Williamson et al., 2018; Paul et al., 2020). Glacial lake inventories using
91 Sentinel-2 images are relatively scarce at regional scales, and studies of the latest glacial lake
92 mapping as well as comparisons of glacial lake datasets derived from Sentinel-2 and Landsat
93 observations are still lacking.

94 Discrepancies between various glacial lake inventories (Zhang et al., 2015; Shugar et al.,
95 2020; Wang et al., 2020; Chen et al., 2021; How et al., 2021) result from differences in
96 mapping methods, minimum mapping units, the definition of glacial lakes, time-periods, data
97 sources and other factors. For example, the manual vectorization method was widely adopted
98 at the earlier stage for its high accuracy. However, it is time-consuming associated with high
99 labor intensity, and is only practical at regional scales (Zhang et al., 2015; Wang et al., 2020).
100 Automated and semi-automated lake mapping methods, such as multi-spectral index
101 classification (Gardelle et al., 2011; Nie et al., 2017; Zhang et al., 2018; How et al., 2021),
102 have been developed to improve the efficiency of glacial lake inventories using optical
103 images, although manual modification is often unavoidable to assure the quality of lake data
104 impacted by cloud cover, mountain shadows, seasonal snow cover and frozen lake surfaces
105 (Sheng et al., 2016; Wang et al., 2017, 2018). Backscatter images from Synthetic Aperture
106 Radar (SAR) (Wangchuk and Bolch, 2020; How et al., 2021) were used to remove the impact

107 of cloud cover for lake mapping. Besides, other approaches such as hydrological sink
108 detection using DEM (How et al., 2021) and land surface temperature-based detection
109 method (Zhao et al., 2020) were also used for lake inventories. Different classification
110 methods impact the results of lake mapping and monitoring. So far, we are lacking a unified
111 standard for the classification system of glacial lakes (Yao et al., 2018). Existing
112 classification systems are generally used for their ~~individual~~ research purposes, mainly based
113 on the relative positions of glacial lakes and glaciers, the supply conditions of glaciers, and
114 the attributes of dams. In addition to different classification standards, the same type of
115 glacial lakes may also have different names given by different scholars. For example, ice-
116 marginal (Carrivick and Quincey, 2014; Carrivick et al., 2020), ice-contact (Carrivick and
117 Tweed, 2013), and proglacial (Nie et al., 2017) lakes all represent glacial lakes sharing the
118 boundary with glaciers. Glacier lakes in currently available datasets have been traditionally
119 categorized by their spatial relationship with upstream glaciers (Gardelle et al., 2011; Wang
120 et al., 2020; Chen et al., 2021), and classification attributes considering the formation
121 mechanism and the properties of dams are rare or incomplete in the CPEC (Yao et al., 2018;
122 Li et al., 2020). ~~Dam-Dam~~-type classification of glacial lakes provides a crucial attribute for
123 glacier-lake interactions and risk assessment (Emmer and Cuřín, 2021). Therefore, an up-to-
124 date glacial lake dataset with critical, quality-assured parameters (e.g. lake area, volume, and
125 type) is necessary.

126 This study aims to (1) present an up-to-date glacial lake dataset in the CPEC in 2020 using
127 both Landsat 8 and Sentinel-2 images to accurately document its detailed lake distribution;
128 (2) present two historical glacial lake datasets for the CPEC to show the extent in 1990 and
129 2000 using consistent 30-m Landsat images to reveal glacial lake changes at three time
130 periods (1990, 2000 and 2020); and (3) generate a range of critical attributes for glacial lake
131 inventories to benefit studies on water resource evaluation, risk assessment of GLOFs, glacier
132 -lake evolution modeling in the HMA.

134
 135 **Figure 1.** Location of the study area associated with [the](#) distribution of glaciers (RGI Consortium, 2017),
 136 mountains, basins, and population (Rose et al., 2021) (a), and its location within the CPCE (b).

137
 138 The northern part of the CPEC is selected as the study area ([Figure 1](#)Figure 1). The CPCE,
 139 originating from Kashgar of the Xinjiang Uygur Autonomous region, China and extending to
 140 Gwadar Port, Pakistan (Ullah et al., 2019; Yao et al., 2020), is connecting China and Pakistan
 141 via the only Karakoram Highway. The study area covers all the drainage basins along
 142 Karakoram Highway starting from Kashgar and ending at Thakot, with a total area of ~125,000
 143 km². The upper Indus basins beyond the Pakistani-administrated border are excluded ~~in~~-from
 144 this study due to [the](#) spatial coverage of the CPCE. The entire study area is divided into eight
 145 sub-basins, covering most of the Karakoram with the highest elevation up to 8611 m, western
 146 Himalaya and Tien Shan, eastern Hindu Kush, and [the](#) Pamir Mountains. The 9710 glaciers in
 147 the study area cover a total area of 17,447 km² and nearly 60% of glaciers are distributed in the
 148 Karakoram (5818 glaciers with a total area of 14,067.52 km²) (RGI Consortium, 2017). Most
 149 glaciers in the western Himalaya and eastern Hindu Kush are losing mass in the context of

带格式的: 字体: 非加粗

150 climate change (Kääb et al., 2012; Yao et al., 2012; Brun et al., 2017; Shean et al., 2020;
151 Hugonnet et al., 2021), whereas the glaciers in the eastern Karakoram and Pamir have shown
152 unusually little changes, including unchanged, retreated, advanced and surged glaciers (Hewitt,
153 2005; Kääb et al., 2012; Bolch et al., 2017; Brun et al., 2017; Shean et al., 2020; Nie et al.,
154 2021). The spatially heterogeneous distribution and changes of glaciers are primarily explained
155 as a result of differences in the dominant precipitation-bearing atmospheric circulation patterns
156 that include the winter westerlies, the Indian summer monsoon, their changing trends, and their
157 interactions with local extreme topography (Yao et al., 2012; Azam et al., 2021; Nie et al.,
158 2021).

159 3 Data sources

160 Both Landsat and Sentinel-2 images have been employed to map glacial lakes between 1990
161 and 2020 in the CPEC (Figure 2). A total number of 71 Landsat Thematic Mapper
162 (TM), Thematic Mapper Plus (ETM+), and Landsat 8 Operational Land Imager (OLI) images
163 with a consistent spatial resolution of 30 m were downloaded from the United States
164 Geological Survey Global Visualization Viewer (GloVis, <https://glovis.usgs.gov/>) to be used
165 to create glacial lake inventories in 1990, 2000 and 2020. High-quality Landsat-5 images
166 around 2010 are insufficient to cover the entire study area, so we were unable to map lakes in
167 2010 due to Landsat-7's scan-line corrector errors and significant cloud covers. In addition,
168 39 Sentinel-2 images (23 scenes in 2020) were downloaded from Copernicus Open Access
169 Hub (<https://scihub.copernicus.eu/>) to produce the 10-m resolution glacial lake inventory in
170 2020. All images used in this study have been orthorectified before download, but we still
171 find that one Sentinel-2 image was not well matched with Landsat images, leading to the
172 discrepancy between the two glacial lake datasets. We manually georeferenced the shifted
173 image to minimize the difference between Sentinel- and Landsat-derived glacial
174 lakes.

175 Cloud and snow covers heavily affect the usability of optical satellite images (Wulder et
176 al., 2019) and their availability in the entire study area, so we took advantage of the images
177 acquired before and after each of the baseline years 1990, 2000 and 2020 to construct the
178 glacial lake inventories. Only 4 images in 1990 (the largest covering the study area), 16
179 images in 2000, and 23 images in 2020 were used for matching baseline year. Spatially, high-
180 quality images in given baseline years were preferentially chosen, or we selected one or more
181 alternative images acquired in adjacent years to delineate glacial lakes by removing the effect
182 of cloud and snow covers. To minimize the impact of intra-annual changes of glacial
183 lakes, most of the used images (82% for Sentinel-2 and 75% for Landsat) were acquired from
184 August to October in the given baseline year with cloud coverage of <20% for each image.
185 For some specific scenes where cloud cover exceeded the threshold of 20%, we selected
186 more than one image to remedy the effect of cloud contamination (Nie et al., 2010, 2017;
187 Jiang et al., 2018).

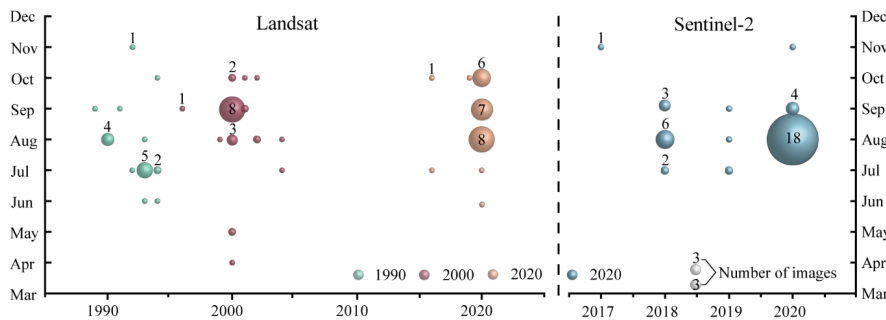

188 Other datasets used include the Randolph Glacier Inventory version 6.0 (Pfeffer et al.,
189 2014; RGI Consortium, 2017) and the Glacier Area Mapping for Discharge from the Asian
190 Mountains (GAMDAM) glacier inventory (Sakai, 2019). These two glacier datasets were
191 used to determine glacial lake types, such as ice-contact, ice-dammed, and unconnected-
192 glacier-fed lakes. The Shuttle Radar Topography Mission Digital Elevation Model (SRTM

带格式的: 字体: (中文) 宋体, 非加粗

DEM) at a 1-arc second (30 m) resolution (Jarvis et al., 2008) was employed to extract the altitudinal characteristics of the glacial lakes. The absolute vertical accuracy of the SRTM DEM is 16 m (90%) (Rabus et al., 2003; Farr et al., 2007). We also applied other published glacial lake datasets for comparative analysis. They include the glacial lake inventories of HMA in 1990 and 2018 downloaded from <http://doi.org/10.12072/casnw.064.2019.db> (Wang et al., 2020), the Third Pole region in 1990, 2000, and 2010 publicly shared at <http://en.tpdatabase.cn/> (Zhang et al., 2015), the Tibet Plateau from 2008 to 2017 accessed at <https://doi.org/10.5281/zenodo.3700282> (Chen et al., 2021), and the entire world in 1990, 2000 and 2015 provided at https://nsidc.org/data/HMA_GLI/versions/1 (Shugar et al., 2020). In addition, field survey data collected between 2017 and 2018 were also used to assist in lake mapping and glacial lake type classification.

204

205

206 **Figure 2.** Acquisition of years and months of Landsat and Sentinel-2 images selected for glacial lake
207 inventories. The bubble size indicates the available high-quality image number.

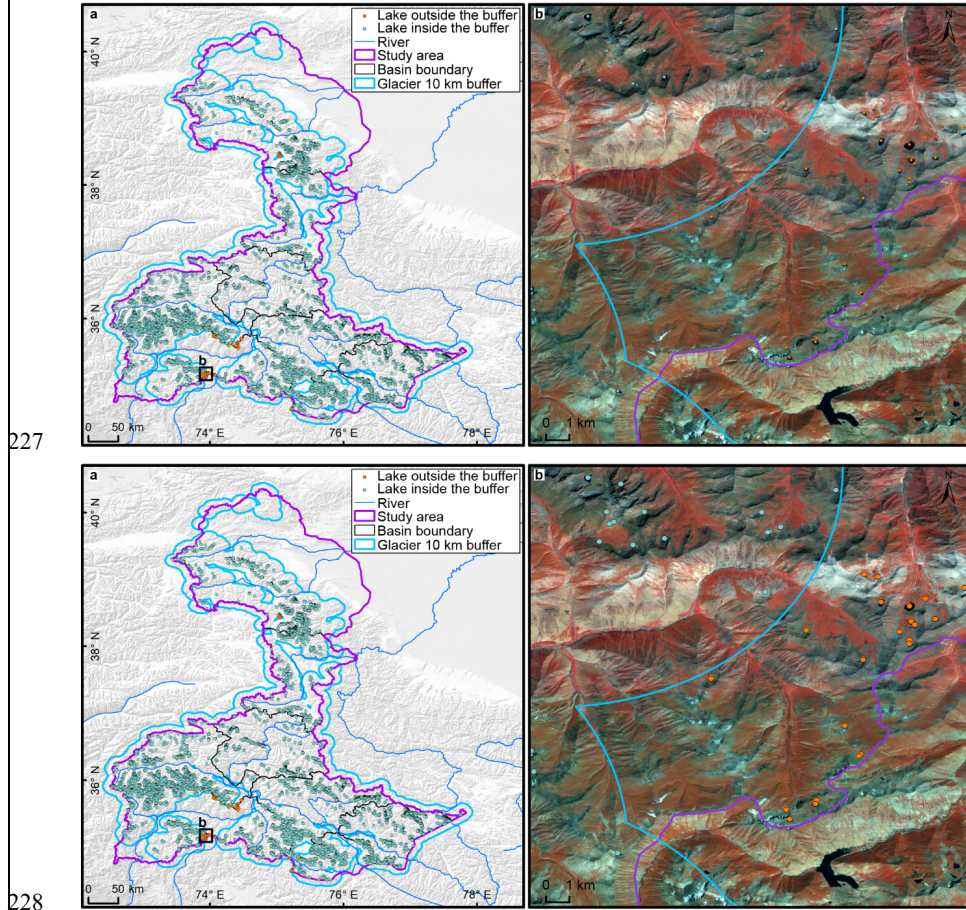

208 4 Glacial lake inventory methods

209 4.1 Definition of glacial lakes

210 We consider a glacial lake as one that formed as a result of modern or ancient glaciation.
211 Contemporary glacial lakes are easily recognized using a combination of glacier inventories
212 and remote sensing images. Ancient glacial lakes can be identified from periglacial
213 geomorphological characteristics, including moraine remnants and U-shaped valleys that are
214 discernible from satellite observations (Post and Mayo, 1971; Westoby et al., 2014; Nie et al.,
215 2018; Martin et al., 2021). A 10-km buffering distance of RGI 6.0 glacier boundaries that has
216 been widely used in previous studies (Zhang et al., 2015; Wang et al., 2020), was created to
217 help mapping glacial lakes. A few glacial lakes in the study area (a total of 84 lakes for the
218 Sentinel-2 dataset and 55 lakes for the Landsat dataset in 2020) beyond the buffering zone,
219 located near buffering boundaries, were intentionally included due to clear evidence of
220 glaciation (Figure 3). Landslide-dammed lakes (Chen et al., 2017) in the buffering
221 zone were excluded from our inventories because of their irrelevance to glaciation. All
222 glacial lakes in the study area were mapped according to our definition. We were able to
223 implement this definition by carefully leveraging the spectral properties of glacial lakes and
224 the periglacial geomorphological features that are often evident in remote sensing images (see

带格式的: 字体: 非加粗

225 more in sections 4.3 and 4.4).
226

227
228
229 **Figure 3.** The 10-km buffer zone of RGI 6.0 glacier boundaries (a) and Sentinel-derived glacial lakes
230 located near buffering boundary within the study area (b).
231

232 4.2 Interactive lake mapping

233 A human-interactive and semi-automated lake mapping method (Wang et al., 2014; Nie et al.,
234 2017, 2020) was adopted to accurately extract glacial lake extents using Landsat and
235 Sentinel-2 images, based on the Normalized Difference Water Index (NDWI) (Mcfeeters,
236 1996). The NDWI uses the green and ~~near~~-near-infrared bands and is calculated by the
237 following equation:

238
$$NDWI = \frac{Band_{Green} - Band_{NIR}}{Band_{Green} + Band_{NIR}} \quad \text{—————} \quad (1)$$

239 where the green band and ~~near-near~~-infrared band were provided by both Landsat and
240 Sentinel multispectral images.

241 Specifically, the method calculated the NDWI histogram based on the pixels with each
242 user-defined and manually-drawn region of interest. The NDWI threshold that separates the
243 lake surface from the land was interactively determined by screening the NDWI histogram
244 against the lake region in the imagery (Wang et al., 2014; Nie et al., 2020). This way, the
245 determined NDWI threshold can be well-tuned to adapt to various spectral conditions of the
246 studied glacier lakes. The raster lake extents segmented by the thresholds were then
247 automatically converted to vector polygons. We first completed the glacial lake inventory in
248 2020 using this interactive mapping method, and the 2020 inventory was then used as a
249 reference to facilitate the lake mapping for other periods.

250 The minimum mapping unit (MMU) was set to 5 pixels for both Landsat (0.0045 km²) and
251 Sentinel-2 images (0.0005 km²) in this study. MMU determines the total number and area of
252 glacial lakes in the dataset; and varies in the previous studies, such as 3 pixels (Zhang et al.,
253 2015), 6 pixels (Wang et al., 2020), or 9 pixels (Chen et al., 2021) for a regional scale, or 55
254 pixels (Shugar et al., 2020) for a global scale. While a smaller threshold leads to a large
255 quantity-number of lakes mapped, it also generates larger mapping noises or uncertainties.
256 Considering this signal-noise balance and our focus on identifying prominent glacier lake
257 dynamics in the study area, we opted to use 5 pixels as the MMU for both Landsat and
258 Sentinel-2 images.

259 Several procedures were taken to assure the quality assurance and quality control for lake
260 mapping, including 1) visual inspection and modification using the threshold-based mapping
261 method for each lake according to Landsat, Sentinel-2, and Google Earth high-resolution
262 images overlaying preliminarily lake boundary extraction at the given time-period; 2) time
263 series check for Landsat-derived glacial lake datasets from 1990 and 2020, and cross-check
264 between Landsat and Sentinel-2-derived lake dataset in 2020 to reduce errors of omission and
265 commission; 3) topological validation of glacial lake mapping, such as repeated removal,
266 elimination of small sliver polygons; and 4) logical check for lake types between two
267 classification systems of glacial lakes. False lake extents resulting from cloud or snow cover,
268 lake ice, and topographic shadows (Nie et al., 2017, 2020) were modified using the previous
269 semi-automated mapping method based on alternative images acquired in adjacent years.
270 Those procedures were time-consuming, but helped to minimize the effect of cloud and snow
271 covers, and lake mapping errors, and to maximize the quality of the produced lake product
272 and the derived glacial lake changes.

273 4.3 Classification of glacial lakes

274 Two glacial lake classification systems (GLCS) have been established based on the
275 relationship of interaction between glacial lakes and glaciers as well as lake formation
276 mechanism and dam material properties. In the first GLCS (GLCS1), glacial lakes were
277 classified into four types based on their spatial relationship to upstream glaciers: supraglacial,
278 ice-contact, unconnected-glacier-fed lakes, and non-glacier-fed lakes according to Gardelle et
279 al. (2011) and Carrivick et al. (2013). Alternatively, combining the formation mechanism of
280 glacial lakes and the properties of natural dam features, glacial lakes were classified into five
281 categories (herein named GLCS2) modified from Yao's classification system (2018):

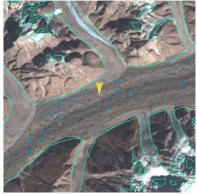

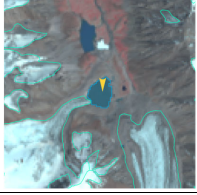

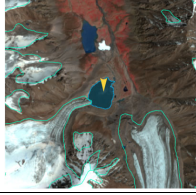

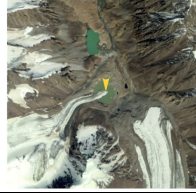

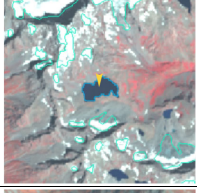

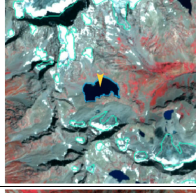

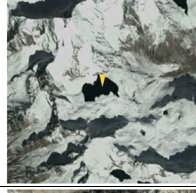

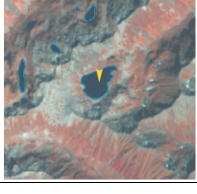

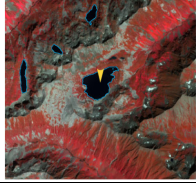

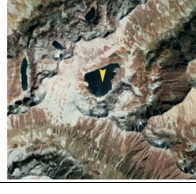

282 supraglacial, end-moraine-dammed, lateral-moraine-dammed, glacial-erosion lakes and ice-
283 dammed lakes. Subglacial lakes were excluded due to the mapping challenge from spectral
284 satellite images alone. Characterization and examples for each type are provided in [Table](#)
285 [1](#) and [Table 2](#). Individual glacial lakes were categorized [into](#) the specific types
286 for each GLCS according to available glacier inventory data, [and](#) geomorphological and
287 spectral characteristics interpreted from Landsat, Sentinel, and Google Earth images. The
288 synergy of these two GLCSs is beneficial to predicting glacier-lake evolutions and providing
289 fundamental data for water resource and glacial lake disaster risk assessment.

292 **Table 1.** Classification A classification system of glacial lake types (GLCS1) according to the relationship
 293 between glacial lakes and glaciers (© Google Earth 2019). Glacier outlines are from RGI 6.0 (RGI
 294 Consortium, 2017), and the yellow marker represents the target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris. Case location: 35°43'49.74" N 76°13'53.88" E			
Ice-contact	Lakes <u>are</u> dammed by moraine, ice, or bedrock, supplied by glacial meltwater, and shared boundary with glaciers. Case location: 39°09'32.40" N 73°43'12.00" E			
Unconnected-glacier-fed	Lakes <u>are</u> currently supplied by upstream glacial meltwater but disconnected <u>with-from</u> glaciers. Case location: 35°47'60.00" N 72°55'15.60" E			
Non-glacier-fed	Lakes formed by glaciology, dammed by moraine or bed rock, and currently not supplied by glacial meltwater. Case location: 34°50'39.99" N 74°48'29.31" E			

295

296 **Table 2.** Classification A classification system of glacial lake types (GLCS2) according to the formation
 297 mechanism of glacial lakes and dam material properties (© Google Earth 2019). Glacier The glacier
 298 outlines from RGI 6.0 (RGI Consortium, 2017), and the yellow marker represents the target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris. Case location: 36°46'7.39" N 74°20'7.59" E			
End-moraine-dammed	Lakes formed behind moraines as a result of glacier retreat and downwasting. Case location: 35°42'50.40" N 73°09'57.60" E			
Lateral-moraine-dammed	Lakes formed behind lateral glacial moraine ridges and <u>are</u> dammed by debris, different from <u>an</u> ice-dammed glacial lake. Case location: 38°28'45.62" N 75°20'52.30" E			
Glacial-erosion	Lakes formed in depressions created by glacial over-deepening. Bedrock dam dominates, partially superimposed by top moraine in rugged terrain. Dams are unclear in the satellite images. Case location: 35°55'55.56" N 73°38'20.13" E			
Ice-dammed	Lakes formed behind glaciers, dammed by glacier ices (partially covered by debris on the top). Case location: 35°28'31.32" N 77°30'46.81" E			

299

300 4.4 Attributes of glacial lake data

301 A total of 18 attribute fields were input into our glacial lake datasets (Table 3 Table 3). They
 302 include lake location (longitude and latitude), lake elevation (centroid elevation), orbital
 303 number of the image source, image acquisition date, lake area, lake perimeter, lake types of the
 304 two GLCSs, mapping uncertainty, lake water volume and the country, sub-basin, and mountain
 305 range associated with the lake. Amongst the attributes, lake location was calculated based on

带格式的: 字体: 非加粗

306 the centroid of each glacial lake polygon associated with the DEM, N represents northing and
 307 E represents easting. ~~Orbital~~The orbital number of the image source was filled with the
 308 corresponding satellite image, with the codes expressed as “PxxxRxxx” or “Txxxxx”, where P
 309 and R indicate the path and row for Landsat image and T represents the tile of Sentinel-2 image
 310 associated with 5 digit code of military grid reference system. SceneID indicated identifying
 311 information of image source for Landsat or Sentinel-2, ~~consisted~~consisting of the orbital
 312 number, sensor ID₂ and acquisition date (YYYYMMDD) for Landsat image, or the orbital
 313 number and acquisition date (YYYYMMDD) for Sentinel-2 image. Area and perimeter were
 314 automatically calculated based on glacial lake extents. Lake water volume was estimated by an
 315 area-volume empirical equation (Cook and Quincey, 2015). Lake types were attributed using
 316 the characterization and interpretation marks described in Section 4.3. Mapping uncertainty
 317 was estimated using our modified equation which will be introduced in section 4.5 and the
 318 appendix tutorial. Located country, sub-basin, and the mountain range of each glacial lake ~~was~~
 319 were identified by overlapping the geographic boundaries of countries, basins, and mountain
 320 ranges.

Table 3. Attributes of glacial lake dataset.

Field Name	Type	Description	Note
FID or OBJECTID	Object ID	Unique code of glacial lake	Number
Shape	Geometry	Feature type of glacial lake	Polygon
Latitude	String	Latitude of the centroid of glacial lake polygon	Degree minute second
Longitude	String	Longitude of the centroid of glacial lake polygon	Degree minute second
Elevation	Double	Elevation of the centroid of glacial lake polygon	Unit: meter above sea level
SceneID	String	Scene ID of image source for Landsat or Sentinel-2	PxxxRxxx_xxxDYYYYMMDD or Txxxxx_YYYYMMDD
ACQDATE	String	Aquisition The acquisition date of <u>the</u> source image	YYYYMMDD
GLCS1	String	The first classification system of glacial lakes based on <u>the</u> relationship of interaction between glacial lakes and glaciers	Supraglacial, Ice-contact, Unconnected-glacier-fed, None-glacier-fed
GLCS2	String	The second classification system of glacial lakes <u>is</u> based on lake formation mechanism and dam material properties	Supraglacial, End-moraine-dammed, Lateral-moraine-dammed, Glacial-erosion and Ice-dammed

Field Name	Type	Description	Note
Basin	String	Basin name where the glacial lake locates in	
Mountain	String	Mountain name where the glacial lake locates in	
Country	String	Country name where the glacial lake locates in	
Perimeter	Double	Perimeter The perimeter of the glacial lake boundary	Unit: meter
Area	Double	Area of glacial lake coverage	Unit: square meter
AreaUncer	Double	Area uncertainty of glacial lake mapping estimated based on modified Hanshaw's equation (2014)	Unit: square meter
Operator	String	Operator The operator of the glacial lake dataset	Muchu, Lesi
Examiner	String	Examiner of glacial lake dataset	Yong, Nie
Volume	Double	Water The water volume of a glacial lake estimated by an area-volume empirical equation	Unit: cubic meter

323

324 4.5 Error and uncertainty assessment

325 4.5.1 Improved uncertainty estimating method

326 We modified Hanshaw's (2014) equation that had been used to calculate lake-area mapping
327 uncertainty. Lake perimeter and displacement error are widely used to estimate the
328 uncertainty of glacier and lake mapping from satellite observation (Carrivick and Quincey,
329 2014; Hanshaw and Bookhagen, 2014; Wang et al., 2020). Hanshaw and Bookhagen (2014)
330 proposed an equation to calculate the error of area measurement by the number of edge pixels
331 of the lake boundary multiplied by half of a single pixel area. The number of edge pixels is
332 simply calculated by the perimeter divided by the grid size. The equation is expressed as
333 below:

$$334 \quad Error(1\sigma) = \frac{P}{G} \times 0.6872 \times \frac{G^2}{2} \quad \underline{\hspace{2cm}} \quad (2)$$

$$335 \quad D = \frac{Error(1\sigma)}{A} \times 100\% \quad \underline{\hspace{2cm}} \quad (3)$$

336 Where G is the cell size of the remote sensing imagery (10 m for Sentinel-2 image and 30 m
 337 for Landsat image). P is the perimeter of individual glacial lake (m), and the coefficient of
 338 0.6872 (1σ), which means nearly 69% of the edge pixels are subject to errors (Hanshaw and
 339 Bookhagen, 2014), was chosen assuming that area measurement errors follow a Gaussian
 340 distribution. Relative error (D) was calculated by equation 3, in which A is the area of an
 341 individual glacial lake.

342 In the original equation 2, the number of edge pixels varies by the shape of the lake and is
 343 indicated by $\frac{P}{G}$. However, the pixels in the corner are ~~double-double~~-counted (Figure 4Figure
 344 4). The total number of repeatedly calculated edge pixels equals the number of inner nodes.
 345 Therefore, we adjusted the calculation of the actual number of edge pixels as the maximum of
 346 edge pixels ($\frac{P}{G}$) subtracting the number of inner nodes. Accordingly, the equation of
 347 uncertainty estimation for lake mapping is modified as below:

$$348 \quad Error(1\sigma) = \left(\frac{P}{G} - N_{Inner}\right) \times 0.6872 \times \frac{G^2}{2} \quad (4)$$

349 Where N_{Inner} is the number of inner nodes (inflection points) of each lake. The modified
 350 equation is also suitable for lakes with islands (as illustrated in Figure 4Figure 4b).

351 For polygons without islands (Figure 4Figure 4a), use the following equation:

$$352 \quad N_{Inner} = \left(\frac{N_{Total}-4-1}{2}\right) \quad (5)$$

353 N_{Total} is the total number of nodes, including both the outer and inner. N_{Total} is calculated by
 354 the “Field Calculator” in ArcGIS, in some cases, it is necessary to remove the redundant
 355 nodes before calculating the total number of nodes (See the Appendix for more details). An
 356 inner node is a polygon vertex where the interior angle surrounding it is greater than 180
 357 degrees. An outer node is the opposite of the inner node, where the interior angle is less than
 358 180 degrees. We found that the outer nodes are usually four more than the inner nodes in our
 359 glacial lake dataset. The total nodes in ArcGIS contain one overlapping node to close the
 360 polygon, meaning the endpoint is also the start point. This extra count was deleted ~~in~~-from
 361 the calculation (equation 5).

362 For polygons with island (Figure 4Figure 4b) use the following equation:

$$363 \quad N_{Inner} = \left(\frac{N_{Total}-(N_{Island}+1)\times 5}{2}\right) \quad (6)$$

364 N_{Island} is the number of islands within each polygon. A calculation method of N_{Island} is
 365 given in the Appendix.

 370

371 4.5.2 Validation of glacial lake mapping

372 A total of 89 glacial lakes were selected by stratified random sampling and manually digitized
 373 based on the Google Earth images in circa 2020 with a spatial resolution of ~ 2 m acquired
 374 from WorldView, GeoEye, Pleiades, etc. satellites to further validate the absolute error of our
 375 glacial lake products in 2020 due to lacking of field measurements for glacial lakes in the
 376 study area. During the sampling, we set a minimum lake area to be 4500 m² and a relative
 377 difference between Landsat- and Sentinel-derived lake areas of less than 18% (nearly
 378 equaling to the average relative error of $\pm 17.36\%$ for Landsat lake mapping) in order to
 379 minimize the effect of lake changes from multi-temporal satellite observations in circa 2020.
 380 The 89 sample lakes range from 0.005 km² to 0.802 km² with a median (standard deviation)
 381 size of 0.047 ± 0.134 km² and a total area of 8.033 km² for Landsat-derived dataset, and range
 382 from 0.005 km² to 0.849 km² with a median (standard deviation) size of 0.045 ± 0.144 km²
 383 and a total area of 8.447 km² for Sentinel-derived dataset.
 384

385 **5 Results**

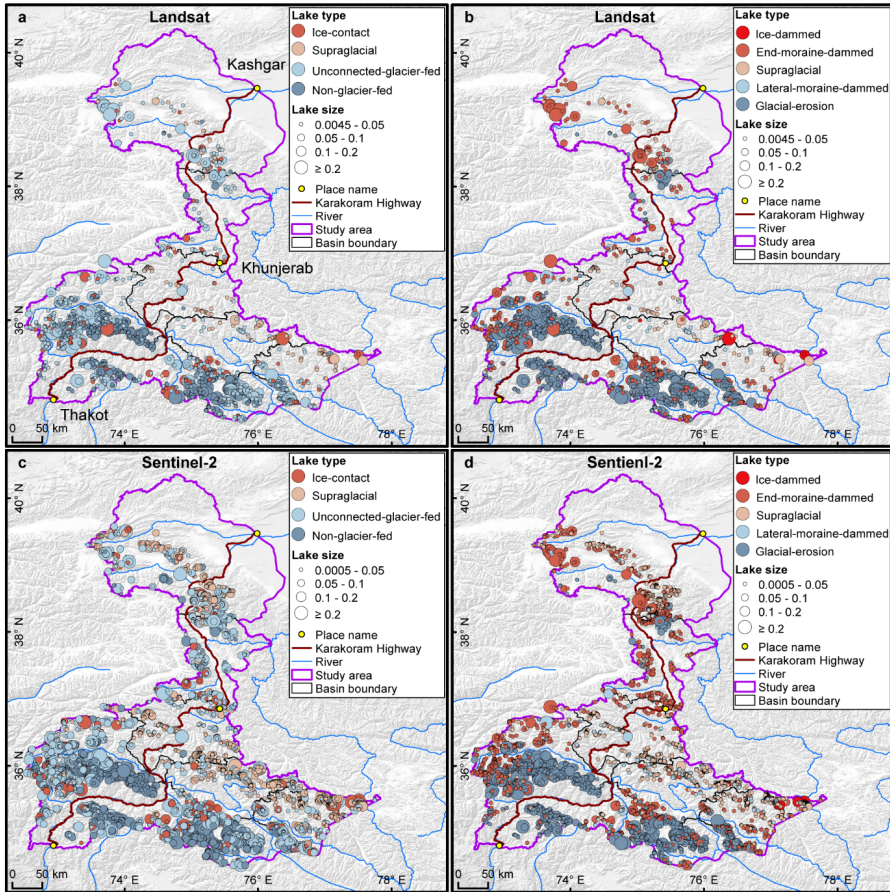

386 5.1 Glacier lake distribution and changes observed from Landsat

387 We mapped 2,234 glacial lakes for 2020 across the studied CPEC from Landsat-8 images,
 388 with a total area of 86.31 ± 14.98 km² (Figure 5 Figure 5a and b). Unconnected-glacier-fed
 389 lakes are dominant in the first classification system, followed by non-glacier-fed lakes
 390 (Figure 6 Figure 6) whereas glacial-erosion lakes dominate at both number (1478) and area
 391 (57.02 km²) in the second classification system (Figure 7 Figure 7), followed by end-moraine-
 392 dammed lakes and supraglacial lakes. Among the classified lakes, 137 are ice-contact lakes
 393 and cover an area of 5.56 km², implying a higher mean size of ice-contact lakes than
 394 supraglacial lakes.
 395

396
 397 **Figure 5.** Distribution of glacial lakes in 2020 extracted from Landsat (a, b) and Sentinel-2 (c, d) images.
 398 Panels a and c are classified by GLCS1₇ and GLCS2 for sub-graph b and d.
 399

400
 401 **Figure 6.** The number and area of different types of glacial lakes are classified based on the

402 condition of glacier supply in the study area (GLCS 1). The outermost ring represents glacial lake data in
 403 2020, the middle ring for 2000, and the innermost ring for 1990. Lake number and area in 2020 were
 404 selected as references, meaning a concept of "100 %" for a complete ring. Labeled values are scaled in
 405 degrees rather than the radius of rings.
 406

407
 408 **Figure 7.** Number The number and area of different types of glacial lakes are classified based on glaciation
 409 and the nature of the dam in the study area (GLCS 2). The outermost ring represents glacial lake data in
 410 2020, the middle ring for 2000, and the innermost ring for 1990. Lake number and area in 2020 were selected
 411 as references, meaning a concept of "100 %" for a complete ring. Labeled values are scaled in degrees rather
 412 than the radius of rings.

413
 414 The total number and area of glacial lakes in the study remain relatively stable with a
 415 slight increase between 1990 and 2020, and the changes in count and area among various
 416 types of glacial lakes vary substantially (Figure 6 and Figure 7). From 1990
 417 to 2020, the total number of glacial lakes increased by 80 or 3.70%, while the area grew by
 418 1.21 km² (or 1.42%). In GLCS1, unconnected-glacier-fed lakes have the largest increase in
 419 number, followed by ice-contact and non-glacier-fed lakes, whereas supraglacial lakes
 420 decreased by 62 in count. Ice-contact lakes expanded by 1.24 km² (equaling an increase of
 421 26% in ice-contact lakes), contributed contributing one-third of the total area increase.
 422 Supraglacial lakes decreased by 0.85 km² in area whereas the areas of unconnected-glacier-
 423 fed and non-glacier-fed lakes remained stable as a result of disconnections from glaciers
 424 (Figure 6). In GLCS2, end-moraine-dammed lakes increased by 2.48 km² and
 425 contributed most of the glacier lake area expansion, whereas supraglacial, ice-dammed, and
 426 lateral-moraine-dammed lakes decreased slightly in both number and area. Glacial-erosion
 427 lakes accounted for the maximum percentage (about 66% for both count and area) in each
 428 time-period and remained stable (Figure 7).

429 5.2 Glacier lake distribution observed from Sentinel-2

430 Sentinel-derived results show that there are 7,560 glacial lakes (103.70±8.45 km²) in
 431 2020 across the entire CPEC under an MMU of 5 pixels (500 m²). Compared with Landsat-
 432 derived product, glacial lakes from Sentinel-2 have similar spatial distribution characteristics
 433 (Figure 5); meanwhile, a larger quantity of glacier lakes, with more accurate
 434 boundaries and a greater total lake area, were generated from Sentinel-2 images (Table

带格式的: 字体: 非加粗

435 ~~4~~Table 4). The smallest size class (0.0005-0.0045 km²) contains the maximum lake number
 436 (4,969) but the least lake area (7.73±2.62 km²), which is not available in the Landsat-derived
 437 lake data due to a coarser spatial resolution. In each size class, the overlap ratios are greater
 438 than 85% in count and area, and there are also a higher number ~~and larger area of larger~~
 439 glacial lakes from Sentinel than that from Landsat images. ~~Sentinel-2 images (10 m) with a~~
 440 ~~finer spatial resolution produces more glacial lakes than those from Landsat images (30~~
 441 ~~m). The discrepancy is mainly attributed to the inconsistency of spatial resolutions and image~~
 442 ~~acquisition dates, more being as discussed in the section 6.2.~~

443
 444 **Table 4.** Count and area of glacial lakes mapped from Sentinel-2 and Landsat images in 2020 in various
 445 size classes.

Lake size km ²	Glacial lakes from Sentinel-2 count (km ²)	Glacial lakes from Landsat count (km ²)	Overlap % (%)
0.0045-0.05	2182 (35.52±3.72)	1870 (31.47±9.57)	85.70 (88.60)
0.05-0.1	237 (16.37±0.89)	204 (14.07±2.18)	86.08 (85.95)
0.1-0.2	122 (16.88±0.68)	115 (15.91±1.83)	94.26 (94.25)
≥0.2	50 (27.20±0.54)	45 (24.86±1.40)	90.00 (91.40)
Total	2591 (95.97±5.83)	2234 (86.31±14.98)	86.22 (89.93)

446 Note: Second column excludes 4969 (7.73±2.62 km²) lakes in the 0.0005 to 0.0045 km² range. Overlap % (%) represents
 447 the ratios between our Landsat-derived dataset and Sentinel-derived product in count and area, respectively.

448 6 Discussions

449 6.1 Uncertainty and error of lake mapping

450 The uncertainty estimated from our improved equation shows that the relative error of
 451 individual glacial lakes decreases when lake size increases or the cell size of remote sensing
 452 images reduces (Lyons et al., 2013; Carrivick and Quincey, 2014) (Figure 8Figure 8). Total
 453 area errors of glacial lakes in the study area are approximate ±14.98 km² and ±8.45 km² in
 454 2020 for Landsat and Sentinel-2 datasets, respectively, and the average relative errors are
 455 ±17.36% and ±8.15%. Generally, small lakes have greater relative errors. For example, the
 456 mean relative error is 35.38% for ~~Landsat-Landsat~~-derived glacial lakes between 0.0045 and
 457 0.1 km² and 10.63% for glacial lakes greater than 0.1 km². The mean area error of Sentinel-
 458 derived glacial lakes is almost ~~one-one~~-third of that extracted from Landsat images for glacial
 459 lakes of all or specific size groups. Because the relative error was estimated as a function of
 460 satellite image spatial resolution and lake perimeter, the calculated error for a large lake is
 461 proportionally smaller than that of a small lake (Salerno et al., 2012) and the error for
 462 Landsat-derived lake is naturally greater than that of Sentinel-derived lake at the same size
 463 group.
 464

465

466

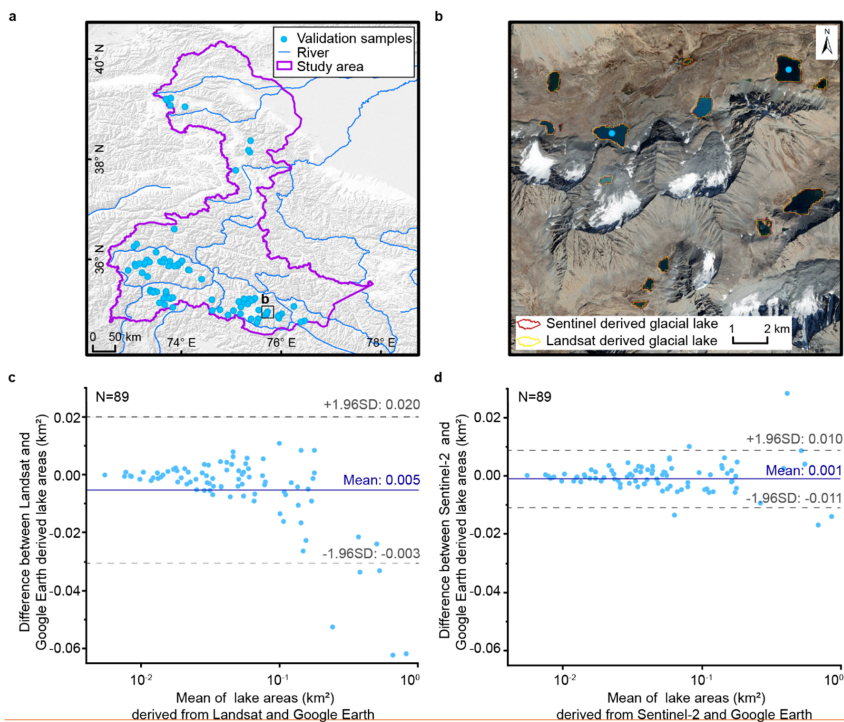

467 **Figure 8.** ~~Estimated~~ The estimated relative error for glacial lakes of all or specific size ranges in the study
 468 area. Error estimation is based on the modified equation and lake data extracted from Landsat (a) and
 469 Sentinel-2 images (b).

471 Our Landsat- and Sentinel-derived glacial lake dataset match well lake boundaries in Google
 472 Earth higher resolution images (Figure 9~~Figure 9~~). The mean difference in area is 0.005 km²
 473 between Landsat- and Google Earth~~Earth~~-derived lakes and 0.001 km² between Sentinel-2
 474 and Google Earth~~Earth~~-derived lakes, and major validation samples (84/89) are within the
 475 confidence interval of 95%, indicating a-high accuracy in lake mapping (Figure 9~~Figure 9c~~
 476 and d). The error of 89 sample lakes is 5.48% in the total area between Landsat- and Google
 477 Earth-derived data, and 0.61% for Sentinel- and Google Earth-derived data. The median
 478 (\pm standard deviation) in a discrepancy of the individual lake area is 7.66 \pm 4.96 % for Landsat-
 479 and Google Earth-derived data, and 4.46 \pm 4.62 % for Sentinel- and Google Earth-derived
 480 data. Our glacial lake dataset shows a-satisfactory mapping accuracy, although Sentinel-
 481 derived lake data performs more accurately than those from Landsat images. We also
 482 validated the sampling of Landsat-derived 89 lakes by the existing Landsat-extracted lake
 483 data produced by Wang et al. (2020). A total of 83 lakes are available in Wang's data with a
 484 mean difference of 0.005 km² in the lake area (Figure A8). This also shows an improvement
 485 of in our lake product in contrast to the existing dataset.

486

487
488 **Figure 9.** Distribution of the validation sample (a), visual comparison of glacial lakes derived from
489 Landsat and Sentinel-2 images overlaying Google Earth imagery (© Google Earth 2019) in a zoomed site
490 (b), and differences between our glacial lake product (mapped from Landsat and Sentinel-2 images) and
491 the validation reference (digitized from Google Earth images) (c and d).

492 6.2 Comparison of Sentinel-2 and Landsat-derived products

493 Glacial lakes from Landsat and Sentinel-2 images have a high consistency in number and
494 area with overlap rates from approximately 86% to 94% for all lakes greater than 0.0045 km²
495 (Table 4 Table 4), indicating a good potential for coordinated utility with Landsat archived
496 observation (Figure 10 Figure 10). Lake extents extracted from Landsat and Sentinel images
497 match well for various types and sizes (Figure 10 Figure 10 and Figure 11 Figure 11, Table
498 4 Table 4). The best consistency rate reaches 94% for the glacial lakes between 0.1 km² and
499 0.2 km². The difference in the area of glacial lakes extracted from Landsat and Sentinel-2
500 images generally lies within the uncertainty ranges.

501
502 **Figure 10.** High consistency of lake extents extracted from Landsat and Sentinel-2 images. Lake types
503 shown include supraglacial (a), glacier-fed moraine-dammed (b), unconnected glacial-erosion lake without
504 glacier melt supply (c), and glacier-fed moraine-dammed lakes (d).

505 Spatial The spatial resolution of satellite images plays a primary role in the discrepancies
506 in count and area of glacial lakes extracted from Landsat (30 m) and Sentinel-2 (10 m)
507 observations. Due to a finer spatial resolution, Sentinel-2 images can extract more glacial
508 lakes and more accurate extents than those from Landsat images. We set the same 5 pixels as
509 the MMU for both Landsat and Sentinel-2 images, which corresponds to a minimum area of
510 0.0045 km² and 0.0005 km², respectively. The minimum mapping area results in generating
511 nearly 5000 more lakes from Sentinel-2 images than from Landsat images, causing the
512 greatest discrepancy in number (Table 4), such as Figure 11. Small lakes such as
513 supraglacial lakes play an important role in analyzing glacier evolution and supraglacial
514 drainage systems (Liu and Mayer, 2015; Miles et al., 2018), implying a potential of our
515 dataset to be applied in studies of glacier-lake evolutions. Meanwhile, Sentinel-2 images are
516 able to can depict boundaries of glacial lakes with a lower uncertainty, as for some small
517 islands and narrow channels (Figure 11. Figure 11b and c) were mapped from Sentinel-2
518 imagery that were was unable to be detected in Landsat imagery.

519
520
521 In addition to the difference in image resolution, different acquisition dates between
522 Sentinel-2 and Landsat images can also contribute to the discrepancy of between those two
523 glacial lake datasets. The total number of supraglacial lakes and ice-dammed glacial lakes
524 are less than 300, but those lakes are controlled by glacier movement and temperature
525 changes (Liu and Mayer, 2015; Miles et al., 2018), and which vary faster with time than
526 relatively stable glacial-erosion and moraine-dammed lakes. Acquiring same-day images
527 from the two sensors were was not always possible due to the impacts of cloud
528 contaminations, topographic shadows, snow cover, and revisit periods (Williamson et al.,
529 2018; Paul et al., 2020). Despite our efforts of leveraging all available high-quality images,

带格式的: 字体: (中文) Times New Roman, 非加粗

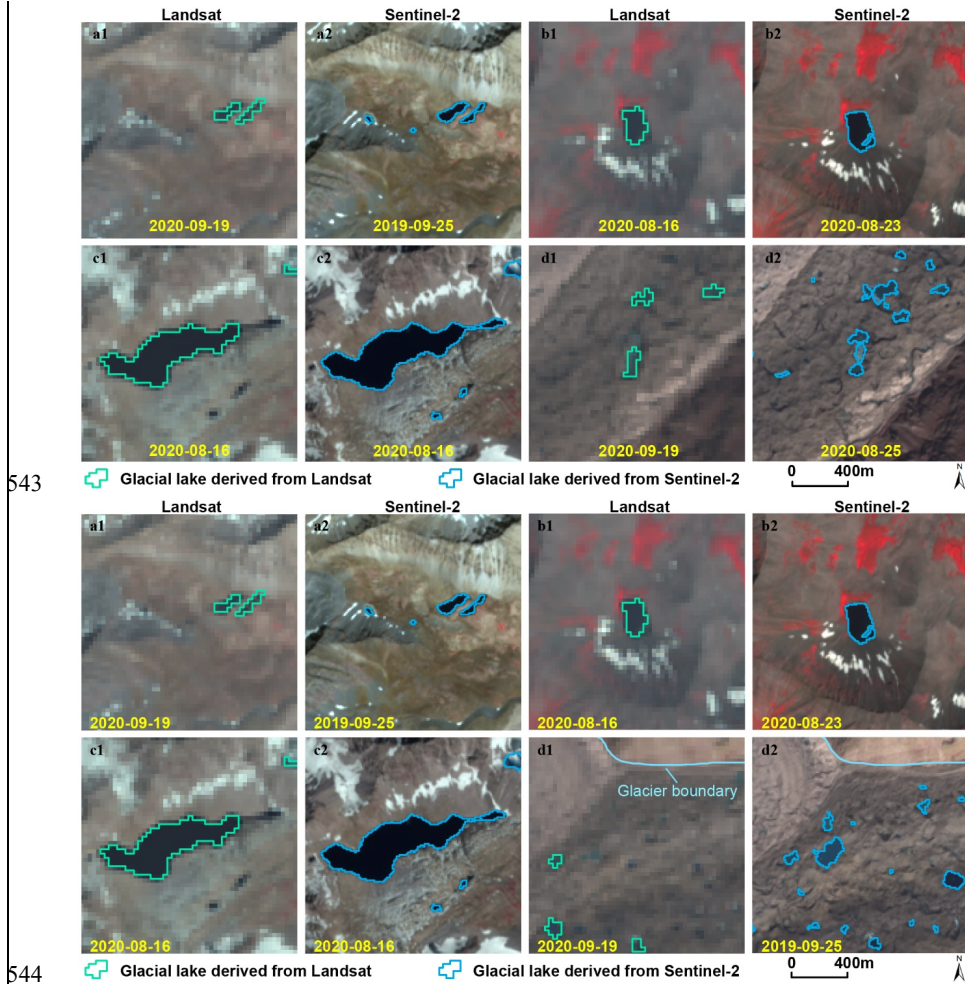

带格式的: 字体: (中文) Times New Roman, 非加粗

530 ~~the overlap of acquisition dates between Landsat and Sentinel-2 images for the same location~~
531 ~~is relatively low (only 7 scenes of Sentinel-2 images or 112 glacial lakes in 2020) in this~~
532 ~~study area, and the consequential temporal gaps led to a difference in the number and area of~~
533 ~~the derived glacial lakes. As exemplified in Figure 11~~~~Figure 11d~~, the mapped ~~supraglacial~~
534 ~~lakes in the same areas exhibit~~~~location exhibit~~ a ~~substantial~~ ~~considerable~~ discrepancy, which
535 is likely a joint consequence of both sensor difference and ~~actual~~ glacier lake ~~dynamics~~
536 ~~evolution~~~~that occurred during this short period of time. Despite our efforts of leveraging all~~
537 ~~available high quality images, the overlap of acquisition dates between Landsat and Sentinel-~~
538 ~~2 images for the same location is relatively low (only 7 scenes of Sentinel-2 images or 112~~
539 ~~glacial lakes in 2020) in this study area, and the consequential temporal gaps led to a~~
540 ~~difference in the number and area of the derived glacial lakes.~~

6.3 Comparison with the previous similar dataset

An increasing number of glacier lake datasets have been released over the past years, and most of them were produced from long-term Landsat archives. Regional glacial lake datasets using Sentinel images are scarce. ~~Lack~~The lack of Sentinel-derived glacial lake data in the study area makes it impossible to compare. Here we selected four available glacial lake datasets to compare with our Landsat-derived dataset at the same MMU and study area.

We provide the latest glacial lake dataset (in 2020) and the most long-term 30-m Landsat observation (1990 to 2020) for this study, with a range of critical attributes including two types of classification systems. Within the same study area, our 2020 glacial lakes appear to

556 be closest to the 2018 dataset produced by Wang et al. (2020), with the highest overlap of
 557 greater than 91% in count at the minimum mapping unit of 5400 m² or 6 pixels (Table 5
 558 5). In Wang's dataset et al. (2020), the minimum mapping unit is 6 pixels so their dataset
 559 has a less lake quantity. However, their dataset contains many large landslide-dammed lakes
 560 that are excluded in our glacial lake mapping. As a result, so their total glacier lake area is
 561 greater than ours.

562 The overlapping rates between Wang's glacial lakes (2020) in 1990 and ours are more than
 563 83.83% in count. However, their results show a distinct increase of glacial lakes in number
 564 and area between 1990 and 2018 (Wang et al., 2020) whereas our data show a more stable
 565 change between 1990 and 2020. One possible reason is that manually delineating glacial
 566 lakes twice by different operators during Wang's lake mapping (2020) exacerbates the errors
 567 of mapping. Another reason is that their data contains landslide-dammed lakes that fluctuate
 568 greatly with time and expanded recently. One example is the Attabad Lake (Located at
 569 36°18'22.33"N, 74°49'34.36"E).

570
571

572 **Table 5.** Comparison between our Landsat-based mapping and other third-party Landsat-based glacial lake
 573 datasets in the study area.

2020 (2016-2020)	Semi-automated	8100 (9)	1813 (83.80±13.63)		This study
2018 (2017-2018)	Manual	5400 (6)	1956 (102.46±15.48)	91.02 (119.24)	Wang et al., 2020
2020 (2016-2020)	Semi-automated	5400 (6)	2119 (85.93±11.71)		This study

Note: MMU represents the minimum mapping unit that is possible to enable a valid comparison between our product and each of the third-party datasets. * The MMU in the dataset of Zhang et al. (2015) is 3 pixels, finer than 5 pixels in our product, so an MMU threshold of 5 pixels was used for this comparison. “% (%)” represents the ratios between the third-party dataset and our product in count and area, respectively.

The second highest overlapping rate is approximate 59% for 2008 and 58% for 2017 in count comparing with Chen’s data (Chen et al., 2021). Similarly, a minimum mapping unit of 55 pixels (50000 m²) in the overlapping rate between Shugar et al.’s; dataset (2020) and ours is led to lower overlap with less than 43% in count and area at the minimum mapping unit of 50000 m². The dataset from Zhang et al. (2015) shows fewer glacial lakes in 1990 and 2000 even with a smaller at the same MMU of 53 pixels. Our product has more lakes than each of the other 4 products at 9 time periods. By inspecting their dataset, we attributed this anomalous discrepancy to a range of glacial lakes that were missing due to a lack of thorough cross-check quality assurance during their manual delineation lake mapping over a larger study area. And those more glacial lakes show an improvement of our product in contrast to the previous similar datasets. Our Landsat-derived glacial lake dataset has been visually cross-checked over three time periods after the step of threshold-based semi-automated lake mapping, and has also been visually validated by Sentinel-2-derived glacial lakes. Through this series of quality assurance, we aim at delivering one of the most reliable multi-decadal glacial lake products for this study area.

Other factors, such as image quality and acquisition dates, mapping methods, and quality assurance workflow, might also lead to the discrepancies between the glacial lake datasets. Despite such discrepancies, an increasing number of publically-shared datasets benefit potential users to select the most suitable one for their objectives. Herein, we provide an up-to-date glacial lake dataset derived from both Landsat and Sentinel-2 observations, which further increased the availability of glacial lake dataset for water resource and GLOFs risk assessment, predicting glacier-lake evolutions (Carrivick et al., 2020) in the context of climate change.

6.4 Limitation and updating plan

We would like to acknowledge several limitations of our glacier lake dataset, largely due to the availability of high-high-quality satellite images in the study area and inadequate field survey data (Wang et al., 2020; Chen et al., 2021). First, it is unlikely to collect enough good-quality images within one calendar year for the entire study area due to the high possibility of cloud or snow covers. Even though the capacity of repeat observations for Landsat-8 OLI and Sentinel-2 increased (Roy et al., 2014; Williamson et al., 2018; Wulder et al., 2019; Paul et al., 2020), the 2020 glacial lake dataset has to employ images acquired in adjacent years besides 2020. Most images used from Landsat and Sentinel-2 platforms were imaged in autumn, and some images taken between April and July and in November also were employed. Distribution and changes in glacial lakes primarily represent the characteristics between August and October. Glacial lakes evolve with time and space (Nie et al., 2017), and

617 subtle inter- and intra-annual changes (Liu et al., 2020) for each ~~time~~ period were ignored.
618 Second, field investigation data are limited due to the low accessibility of the high mountain
619 environment in the study area, which restrained the accuracy in classifying the glacial lake
620 types. Although very high-resolution Google Earth images were utilized to assist in ~~lake-lake-~~
621 type interpretation, occasional misclassification was unavoidable. We implemented two types
622 of classification systems based on a careful utilization of glacier data, DEM,
623 geomorphological features, and expert knowledge. However, the lack of in situ surveys
624 prohibited a thorough validation of the glacial lake types. Third, the rigorous quality
625 assurance and ~~cross-check~~ after semi-automated lake mapping assures the quality of our
626 lake dataset but are still time and ~~cost~~-prohibitive. State-of-the-art mapping methods,
627 such as deep learning method (Wu et al., 2020), Google Earth Engine cloud-computing (Chen
628 et al., 2021), and synergy of SAR and optical images (Wangchuk and Bolch, 2020; How et
629 al., 2021), would be used in the future to balance product accuracy and time cost.

630 The glacial lake dataset will be updated using newly collected Landsat and Sentinel
631 images at a five-year interval or modified according to user feedbacks. The updated glacial
632 lake dataset will continue to be released freely and publicly on the Mountain Science Data
633 Center sharing platform.

634 7 Data availability

635 Our glacial lake dataset extracted from Sentinel-2 images in 2020 and Landsat observation
636 between 1990 and 2020 are available online via the Mountain Science Data Center, the
637 Institute of Mountain Hazards and Environment, the Chinese Academy of Sciences at
638 <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022). The glacial lake dataset is
639 provided in both ESRI shapefile format (total size of 22.6 MB) and the Geopackage format
640 (version 1.2.1) with a total size of 9.2MB, which can be opened and further processed by
641 open-source geographic information system software such as QGIS.

642 8 Conclusions

643 Glacial lake inventories of the entire China-Pakistan Economic Corridor in 2020 were
644 provided based on Landsat and Sentinel-2 images using a threshold-based semi-automated
645 mapping method. Both Landsat and Sentinel-2 derived glacial lake dataset show similar
646 characteristics in spatial distribution and ~~in~~ the statistics of count and area. By contrast, the
647 glacial lake dataset derived from Sentinel-2 images with a spatial resolution of 10 m has a
648 lower mapping error and more accurate lake boundary than those from 30 m spatial
649 resolution Landsat images whereas Landsat imagery is more suitable to analyze spatial-
650 temporal changes at a longer time scale due to its long-term archived observations at a
651 consistent 30 m spatial resolution starting from the late 1980s.

652 Glacial lakes in the study area remain relatively stable with a slight increase in number and
653 area between 1990 and 2020 according to Landsat observations. Our dataset reveals that 2154
654 glacial lakes in 1990 covering 85.1 ± 14.66 km² increased to 2234 lakes with a total area of
655 86.31 ± 14.98 km². The same mapping method and rigorous workflow of quality assurance
656 and quality control used in this study reduced the error in multi-temporal changes of glacial
657 lakes.

658 ~~The~~ Hanshaw's error estimation method for pixel-based lake mapping was improved by
659 removing repeatedly calculated edge pixels that vary with lake shape. Therefore, the newly
660 proposed method reduces the estimated value of uncertainty from satellite observations. The
661 average relative error is $\pm 17.36\%$ for ~~the~~ Landsat-derived ~~product dataset~~ and $\pm 8.15\%$ for ~~the~~
662 product from Sentinel-2.

663 Our glacial lake dataset contains a range of critical parameters that maximize their
664 potential utility for water resource and GLOFs risk evaluation, cryosphere-hydrological, and
665 glacier-lake evolution projection. The dual classification systems of glacial lake types were
666 developed and are very likely to attract broader researchers and scientists to use our datasets.
667 In comparison with other existing glacial lake datasets, our products were created through a
668 thorough consideration of lake types, ~~cross-cross~~-checks, and rigorous quality assurance, and
669 will be updated and released continuously in the Mountain Science Data Center. As such, we
670 expect that our glacial lake dataset will have significant value to cryospheric-hydrology
671 research, the assessment of water resources, and glacier-related hazards in the CPEC.

672
673 **Appendix.** The appendix related to this article is available online.

674
675 **Author contributions.** ML and YN conceived the study, ML, YN and XD performed data
676 processing and analysis of the glacial lake inventory data, JW contributed to tool
677 development and mapping methods, ~~and~~ ML and YN wrote the manuscript. All authors
678 reviewed and edited the manuscript before submission.

679
680 **Competing interests.** The authors declare no conflict of interest.

681
682 **Acknowledgements.**

683 We are grateful ~~for to~~ the ~~chief~~ editor (~~ice~~) Kenneth Mankoff and three anonymous referees
684 for their constructive comments that greatly help us to improve this manuscript. This study
685 was supported by the second Tibetan Plateau Scientific Expedition and Research Program
686 (grant 2019QZKK0603), the National Natural Science Foundation of China (Grant Nos.
687 42171086, 41971153), the International Science & Technology Cooperation Program of
688 China (No. 2018YFE0100100), the Chinese Academy of Sciences "Light of West China" and
689 Natural Sciences and Engineering Research Council of Canada (Grant No. DG-2020-04207).

690
691

692 **Appendix**

693 **Tutorial for Improved Uncertainty Estimating Method**

694
695 ~~The~~ Hanshaw’s equation was originally proposed for pixelated polygons (such as a polygon
696 directly extracted from a remote sensing image), and performed more robustly than manually
697 digitized polygons (where vertices do not necessarily follow the pixel edges). Our improved
698 method also performs better for pixelated polygons. This tutorial is dedicated to helping
699 implement our improved uncertainty estimation method.

700
701 **Procedure** The procedure of uncertainty estimating method (using ArcGIS (© ESRI) for
702 **example)**

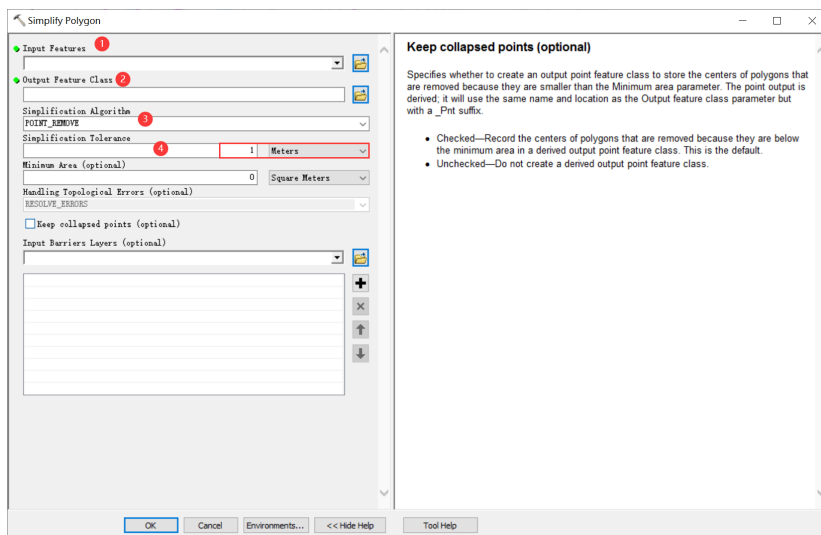

703 1. Removing redundant nodes (optional)

704 We found that a small proportion (~1%) of the pixelated lake polygons (directly extracted
705 from satellite images) have redundant nodes, which affects the value of inner nodes. If no
706 redundant nodes exist, this step can be skipped. Or, we recommend using the “Simplify
707 Polygon” tool in ArcGIS to remove those nodes (Figure A1 ~~Figure A1~~).

708 In the Simplify Polygon panel

- 709 • Input your dataset.
- 710 • Set the output path and output file name.
- 711 • Choose the simplification algorithm. We recommended “POINT_REMOVE”.
- 712 • Set the tolerance of the simplification algorithm. In this step, we need to ensure that the
713 polygon boundaries remain unchanged after deleting redundant nodes. Generally, a
714 tolerance of 1 meter will suffice, or you can adjust the threshold until your satisfaction.

716 **Figure A1.** Input and option for Simplify Polygon in ArcGIS.

717
718
719
720
721
722
723

2. Calculating the total number of nodes using ArcGIS (Figure A2):
- Add a new field in the attribute table of the dataset.
 - Open Field Calculator.
 - Switch the parser to python-mode, and enter the following code “!shape.pointcount!” in the blue box to calculate the total number of nodes for each glacial lake boundary.

带格式的: 字体: 非加粗

725
726
727
728
729
730
731
732
733

3. Calculating the number of inner nodes:

For polygons without islands (Figure A3), use the equation 5. An inner node is a polygon vertex where the interior angle surrounding it is greater than 180 degrees. An outer node is the opposite of the inner node, where the interior angle is less than 180 degrees. We found that the outer nodes are usually four more than the inner nodes in our glacial lake dataset. The total nodes in ArcGIS contain one overlapping node to close the polygon,

带格式的: 字体: 非加粗

734 meaning the endpoint is also the start_point. This extra count was deleted ~~in~~ from the
 735 calculation (equation 5).
 736

737 **Figure A3.** Sketch of outer and inner nodes of various glacial lakes without island.
 738
 739

740 For polygons with islands (Figure A4) use the equation 6.
 741

742 **Figure A4.** Sketch of outer and inner nodes for a glacial lake with an island.
 743
 744

745 We further specify the steps below to help implement equation 6.

746
 747 Sept 1: detect the number of islands within each polygon.

- 748 • Convert the initial lake polygon to a polyline using the “Feature To Line” tool (Figure
 749 A5Figure A5).

带格式的: 字体: 非加粗

带格式的: 字体: 非加粗

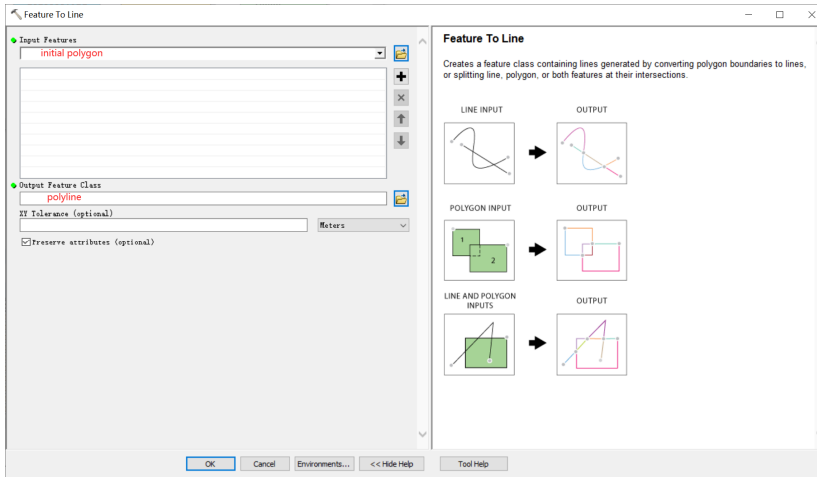

Figure A5. Feature To Line tool in ArcGIS

750
751
752
753

- Convert the polyline to generate a new polygon (Figure A6 Figure A6).

带格式的: 字体: 非加粗

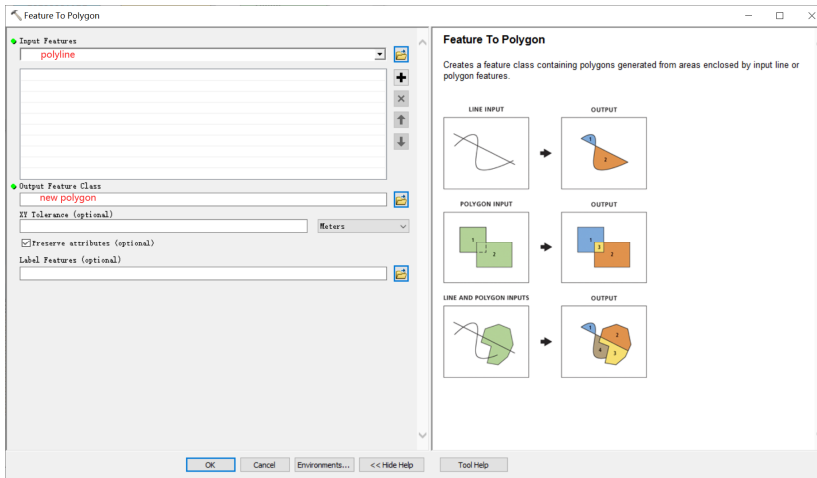

Figure A6. Feature To Polygon tool in ArcGIS

754
755
756
757
758

- Erase the new polygon by the initial polygon, which outputs the islands. Then we can count how many islands there are in each lake (Figure A7 Figure A7).

带格式的: 字体: 非加粗

Figure A7. Erase tool in ArcGIS.

759
760
761
762
763
764
765
766

Step 2: calculate the number of inner nodes for each polygon with an island or islands using equation 6.

4. Calculating the uncertainty of lake mapping using equation 4.

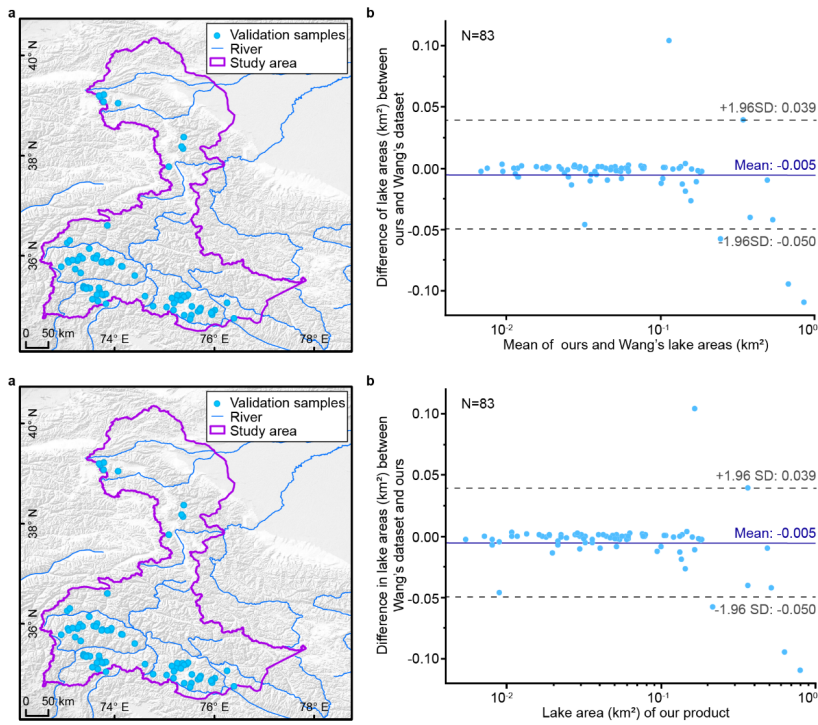

Figure A8. Distribution of validation samples (a) and comparison of glacial lakes (b) derived from our Landsat product in 2020 and Wang's lake data in 2018.
