20 **Abstract.** The China-Pakistan Economic Corridor (CPEC) is one of the flagship projects of
21 the One Belt One Road Initiative, which faces threats from water shortage and mountain
22 disasters in the high-elevation region, such as glacial lake outburst floods (GLOFs). An up-to-
23 date high-quality glacial lake dataset with parameters such as lake area, volume and type,
24 which is fundamental to water resource and flood risk assessments, and predicting glacier-
25 lake evolutions, is still largely absent for the entire CPEC. This study describes a glacial lake
26 dataset for the CPEC using a threshold-based mapping method associated with rigorous
27 visual inspection workflows. This dataset includes (1) multi-temporal inventories for 1990,
28 2000, and 2020 produced from 30 m resolution Landsat images, and (2) a glacial lake
29 inventory for the year 2020 at 10 m resolution produced from Sentinel-2 images. The results
30 show that, in 2020, 2234 lakes were derived from the Landsat images, covering a total area of
31 $86.31 \pm 14.98 \text{ km}^2$ with a minimum mapping unit of 5 pixels (4500 m^2), whereas 7560 glacial
32 lakes were derived from the Sentinel-2 images with a total area of $103.70 \pm 8.45 \text{ km}^2$ with a
33 minimum mapping unit of 5 pixels (500 m^2). The discrepancy shows that Sentinel-2 is able to
34 detect a significant quantity of smaller lakes than Landsat due to its finer spatial resolution.
35 Glacial lake data in 2020 was validated by Google Earth-derived lake boundaries with a
36 median (\pm standard deviation) difference of $7.66 \pm 4.96 \%$ for Landsat-derived product and
37 $4.46 \pm 4.62 \%$ for Sentinel-derived product. The total number and area of glacial lakes from
38 consistent 30 m resolution Landsat images remain relatively stable despite a slight increase
39 from 1990 to 2020. A range of critical attributes have been generated in the dataset, including
40 lake types and mapping uncertainty estimated by an improved Hanshaw's equation. This
41 comprehensive glacial lake dataset has potential to be widely applied in studies on water
42 resource assessment, glacial lake-related hazards, glacier-lake interactions, and is freely
43 available at <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022).

44 **1 Introduction**

45 Glaciers in High-mountain Asia (HMA) play a crucial role in regulating climate, supporting
46 ecosystems, modulating the release of freshwater into rivers, and sustaining municipal water
47 supplies (Wang et al., 2019; Viviroli et al., 2020), agricultural irrigation, and hydropower
48 generation (Pritchard, 2019; Nie et al., 2021). Most HMA glaciers are losing mass in the
49 context of climate change (Brun et al., 2017; Maurer et al., 2019; Shean et al., 2020;
50 Bhattacharya et al., 2021), therefore, unsustainable glacier melt and the passing of peak water
51 are reducing the hydrological role of glaciers (Huss and Hock, 2018) and impacting
52 downstream ecosystem services, agriculture, hydropower and other socioeconomic values
53 (Carrivick and Tweed, 2016; Nie et al., 2021). The present and future glacier changes not
54 only impact water supply for downstream area but also alter the frequency and intensity of
55 glacier-related hazards, such as glacier lake outburst floods (GLOFs) (Nie et al., 2018;
56 Rounce et al., 2020; Zheng et al., 2021), and rock and ice avalanches (Shugar et al., 2021).
57 Global glacial lake number and total area both increased between 1990 and 2018 in response
58 to glacier retreat and climate change (Shugar et al., 2020), affecting the allocation of
59 freshwater resource. The Indus is globally the most important and vulnerable water tower unit
60 where glaciers, lakes and reservoir storage contribute about two-thirds of the water supply
61 (Immerzeel et al., 2020). Ice-marginal lakes store $\sim 1\%$ of total ice discharge in Greenland and
62 accelerate lake-terminating ice velocity by $\sim 25\%$ (Carrivick et al., 2022). An increasing

63 frequency and risk of GLOFs (Nie et al., 2021; Zheng et al., 2021) is threatening Asian
64 population and infrastructures in the mountain ranges, such as the China-Pakistan Economic
65 Corridor (CPEC), as a flagship component of One Belt One Road Initiative (Battamo et al.,
66 2021; Li et al., 2021). The northern section of the CPEC passes through Pamir, Karakoram,
67 Hindu Kush and Himalaya mountains where droughts and glacier-related hazards are frequent
68 and severe (Hewitt, 2014; Bhambri et al., 2019; Pritchard, 2019), threatening local people,
69 the existing, under-construction and planned infrastructures, such as highways, hydropower
70 plants and railways. Understanding the risk posed by water shortage and glacier-related
71 hazards is a critical step to sustainable development for the CPEC.

72 Glacial lake inventories with a range of attributes benefit water resource assessment and
73 disaster risk assessment related to glacial lake (Wang et al., 2020; Carrivick et al., 2022), and
74 contribute to predicting glacier-lake evolution and cryosphere-hydrosphere interactions under
75 climate change (Nie et al., 2017; Brun et al., 2019; Maurer et al., 2019; Carrivick et al., 2020;
76 Liu et al., 2020). Remote sensing is the most viable way to map glacial lakes and detect their
77 spatio-temporal changes in the high-elevation zones where in situ accessibility is extremely
78 low (Huggel et al., 2002; Quincey et al., 2007). Studies in glacial lake inventories using
79 satellite observations have been heavily conducted at regional scales recently, such as in the
80 Tibetan Plateau (Zhang et al., 2015), the Himalaya (Gardelle et al., 2011; Nie et al., 2017),
81 the HMA (Wang et al., 2020; Chen et al., 2021), the Tien Shan (Wang et al., 2013), the
82 Alaska (Rick et al., 2022), the Greenland (How et al., 2021) and the northern Pakistan
83 (Ashraf et al., 2017). However, the latest glacial lake mapping in 2020 is still absent along the
84 CPEC. Among existing studies, Landsat archival images are the most widely used due to their
85 multi-decadal record of earth surface observations, reasonably high spatial resolution (30 m),
86 and publicly available distribution (Roy et al., 2014). Freely available Sentinel-2 satellite
87 images show a better potential than Landsat in glacial lake mapping and inventories due to
88 their higher spatial resolution (10 m) and a global coverage, but have only been available
89 since late 2015 (Williamson et al., 2018; Paul et al., 2020). Glacial lake inventories using
90 Sentinel-2 images are relatively scarce at regional scales, and studies of the latest glacial lake
91 mapping as well as comparisons of glacial lake dataset derived from Sentinel-2 and Landsat
92 observations are still lacking.

93 Discrepancies between various glacial lake inventories (Zhang et al., 2015; Shugar et al.,
94 2020; Wang et al., 2020; Chen et al., 2021; How et al., 2021) result from differences in
95 mapping methods, minimum mapping units, definition of glacial lakes, time periods, data
96 sources and other factors. For example, manual vectorization method was widely adopted at
97 the earlier stage for its high accuracy. However, it is time-consuming associated with high
98 labor intensity and is only practical at regional scales (Zhang et al., 2015; Wang et al., 2020).
99 Automated and semi-automated lake mapping methods, such as multi-spectral index
100 classification (Gardelle et al., 2011; Nie et al., 2017; Zhang et al., 2018; How et al., 2021),
101 have been developed to improve the efficiency of glacial lake inventories using optical
102 images, although manual modification is often unavoidable to assure the quality of lake data
103 impacted by cloud cover, mountain shadows, seasonal snow cover and frozen lake surfaces
104 (Sheng et al., 2016; Wang et al., 2017, 2018). Backscatter images from Synthetic Aperture
105 Radar (SAR) (Wangchuk and Bolch, 2020; How et al., 2021) were used to remove the impact
106 of cloud cover for lake mapping. Besides, other approaches such as hydrological sink

107 detection using DEM (How et al., 2021) and land surface temperature-based detection
108 method (Zhao et al., 2020) were also used for lake inventories. Different classification
109 methods impact the results of lake mapping and monitoring. So far, we are lacking a unified
110 standard for the classification system of glacial lakes (Yao et al., 2018). Existing
111 classification systems are generally used for their individual research purposes, mainly based
112 on the relative positions of glacial lakes and glaciers, the supply conditions of glaciers, and
113 the attributes of dams. In addition to different classification standards, the same type of
114 glacial lakes may also have different names given by different scholars. For example, ice-
115 marginal (Carrivick and Quincey, 2014; Carrivick et al., 2020), ice-contact (Carrivick and
116 Tweed, 2013) and proglacial (Nie et al., 2017) lakes all represent glacial lakes sharing the
117 boundary with glaciers. Glacier lakes in currently available datasets have been traditionally
118 categorized by their spatial relationship with upstream glaciers (Gardelle et al., 2011; Wang
119 et al., 2020; Chen et al., 2021), and classification attributes considering the formation
120 mechanism and the properties of dams are rare or incomplete in the CPEC (Yao et al., 2018;
121 Li et al., 2020). Dam type classification of glacial lakes provides a crucial attribute for
122 glacier-lake interactions and risk assessment (Emmer and Cuřín, 2021). Therefore, an up-to-
123 date glacial lake dataset with critical, quality-assured parameters (e.g. lake area, volume and
124 type) is necessary.

125 This study aims to (1) present an up-to-date glacial lake dataset in the CPEC in 2020 using
126 both Landsat 8 and Sentinel-2 images to accurately document its detailed lake distribution;
127 (2) present two historical glacial lake datasets for the CPEC to show extent in 1990 and 2000
128 using consistent 30-m Landsat images to reveal glacial lake changes at three time periods
129 (1990, 2000 and 2020); and (3) generate a range of critical attributes for glacial lake
130 inventories to benefit studies on water resource evaluation, risk assessment of GLOFs, glacier
131 –lake evolution modeling in the HMA.

132 **2 Study area**

133
 134 **Figure 1.** Location of the study area associated with distribution of glaciers (RGI Consortium, 2017),
 135 mountains, basins and population (Rose et al., 2021) (a), and its location within the CPCE (b).
 136

137 The northern part of the CPCE is selected as the study area (Figure 1). The CPCE, originating
 138 from Kashgar of the Xinjiang Uygur Autonomous region, China and extending to Gwadar Port,
 139 Pakistan (Ullah et al., 2019; Yao et al., 2020), is connecting China and Pakistan via the only
 140 Karakoram Highway. The study area covers all the drainage basins along Karakoram Highway
 141 starting from Kashgar and ending at Thakot, with a total area of ~125,000 km². The upper Indus
 142 basins beyond the Pakistani-administrated border are excluded in this study due to spatial
 143 coverage of the CPCE. The entire study area is divided into eight sub-basins, covering most of
 144 the Karakoram with the highest elevation up to 8611 m, western Himalaya and Tien Shan,
 145 eastern Hindu Kush and Pamir Mountains. The 9710 glaciers in the study area cover a total
 146 area of 17,447 km² and nearly 60% of glaciers are distributed in the Karakoram (5818 glaciers
 147 with a total area of 14,067.52 km²) (RGI Consortium, 2017). Most glaciers in the western
 148 Himalaya and eastern Hindu Kush are losing mass in the context of climate change (Kääb et

149 al., 2012; Yao et al., 2012; Brun et al., 2017; Shean et al., 2020; Hugonnet et al., 2021), whereas
150 the glaciers in the eastern Karakoram and Pamir have shown unusually little changes, including
151 unchanged, retreated, advanced and surged glaciers (Hewitt, 2005; Kääb et al., 2012; Bolch et
152 al., 2017; Brun et al., 2017; Shean et al., 2020; Nie et al., 2021). The spatially heterogeneous
153 distribution and changes of glaciers are primarily explained as a result of differences in the
154 dominant precipitation-bearing atmospheric circulation patterns that include the winter
155 westerlies the Indian summer monsoon, their changing trends and their interactions with local
156 extreme topography (Yao et al., 2012; Azam et al., 2021; Nie et al., 2021).

157 **3 Data sources**

158 Both Landsat and Sentinel-2 images have been employed to map glacial lakes between 1990
159 and 2020 in the CPEC (Figure 2). A total number of 71 Landsat Thematic Mapper (TM),
160 Thematic Mapper Plus (ETM+) and Landsat 8 Operational Land Imager (OLI) images with a
161 consistent spatial resolution of 30 m were downloaded from the United States Geological
162 Survey Global Visualization Viewer (GloVis, <https://glovis.usgs.gov/>) to be used to create
163 glacial lake inventories in 1990, 2000 and 2020. High-quality Landsat-5 images around 2010
164 are insufficient to cover the entire study area, so we were unable to map lakes in 2010 due to
165 Landsat-7's scan-line corrector errors and significant cloud covers. In addition, 39 Sentinel-2
166 images (23 scenes in 2020) were downloaded from Copernicus Open Access Hub
167 (<https://scihub.copernicus.eu/>) to produce the 10-m resolution glacial lake inventory in 2020.
168 All images used in this study have been orthorectified before download, but we still find that
169 one Sentinel-2 image was not well matched with Landsat images, leading to the discrepancy
170 between the two glacial lake datasets. We manually georeferenced the shifted image to
171 minimize the difference between Sentinel and Landsat derived glacial lakes.

172 Cloud and snow covers heavily affect the usability of optical satellite images (Wulder et
173 al., 2019) and their availability in the entire study area, so we took advantage of the images
174 acquired before and after each of the baseline years 1990, 2000 and 2020 to construct the
175 glacial lake inventories. Only 4 images in 1990 (the largest covering the study area), 16
176 images in 2000 and 23 images in 2020 were used for matching baseline year. Spatially, high-
177 quality images in given baseline years were preferentially chosen, or we selected one or more
178 alternative images acquired in adjacent years to delineate glacial lakes by removing the effect
179 of cloud and snow covers. To minimize the impact of intra-annual changes of glacial lakes,
180 most of used images (82% for Sentinel-2 and 75% for Landsat) were acquired from August to
181 October in the given baseline year with cloud coverage of <20% for each image. For some
182 specific scenes where cloud cover exceeded the threshold of 20%, we selected more than one
183 image to remedy the effect of cloud contamination (Nie et al., 2010, 2017; Jiang et al., 2018).

184 Other datasets used include the Randolph Glacier Inventory version 6.0 (Pfeffer et al.,
185 2014; RGI Consortium, 2017) and the Glacier Area Mapping for Discharge from the Asian
186 Mountains (GAMDAM) glacier inventory (Sakai, 2019). These two glacier datasets were
187 used to determine glacial lake types, such as ice-contact, ice-dammed and unconnected-
188 glacier-fed lakes. The Shuttle Radar Topography Mission Digital Elevation Model (SRTM
189 DEM) at a 1-arc second (30 m) resolution (Jarvis et al., 2008) was employed to extract the
190 altitudinal characteristics of the glacial lakes. The absolute vertical accuracy of the SRTM
191 DEM is 16 m (90%) (Rabus et al., 2003; Farr et al., 2007). We also applied other published

192 glacial lake datasets for comparative analysis. They include the glacial lake inventories of
 193 HMA in 1990 and 2018 downloaded from <http://doi.org/10.12072/casnw.064.2019.db> (Wang
 194 et al., 2020), the Third Pole region in 1990, 2000 and 2010 publicly shared at
 195 <http://en.tpdatabase.cn/> (Zhang et al., 2015), the Tibet Plateau from 2008 to 2017 accessed at
 196 <https://doi.org/10.5281/zenodo.3700282> (Chen et al., 2021), and the entire world in 1990,
 197 2000 and 2015 provided at https://nsidc.org/data/HMA_GLI/versions/1 (Shugar et al.,
 198 2020). In addition, field survey data collected between 2017 and 2018 were also used to assist
 199 in lake mapping and glacial lake type classification.
 200

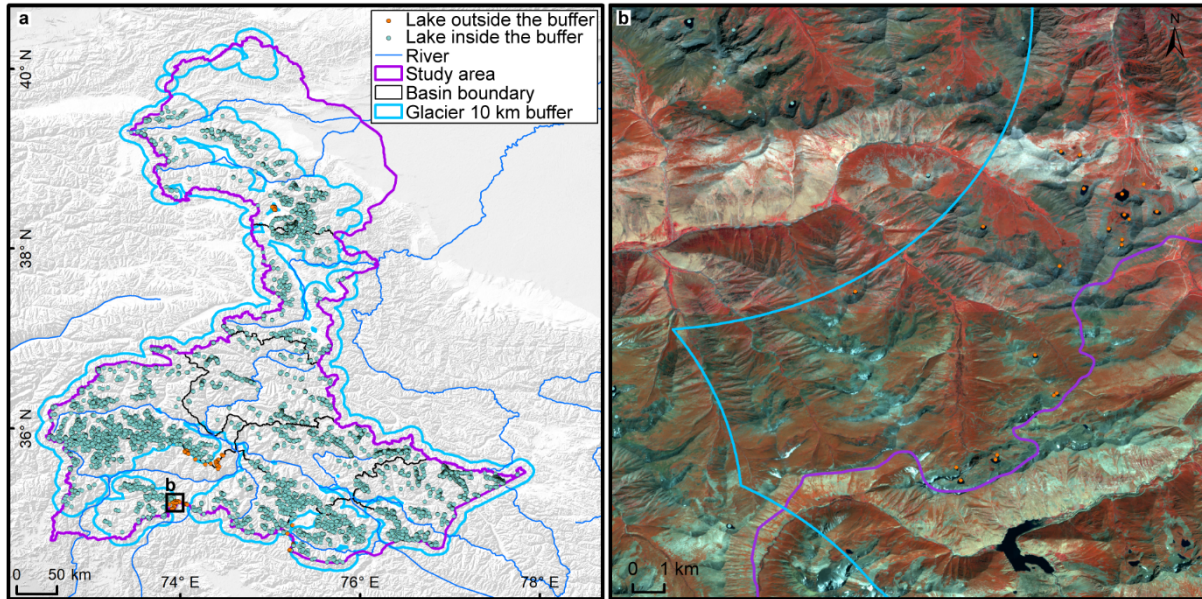

201
 202 **Figure 2.** Acquisition years and months of Landsat and Sentinel-2 images selected for glacial lake
 203 inventories. The bubble size indicates the available high-quality image number.

204 4 Glacial lake inventory methods

205 4.1 Definition of glacial lakes

206 We consider a glacial lake as one that formed as a result of modern or ancient glaciation.
 207 Contemporary glacial lakes are easily recognized using a combination of glacier inventories
 208 and remote sensing images. Ancient glacial lakes can be identified from periglacial
 209 geomorphological characteristics, including moraine remnants and U-shaped valleys that are
 210 discernible from satellite observations (Post and Mayo, 1971; Westoby et al., 2014; Nie et al.,
 211 2018; Martín et al., 2021). A 10-km buffering distance of RGI 6.0 glacier boundaries that has
 212 been widely used in previous studies (Zhang et al., 2015; Wang et al., 2020), was created to
 213 help mapping glacial lakes. A few glacial lakes in the study area (a total of 84 lakes for
 214 Sentinel-2 dataset and 55 lakes for Landsat dataset in 2020) beyond the buffering zone,
 215 located near buffering boundaries, were intentionally included due to clear evidence of
 216 glaciation (Figure 3). Landslide-dammed lakes (Chen et al., 2017) in the buffering zone were
 217 excluded in our inventories because of their irrelevance to glaciation. All glacial lakes in the
 218 study area were mapped according to our definition. We were able to implement this
 219 definition by carefully leveraging the spectral properties of glacial lakes and the periglacial
 220 geomorphological features that are often evident in remote sensing images (see more in
 221 sections 4.3 and 4.4).
 222

223
224
225
226

Figure 3. The 10-km buffer zone of RGI 6.0 glacier boundaries (a) and Sentinel-derived glacial lakes located near buffering boundary within the study area (b).

227 4.2 Interactive lake mapping

228 A human-interactive and semi-automated lake mapping method (Wang et al., 2014; Nie et al.,
229 2017, 2020) was adopted to accurately extract glacial lake extents using Landsat and
230 Sentinel-2 images, based on the Normalized Difference Water Index (NDWI) (Mcfeeters,
231 1996). The NDWI uses the green and near infrared bands and is calculated by the following
232 equation:

$$233 \quad NDWI = \frac{Band_{Green} - Band_{NIR}}{Band_{Green} + Band_{NIR}} \quad (1)$$

234 where the green band and near infrared band were provided by both Landsat and Sentinel
235 multispectral images.

236 Specifically, the method calculated the NDWI histogram based on the pixels with each
237 user-defined and manually-drawn region of interest. The NDWI threshold that separates lake
238 surface from land was interactively determined by screening the NDWI histogram against the
239 lake region in the imagery (Wang et al., 2014; Nie et al., 2020). This way, the determined
240 NDWI threshold can be well-tuned to adapt various spectral conditions of the studied glacier
241 lakes. The raster lake extents segmented by the thresholds were then automatically converted
242 to vector polygons. We first completed the glacial lake inventory in 2020 using this
243 interactive mapping method, and the 2020 inventory was then used as a reference to facilitate
244 the lake mapping for other periods.

245 The minimum mapping unit (MMU) was set to 5 pixels for both Landsat (0.0045 km²) and
246 Sentinel-2 images (0.0005 km²) in this study. MMU determines the total number and area of
247 glacial lakes in the dataset, and varies in the previous studies, such as 3 pixels (Zhang et al.,
248 2015), 6 pixels (Wang et al., 2020), or 9 pixels (Chen et al., 2021) for a regional scale, or 55
249 pixels (Shugar et al., 2020) for a global scale. While a smaller threshold leads to a large
250 quantity of lakes mapped, it also generates larger mapping noises or uncertainties.

251 Considering this signal-noise balance and our focus on identifying prominent glacier lake
252 dynamics in the study area, we opted to use 5 pixels as the MMU for both Landsat and
253 Sentinel-2 images.

254 Several procedures were taken to assure the quality assurance and quality control for lake
255 mapping, including 1) visual inspection and modification using the threshold-based mapping
256 method for each lake according to Landsat, Sentinel-2 and Google Earth high-resolution
257 images overlaying preliminarily lake boundary extraction at the given time period; 2) time
258 series check for Landsat-derived glacial lake datasets from 1990 and 2020, and cross-check
259 between Landsat and Sentinel-2-derived lake dataset in 2020 to reduce errors of omission and
260 commission; 3) topological validation of glacial lake mapping, such as repeated removal,
261 elimination of small sliver polygons; and 4) logical check for lake types between two
262 classification systems of glacial lakes. False lake extents resulting from cloud or snow cover,
263 lake ice, and topographic shadows (Nie et al., 2017, 2020) were modified using previous
264 semi-automated mapping method based on alternative images acquired in adjacent years.
265 Those procedures were time-consuming, but helped to minimize the effect of cloud and snow
266 covers, lake mapping errors, and to maximize the quality of the produced lake product and
267 the derived glacial lake changes.

268 4.3 Classification of glacial lakes

269 Two glacial lake classification systems (GLCS) have been established based on relationship
270 of interaction between glacial lakes and glaciers as well as lake formation mechanism and
271 dam material properties. In the first GLCS (GLCS1), glacial lakes were classified into four
272 types based on their spatial relationship to upstream glaciers: supraglacial, ice-contact,
273 unconnected-glacier-fed lakes, and non-glacier-fed lakes according to Gardelle et al. (2011)
274 and Carrivick et al. (2013). Alternatively, combining the formation mechanism of glacial
275 lakes and the properties of natural dam features, glacial lakes were classified into five
276 categories (herein named GLCS2) modified from Yao's classification system (2018):
277 supraglacial, end-moraine-dammed, lateral-moraine-dammed, glacial-erosion lakes and ice-
278 dammed lakes. Subglacial lakes were excluded due to the mapping challenge from spectral
279 satellite images alone. Characterization and examples for each type are provided in Table 1
280 and Table 2. Individual glacial lakes were categorized to the specific types for each GLCS
281 according to available glacier inventory data, geomorphological and spectral characteristics
282 interpreted from Landsat, Sentinel and Google Earth images. The synergy of these two
283 GLCSs is beneficial to predicting glacier-lake evolutions and providing fundamental data for
284 water resource and glacial lake disaster risk assessment.

285

288

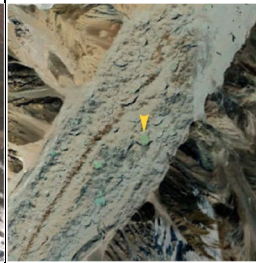

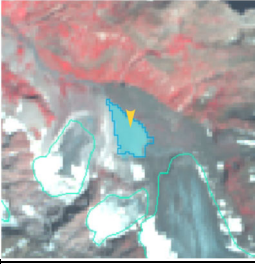

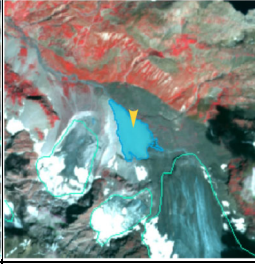

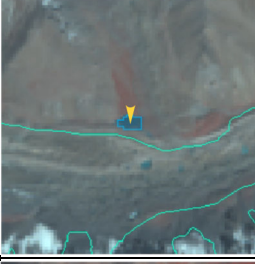

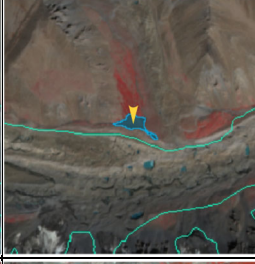

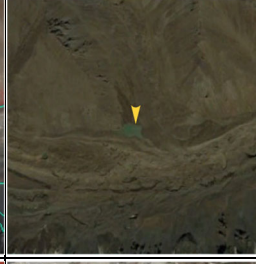

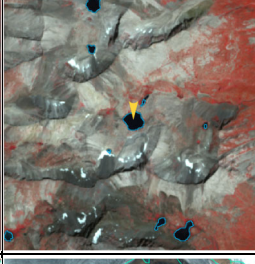

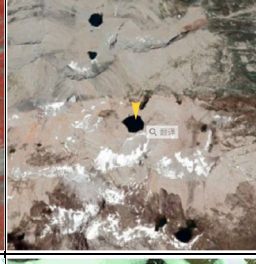

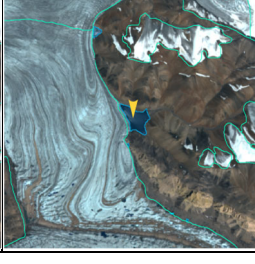

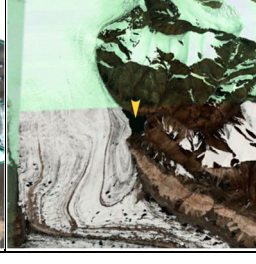

289

Table 1. Classification system of glacial lake types (GLCS1) according to the relationship between glacial lakes and glaciers (© Google Earth 2019). Glacier outlines are from RGI 6.0 (RGI Consortium, 2017), and the yellow marker represents target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris. Case location: 35°43'49.74" N 76°13'53.88" E			
Ice-contact	Lakes dammed by moraine, ice or bedrock, supplied by glacial meltwater and shared boundary with glaciers. Case location: 39°09'32.40" N 73°43'12.00" E			
Unconnected-glacier-fed	Lakes currently supplied by upstream glacial meltwater but disconnected with glaciers. Case location: 35°47'60.00" N 72°55'15.60" E			
Non-glacier-fed	Lakes formed by glaciology, dammed by moraine or bed rock, and currently not supplied by glacial meltwater. Case location: 34°50'39.99" N 74°48'29.31" E			

290

291 **Table 2.** Classification system of glacial lake types (GLCS2) according to the formation mechanism of
 292 glacial lakes and dam material properties (© Google Earth 2019). Glacier outlines from RGI 6.0 (RGI
 293 Consortium, 2017), and the yellow marker represents target lake.

Lake types	Characteristics	Landsat	Sentinel-2	Google Earth
Supraglacial	Lakes formed on the surface of glaciers, generally dammed by ice and thin debris. Case location: 36°46'7.39" N 74°20'7.59" E			
End-moraine-dammed	Lakes formed behind moraines as a result of glacier retreat and downwasting. Case location: 35°42'50.40" N 73°09'57.60" E			
Lateral-moraine-dammed	Lakes formed behind lateral glacial moraine ridges and dammed by debris, different from ice-dammed glacial lake. Case location: 38°28'45.62" N 75°20'52.30" E			
Glacial-erosion	Lakes formed in depressions created by glacial over-deepening. Bedrock dam dominates, partially superimposed by top moraine in rugged terrain. Dams are unclear in the satellite images. Case location: 35°55'55.56" N 73°38'20.13" E			
Ice-dammed	Lakes formed behind glaciers, dammed by glacier ices (partially covered by debris on the top). Case location: 35°28'31.32" N 77°30'46.81" E			

294

295 4.4 Attributes of glacial lake data

296 A total of 18 attribute fields were input into our glacial lake datasets (Table 3). They include
 297 lake location (longitude and latitude), lake elevation (centroid elevation), orbital number of the
 298 image source, image acquisition date, lake area, lake perimeter, lake types of the two GLCSs,
 299 mapping uncertainty, lake water volume and the country, sub-basin, and mountain range
 300 associated with the lake. Amongst the attributes, lake location was calculated based on the

301 centroid of each glacial lake polygon associated with the DEM, N represents northing and E
 302 represents easting. Orbital number of the image source was filled with the corresponding
 303 satellite image, with the codes expressed as “PxxxRxxx” or “Txxxxx”, where P and R indicate
 304 the path and row for Landsat image and T represents the tile of Sentinel-2 image associated
 305 with 5 digit code of military grid reference system. SceneID indicated identifying information
 306 of image source for Landsat or Sentinel-2, consisted of the orbital number, sensor ID and
 307 acquisition date (YYYYMMDD) for Landsat image, or the orbital number and acquisition date
 308 (YYYYMMDD) for Sentinel-2 image. Area and perimeter were automatically calculated based
 309 on glacial lake extents. Lake water volume was estimated by area-volume empirical equation
 310 (Cook and Quincey, 2015). Lake types were attributed using the characterization and
 311 interpretation marks described in Section 4.3. Mapping uncertainty was estimated using our
 312 modified equation which will be introduced in section 4.5 and appendix tutorial. Located
 313 country, sub-basin and mountain range of each glacial lake was identified by overlapping the
 314 geographic boundaries of countries, basins and mountain ranges.

315

316 **Table 3.** Attributes of glacial lake dataset.

Field Name	Type	Description	Note
FID or OBJECTID	Object ID	Unique code of glacial lake	Number
Shape	Geometry	Feature type of glacial lake	Polygon
Latitude	String	Latitude of the centroid of glacial lake polygon	Degree minute second
Longitude	String	Longitude of the centroid of glacial lake polygon	Degree minute second
Elevation	Double	Elevation of the centroid of glacial lake polygon	Unit: meter above sea level
SceneID	String	Scene ID of image source for Landsat or Sentinel-2	PxxxRxxx_xxxYYYYMMDD or Txxxxx_YYYYMMDD
ACQDATE	String	Acquisition date of source image	YYYYMMDD
GLCS1	String	The first classification system of glacial lakes based on relationship of interaction between glacial lakes and glaciers	Supraglacial, Ice-contact, Unconnected-glacier-fed, None-glacier-fed

Field Name	Type	Description	Note
GLCS2	String	The second classification system of glacial lakes based on lake formation mechanism and dam material properties	Supraglacial, End-moraine-dammed, Lateral-moraine-dammed, Glacial-erosion and Ice-dammed
Basin	String	Basin name where glacial lake locates in	
Mountain	String	Mountain name where glacial lake locates in	
Country	String	Country name where glacial lake locates in	
Perimeter	Double	Perimeter of glacial lake boundary	Unit: meter
Area	Double	Area of glacial lake coverage	Unit: square meter
AreaUncer	Double	Area uncertainty of glacial lake mapping estimated based on modified Hanshaw's equation (2014)	Unit: square meter
Operator	String	Operator of glacial lake dataset	Muchu, Lesi
Examiner	String	Examiner of glacial lake dataset	Yong, Nie
Volume	Double	Water volume of glacial lake estimated by area-volume empirical equation	Unit: cubic meter

318 4.5 Error and uncertainty assessment

319 4.5.1 Improved uncertainty estimating method

320 We modified Hanshaw's (2014) equation that had been used to calculate lake-area mapping
321 uncertainty. Lake perimeter and displacement error are widely used to estimate the
322 uncertainty of glacier and lake mapping from satellite observation (Carrivick and Quincey,
323 2014; Hanshaw and Bookhagen, 2014; Wang et al., 2020). Hanshaw and Bookhagen (2014)
324 proposed an equation to calculate the error of area measurement by the number of edge pixels
325 of the lake boundary multiplied by half of a single pixel area. The number of edge pixels is
326 simply calculated by the perimeter divided by the grid size. The equation is expressed as
327 below:

$$328 \quad \text{Error}(1\sigma) = \frac{P}{G} \times 0.6872 \times \frac{G^2}{2} \quad (2)$$

$$329 \quad D = \frac{\text{Error}(1\sigma)}{A} \times 100\% \quad (3)$$

330 Where G is the cell size of the remote sensing imagery (10 m for Sentinel-2 image and 30 m
331 for Landsat image). P is the perimeter of individual glacial lake (m), and the coefficient of
332 0.6872 (1σ), which means nearly 69% of the edge pixels are subject to errors (Hanshaw and
333 Bookhagen, 2014), was chosen assuming that area measurement errors follow a Gaussian
334 distribution. Relative error (D) was calculated by equation 3, in which A is the area of an
335 individual glacial lake.

336 In the original equation 2, the number of edge pixels varies by the shape of lake and is
337 indicated by $\frac{P}{G}$. However, the pixels in the corner are double counted (Figure 4). The total
338 number of repeatedly calculated edge pixels equals the number of inner nodes. Therefore, we
339 adjusted the calculation of the actual number of edge pixels as the maximum of edge pixels
340 ($\frac{P}{G}$) subtracting the number of inner nodes. Accordingly, the equation of uncertainty
341 estimation for lake mapping is modified as below:

$$342 \quad \text{Error}(1\sigma) = \left(\frac{P}{G} - N_{Inner}\right) \times 0.6872 \times \frac{G^2}{2} \quad (4)$$

343 Where N_{Inner} is the number of inner nodes (inflection points) of each lake. The modified
344 equation is also suitable for lakes with islands (as illustrated in Figure 4b).

345 For polygons without islands (Figure 4a), use the following equation:

$$346 \quad N_{Inner} = \left(\frac{N_{Total}-4-1}{2}\right) \quad (5)$$

347 N_{Total} is the total number of nodes, including both the outer and inner. N_{Total} is calculated
348 by the "Field Calculator" in ArcGIS, in some cases, it is necessary to remove the redundant
349 nodes before calculating the total number of nodes (See the Appendix for more details). An
350 inner node is a polygon vertex where the interior angle surrounding it is greater than 180
351 degrees. An outer node is the opposite of the inner node, where the interior angle is less than
352 180 degrees. We found that the outer nodes are usually four more than the inner nodes in our

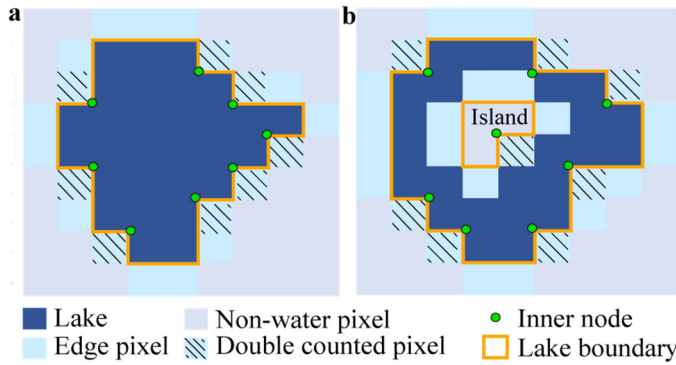

353 glacial lake dataset. The total nodes in ArcGIS contain one overlapping node to close the
 354 polygon, meaning the endpoint is also the startpoint. This extra count was deleted in the
 355 calculation (equation 5).

356 For polygons with island (Figure 4b) use the following equation:

357
$$N_{Inner} = \left(\frac{N_{Total} - (N_{Island} + 1) \times 5}{2} \right) \quad (6)$$

358 N_{Island} is the number of islands within each polygon. A calculation method of N_{Island} is
 359 given in the Appendix.

360

361

362 **Figure 4.** Sketch of estimating the actual edge pixels for uncertainty calculation of individual glacial lake
 363 (with (a) and without islands (b)).

364

365 4.5.2 Validation of glacial lake mapping

366 A total of 89 glacial lakes were selected by stratified random sampling and manually digitized
 367 based on the Google Earth images in circa 2020 with a spatial resolution of ~ 2 m acquired
 368 from WorldView, GeoEye, Pleiades etc. satellites to further validate the absolute error of our
 369 glacial lake products in 2020 due to lacking of field measurements for glacial lakes in the
 370 study area. During the sampling, we set a minimum lake area to be 4500 m² and a relative
 371 difference between Landsat- and Sentinel-derived lake areas less than 18% (nearly equaling
 372 to the average relative error of $\pm 17.36\%$ for Landsat lake mapping) in order to minimize the
 373 effect of lake changes from multi-temporal satellite observations in circa 2020. The 89
 374 sample lakes range from 0.005 km² to 0.802 km² with a median (standard deviation) size of
 375 0.047 ± 0.134 km² and a total area of 8.033 km² for Landsat-derived dataset, and range from
 376 0.005 km² to 0.849 km² with a median (standard deviation) size of 0.045 ± 0.144 km² and a
 377 total area of 8.447 km² for Sentinel-derived dataset.

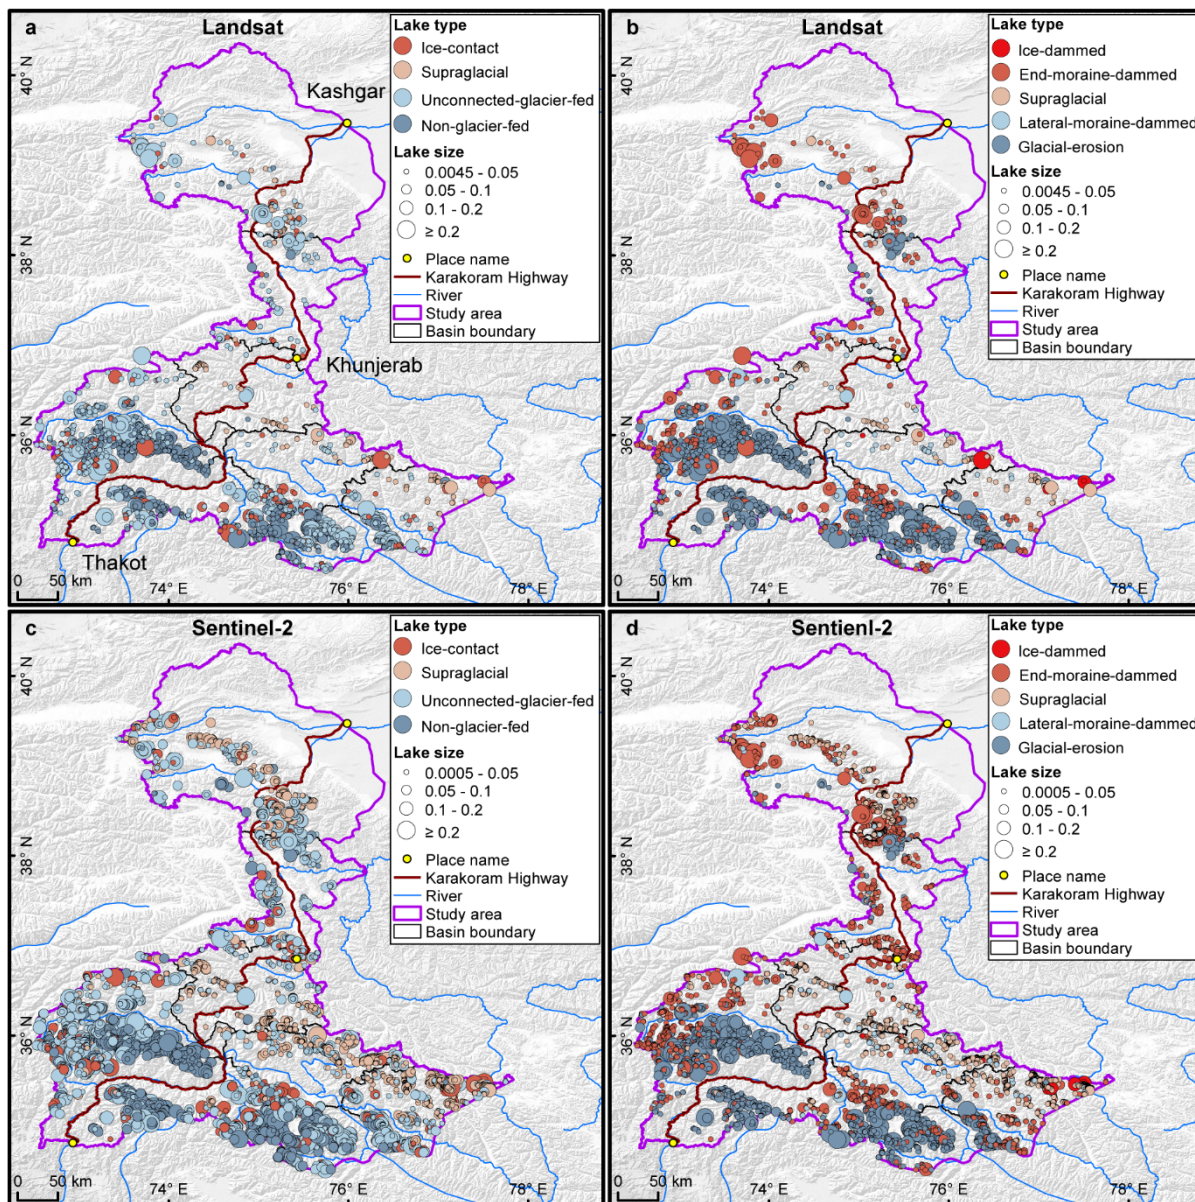

378

379 5 Results

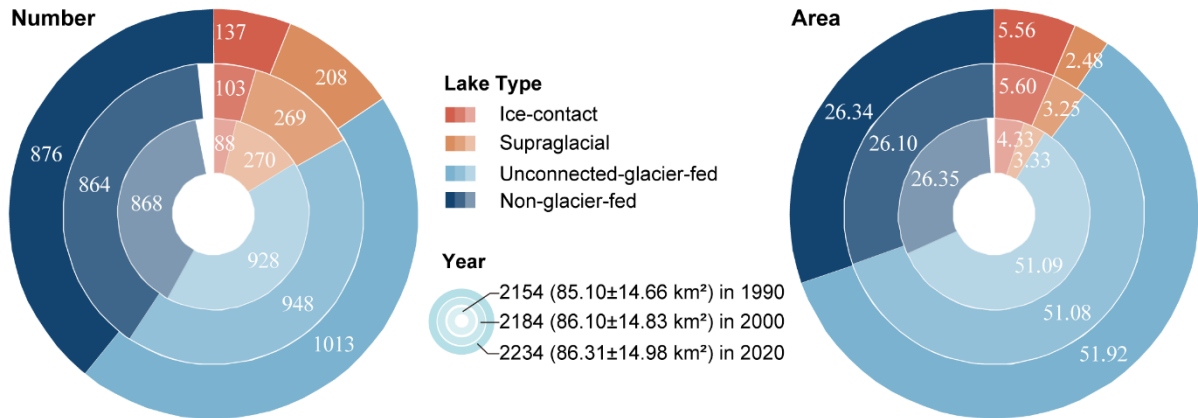

380 5.1 Glacier lake distribution and changes observed from Landsat

381 We mapped 2,234 glacial lakes for 2020 across the studied CPEC from Landsat-8 images,
 382 with a total area of 86.31 ± 14.98 km² (Figure 5a and b). Unconnected-glacier-fed lakes are

383 dominant in the first classification system, followed by non-glacier-fed lakes (Figure 6)
 384 whereas glacial-erosion lakes dominate at both number (1478) and area (57.02 km²) in the
 385 second classification system (Figure 7), followed by end-moraine-dammed lakes and
 386 supraglacial lakes. Among the classified lakes, 137 are ice-contact lakes and cover an area of
 387 5.56 km², implying a higher mean size of ice-contact lakes than supraglacial lakes.
 388

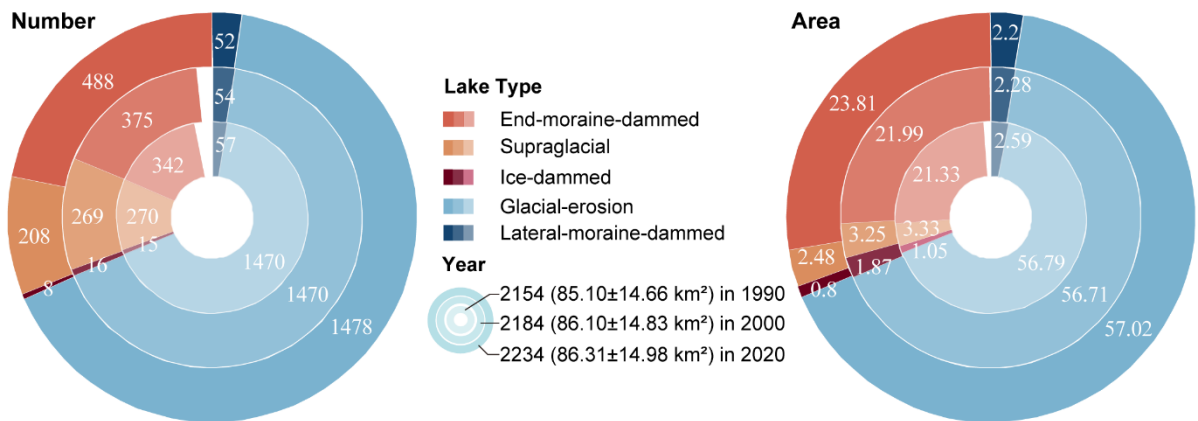

389 **Figure 5.** Distribution of glacial lakes in 2020 extracted from Landsat (a, b) and Sentinel-2 (c, d) images.
 390
 391 Panels a and c are classified by GLCS1, and GLCS2 for sub-graph b and d.
 392

393

394 **Figure 6.** Number and area of different types of glacial lakes classified based on the condition of glacier
 395 supply in the study area (GLCS 1). The outermost ring represents glacial lake data in 2020, middle ring for
 396 2000 and innermost ring for 1990. Lake number and area in 2020 were selected as reference, meaning a
 397 concept of "100 %" for a complete ring. Labeled values are scaled in degrees rather the radius of rings.
 398

399

400 **Figure 7.** Number and area of different types of glacial lakes classified based on glaciation and nature of
 401 dam in the study area (GLCS 2). The outermost ring represents glacial lake data in 2020, middle ring for
 402 2000 and innermost ring for 1990. Lake number and area in 2020 were selected as reference, meaning a
 403 concept of "100 %" for a complete ring. Labeled values are scaled in degrees rather the radius of rings.
 404

405 The total number and area of glacial lakes in the study remain relatively stable with a
 406 slight increase between 1990 and 2020, and the changes in count and area among various
 407 types of glacial lakes vary substantially (Figure 6 and Figure 7). From 1990 to 2020, the total
 408 number of glacial lakes increased by 80 or 3.70%, while the area grew by 1.21 km² (or
 409 1.42%). In GLCS1, unconnected-glacier-fed lakes have the largest increase in number,
 410 followed by ice-contact and non-glacier-fed lakes, whereas supraglacial lakes decreased by
 411 62 in count. Ice-contact lakes expanded by 1.24 km² (equaling an increase of 26% in ice-
 412 contact lakes), contributed one third of the total area increase. Supraglacial lakes decreased
 413 by 0.85 km² in area whereas the areas of unconnected-glacier-fed and non-glacier-fed lakes
 414 remained stable as a result of disconnections from glaciers (Figure 6). In GLCS2, end-
 415 moraine-dammed lakes increased by 2.48 km² and contributed most of the glacier lake area
 416 expansion, whereas supraglacial, ice-dammed and lateral-moraine-dammed lakes decreased

417 slightly in both number and area. Glacial-erosion lakes accounted for the maximum
 418 percentage (about 66% for both count and area) in each time period and remained stable
 419 (Figure 7).

420 5.2 Glacier lake distribution observed from Sentinel-2

421 Sentinel-derived results shows that there are 7,560 glacial lakes ($103.70 \pm 8.45 \text{ km}^2$) in 2020
 422 across the entire CPEC under a MMU of 5 pixels (500 m^2). Compared with Landsat-derived
 423 product, glacial lakes from Sentinel-2 have similar spatial distribution characteristics (Figure
 424 5); meanwhile, a larger quantity of glacier lakes, with more accurate boundaries and a greater
 425 total lake area, were generated from Sentinel-2 images (Table 4). The smallest size class
 426 ($0.0005\text{-}0.0045 \text{ km}^2$) contains the maximum lake number (4,969) but the least lake area
 427 ($7.73 \pm 2.62 \text{ km}^2$), which is not available in the Landsat-derived lake data due to a coarser
 428 spatial resolution. In each size class, the overlap ratios are greater than 85% in count and
 429 area, and there are also a higher number of larger glacial lakes from Sentinel than that from
 430 Landsat images. The discrepancy is mainly attributed to the inconsistency of spatial
 431 resolutions and image acquisition dates.

432

433 **Table 4.** Count and area of glacial lakes mapped from Sentinel-2 and Landsat images in 2020 in various
 434 size classes.

Lake size km ²	Glacial lakes from Sentinel-2 count (km ²)	Glacial lakes from Landsat count (km ²)	Overlap % (%)
0.0045-0.05	2182 (35.52 ± 3.72)	1870 (31.47 ± 9.57)	85.70 (88.60)
0.05-0.1	237 (16.37 ± 0.89)	204 (14.07 ± 2.18)	86.08 (85.95)
0.1-0.2	122 (16.88 ± 0.68)	115 (15.91 ± 1.83)	94.26 (94.25)
≥ 0.2	50 (27.20 ± 0.54)	45 (24.86 ± 1.40)	90.00 (91.40)
Total	2591 (95.97 ± 5.83)	2234 (86.31 ± 14.98)	86.22 (89.93)

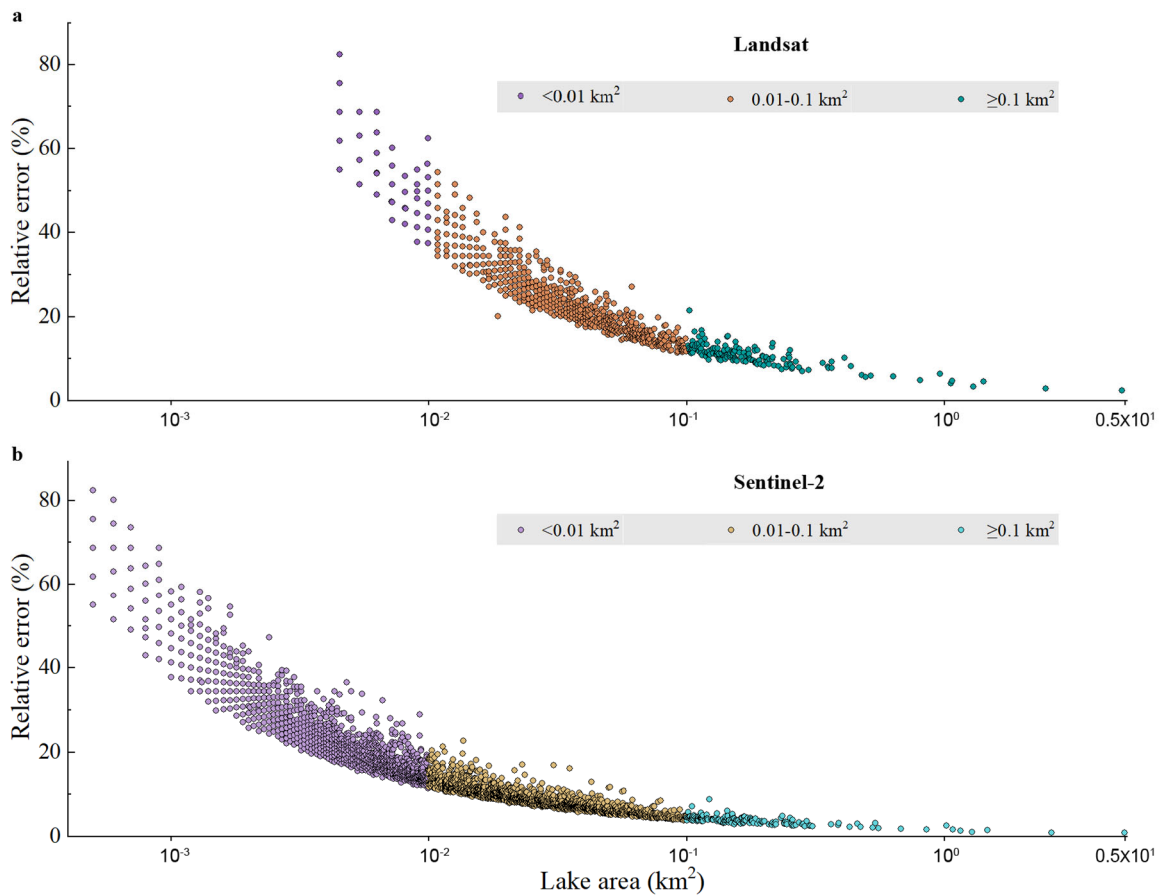

435 Note: Second column excludes 4969 (7.73 ± 2.62) lakes in the 0.0005 to 0.0045 km^2 range. Overlap % (%) represent the ratios
 436 between our Landsat-derived dataset and Sentinel-derived product in count and area, respectively.

437 6 Discussions

438 6.1 Uncertainty and error of lake mapping

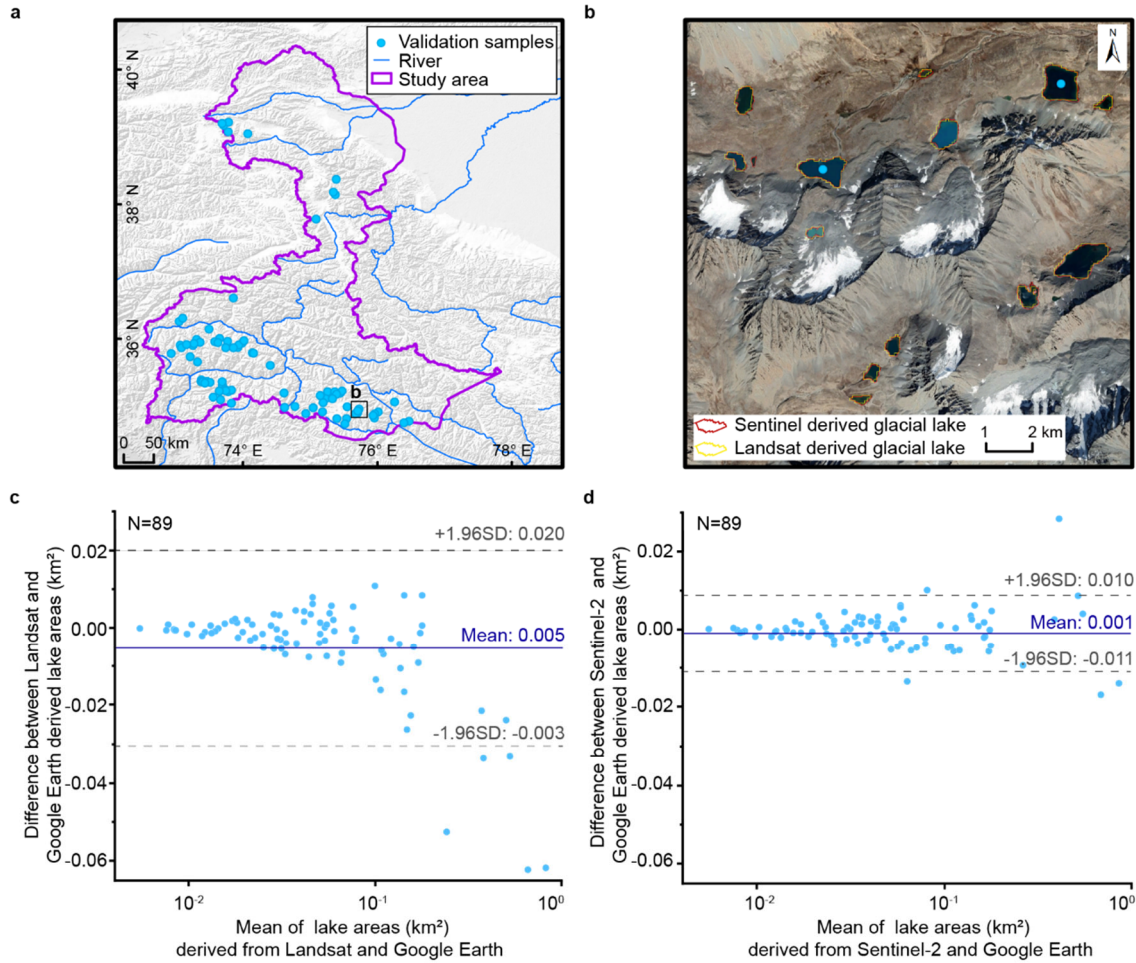

439 The uncertainty estimated from our improved equation shows that the relative error of
 440 individual glacial lake decreases when lake size increases or cell size of remote sensing
 441 images reduces (Lyons et al., 2013; Carrivick and Quincey, 2014) (Figure 8). Total area
 442 errors of glacial lakes in study area are approximate $\pm 14.98 \text{ km}^2$ and $\pm 8.45 \text{ km}^2$ in 2020 for
 443 Landsat and Sentinel-2 dataset, respectively, and the average relative errors are $\pm 17.36\%$ and
 444 $\pm 8.15\%$. Generally, small lakes have greater relative errors. For example, the mean relative
 445 error is 35.38% for Landsat derived glacial lakes between 0.0045 and 0.1 km^2 and 10.63% for
 446 glacial lakes greater than 0.1 km^2 . The mean area error of Sentinel-derived glacial lakes is
 447 almost one third of that extracted from Landsat images for glacial lakes of all or specific size
 448 groups. Because the relative error was estimated as a function of satellite image spatial
 449 resolution and lake perimeter, the calculated error for large lake is proportionally smaller than

450 that of small lake (Salerno et al., 2012) and the error for Landsat-derived lake is naturally
451 greater than that of Sentinel-derived lake at the same size group.
452

453
454 **Figure 8.** Estimated relative error for glacial lakes of all or specific size ranges in study area. Error
455 estimation is based on the modified equation and lake data extracted from Landsat (a) and Sentinel-2
456 images (b).

457
458 Our Landsat- and Sentinel-derived glacial lake dataset match well lake boundaries in Google
459 Earth higher resolution images (Figure 9). The mean difference in area is 0.005 km² between
460 Landsat and Google Earth derived lakes and 0.001 km² between Sentinel-2 and Google Earth
461 derived lakes, and major validation samples (84/89) are within the confidence interval of
462 95%, indicating a high accuracy in lake mapping (Figure 9c and d). The error of 89 sample
463 lakes is 5.48% in total area between Landsat- and Google Earth-derived data, and 0.61% for
464 Sentinel- and Google Earth-derived data. The median (\pm standard deviation) in discrepancy of
465 individual lake area is 7.66 \pm 4.96 % for Landsat- and Google Earth-derived data, and
466 4.46 \pm 4.62 % for Sentinel- and Google Earth-derived data. Our glacial lake dataset shows a
467 satisfactory mapping accuracy, although Sentinel-derived lake data performs more accurate
468 than those from Landsat images. We also validated the sampling Landsat-derived 89 lakes by
469 the existing Landsat-extracted lake data produced by Wang et al. (2020). A total of 83 lakes
470 are available in Wang's data with a mean difference of 0.005 km² in lake area (Figure A8).
471 This also shows an improvement of our lake product in contrast to the existing dataset.

472

473 **Figure 9.** Distribution of the validation sample (a), visual comparison of glacial lakes derived from
 474 Landsat and Sentinel-2 images overlaying Google Earth imagery (© Google Earth 2019) in a zoomed site
 475 (b), and differences between our glacial lake product (mapped from Landsat and Sentinel-2 images) and
 476 the validation reference (digitized from Google Earth images) (c and d).

477 **6.2 Comparison of Sentinel-2 and Landsat derived products**

478 Glacial lakes from Landsat and Sentinel-2 images have a high consistency in number and
 479 area with overlap rates from approximately 86% to 94% for all lakes greater than 0.0045 km²
 480 (Table 4), indicating a good potential for coordinated utility with Landsat archived
 481 observation (Figure 10). Lake extents extracted from Landsat and Sentinel images match well
 482 for various types and sizes (Figure 10 and Figure 11, Table 4). The best consistency rate
 483 reaches 94% for the glacial lakes between 0.1 km² and 0.2 km². The difference in area of
 484 glacial lakes extracted from Landsat and Sentinel-2 images generally lies within the
 485 uncertainty ranges.

486

487 **Figure 10.** High consistency of lake extents extracted from Landsat and Sentinel-2 images. Lake types
 488 shown include supraglacial (a), glacier-fed moraine-dammed (b), unconnected glacial-erosion lake without
 489 glacier melt supply (c) and glacier-fed moraine-dammed lakes (d).

490

491 Spatial resolution of satellite images plays a primary role in the discrepancies in count and
 492 area of glacial lakes extracted from Landsat (30 m) and Sentinel-2 (10 m) observations. Due
 493 to a finer spatial resolution, Sentinel-2 images can extract more glacial lakes and more
 494 accurate extents than those from Landsat images. We set the same 5 pixels as the MMU for
 495 both Landsat and Sentinel-2 images, which corresponds to a minimum area of 0.0045 km²
 496 and 0.0005 km², respectively. The minimum mapping area results in generating nearly 5000
 497 more lakes from Sentinel-2 images than from Landsat images, causing the greatest
 498 discrepancy in number (Table 4), such as Figure 11a. Small lakes such as supraglacial lakes
 499 play an important role in analyzing glacier evolution and supraglacial drainage systems (Liu
 500 and Mayer, 2015; Miles et al., 2018), implying a potential of our dataset to be applied in
 501 studies of glacier-lake evolutions. Meanwhile, Sentinel-2 images are able to depict
 502 boundaries of glacial lake with a lower uncertainty, as for some small islands and narrow
 503 channels (Figure 11b and c) were mapped from Sentinel-2 imagery that were unable to be
 504 detected in Landsat imagery.

505

506 In addition to the difference in image resolution, different acquisition dates between
 507 Sentinel-2 and Landsat images can also contribute to the discrepancy of those two glacial
 508 lake datasets. Acquiring same-day images from the two sensors were not always possible due
 509 to the impacts of cloud contaminations, topographic shadows, snow cover and revisit periods
 510 (Williamson et al., 2018; Paul et al., 2020). As exemplified in Figure 11d, the mapped glacial
 511 lake areas exhibit a substantial discrepancy, which is likely a joint consequence of both
 512 sensor difference and actual glacier lake dynamics that occurred during this short period of
 513 time. Despite our efforts of leveraging all available high-quality images, the overlap of
 514 acquisition dates between Landsat and Sentinel-2 images for the same location is relatively
 low (only 7 scenes of Sentinel-2 images or 112 glacial lakes in 2020) in this study area, and

515 the consequential temporal gaps led to a difference in the number and area of the derived
 516 glacial lakes.
 517

518
 519 **Figure 11.** Discrepancy of lake extents extracted from Landsat and Sentinel-2 images.
 520

521 6.3 Comparison with previous similar dataset

522 An increasing number of glacier lake datasets have been released over the past years, and
 523 most of them were produced from long-term Landsat archives. Regional glacial lake datasets
 524 using Sentinel images are scarce. Lack of Sentinel-derived glacial lake data in the study area
 525 makes it impossible to compare. Here we selected four available glacial lake datasets to
 526 compare with our Landsat-derived dataset.

527 We provide the latest glacial lake dataset (in 2020) and the most long-term 30-m Landsat
 528 observation (1990 to 2020) for this study, with a range of critical attributes including two
 529 types of classification systems. Within the same study area, our 2020 glacial lakes appear to
 530 be closest to the 2018 dataset produced by Wang et al. (2020), with the highest overlap of
 531 greater than 91% in count (Table 5). In Wang et al. (2020), the minimum mapping unit is 6
 532 pixels so their dataset has a less lake quantity. However, their dataset contains many large
 533 landslide-dammed lakes that are excluded in our glacial lake mapping. As a result, their total
 534 glacier lake area is greater than ours. The overlapping rates between Wang's glacial lakes
 535 (2020) in 1990 and ours are more than 83% in count. However, their results show a distinct
 536 increase of glacial lakes in number and area between 1990 and 2018 (Wang et al., 2020)
 537 whereas our data show a more stable change between 1990 and 2020. One possible reason is
 538 that manually delineating glacial lakes twice by different operators during Wang's lake
 539 mapping (2020) exacerbates the errors of mapping. Another reason is that their data contains
 540 landslide-dammed lakes that fluctuate greatly with time and expanded recently. One example
 541 is the Attabad Lake (Located at 36°18'22.33"N, 74°49'34.36"E).
 542

543

546 Note: MMU represents the minimum mapping unit that is possible to enable a valid comparison between our product and each
547 of the third-party datasets. * The MMU in the dataset of Zhang et al. (2015) is 3 pixels, finer than 5 pixels in our product, so a
548 MMU threshold of 5 pixels was used for this comparison. “% (%)” represents the ratios between the third-party dataset and
549 our product in count and area, respectively.

550
551 The second highest overlapping rate is approximate 59% for 2008 and 58% for 2017 in
552 count comparing with Chen’s data (Chen et al., 2021). Similarly, a minimum mapping unit of
553 55 pixels (50000 m²) in Shugar et al.’s, dataset (2020) led to lower overlap with less than 43%
554 in count and area. The dataset from Zhang et al. (2015) shows fewer glacial lakes in 1990 and
555 2000 even with a smaller MMU of 3 pixels. By inspecting their dataset, we attributed this
556 anomalous discrepancy to a range of glacial lakes that were missing due to lack of thorough
557 cross-check quality assurance during their manual delineation. Our Landsat derived glacial lake
558 dataset has been visually cross-checked over three time periods after the step of threshold-
559 based semi-automated lake mapping, and also been visually validated by Sentinel-2 derived
560 glacial lakes. Through this series of quality assurance, we aim at delivering one of the most
561 reliable multi-decadal glacial lake products for this study area.

562 Other factors, such as image quality and acquisition dates, mapping methods and quality
563 assurance workflow, might also lead to the discrepancies between the glacial lake datasets.
564 Despite such discrepancies, an increasing number of publically-shared datasets benefit
565 potential users to select the most suitable one for their objectives. Herein, we provide an up-to-
566 date glacial lake dataset derived from both Landsat and Sentinel-2 observations, which further

567 increased the availability of glacial lake dataset for water resource and GLOFs risk assessment,
568 predicting glacier-lake evolutions (Carrivick et al., 2020) in the context of climate change.
569

570 6.4 Limitation and updating plan

571 We would like to acknowledge several limitations of our glacier lake dataset, largely due the
572 availability of high quality satellite images in the study area and inadequate field survey data
573 (Wang et al., 2020; Chen et al., 2021). First, it is unlikely to collect enough good-quality
574 images within one calendar year for the entire study area due to high possibility of cloud or
575 snow covers. Even though the capacity of repeat observations for Landsat-8 OLI and
576 Sentinel-2 increased (Roy et al., 2014; Williamson et al., 2018; Wulder et al., 2019; Paul et
577 al., 2020), the 2020 glacial lake dataset has to employ images acquired in adjacent years
578 besides 2020. Most images used from Landsat and Sentinel-2 platforms were imaged in
579 autumn, and some images taken between April and July and in November also were
580 employed. Distribution and changes in glacial lakes primarily represent the characteristics
581 between August and October. Glacial lakes evolve with time and space (Nie et al., 2017), and
582 subtle inter- and intra-annual changes (Liu et al., 2020) for each time period were ignored.
583 Second, field investigation data are limited due to low accessibility of high mountain
584 environment in the study area, which restrained the accuracy in classifying the glacial lake
585 types. Although very high-resolution Google Earth images were utilized to assist in lake type
586 interpretation, occasional misclassification was unavoidable. We implemented two types of
587 classification systems based on a careful utilization of glacier data, DEM, geomorphological
588 features and expert knowledge. However, the lack of in situ survey prohibited a thorough
589 validation of the glacial lake types. Third, the rigorous quality assurance and cross check after
590 semi-automated lake mapping assure the quality of our lake dataset but are still time and cost
591 prohibitive. State-of-the-art mapping methods, such as deep learning method (Wu et al.,
592 2020), Google Earth Engine cloud-computing (Chen et al., 2021) and synergy of SAR and
593 optical images (Wangchuk and Bolch, 2020; How et al., 2021), would be used in the future to
594 balance product accuracy and time cost.

595 The glacial lake dataset will be updated using newly collected Landsat and Sentinel
596 images at a five-year interval or modified according to user feedbacks. The updated glacial
597 lake dataset will continue to be released freely and publicly on the Mountain Science Data
598 Center sharing platform.

599 **7 Data availability**

600 Our glacial lake dataset extracted from Sentinel-2 images in 2020 and Landsat observation
601 between 1990 and 2020 are available online via the Mountain Science Data Center, the
602 Institute of Mountain Hazards and Environment, the Chinese Academy of Sciences at
603 <https://doi.org/10.12380/Glaci.msdc.000001> (Lesi et al., 2022). The glacial lake dataset is
604 provided in both ESRI shapefile format (total size of 22.6 MB) and the Geopackage format
605 (version 1.2.1) with a total size of 9.2MB, which can be opened and further processed by
606 open-source geographic information system software such as QGIS.

607 **8 Conclusions**

608 Glacial lake inventories of the entire China-Pakistan Economic Corridor in 2020 were
609 provided based on Landsat and Sentinel-2 images using a threshold-based semi-automated
610 mapping method. Both Landsat and Sentinel-2 derived glacial lake dataset show similar
611 characteristics in spatial distribution and in the statistics of count and area. By contrast,
612 glacial lake dataset derived from Sentinel-2 images with a spatial resolution of 10 m has a
613 lower mapping error and more accurate lake boundary than those from 30 m spatial
614 resolution Landsat images whereas Landsat imagery is more suitable to analyze spatial-
615 temporal changes at a longer time scale due to its long-term archived observations at a
616 consistent 30 m spatial resolution starting from the late 1980s.

617 Glacial lakes in the study area remain relatively stable with a slight increase in number and
618 area between 1990 and 2020 according to Landsat observations. Our dataset reveals that 2154
619 glacial lakes in 1990 covering $85.1 \pm 14.66 \text{ km}^2$ increased to 2234 lakes with a total area of
620 $86.31 \pm 14.98 \text{ km}^2$. The same mapping method and rigorous workflow of quality assurance
621 and quality control used in this study reduced the error in multi-temporal changes of glacial
622 lakes.

623 The Hanshaw's error estimation method for pixel-based lake mapping was improved by
624 removing repeatedly calculated edge pixels that vary with lake shape. Therefore, the newly
625 proposed method reduces the estimated value of uncertainty from satellite observations. The
626 average relative error is $\pm 17.36\%$ for Landsat-derived product and $\pm 8.15\%$ for product from
627 Sentinel-2.

628 Our glacial lake dataset contains a range of critical parameters that maximize their
629 potential utility for water resource and GLOFs risk evaluation, cryosphere-hydrological and
630 glacier-lake evolution projection. The dual classification systems of glacial lake types were
631 developed and are very likely to attract broader researchers and scientists to use our datasets.
632 In comparison with other existing glacial lake datasets, our products were created through a
633 thorough consideration of lake types, cross checks and rigorous quality assurance, and will be
634 updated and released continuously in the Mountain Science Data Center. As such, we expect
635 that our glacial lake dataset will have significant value to cryospheric-hydrology research, the
636 assessment of water resource and glacier-related hazards in the CPEC.

637

638 **Appendix.** The appendix related to this article is available online.

639

640 **Author contributions.** ML and YN conceived the study, ML, YN and XD performed data
641 processing and analysis of the glacial lake inventory data, JW contributed to tool
642 development and mapping methods, ML and YN wrote the manuscript. All authors reviewed
643 and edited the manuscript before submission.

644

645 **Competing interests.** The authors declare no conflict of interest.

646

647 **Acknowledgements.**

648 We are grateful for the editor Kenneth Mankoff and three anonymous referees for their
649 constructive comments that greatly help us to improve this manuscript. This study was

656

657 **Appendix**

658 **Tutorial for Improved Uncertainty Estimating Method**

659
660 The Hanshaw’s equation was originally proposed for pixelated polygons (such as a polygon
661 directly extracted from a remote sensing image), and performed more robustly than manually
662 digitized polygons (where vertices do not necessarily follow the pixel edges). Our improved
663 method also performs better for pixelated polygons. This tutorial is dedicated to helping
664 implement our improved uncertainty estimation method.

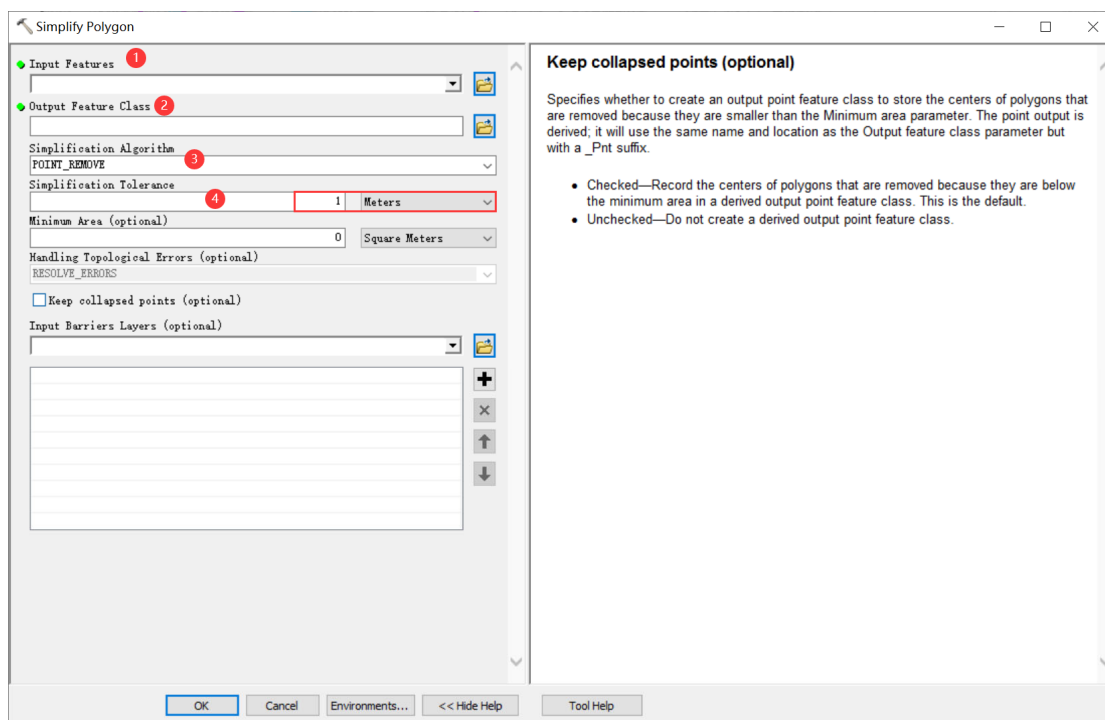

665
666 **Procedure of uncertainty estimating method (using ArcGIS (© ESRI) for example)**

667 1. Removing redundant nodes (optional)

668 We found that a small proportion (~1%) of the pixelated lake polygons (directly extracted
669 from satellite images) have redundant nodes, which affects the value of inner nodes. If no
670 redundant nodes exist, this step can be skipped. Or, we recommend using the “Simplify
671 Polygon” tool in ArcGIS to remove those nodes (Figure A1).

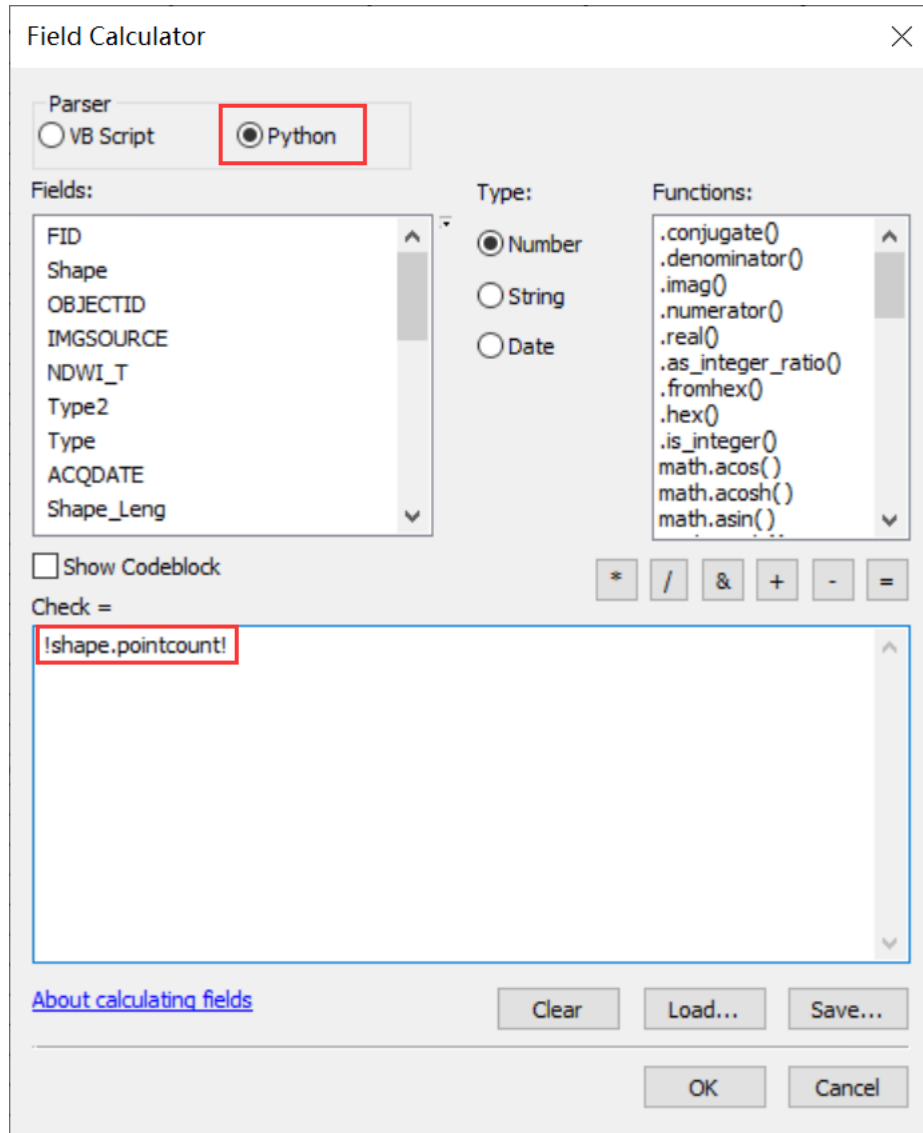

672 In the Simplify Polygon panel

- 673 • Input your dataset.
- 674 • Set the output path and output file name.
- 675 • Choose the simplification algorithm. We recommended “POINT_REMOVE”.
- 676 • Set the tolerance of simplification algorithm. In this step, we need to ensure that the
677 polygon boundaries remain unchanged after deleting redundant nodes. Generally, a
678 tolerance of 1 meter will suffice, or you can adjust the threshold until your satisfaction.

679
680 **Figure A1.** Input and option for Simplify Polygon in ArcGIS.
681

- 682 2. Calculating the total number of nodes using ArcGIS (Figure A2):
- 683 • Add a new field in the attribute table of dataset.
- 684 • Open Field Calculator.
- 685 • Switch the parser to python mode, and enter the following code “!shape.pointcount!” in
- 686 the blue box to calculate the total number of nodes for each glacial lake boundary.

687

688 **Figure A2.** Total node calculation in ArcGIS.

689

- 690 3. Calculating the number of inner nodes:
- 691

692 For polygons without islands (Figure A3), use the equation 5. An inner node is a polygon

693 vertex where the interior angle surrounding it is greater than 180 degrees. An outer node is

694 the opposite of the inner node, where the interior angle is less than 180 degrees. We found

695 that the outer nodes are usually four more than the inner nodes in our glacial lake dataset. The

696 total nodes in ArcGIS contain one overlapping node to close the polygon, meaning the

697 endpoint is also the startpoint. This extra count was deleted in the calculation (equation 5).

698

699
700 **Figure A3.** Sketch of outer and inner nodes of various glacial lakes without island.
701

702 For polygons with island (Figure A4) use the equation 6.
703

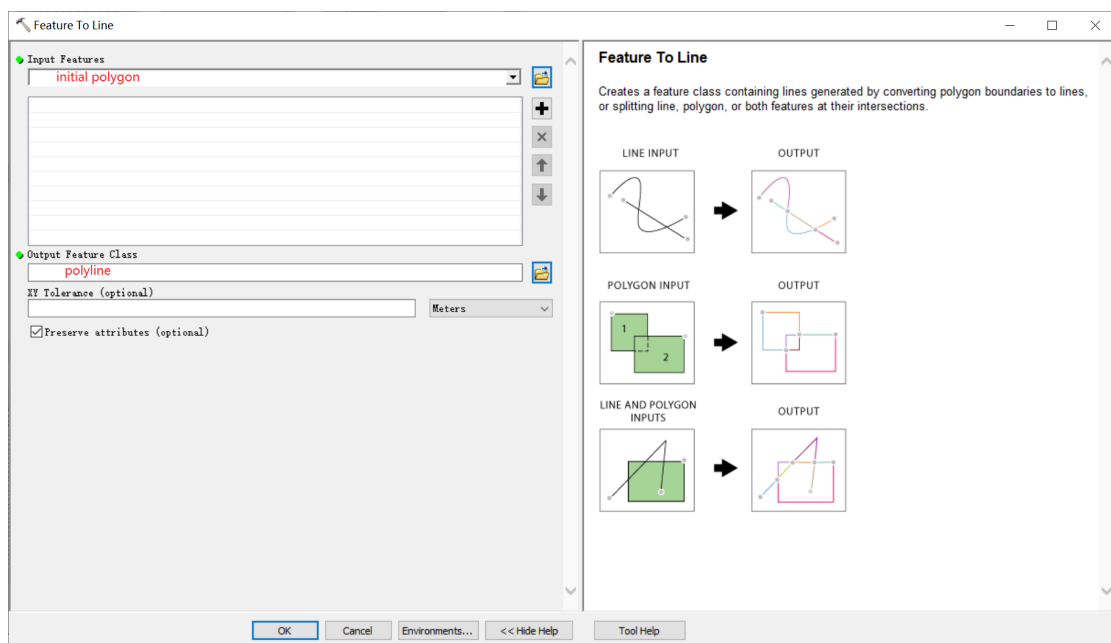

704
705 **Figure A4.** Sketch of outer and inner nodes for glacial lake with island.
706

707 We further specify the steps below to help implement equation 6.
708

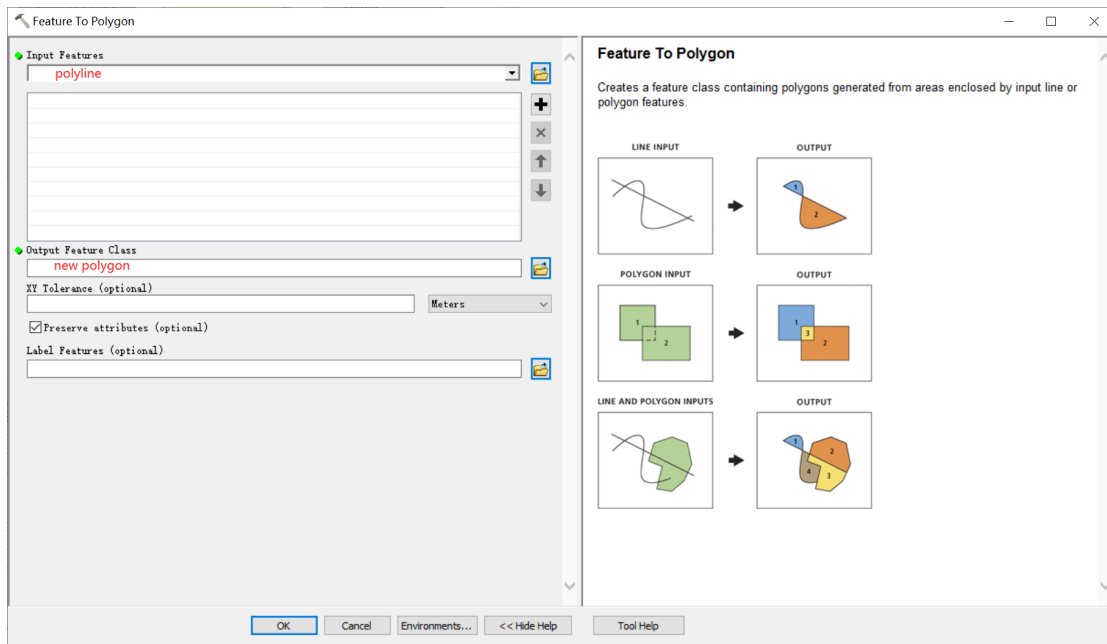

709 Sept 1: detect the number of islands within each polygon.
710

- Convert the initial lake polygon to polyline using the “Feature To Line” tool (Figure A5).

711
712 **Figure A5.** Feature To Line tool in ArcGIS
713

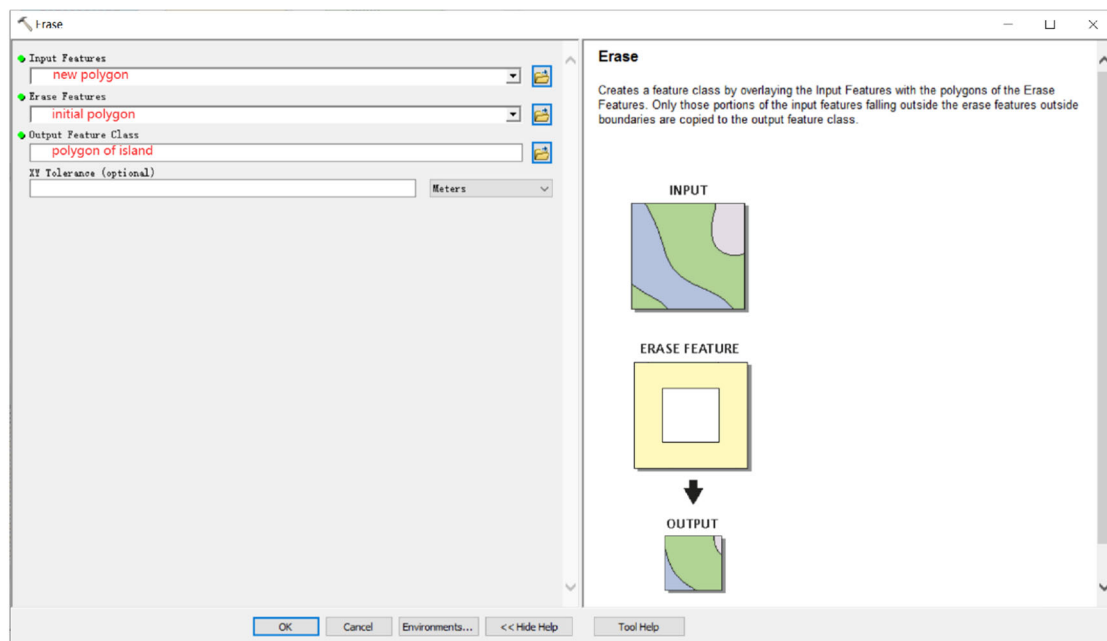

- 714 • Convert the polyline to generate a new polygon (Figure A6).

715
716
717
718
719

Figure A6. Feature To Polygon tool in ArcGIS

- Erase the new polygon by the initial polygon, which outputs the islands. Then we can count how many islands there are in each lake (Figure A7).

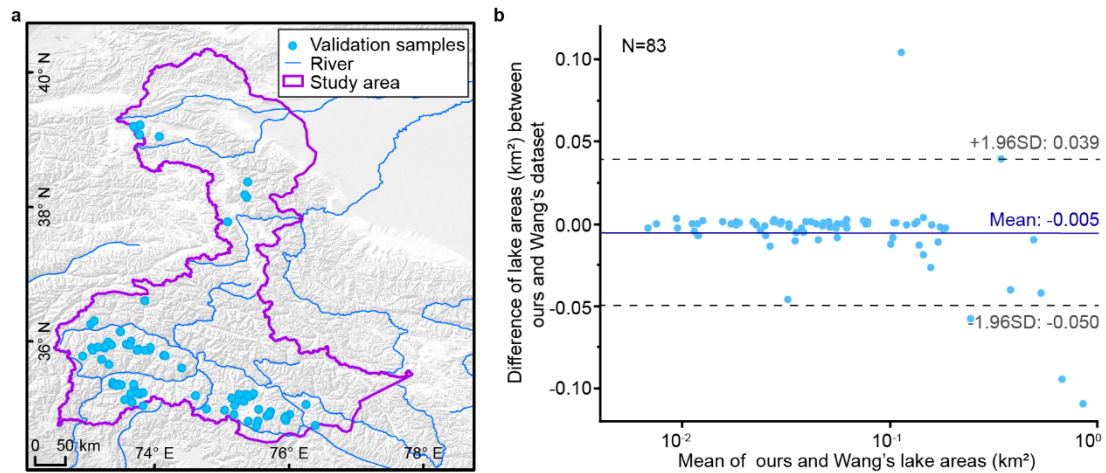

720
721
722
723
724
725
726

Figure A7. Erase tool in ArcGIS.

Step 2: calculate the number of inner nodes for each polygon with island using equation 6.

4. Calculating the uncertainty of lake mapping using equation 4.

727
 728 **Figure A8.** Distribution of validation samples (a) and comparison of glacial lakes (b) derived from our
 729 Landsat product in 2020 and Wang's lake data in 2018.
