31 **Abstract**

32 The African Tropics are hotspots of modern-day land-use change and are, at the same time, of  
33 great relevance for the cycling of carbon (C) and nutrients between plants, soils and the  
34 atmosphere. However, the consequences of land conversion on biogeochemical cycles are still  
35 largely unknown as they are not studied in a landscape context that defines the geomorphic,  
36 geochemically and pedological framework in which biological processes take place. Thus, the  
37 response of tropical soils to disturbance by erosion and land conversion is one of the great  
38 uncertainties in assessing the carrying capacity of tropical landscapes to grow food for future  
39 generations and in predicting greenhouse gas fluxes (GHG) from soils to the atmosphere and,  
40 hence, future earth system dynamics.

41 Here, we describe version 1.0 of an open access database created as part of the project  
42 **“Tropical soil organic carbon dynamics along erosional disturbance gradients in relation**  
43 **to variability in soil geochemistry and land use” (TropSOC)**. TropSOC v1.0 contains spatial  
44 and temporal explicit data on soil, vegetation, environmental properties and land management  
45 collected from 136 pristine tropical forest and cropland plots between 2017 and 2020 as part of  
46 several monitoring and sampling campaigns in the Eastern Congo Basin and the East African Rift  
47 Valley System. The results of several laboratory experiments focusing on soil microbial activity,  
48 C cycling and C stabilization in soils complement the dataset to deliver one of the first landscape  
49 scale datasets to study the linkages and feedbacks between geology, geomorphology and  
50 pedogenesis as controls on biogeochemical cycles in a variety of natural and managed systems  
51 in the African Tropics.

52 The hierarchical and interdisciplinary structure of the TropSOC database allows for linking a wide  
53 range of parameters and observations on soil and vegetation dynamics along with other  
54 supporting information that may also be measured at one or more levels of the hierarchy.  
55 TropSOC's data marks a significant contribution to improve our understanding of the fate of  
56 biogeochemical cycles in dynamic and diverse tropical African (agro-)ecosystems. TropSOC v1.0  
57 can be accessed through the supplementary material provided as part of this manuscript or as a  
58 separate download via the websites of the Congo Biogeochemistry observatory and the GFZ data  
59 repository where version updates to the database will be provided as the project develops.

60

61

## 62 1. Rationale to project TropSOC

### 63 1.1 Changing tropical environments in Africa

64 Tropical ecosystems provide many services of global importance. Tropical forests are among the  
65 largest terrestrial carbon (C) reservoirs and show some of the highest levels of biodiversity (Losos  
66 and Leigh, 2004; Pan et al., 2014). At the same time, tropical landscapes are among the most  
67 dynamic regions worldwide and hotspots of modern day land-use change (Hansen et al., 2013)  
68 as they have to provide food for some of the poorest yet fastest growing populations on the planet.  
69 In particular, the African continent is facing huge environmental and societal challenges with a  
70 projected population growth of 400% by the end of this century (Gerland et al., 2014), much of it  
71 happening in (sub-)tropical sub-Saharan Africa. In consequence, forested landscapes in tropical  
72 Africa are currently facing unprecedented levels of land conversion and land degradation,  
73 accompanied by decreasing soil fertility (UNESCO and WHC, 2010). At the same time, unlike  
74 other tropical regions of the world, where deforestation are driven by the extension of commodity  
75 plantations and commercial logging, much of the deforestation in tropical African countries is  
76 driven by smallholder farms that apply slash and burn practices for subsistence farming with little  
77 alternatives to provide food for their families (Curtis et al., 2018; Tyukavina et al., 2018). As a  
78 result, deforestation and soil degradation have accelerated greatly since the second half of the  
79 20<sup>th</sup> century with soil erosion, in particular, emerging as the main driver of soil degradation.

80 Today, erosion rates of tropical agricultural land globally are estimated at approx. 10.4 billion tons  
81 of soil per year and 0.2 billion tons of C per year. Tropical agricultural soil erosion represents  
82 therefore about half of the annual agricultural erosion globally, while only representing about one  
83 third of global cropland (Doetterl et al., 2012). An exemplary region to observe the consequences  
84 of land use change on soil resources and biogeochemical cycles in the tropical African region  
85 context is the African great lakes region along the East African Rift Valley System along the  
86 borders between the Democratic Republic of the Congo, Burundi, Rwanda and Uganda.

87 The region is a model for the complex interplay of socio-economic factors and their  
88 consequences for environmental systems in the Tropics. One of the highest human fertility rates  
89 globally (e.g. recent estimates for the last decade range from 7.3-7.7 children per woman in the  
90 province of South Kivu, Eastern DRC) (Dumbaugh et al., 2018) leads to massive population  
91 growth in the region, largely relying on local food and energy resources. Ridden by conflict and  
92 open warfare in the 1990s and early 2000s, population growth in the region is further aggravated

93 as a result of refugees from remote areas settling nearby safer, larger cities in the region  
94 (Kuijrakginia et al., 2010). In consequence, massive deforestation of upland forests for fuel  
95 gathering and cropland expansion is taking place (Hansen et al., 2013), leading to large erosional  
96 soil fluxes and consequential soil degradation threatening soil quality (Karamage et al., 2016).  
97 Once conversion to agricultural land takes place, soil conservation measures could counteract  
98 the loss of soil quality (Veldkamp et al., 2020). But these measures are rare in the Eastern Congo  
99 Basin due to poverty of subsistence farmers, socio-economic instability and a lack of  
100 governmental intervention (Heri-Kazi Bisimwa and Biielders, 2020). Soil tillage and harvesting  
101 further degrade the nutrient containing litter and topsoil layers. In consequence, fields often have  
102 to be abandoned after only a few decades of use and recover only poorly (Carreño-Rocabado et  
103 al., 2012; Ewel et al., 1991; Hattori et al., 2019; Heinrich et al., 2020; Kleinman et al., 1996;  
104 Lawrence et al., 2010).

## 105 **1.2 Tropical soils responding to disturbance**

106 With the expansion of cropland into forested landscapes soil erosion rates are expected to  
107 continue to increase. Soil erosion will undoubtedly impact biogeochemical cycles and change the  
108 input, storage and exchange of C between soils and atmosphere as well as the flux of nutrients  
109 between plants and soils in tropical systems in the region. To understand how tropical soils and  
110 ecosystems respond to erosional disturbance, it is necessary to consider the combined effects of  
111 climate, geology, topography, soil formation, biological processes and human disturbance. To  
112 date, no study on the interrelationship of these controls on biogeochemical cycles has been  
113 carried out in tropical ecosystems. However, studies carried out in other regions have shown that  
114 controls on soil C dynamics, for example, are highly interlinked (Doetterl et al., 2015a; Hobbey and  
115 Wilson, 2016; Nadeu et al., 2015).

116 Soil redistribution as a consequence of erosion also changes the functionality of landscape units.  
117 For example, soil degradation on hillslopes is matched by a rapid buildup of sediment deposits in  
118 valley bottoms, where C and nutrient rich soil is rapidly buried in subsoils under new sediments.  
119 While this consequence of deforestation can lead to an increase in the residence time of C due  
120 to slower microbial C turnover in buried soil (Doetterl et al., 2012; Alcantara et al., 2017), important  
121 nutrients are now lost to plants leading to a decrease in biomass productivity (Veldkamp et al.  
122 2020) and degraded tropical forests, lowering also microbial activity ~~generally negative for~~  
123 ~~microbial processes~~ in soils (Sahani & Behera, 2001). Soil redistribution is also known to change  
124 the temporal and spatial patterns of soil weathering and affects C stabilization. In agricultural

125 systems, the effects of this pressure can be observed very clearly: erosion removes weathered  
126 soil from eroding slopes but also brings the soil weathering front into closer contact with the C  
127 cycle (which occurs primarily in topsoils), thereby affecting CNP cycling and the stabilization of C  
128 with minerals in these systems (e.g. Berhe et al., 2012; Park et al., 2014; Doetterl et al., 2016).

129 Feedbacks on biogeochemical cycles between soil weathering, erosion will differ significantly not  
130 only between natural and disturbed systems, but also between systems with differing soil mineral  
131 reactivity. Recent advances have shown that mineral reactivity, constrained predominantly by soil  
132 weathering and the mineralogy of the soil parent material, has direct control over soil organic  
133 carbon, with climate exerting only indirect control through its impact on biogeochemical processes  
134 and matter fluxes (Doetterl et al., 2015a; Tang and Riley, 2015). However, the exact effects of  
135 mineralogy on the temperature sensitivity of microbial decomposer communities and the primary  
136 productivity of ecosystems have, to date, not been constrained (Hahm et al., 2014; Tang and  
137 Riley, 2015).

### 138 **1.3 Importance and outlook of research on the future of tropical biogeochemical cycles**

139 Tropical Africa is expected to experience great changes to both soil biogeochemical cycling and  
140 ecosystem level carbon (C) fluxes between soil, plants and the atmosphere, with unknown  
141 consequences for biogeochemical cycles. Despite decades of recognizing their importance,  
142 tropical soils remain among the least studied in the world (Mohr and van Baren, 1954; Mohr et  
143 al., 1972; Ssali et al., 1986; Juo and Franzluebbers, 2003). Although a more complete  
144 understanding on soil-plant coupling in tropical environments is critical, most of our process  
145 understanding on biogeochemical cycling between plant and soil is still derived from temperate  
146 regions. However, due to differences in their environmental setting and soil forming history, many  
147 tropical soil systems will likely react very differently to soil disturbance and land conversion than  
148 temperate soil systems. For example, temperate ecosystems can differ fundamentally in the way  
149 nutrients cycle and in the dominating and limiting factors for plant growth (Du et al., 2020). In  
150 contrast to soils in the temperate zone, long lasting chemical weathering has led to a massive  
151 depletion of mineral nutrients from soils in many tropical systems, although the remaining  
152 available nutrients are very efficiently re-cycled in natural tropical biospheres (Walker and Syers,  
153 1976; Vitousek, 1984). Hence, any loss of nutrients is therefore a critical disturbance with direct  
154 effects on the functioning of tropical (agro-)ecosystems. Recent studies highlight the importance  
155 of soil degradation and the change in chemical soil properties that follows land conversion on  
156 plant communities in tropical systems (Bauters et al., 2021), organic matter turnover by microbial

157 decomposers (Kidinda et al., 2020 in review; Bukombe et al., 2021 in review) and the stabilization  
158 of C and nutrients in soil of varying mineralogical properties (Reichenbach et al., 2021 in review).

159 Improving our process understanding on the ~~consequences~~ coupling between soil  
160 biogeochemistry and plant responses in the context of tropical land use changes ~~of land use~~  
161 ~~change on plant-soil interactions~~ will help to better constrain plant-soil interactions in ecosystem  
162 and land surface models. Furthermore, insights in plant- soil interactions can help and to better  
163 inform policy makers and stakeholders in improving land management practices.

#### 164 **1.4 Objectives and framework**

165 In the following we aim at providing an overview on the data collected by project TropSOC which  
166 is now available to the research community as an open access database. We give a brief  
167 description of the project's design before elaborating the structure of the database and its content.  
168 Note that beyond the overview information presented here, more details to methods and sampling  
169 designs for each assessed parameter is explained in great detail in the supplementary metadata  
170 files accompanying the database.

171 The main objective of project TropSOC was to develop a mechanistic understanding of plant and  
172 microbial process responses to changing soil properties in the African Tropics exemplified along  
173 land use, erosional and soil geochemical gradients studied in the Congo and the Albertine Rift.  
174 Trying to understand biogeochemical cycling affected by human activities in tropical (agro-  
175 )ecosystems as a whole, TropSOC had two main foci:

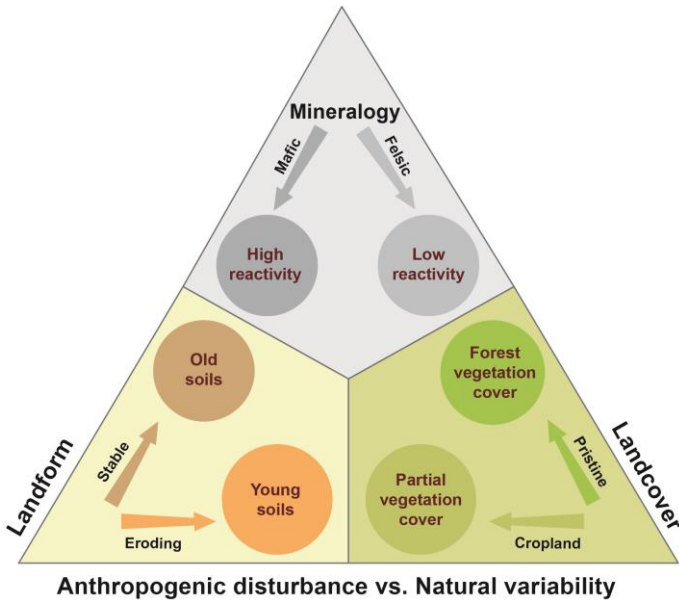

176 (i) investigate how nutrient fluxes and organic matter allocation between tropical soils, plants differ  
177 in relation to the controlling factors geochemistry, topography and land use.

178 (ii) investigate how the geochemistry of soils and their parent material control, interact with or  
179 mediate the severity of erosional disturbance on C cycling in tropical soils.

180 In order to address these objectives, project TropSOC investigates effects on tropical soil  
181 biogeochemical cycling and biological responses to variation in soil and environmental properties  
182 along three main vectors (Figure 1): (i) Mineralogy of parent material, since it may drive the the  
183 geochemical features of soils developed which control soil fertility and the potential of soils to  
184 stabilize organic matter and nutrients. (ii) Landform, since topography may influence water and  
185 soil fluxes, particularly erosional soil loss on slopes and soil deposition in valleys. (iii) Vegetation  
186 and land cover, since it may control the input to and extraction of organic matter from soil, and

187 respond to variation in soil properties and hydrology, as well as mediate the impact of rainfall to  
188 induce soil erosion.

189

**Figure 1.** Factorial design of the project TropSOC studying biogeochemical cycles in Central African tropical forest and agricultural landscapes in relation to mineralogy, landform and land cover types.

190 Conducted in one of the hotspots of Global Change, the Central African Congo Basin and African  
191 Great Lakes region the database described here is the foundation for several manuscripts  
192 published as a part of the 2021 special issue “*Tropical biogeochemistry of soils in the Congo*  
193 *Basin and the African Great Lakes region*” in SOIL Journal (Bukombe et al. 2021, in review;  
194 Kidinda et al. 2020; Summerauer et al. 2021 in review; Reichenbach et al. 2021 in review; Wilken  
195 et al. 2020 in review).

## 196 2. Study and sampling design

### 197 2.1 Study area - Climate, topography, land use

198 The study area of TropSOC is located in the eastern part of the Democratic Republic of the Congo,  
199 Rwanda and Uganda, in the border region between the Congo and the Nile basin (Figure 2). It is  
200 yet largely understudied (Schimel et al., 2015) despite its great significance for the global climate  
201 system (Jobbágy and Jackson, 2000, Amundson et al., 2015) and being confronted with rapid

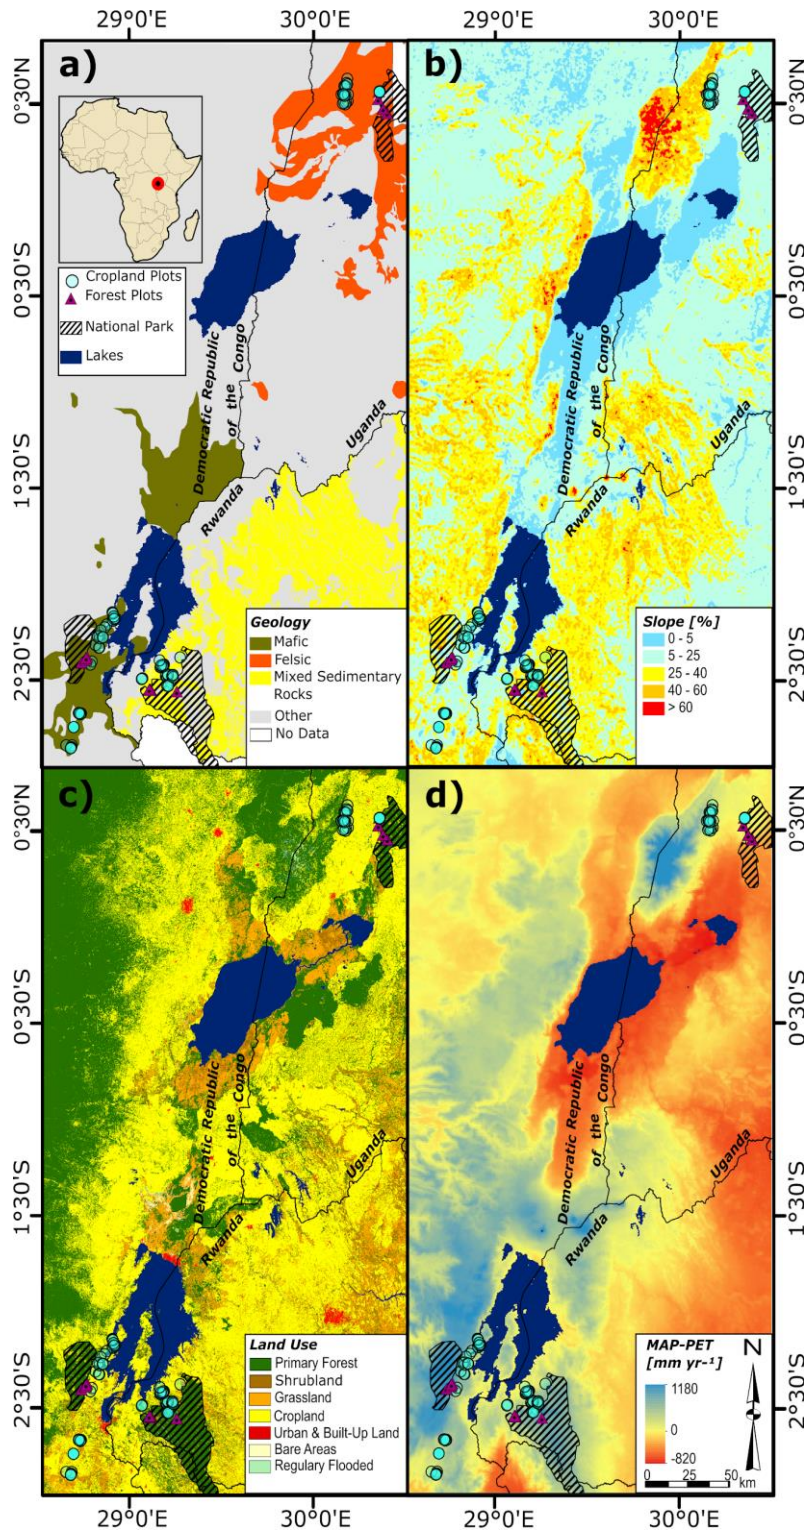

202 land conversion (Hansen et al., 2013) and forest degradation). The Climate of the study region is  
203 classified as tropical humid with weak monsoonal dynamics (Köppen Af - Am) and mean annual  
204 temperatures (MAT) ranging between 15.3 and 19.3 °C and mean annual precipitation (MAP)  
205 between 1498 and 1924 mm (Fick & Hijmans, 2017) with high potential erosivity (Fenta et al.  
206 2017) (Figure 2d).

207 As a part of the Eastern African Rift Mountain System, the active tectonism within the study region  
208 produced a hilly, patchy landscape with steep slopes up to 60% and soil parent material ranging  
209 from volcanic ashes to mafic and felsic magmatic rocks as well as a sedimentary rocks of varying  
210 geochemistry and texture (Schlüter 2006) (Figure 2a,b).

211 The study area is dominated by agricultural land use, with larger patches of protected, old growth  
212 closed canopy forest in highland areas (Figure 2c). Typical crops planted for subsistence farming  
213 are rotations of cassava (*Manihot esculenta*), maize (*Zea mays*) and a variety of legumes and  
214 vegetables. The dominant vegetation in all studied forests of the region is characterized as tropical  
215 mountain forest (Verhegghen et al. 2012; van Breugel et al. 2015). Note that while forest  
216 vegetation is thought to be largely spared from direct disturbance by human activities, large  
217 mammal populations (i.e. African forest elephants, Great Apes) became extinct or largely reduced  
218 due to hunting during the 20th century resulting in a massive increase in understory.

219

**Figure 2.** Overview of the study region with respect to major investigated factors: soil parent material geology and geochemical regions (a), slope steepness (b), land use (c) and climate (d).

## 221 **2.2 Study area - Geochemistry and soil types**

222 Within the study area three regions each representing a geochemical differing parent material for  
223 soil formation were determined. The first region (Figure 2a) is predominantly situated on mafic  
224 magmatic rocks, typically mafic alkali-basalts ranging in age between 9-13 Ma (Schlüter 2006),  
225 resulting from extinct (Mount Kahuzi) and active (Mount Nyiragongo) volcanic activities between  
226 the cities of Bukavu and Goma, Kivu, DRC. The second region is situated on felsic magmatic and  
227 metamorphic rocks typically consisting of gneissic granites ranging in age between 1600-2500  
228 Ma (Schlüter 2006) near the city of Fort Portal on the foothill of the Rwenzori Mountain range,  
229 Uganda. The third region is situated on a mixture of sedimentary rocks of varying geochemistry  
230 consisting of alternate layers of quartz-rich sandstone, siltstone and dark clay schists ranging in  
231 age between 1000-1600 Ma (Schlüter 2006) and spread across the Western Province of Rwanda  
232 in and around the district of Rusizi.

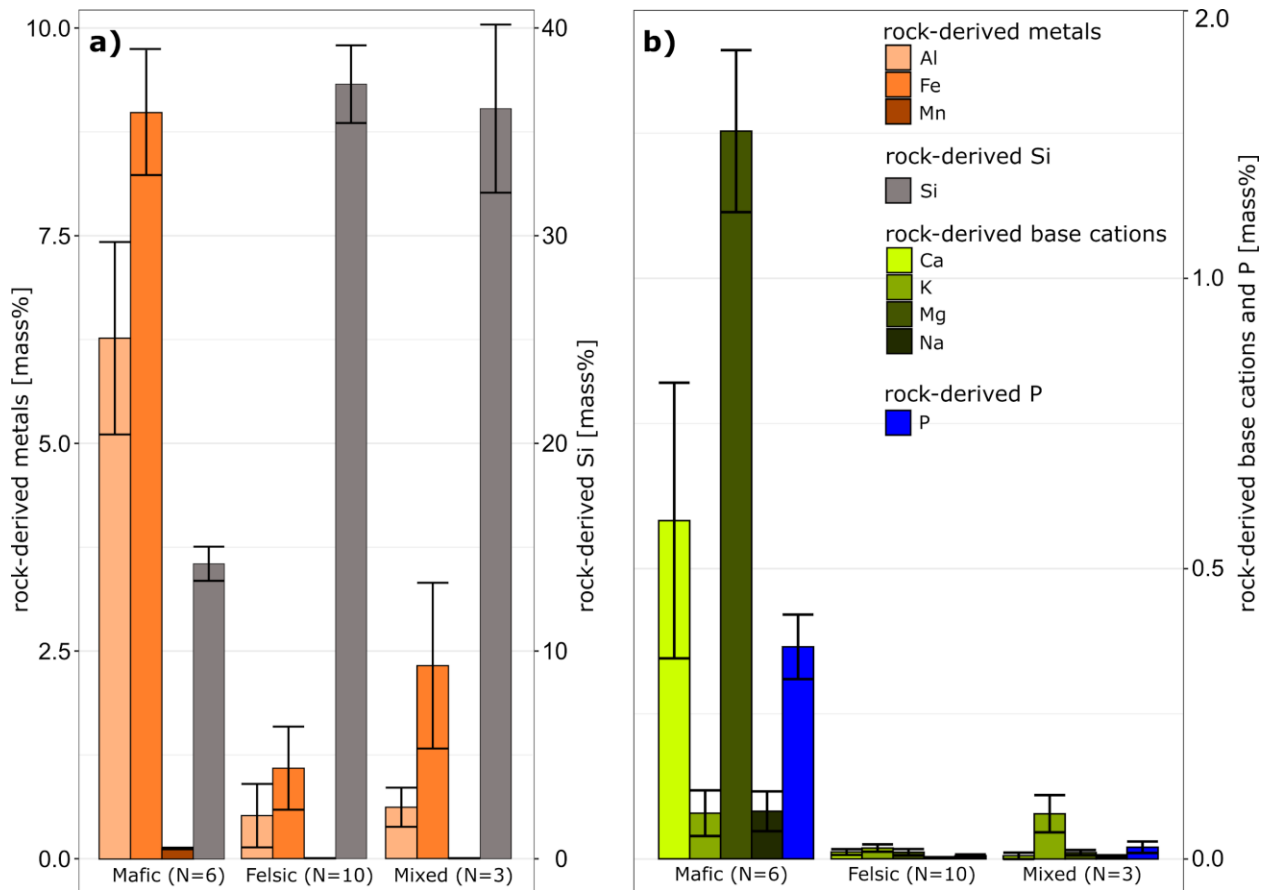

233 The dominant soil types of the study region are various forms of deeply weathered tropical soils  
234 (FAO, 2015). Potential ash deposition through the region's active volcanism occurs frequently,  
235 re-fertilizing soils to various degrees. Following World Reference Base (WRB) soil classification  
236 (IUSS WRB, 2015), soils in the mafic region can be described as umbric, vetic and geric Ferralsol  
237 and ferralic vetic Nitisol. Soils in the mixed sedimentary rock region and the felsic region can be  
238 described as geric and vetic Ferralsol. Soils in valley bottoms can locally show gleyic features,  
239 where the dominating soil types are variations of fluvic Gleysol.

240 Several striking differences in the elemental composition of the three parent materials can be  
241 noted. In the mafic region, bedrock is characterized by high iron (Fe) and aluminum (Al) content  
242 as well as a comparably high content of rock-derived nutrients such as base cations and  
243 phosphorus (P). The felsic and the sedimentary rock regions are characterized by lower contents  
244 of Fe, Al as well as lower rock-derived nutrients contents and characterized by higher Si content  
245 (Figure 3). A specific feature of the sedimentary site is the presence of fossil organic C in the  
246 parent material of soils ranging between 1.29 - 4.03% C. Fossil organic C in these sediments is  
247 further characterized by a high CN ratio (mean  $\pm$  standard deviation:  $153.9 \pm 68.5$ ), depleted in N  
248 and free of  $^{14}\text{C}$  (due to the high age of sedimentary rock formation). The elemental composition  
249 of soils at stable landscape position between the three regions retains the geochemical features  
250 of its parent material to some degree and illustrates the process of enrichment of metal oxy-  
251 hydroxides and the depletion of silica as a consequence of weathering. Generally, differences in  
252 the elemental concentrations between the three regions are less pronounced in soil (figure 4)

253 compared to differences in parent material (figure 3). Remarkably, levels of rock-derived nutrients  
 254 in soil, while overall depleted compared to the parent material, are comparably similar, potentially  
 255 indicating biological mechanisms that keep these important nutrients in the plant-soil system  
 256 against a general trend of leaching and depletion, typical for weathered, old and nutrient poor  
 257 tropical soils (Grau et al., 2017 and references therein).

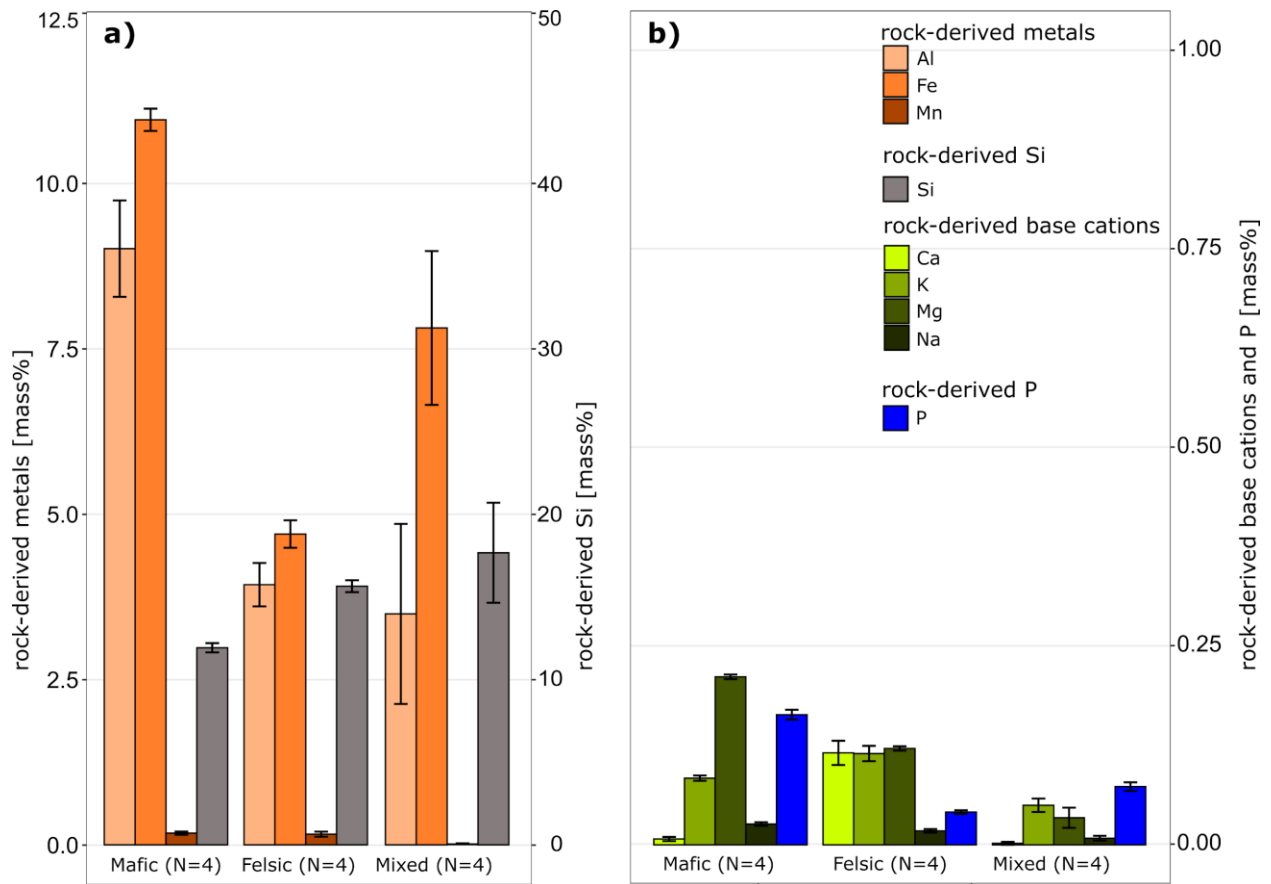

258

259

260

261 **Figure 3.** Chemical composition of unweathered rock samples representing the parent material  
 262 for soil formation in three studied geochemical regions (mean +/- standard error). Panel 3a shows  
 263 the distribution and concentration of rock derived aluminum (Al), iron (Fe) and manganese (Mn)  
 264 and total silica content (Si). Panel 3b shows the distribution and concentration of rock derived  
 265 calcium (Ca), potassium (K), magnesium (Mg), sodium (Na) and phosphorus (P). Note the  
 266 difference in scale on y axis between panel 3a and 3b.

267

268 **Figure 4.** Soil chemical composition of subsoil in stable, old growth closed canopy forests (no  
 269 erosion) in the three investigated geochemical regions (mean +/- standard error). The data  
 270 illustrates the convergence of elemental concentrations between the three regions as a result of  
 271 weathering and soil development. Abbreviations explained in figure 3. Note the difference in scale  
 272 on y axis between panel 4a and 4b.

273

274 In summary, the study region provides a unique combination of (i) near-pristine forest and  
 275 agricultural land use, (ii) steep terrain and heavy tropical precipitation with high erosion potential  
 276 and (iii) geologically diverse parent material for soil formation. These factors make the study  
 277 region ideal for identifying the importance of various controls on tropical soil biogeochemical  
 278 cycles.

279

### 280 **2.3 Overview ~~to~~-of plots and sampling design**

281 Plots were established along geomorphic gradients in old-growth closed canopy forest as well as  
 282 cropland in all three geochemical regions. Field campaigns to collect soil and plant samples at  
 283 136 forest and cropland plots along slope gradients (catena and stratified random approaches)  
 284 and additionally within several cropped nearby micro-catchments were carried out between March  
 285 2018 and July 2020. A detailed description on data quantity and quality can be found in the  
 286 metadata files accompanying the database and are briefly described in section 4.1 of this  
 287 publication. In order to cover potentially stable, eroding and depositional landforms, topographic  
 288 positions of plots ranged from plateaus (slope < 5%), over two slope positions (slopes between 9  
 289 and 60%) to valley positions (slopes < 5%) (Table 1).

**Table 1.** Topographic information of TropSOC plots across different geochemical regions and land use. Slope and altitude are displayed as minimum and maximum values. Each topographic position per geochemical region contains the range between 3-7 field replicate plots.

## 290 **2.4 Sampling design forest**

### 291 **2.4.1 Forest plot installation**

292 Sampling in forests followed a strict catena approach and plots were established following an  
 293 international, standardized protocol for tropical regions (Phillips et al. 2016). Within each  
 294 geochemical region, three plots covered by old-growth closed canopy tropical forest vegetation  
 295 (forest that developed a complex structure characterized by large, live and dead trees) were  
 296 established per topographic position as field replicates representing an area of 40 m x 40 m per  
 297 plot were established from February to June 2018. Each plot was subdivided in four 20 m x 20 m  
 298 subplots and a total of 36 forest plots were established this way (four topographic positions with  
 299 three replicate plots each in three geochemical regions). Note that three plots in the mafic region  
 300 had to be relocated due to safety reasons after the sampling period. For an overview on forest  
 301 plot sampling design see Figure 5a.

### 302 **2.4.2 Sampling mineral and organic soil layers**

303 At the time of plot installation, four replicate soil cores per plot (one in each subplot) were taken  
 304 in a depth-explicit way in 10 cm increments up to 1 m soil depth, and combined as composites  
 305 per plot. In addition, one soil profile pit was dug to a depth of 100 cm in the center of one of three  
 306 replicate plots (Figure 5) per topographic position in each geochemical region. These soil pits  
 307 were dug and described according to FAO guidelines (FAO, 2006).

308 Leaf litter (L horizon) and partially decomposed organic material in O horizons were sampled at  
 309 eight points along the border and in the center of each forest plot (Figure 5a) at the time of soil  
 310 sampling. At each sampling point, the thickness of the L and O horizon layer were measured with  
 311 a ruler and then sampled within a 5 cm x 5 cm square. When the litter layer was too thin (= no  
 312 closed coverage of forest floor with litter), the sampling square was expanded to a 10 cm x 10 cm

313 to retrieve enough sample material. The nine samples of each layer per plot were combined to  
314 one composite sample.

315 All collected composite samples were kept cooled until being brought to the laboratory (usually  
316 within 48 hours). In the laboratory, samples were oven-dried at 40°C for 48-96 hours and then  
317 weighed (accuracy: +/- 0.01 g). Derived soil parameters are detailed in section 2.7.

### 318 **2.4.3 Forest inventory and aboveground standing biomass**

319 In 2018, full inventories of the forest tree species and standing aboveground biomass (AGB) were  
320 conducted on all forest plots. The forest inventory followed an international, standardized protocol  
321 for tropical regions (Matthews et al., 2012). First, we identified the species of all living trees with  
322 a diameter at breast height (DBH, measured at 1.3 m above ground) greater than 10 cm in each  
323 plot. Second, these identified trees were classified into the following empirical DBH classes: 10 –  
324 20 cm, 20 – 30 cm, 30 – 50 cm and > 50 cm. Third, to estimate the above-ground biomass (AGB),  
325 we constructed stand-specific height diameter (H–D) allometric relationships using a  
326 representative subset of the plot-specific trees (Méchain et al., 2017). For this, 20% of all  
327 measured, specific trees were selected for height measurement, across the DBH range that was  
328 recorded per plot. Depending on the tree abundance of each DBH class, the height of three to  
329 five individual trees were then measured using a hypsometer (Nikon Laser Rangefinder Forestry  
330 Pro II, Nikon, Japan). AGB for each individual tree was then estimated using the allometric  
331 equation as described by Chave et al. (2014) for moist tropical forests. To estimate wood density  
332 data, we used species averages from the DRYAD global wood density database (Zanne et al.,  
333 2009). To extrapolate this information for the entire plot for all our sites, we applied a stand-  
334 specific height-diameter regression model; modelHD, available within the R package BIOMASS  
335 (Méchain et al., 2017). In a last step, aboveground standing biomass carbon stock was estimated  
336 assuming that that all samples standing biomass has a 50 wt.% share of C (Chave et al., 2005).  
337 A re-census was carried out in 2020, in order to detect changes in above-ground standing  
338 biomass and to determine tree mortality. Tree mortality rate ( $\lambda$ ) at each plot was assessed  
339 following Lewis et al. (2004), using inventories conducted in 2018 and 2020. Tree mortality rate  
340 was calculated for all tree stems with DBH>10cm in every plot.

### 341 **2.4.4 Canopy leaves**

342 To assess plant functional traits (leaf nitrogen, phosphorus, potassium, magnesium and calcium  
343 content) of living canopy leaves (see section 2.7), we sampled, at the beginning of the weak dry

344 season (December-February), sun-exposed shoots from the outer canopy of selected tree  
345 species that collectively make up 80% of the standing basal area per plot with the help of trained  
346 tree climbers and following a sampling protocol described in Pérez-Harguindeguy et al. (2016).  
347 For every tree species, we selected at least 3 individual trees, and a minimum of five and  
348 maximum of 17 trees per plot were sampled for mature, healthy-looking (= without signs of  
349 herbivory) individual canopy leaves. Where sampling of outer canopy leaves was physically not  
350 feasible, partially shaded leaves situated below the uppermost canopy were sampled.

## 351 **2.5. Sampling design cropland**

### 352 **2.5.1 Cropland plot installation**

353 Plots on cropland were established following a stratified random approach using the same slope  
354 classification and selection criteria as for forest sites. However, cropland plots belonging to the  
355 same geochemical region and topographic position were not connected along a hillslope catena.  
356 On cropland only fields that were currently covered by cassava were sampled. Cassava fields  
357 were chosen since cassava is one of the most important food crops in the region, harvested for  
358 both tubers and leaves. Rotations of cassava, maize, pulses and vegetables are common  
359 throughout the area and two harvests are possible per year. The main varieties of cassava on our  
360 sites were Mwabailon, Nabiombo, Mwamizinzi, Sawasawa (in Eastern DRC), Bukalasa,  
361 Shayidire, Gitamisi, Amaduda (in Rwanda), Sambati, and Mubalaya (in Uganda). Only fields  
362 without soil protection measurements (i.e. terraced systems) were sampled. For an overview on  
363 forest plot sampling design see Figure 5b.

### 364 **2.5.2 Soil sampling**

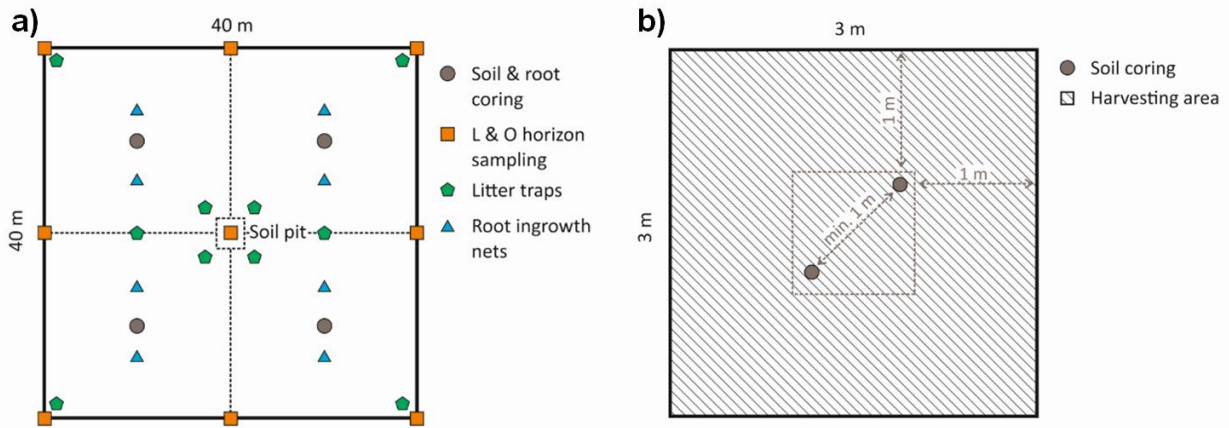

365 Soil sampling was carried out in the same way as for forest soils with the exception that only two  
366 cores were combined per plot taken within a 3 m x 3 m area to create depth explicit composite  
367 samples. A total of 100 cropland plots were sampled this way (Figure 5) with 3-7 field replicate  
368 plots per topographic position (plateaus, slopes, valleys) in each geochemical region. No L and  
369 O horizons were present in cropland, and no soil profile description was carried out. Derived soil  
370 parameters are detailed in section 2.7.

### 371 **2.5.3 Biomass and crop yield**

372 As part of the regional stratified random sampling design for cropland plots (see cropland plot  
373 installation), biomass from different cassava varieties was collected for 65 plots out of the 100

374 sampled cropland plots. Biomass was sampled shortly before harvest, approximately at the time  
 375 of the plant tuber's maximum development. The timing of harvest differed between 12 - 24 months  
 376 after planting depending on the variety and season. Within each plot, a 3 m x 3 m sampling area  
 377 was chosen close to the center of each field and all cassava plants in this area were counted and  
 378 harvested. The biomass of all plants was separated into leaves, stems and tubers. These parts  
 379 were then weighed separately and individually at the time of sampling (i.e. in a field moist state).

380  
 381 **Figure 5.** Overview on forest (a) and cropland (b) plot sampling design. Forest plots were  
 382 subdivided into four 20 m x 20 m subplots and one soil profile pit was established per topographic  
 383 position in each geochemical region for one of three replicate plots.

384 **2.5.4 Land use history and management assessment**

385 Farmers were sent a questionnaire to collect information on the land use and management history  
 386 of sampled fields following McCarthy et al. (2018). This questionnaire was completed for a  
 387 corresponding total count of 87 out of the 100 sampled cropland plots.

388 **2.6 Monitoring design**

389 **2.6.1 Micrometeorological data**

390 Three weather stations (ATMOS 41, Meter, Germany) were installed in August 2018 in each  
 391 geochemical region of project TropSOC close to the investigated forest catenae (mafic: latitude:  
 392 -2.324457° / longitude: 28.740818°; felsic: latitude: 0.561767° / longitude: 30.356808°, mixed  
 393 sedimentary rocks: latitude: -2.460503° / longitude: 29.095251°). An additional weather station  
 394 was installed in the mafic region near a cropland catchment, (latitude: -2.583984° / longitude:  
 395 28.715298°) which was selected for high-resolution erosion monitoring (see Wilken et al. 2021).

396 Furthermore, a meteorological station in the city of Bukavu (latitude: -2.499979°, longitude:  
397 28.845009°) and Lukananda (latitude: -2.344073°, longitude: 28.750937°) were put into  
398 operation. All stations collected data at a temporal resolution of 5 minutes on precipitation, air  
399 temperature, relative humidity and air pressure. Additionally, global radiation and wind speed  
400 were measured at stations Bukavu and Lukananda.

### 401 **2.6.2 Litterfall sampling**

402 Litterfall was assessed following a standardized protocol to measure tropical forest carbon  
403 allocation and cycling (Matthews et al., 2012). At each of our 36 forest soil sampled plots, 10 litter  
404 traps were installed and distributed evenly and systematically per plot. These had a diameter of  
405 60 cm each and were installed at a height of 1.0 m above ground. Litter samples were collected  
406 every two weeks for the period between August 2018 and February 2020 and later aggregated,  
407 to assess seasonal and annual variability in litter productivity and quality (see section 2.4).  
408 Collected litter included all organic residues collected by the traps. Larger, dead animals and  
409 woody material > 2 cm in diameter were discarded. After sampling, material from all 10 traps per  
410 plot was mixed to obtain a composite sample. These composite samples were taken to the  
411 laboratory the day of sampling, oven-dried at 70°C for 72 hours and subsequently weighed (dry  
412 weight, accuracy: +/- 0.01g). Data is provided as Mg ha<sup>-1</sup> day<sup>-1</sup> per plot and as the sum of total  
413 litter production per plot, aggregated at the seasonal level and annual level. The considered  
414 seasons were categorized based on the average precipitation for each period: weak dry season  
415 (December-February), strong rain season (March-May), strong dry season (June-August) and  
416 weak rain season (September-November).

417

### 418 **2.6.3 Belowground standing root biomass**

419 For all soil sampled forest plots, standing root biomass and fine root production were assessed  
420 from September 2018 to December 2019. Sampling took place once per season within this period  
421 (one coring every three months) and a total of three rain seasons and three dry seasons) in 2018  
422 and 2019 were covered. Each plot was divided into four equally sized subplots of 20 m x 20 m.  
423 Prior to deciding the root sampling strategy and size of depth intervals, root distribution was  
424 assessed using soil profiles that were dug in the plot centers for soil classification purposes. This  
425 assessment revealed that roots mostly dominated the organic horizons and the upper 50 cm of  
426 mineral soil (data not shown).

427

428 Belowground standing root biomass was sampled using a soil core sampler (Vienna Scientific  
429 Instruments, Austria). Two cores were sampled per subplot where undisturbed soil cores were  
430 divided into five depth layers: one organic soil layer (O horizon), and four mineral soil layers from  
431 0 – 10 cm, 10 – 20 cm, 20 – 30 cm, 30 – 50 cm. After transport to the laboratory, each sample  
432 was rinsed inside a 2 mm sieve; roots were separated into fine roots ( $\leq 2$  mm diameter) coarse  
433 ( $> 2$  mm diameter) using calipers. In addition, fine and coarse roots were separated into living and  
434 dead roots based on criteria such as color, root elasticity and the degree of cohesion of cortex,  
435 periderm and stele; i.a. roots were considered living when root steles were bright and resilient  
436 (Ostonen et al., 2005). The dry mass of isolated roots per plot was assessed after previously  
437 having dried the root samples at 70 °C for 72 hours. Data is provided as  $\text{mg cm}^{-3}$  per plot per  
438 sampling date and is also aggregated at the seasonal and annual level.

439

#### 440 **2.6.4 Fine root net primary production**

441 Fine root net primary productivity was assessed using the ingrowth net method following (Ohashi  
442 et al., 2016). Two net sheets (polyester mesh aperture size 2 mm, 10 cm wide, 20 cm high) were  
443 installed per subplot in a regular pattern with a distance of approximately 1 m between the two  
444 nets. Each net was vertically inserted in the top 20 cm of soil starting from the surface of the  
445 mineral layer. Nets were sampled every three months after installation and seasonally four times  
446 a year, from September 2018 to December 2019. Data is provided as  $\text{g m}^{-2}$  and  $\text{g m}^{-2} \text{day}^{-1}$  of  
447 total fine root production per plot over a certain period of time, and also provided aggregated at  
448 the seasonal and annual level.

449

#### 450 **2.7 Chemical and physical analyses**

451 A wide range of chemical and physical parameters were assessed for the sampled soil and plant  
452 material with the aim to (i) characterize indicators of soil redistribution, (ii) the degree of soil  
453 weathering, (iii) the physical structure of soil as well as (iv) soil fertility and (v) soil organic carbon  
454 characteristics in order to link them to (vi) functional traits of the sampled biomass, (vii) biomass  
455 production and (viii) land management. For a full overview of all assessed parameters including  
456 their assessment methods, please consult the metadata accompanying the database.

457 Among others, key measured parameters encompass:

458

459 ***Basic physical parameters***

460 - Soil bulk density

461 - Soil texture

462 - Soil water holding capacity

463 ***Basic chemical parameters***

464 - Soil pH (KCl)

465 - Soil potential cation exchange capacity and its base saturation

466 - Soil effective cation exchange capacity and its base saturation

467 - Main elemental composition of bulk soil (Al, Fe, Mn, Si, Ti, Zr, P) and the total reserve in  
468 base cations (Ca, Mg, Na, K) in rock parent material, soil, litter and vegetation samples

469 - Pedogenic oxides concentration (Al, Fe, Mn)

470 ***Available nutrients***

471 - Dissolvable soil organic nitrogen and carbon

472 - Plant available phosphorus in soil

473 ***Organic matter characteristics***

474 - Total and organic carbon and nitrogen content in rock parent material, soil, litter and  
475 vegetation samples

476 - Bulk soil radiocarbon signature

477 - CN ratio in soil, litter and vegetation samples

478 - Soil carbon stabilization mechanisms

479 **Microbial activity**

480 - Heterotrophic soil respiration (including isotopic signature of respired gas)

481 - Microbial biomass during incubation

482 - Extracellular enzyme activity during incubation

483 **Soil redistribution**

484 - <sup>239+240</sup>Pu activity

485 All of the parameters listed above have been measured in soil for three depth layers (0-10 cm,  
486 30-40 cm, 60-70 cm) representing distinct sections of the soil profile. Physico-chemical key  
487 properties of the remainder of soil samples in other soil layers have been assessed using mid-  
488 infrared spectroscopy and predicted following the workflow of Summerauer et al., 2021 in review).  
489 An overview of chemical and physical key soil parameters is provided in Appendix Table A1. Note  
490 that all physico-chemical soil properties and the corresponding mid-infrared data are part of the  
491 central African spectral library (Summerauer et al., 2021 in review) and minimize the need for  
492 future traditional soil analyses.

493

494 **2.8 Milestones reached**

495 Overall a total of approximately 2100 soil and rock samples were collected, of which about 10 -  
496 30% were used ~~yet~~ for yet more detailed analyses in different experiments by our group (see  
497 below). Additionally, 6000 above- and belowground biomass and litter samples were taken during  
498 several sampling and monitoring campaigns at forest and cropland sites. Several thousand and  
499 mid-infrared (NIR-MIR) spectra in the wavenumber range 600 cm<sup>-1</sup> to 7500<sup>-1</sup> (wavelength 1333.7  
500 nm - 16666.7 nm) were collected across the sampled plant and soil samples and were used to  
501 train calibration models for each property to predict spatially and depth explicit soil parameters in  
502 relation to soil fertility, carbon stocks and carbon stabilization using partial least square  
503 regressions following the workflow of Summerauer et al., (2021 in review). Furthermore, since  
504 2018, continuous monitoring has been carried out for the installed weather stations and vegetation  
505 dynamics in tropical forests have been assessed from August 2018 until December 2019. Water

506 and heat fluxes between soil and atmosphere are monitored using several weather stations and  
507 soil probes to monitor heat and water transfer into soil.

508 Analyses conducted on collected samples, so far, contributed to scientific advances realized  
509 through

510 - the creation of a data frame of reference samples for calibration used in the newly  
511 developed soil spectral library for central Africa (Summerauer et al., 2021 in review).

512 - an investigation on the role of geochemistry and geomorphic position for soil organic  
513 matter stabilization mechanism and patterns of SOC stocks in tropical rainforests  
514 (Reichenbach et al., 2021 in review).

515 - an investigation of the role of geochemistry and geomorphic position on the heterotrophic  
516 soil respiration (Bukombe et al., 2021 in review) as well as the role of adaptations of  
517 microbial communities and their strategies to access nutrients along the investigated  
518 forest gradients (Kidinda et al., 2020 in review).

519 - an assessment of the suitability and the application of radioisotope  $^{239+240}\text{Pu}$  inventories  
520 for studying soil erosion processes in tropical forests and cropland (Wilken et al., 2020 in  
521 review)

522 - soil fractionation and incubation experiments encompassing cropland soils along  
523 geomorphic and geochemical gradients (unpublished).

524 - as part of this manuscript, the entirety of TropSOC's data is available as an open-access  
525 database with extensive metadata documenting experimental approaches, framing of the  
526 analyses, data quality and methodology. An overview of all datasets presented in this  
527 database is given in Appendix Table A2.

528 In summary, TropSOC's first results demonstrate that even in deeply weathered tropical soils,  
529 parent material has a long-lasting effect on soil chemistry that can influence and control microbial  
530 activity, the size of subsoil C stocks, and the turnover of C in soil. Soil parent material and the  
531 resulting soil chemistry need to be taken into account in understanding and predicting C  
532 stabilization and turnover in tropical forest soils. Given the investigated rates of erosion on  
533 cropland, our findings confirm the threat of large losses of organic matter leading to sharp decline  
534 in soil fertility with little potential of soils to recover from nutrient losses naturally on decadal or

535 centennial timescales. TropSOC highlights that considering feedbacks between geochemistry  
536 and topography to understand the development of soil fertility in the African Great Lakes Region  
537 regions can significantly improve our insights into the role of tropical soils for reaching several key  
538 sustainable development goals such as climate mitigation and zero hunger and help to raise  
539 awareness for the need to maintain limited soil resources for future generations. Future work  
540 realized in project TropSOC based on the database will provide further insights into biomass and  
541 plant trait responses to soil geochemistry in forests, as well as cassava yield responses and SOC  
542 dynamics in cropland along the investigated geomorphic and geochemical gradients across the  
543 region.

### 544 **3. Structure of TropSOC project database (TropSOC v1.0)**

#### 545 **3.1 Database hierarchy**

546 Datasets are given as tab-delimited .csv files. For each .csv file the metadata describing data  
547 structure and assessment methods are given in a .pdf file of the same name. Moreover, additional  
548 .pdf files for each main section of the database (basic information, forest, cropland, and  
549 microscale meteorology) are given, providing an overview of the structure within each section.  
550 Note that the '**basic information**' section of the database provides the linkages between  
551 individual data, e.g. from soil analysis and the location and/or soil depths where these samples  
552 were acquired (for linkages see also Figure 6).

553

554

555 **Figure 6.** Overview of linkages between datasets in the TropSOC database v1.0. Note that for  
 556 each data .csv-file an .pdf-file is given detailing the metadata of the respective data sheet.

557

558

559

560

## 561 **3.2 Database infrastructure**

### 562 **3.2.1 Basic information**

563 The database comprises basic information of all plots and single point sampling positions where  
564 data were collected during project TropSOC. An overview of the structure of the database is  
565 presented in Appendix Table A2. The basic information of the database is structured in the  
566 following way:

567 **Part 1** – Location and basic background information for all plots and points where data were  
568 collected. Data can be found in file *11\_plots\_points.csv*, with description given in  
569 *11\_plots\_points.pdf*.

570 **Part 2** – Sample identifier for the database' internal connection between location of plots, points  
571 and soil data from different soils depths as well as vegetation data. Data is stored in  
572 *12\_sample\_identifier.csv*, with description given in *12\_sample\_identifier.pdf*.

573 The key element to link all datatables for which data was collected and samples analyzed is the  
574 plot ID and its derivative the sample ID. This identifier allows to link the results from sample  
575 analysis with the locations given in *11\_plots\_points.csv*. This results in a n:1 connection between  
576 *12\_sample\_identifier.csv* and *11\_plots\_points.csv*. See metadata file *11\_plots\_points.pdf* for an  
577 overview on the structure of the plots ID and *12\_sample\_identifier.pdf* for an overview on the  
578 structure of the sample ID.

579

### 580 **3.2.2 Forest**

581 TropSOC's forest data consists of seven parts (Table A2 for overview) structured as paired *.csv* /  
582 *.pdf* files, containing the data (*.csv*) and accompanying metadata (*.pdf*) describing parameters  
583 and methods. Additionally, an overview to all collected forest data is given in file *2\_forest.pdf*.

584 **Part 1** – Above and belowground vegetation data acquired in 2018, 2019 and 2020 at all forest  
585 plots, comprising 13 data sets (Dataset files 2.1.1 - 2.1.13).

586 **Part 2** – Mineral soil layer data acquired in 2018 at all forest plots, comprising 3 data sets (Dataset  
587 files 2.2.1 - 2.2.3).

588 **Part 3** – Organic soil layer data acquired in 2018 at all forest plots, comprising 1 data set (Dataset  
589 file 2.3).

590 **Part 4** – <sup>239+240</sup>Pu soil inventory carried out in 2018. In contrast to part 1 to 3 of the forest data, Pu  
591 data represents individual points and does not follow the plot concept in a strict manner (Dataset  
592 file 2.4).

593 **Part 5** – Soil experiments carried out from 2018 to 2020, comprising 3 data sets with results from  
594 laboratory soil incubation and fractionation experiments and additional data from soil sample  
595 analyses (Dataset files 2.5.1 - 2.5.3).

596 **Part 6** – Parent material elemental composition analysed based on unweathered rock samples  
597 taken within plots or from nearby road cuts and mines surrounding the study sites (Dataset file  
598 2.6).

599 **Part 7** – Soil profile descriptions done in soil pits at the centre of plots following WRB-FAO soil  
600 description (Dataset file 2.7).

601

### 602 **3.2.3 Cropland**

603 TropSOC's cropland data consists of the following seven parts (Table A2 for overview) structured  
604 as paired .csv / .pdf files, containing the data (.csv) and accompanying metadata (.pdf) describing  
605 parameters and methods. Additionally, an overview to all collected cropland data is given in file  
606 *3\_cropland.pdf*.

607 **Part 1** – Biomass and management data acquired in 65 and 87 out of 100 sampled cropland plots  
608 respectively, comprising 2 datasets (Dataset files 3.1.1 - 3.1.2).

609 **Part 2** – Data on mineral soil layers was acquired in 2018 for 100 cropland plots and comprising  
610 3 datasets (Dataset files 3.2.1 - 3.2.3).

611 **Part 3** – Pu soil inventory carried out in 2018. In contrast to part 1 and 2 of the cropland data, Pu  
612 data represents individual points and not plots and was sampled across several catchments  
613 (Dataset file 3.3).

614 **Part 4** – Soil experiments. This part of the database comprises 2 datasets with results from  
615 laboratory soil incubation and fractionation experiments and additional data from soil sample  
616 analyses (Dataset files 3.4.1 - 3.4.2).

617

### 618 **3.2.4 Meteorological data**

619 The meteorological data comprises 4 parts (Table A2 for overview) structured as paired .csv / .pdf  
620 files containing the data (.csv) and accompanying metadata (.pdf) describing parameters and  
621 methods:

622 **Part 1:** Locations of meteorological stations: Coordinates, elevations and contact addresses for  
623 the respective data (Dataset file 4.1).

624 **Part 2:** Daily meteorological data: six meteorological stations recording precipitation, air  
625 temperature, relative humidity, air pressure, solar radiation, wind speed (Dataset file 4.2).

626 **Part 3:** High resolution five-minute triggered precipitation data: Precipitation recorded at the time  
627 of tipping bucket tilt at a resolution of five-minutes resolution (Dataset file 4.3).

628

## 629 **4. Database status**

### 630 **4.1 TropSOC v1.0**

631 The current version, v1.0, of TropSOC includes several thousand individual plant and soil samples  
632 collected across 136 sites spanning cropland and forests in the East African Rift Valley System  
633 and a large variety of parameters. A total of 36 .csv datasheets is available that gives all analyses  
634 done for specific samples. Datasheets are structured according to the descriptions given in  
635 section 3 and described and elaborated on in the accompanying metadata files. The current  
636 distribution of data points across the various levels of the database hierarchy is shown in Table  
637 2. All individual data entries present in the database have passed quality control done by experts  
638 that were involved in the creation of the data. Where applicable, reports on the quality assessment  
639 of each parameter can be found in the metadata .pdf files accompanying the .csv files.

640 **Table 2.** Overview on the current number of data points in TropSOC v1.0 on plant, soil and  
641 meteorological and their affiliation to the hierarchical levels forest and cropland. Numbers in tables  
642 refer to the number of data entries at the lowest available aggregation level (= highest resolution  
643 of data). For details on parameters, see the according metadata descriptions. Note that in the  
644 felsic (Uganda) and mixed sediment region (Rwanda) collected weather station data represents  
645 both cropland and forest while separate stations were available for the two land cover classes in  
646 the mafic region (DRC). Abbreviations: SOM = Soil organic matter.

Plant-Soil observations	Plots	Bulk soil samples (0-100 cm soil depth, 10cm increments)	Bulk Vegetation samples (above/belowground)	Incubated soil layers	SOM fractionated soil layers	Plots with vegetation assessments
Forest	36	916	1437/4374	112	145	40
Cropland	100	1190	132/66	131	159	65
<b>Total</b>	<b>136</b>	<b>2106</b>	<b>1569/4400</b>	<b>243</b>	<b>304</b>	<b>105</b>
Meteorological observations	Stations	Precipitation	Air temperature	Relative humidity	Global Radiation	Wind speed
Felsic region	1	541	541	541	0	0
Mafic region (forest)	1	674	858	860	860	644
Mafic region (cropland)	3	1310	1310	1312	709	650
Mixed sediment region	1	90	520	565	0	0
<b>Total</b>	<b>6</b>	<b>2615</b>	<b>3229</b>	<b>3278</b>	<b>1569</b>	<b>1294</b>

647

648 **4.2 Accessing TropSOC v1.0 and reporting issues/ask questions to its hosting platform**649 **CBO**

650 Users may access the TropSOC database v1.0 and its supporting information through the  
651 supplementary material provided as part of this submission. Version v1.0 of the database is also  
652 available through the data download section of the Congo Biogeochemistry Observatory (CBO)  
653 (<https://www.congo-biogeochem.com/data>) and the PANGEA open access environmental data  
654 repository. CBO is a consortium of researchers who study biogeochemical cycles and  
655 atmosphere-plant-soil interactions in tropical Africa with a focus on the Congo Basin and the  
656 African Great Lakes region (Doetterl et al. 2020). Within CBO's framework, a multinational group  
657 of young scientists from Africa, Europe and the United States conducts cross-disciplinary  
658 environmental research across tropical Africa but with focus on the Congo basin. The dedication  
659 of young African researchers to understand and preserve the threatened natural resources of  
660 their home countries is paired with the resources of some of the most experienced and largest  
661 research groups focusing on African tropical forest and agroecosystems. Founded in 2018 by  
662 scientists of several African and European institutions and support by multinational organization  
663 such as [the International Institute of Tropical Agriculture \(CGIAR-IITA\)](#) and [the World Agroforestry](#)  
664 [Centre \(CGIAR-ICRAF\)](#), CBO has become an important scientific network in tropical Africa for  
665 studying biogeochemistry in soils and sediments creating synergies between local key institutions  
666 and international researchers, crucial for the implementation of research in remote and difficult to  
667 access environments. Research at CBO is funded and supported by German, Belgian, US and  
668 Swiss Research foundations and linked to research institutes at Ghent University, Augsburg  
669 University, Florida State University, ETH Zurich, the University of Louvain and the Max Planck  
670 Society.

671 Users are encouraged to provide feedback and corrections to existing data if problems are  
672 discovered by contacting CBO ([contact@congo-biogeochem.com](mailto:contact@congo-biogeochem.com)) or the corresponding author  
673 of this manuscript ([sdoetterl@usys.ethz.ch](mailto:sdoetterl@usys.ethz.ch)). Corrections will be implemented in consecutive  
674 versions of the database that can be downloaded via the CBO site.

#### 675 **4.3 Consecutive database versioning and archiving**

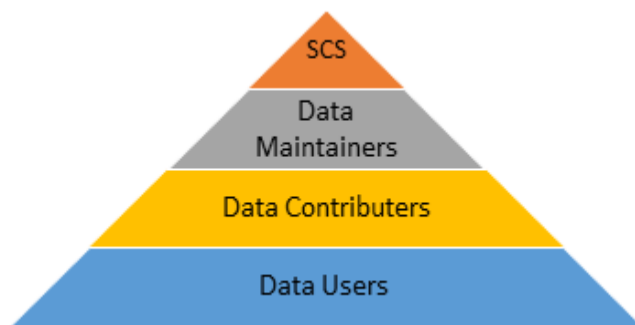

676 Updated versions of the database will be periodically released following either substantial  
677 changes or new peer-reviewed publications, leveraging the dataset. Versioning of these official  
678 releases are tracked using an associated version number, e.g. TropSOC v1.0, and so on. These  
679 official releases will be archived at ETH Zurich's Research collection via ETH's Soil Resources  
680 Group (<https://soilres.ethz.ch/>) and the CBO data storage ([https://www.congo-  
681 biogeochem.com/data](https://www.congo-biogeochem.com/data)) with a dataset DOI issued for each release via ETH Zurich so that users  
682 may revert back to the earlier version if so required. These archived releases will be maintained  
683 into perpetuity to facilitate reproduction of any analyses conducted using a past version of the  
684 database. When accessing the dataset and using it for own research, users commit to cite the  
685 original manuscript provided here in addition to the version number, DOI and any description  
686 provided to future versions of the database (see section 6 for details).

#### 687 **5. Database governance and participation**

688 TropSOC is a community effort with multiple contributors operating at different levels (Figure 7).  
689 Governance of TropSOC is required in order to ensure continuity of services and to plan for the  
690 future evolution of this data repository. Studying the rapid environmental changes to the African  
691 Tropics is a central research objective for the scientists of the Congo Biogeochemistry  
692 Observatory (CBO) making it the ideal body to govern future versions of TropSOC. The  
693 governance structure of TropSOC is briefly described in Figure 7. While the TropSOC core team  
694 is responsible for the original version of the database, its maintenance, management and  
695 archiving, scientists involved in the Congo Biogeochemistry Observatory (CBO) oversee the  
696 establishment of cooperative agreements on the long term and act as a steering committee for  
697 modifications on TropSOC suggested by the research community. The main role of the steering  
698 committee is to determine the feasibility of major changes to TropSOC proposed by the  
699 community and to coordinate activities that would like to build upon TropSOC or continue similar  
700 research work within the framework of CBO. Although the structure of TropSOC is oriented  
701 around individual and research projects, the nature of scientific research is often more group-

702 focused. For example, teams of researchers generally work together to seek out funding and to  
703 conduct research. Thus, in some cases a group or team of individuals may seek to utilize or  
704 modify TropSOC for their purposes. Such groups can petition the scientific steering committee to  
705 be formally designated a CBO member group. Approved organizations should nominate a  
706 member to serve on the steering committee.

707 Interested researchers are also invited to contribute data to future versions of TropSOC in order  
708 to grow the database. Anyone can be a data contributor provided they agree to the terms of use  
709 and follow the proper steps for contributing data to TropSOC. If such suggestions arise, the CBO  
710 steering committee together with the TropSOC core team are responsible for approving the  
711 suggested changes and additions to the database. Upon approval, the TropSOC core team will  
712 interact with the new data contributors to implement the suggested data additions. In the case of  
713 organizations or individuals making larger changes or additions to TropSOC, a designated data  
714 maintainer from new contributor groups is required to coordinate the technical aspects of the  
715 implementation of changes together with the TropSOC core team. Within the pool of data  
716 contributors, individuals with significant experience working with TropSOC may be designated,  
717 either by the steering committee or database maintainers, as expert reviewers. These individuals  
718 are tasked to assist maintainers and oversee peer review and quality assessment of contributed  
719 new entries.

720

721 **Figure 7.** A simplified depiction of the TropSOC governance. The scientific steering committee  
722 (SCS) is responsible for approving major management decisions. The TropSOC core team as  
723 data maintainers are responsible for implementing broader changes together with new data  
724 contributors. All interested scientists are welcome to contribute data to future versions of the data  
725 base or access the data for their own research.

## 726 6. Data Availability and User Guidelines

727 All data presented in this study is part of the publication and added as a supplement consisting of  
728 datatables (.csv) and accompanying metadata descriptions (.pdf files). In addition, the database  
729 and its metadata is archived and published in the open access environmental and geoscience  
730 data repository at the German Research Centre for Geosciences (GFZ), accessible at:  
731 <https://doi.org/10.5880/fidgeo.2021.009>. Please note that the database DOI is currently in  
732 preparation and will be released as soon as the review process is completed. In the meanwhile,  
733 please use the following link to access the database (version 1.0) or consult the supplement  
734 added to this submission:

735 [https://dataservices.gfz-](https://dataservices.gfz-potsdam.de/panmetaworks/review/efed3d5f6035ca261a95aaab45704c2d7d69ac1219d4abd3773d5f104a4900d3/)  
736 [potsdam.de/panmetaworks/review/efed3d5f6035ca261a95aaab45704c2d7d69ac1219d4abd3773](https://dataservices.gfz-potsdam.de/panmetaworks/review/efed3d5f6035ca261a95aaab45704c2d7d69ac1219d4abd3773d5f104a4900d3/)  
737 [d5f104a4900d3/](https://dataservices.gfz-potsdam.de/panmetaworks/review/efed3d5f6035ca261a95aaab45704c2d7d69ac1219d4abd3773d5f104a4900d3/)

738 Additionally the database is accessible via the website of the Congo Biogeochemistry Repository  
739 (<https://www.congo-biogeochem.com/data>). Updated versions of the database will be made  
740 available as version updates at both repository.

741

742 As detailed above, TropSOC is an open source project that provides several ways for  
743 participation. Anyone may share the TropSOC dataset provided they do so in accordance with  
744 the Creative Commons Attribution 4.0 International Public License  
745 (<https://creativecommons.org/licenses/by/4.0/legalcode>) and by citing the according references  
746 of the original database description and future modifications under their separate DOI.

747 In addition, we strongly encourage TropSOC users to follow these simple guidelines for use:

748 (1) TropSOC users must agree not to manipulate the original source data without permission of  
749 the TropSOC governance team described in section 5. This process should be followed in  
750 particular when groups or individuals seek to use the TropSOC database beyond the scope  
751 of its original objectives (see section 1.1).

752 (2) When utilizing TropSOC data, including the complete dataset, individually curated entries, or  
753 value-added calculations, users should cite this publication and reference the version of  
754 TropSOC that was used for their work under its specific DOI.

755 When using the database, please cite TropSOC v1.0 as:

756 Doetterl, S.; Bukombe, B.; Cooper, M.; Kidinda, L.; Muhindo, D.; Reichenbach, M.; Stegmann, A.; Summerauer, L.;  
757 Wilken, F.; Fiener, P. TropSOC Database. Version 1.0. GFZ Data Services. <https://doi.org/10.5880/fidgeo.2021.009>,  
758 2021.

759 Additionally, please cite this publication here where the data is first described as:

760 Doetterl S., Asifiwe R.K., Baert G., Bamba F., Bauters M., Boeckx P., Bukombe B., Cadisch G., Cizungu L.N., Cooper  
761 M., Hoyt A., Kabaseke C., Kalbitz K., Kidinda L., Maier A., Mainka M., Mayrock J., Muhindo D., Mujinya B.B., Mukotanyi,  
762 S.M., Nabahungu L., Reichenbach M., Rewald B., Six J., Stegmann A., Summerauer L., Unseld R., Vanlauwe B., Van  
763 Oost K., Verheyen K., Vogel C., Wilken F., Fiener P. Organic matter cycling along geochemical, geomorphic and  
764 disturbance gradients in forests and cropland of the African Tropics - TropSOC Database Version 1.0. *Earth System*  
765 *Science* XXX, DOI XXX, 2021.

766 (3) If users leverage individual data entries from the database, they should also cite the original  
767 research studies in which this particular data has been used for its first time (e.g. Bukombe et  
768 al., 2021, Kidinda et al., 2021; Reichenbach et al., 2021; Summerauer et al., 2021; Wilken et  
769 al., 2021)

770 (4) When users interpret their own data in the context of data accessed from TropSOC, they  
771 should submit those new data for inclusion in TropSOC after they have published their results  
772 and/or obtained a DOI for their dataset (Details of contributing process see section 5).

## 773 **7. Conclusions and Outreach**

774 The TropSOC database is an attempt to gather the data used in individual studies in one place  
775 and in the same format to facilitate comparisons and synthesis activities. TropSOC is unique in  
776 that it includes measurements and monitoring data of bulk soil and vegetation responses in the  
777 African tropical context for the first time on carefully selected and comparable land use,  
778 geomorphic and geochemical gradients at the landscape scale. Building on the data gathered  
779 along these gradients during several years of field activities and carrying out numerous lab  
780 experiments to investigate the impact of soil geochemistry and land degradation on  
781 biogeochemical cycles in tropical plant-soil systems, TropSOC is the largest integrative project  
782 database on plant-microbial-soil systems in the Congo basin to date. TropSOC's open-access  
783 database structure and participatory approach makes it a suitable tool for scientists to study  
784 experimentally defined soil disturbance and plant responses, as well as to test some of the  
785 assumptions behind modelling biogeochemical cycles in land surface models. Furthermore, we  
786 hope to encourage the community to increase the effectiveness of that investment, and to use the  
787 TropSOC database as a repository to increase the impact of your own research results. As such,  
788 TropSOC is an interactive database that is open for contributions. In addition, TropSOC now  
789 manages one of the largest topically structured soil and plant sample archives for tropical eastern

790 Africa with several thousand samples and more than three tons of plant and soil material stored at  
791 ETH Zurich. Subsamples of all the above are available upon request to interested researchers.

792 Finally, we hope that work based on the TropSOC database can help to provide answers on the  
793 role and magnitude of geochemistry, as well as soil mobilization, in controlling biological processes  
794 and fluxes of carbon and nutrients in the Tropics in order to better constrain soil processes in  
795 models ranging from profile to global scales (Todd-Brown et al. 2013). Reducing the uncertainties  
796 associated with our understanding of tropical (agro-) ecosystems in diverse but rapidly changing  
797 landscapes is one of the most pressing issues for securing the future well being of hundreds of  
798 millions of people and to constrain land loss in an area that is home to some of the last and most  
799 fragile populations of great apes in the wild. Elucidating the gravity of the consequences for soil  
800 functioning that can be observed in the TropSOC's study area can contribute to reducing the large  
801 uncertainty associated with terrestrial biogeochemical processes in models and raise awareness  
802 for the necessity of pressing for and creating socio-economic fundament for sustainable land  
803 management in tropical Africa.

804

805 **8. Appendix**

806 **Appendix Table A1.** Basic chemical and physical soil parameters aggregated at land use and  
 807 geochemical regions. Displayed are average values and standard deviation taken over ten soil  
 808 increments á 10 cm taken from 0 - 100 cm soil depth derived from NIR-MIR spectral data,  
 809 calibrated on samples from three depth increments (0 – 10 cm; 30 – 40 cm; 60 – 70 cm). See  
 810 metadata files 223\_soil\_spec.pdf and 323\_soil\_spec.pdf for details. Abbreviations: CEC =  
 811 potential cation exchange capacity; ECEC = effective cation exchange capacity; Si = Silica; Al =  
 812 Aluminum; Fe = Iron; Mn = Manganese; SOC = Soil organic carbon; SON = Soil organic nitrogen;  
 813 P = Phosphorus; TRB = Total reserve in base cations; BD = Bulk density. All assessment methods  
 814 are explained in the according .pdf metadata files accompanying the database.

830 **9. Sample availability**

831 Remaining soil and plant samples are logged and barcoded at the Department of Environmental  
832 Science at ETH Zurich, Switzerland. As long as idle sample mass remains available, samples for  
833 independent research and to stimulate collaboration with the CBO network and the TropSOC  
834 project group are available upon request. The authors cannot guarantee to revisit the study sites  
835 in order to provide additional sample material in future campaigns. Samples will be given to  
836 researchers free of charge. Sample preparation and transport are subject to a handling fee.

837 **10. Team list**

838 See acknowledgements and author list.

839 **11. Author contribution statement**

840 SD functioned as the project leader. SD and PF were lead coordinators for compiling the data  
841 base, responsible for data analysis and designed the metadata. BB, MC, LK, DM, MR, LS and FW  
842 were collecting and creating datasets and also analyzed these data before inclusion into the  
843 database. RKA, FB, MC, CB, AM, MM, JM, SMM, LN, AS, RU and CV were technical contributors  
844 and participated via data collection. GB, MB, PB, GC, LNC, AH, KK, BBM, BR, JS, BV, KVO and  
845 KV were conceptual contributors and participated in the design of the study as well as by giving  
846 advice and feedback during the campaign. SD and PF wrote the paper. All authors supported data  
847 analysis and gave feedback during the writing process.

848 **12. Competing interests**

849 All other authors declare that they have no conflict of interest.

850 **13. Special issue statement**

851 Data presented in this article is the fundament for several research articles published as part of  
852 the Copernicus Special Issue in SOIL with the title: *Tropical biogeochemistry of soils in the Congo*  
853 *Basin and the African Great Lakes region.*

854 **14. Acknowledgement**

This work is part of the DFG funded Emmy Noether Junior Research Group “Tropical soil organic carbon dynamics along erosional disturbance gradients in relation to soil geochemistry and land use” (TROP SOC; project number 387472333). Micrometeorological data from three of our weather stations (Bukavu, Lukananda, Bugulumiza) were made available and are administered by the Trans-African Hydro-Meteorological Observatory (TAHMO). The authors

863 like to thank in particular the following collaborating institutions for the support given to our  
864 scientists and this project: International Institute of Tropical Agriculture (CGIAR-IITA), Catholic  
865 University of Bukavu (UCB), Mountain of the Moon University (MMU), Kyaninga Forest Foundation  
866 (KFF), ETH Zurich and the Max Planck Institute for Biogeochemistry in Jena. Special thanks goes  
867 to the many student assistants for their important work in the laboratory and all guards, sentinels  
868 and field work helpers making the sampling campaign possible under difficult conditions. Lastly,  
869 we thank the editors of ESSD as well as the reviewers Dr. Yao Zhang and Dr. Rose Abramoff for  
870 their valuable insights and comments during the review process.
