1. Abstract

The Gulf of Guinea is a very active area regarding maritime traffic as well as oil and gas exploitation. Due to some actors failure to comply with environmental standards, this region has been subject to a large number of oil pollution. This pollution comes in addition to natural oil seepages from the ocean floor. This study aims to detect oil slicks spilled in the Gulf of Guinea and analyse their spatial distribution using Synthetic Aperture Radar (SAR) images. The previous works have already locally mapped oil slicks in this area, this study proves to be the first one to achieve a global statistical analysis based on 10 years of radar images covering 17 Exclusive Economic Zones of the Gulf of Guinea. The present study has been based on a database of 3,644 SAR images, collected between 2002 and 2012 by the Advanced SAR (ASAR) sensor onboard the European Spatial Agency (ESA) Envisat mission, which allowed the identification of 18,063 oil slicks. These "Oil slicks" herein detected encompass: -"oil spills" of anthropogenic origin and - "oil seeps" of natural origin (natural oil reservoir leaks).

2. Introduction

The Deep Water Horizon (DWH) disaster that occurred on April 20, 2010 in the Gulf of Mexico aroused worldwide outrage both for its human and environmental impacts (Leifer et al., 2012). There was great interest of the public, media, politicians and scientists characterized by a meticulous follow-up of the progression of the oil slicks (Caruso et al., 2013; Pinkston and Flemings, 2019). And yet, a disaster similar to that of the DWH would not be surprising along the African coast and, in particular, in the Gulf of Guinea, where recurrent oil spills are observed. These may be caused by deballasting operations (Albakjaji, 2010) and releases due to shipwrecks (Fuhrer, 2012).

If oil constitutes an important resource for the countries of the Gulf of Guinea from an economic point of view (Ovadia, 2016), the environmental impact caused by the frequent oil spills has provoked serious negative effects on both the environment and the local economy (Jafarzadeh et al., 2021; Okafor-Yarwood, 2018; Yaghmour et al., 2022). The weakness of national monitoring and legislation control is likely to limit the compliance to the major standards followed by large companies. Thus, the provision of observation tools that can enable people of Africa to ensure good monitoring and better management of the Gulf of Guinea is necessary. This facility is to enable African countries to monitor offshore oil exploitation concessions using free data provided by ESA and now the European Union (EU) in the

31   framework of the Copernicus programme.

32   Synthetic Aperture Radar (SAR) images have proven to be a useful tool for oil slicks mapping due to the dampening effect that oil has

33   on capillary and small gravity waves, called Bragg waves. The latter are generated on water by local winds and they are responsible for the

34   radar backscattering (Gade et al., 1998; Jackson et al., 2004; Mercier and Girard-Ardhuin, 2006; Shu et al., 2010; Xu et al., 2015). As a

35   consequence, oil slicks appear darker compared to nearby undampened water surface where Bragg waves produce brighter radar

36   backscattering. In addition, long-term time-series of radar images are freely available since 1991 (ERS-1 mission was launched in 1991,

37   ERS-2 in 1995, Envisat in 2002, Sentinel-1a in 2014 and Sentinel-1b in 2016) while near real time radar images are foreseen to be freely

38   available at least until 2030 owing to Sentinel constellation. This data availability allows extensive studies of past and future pollution as

39   well as operational detection of oil slicks using satellite radar imagery (Kubat et al., 1998).

40   In this study, SAR images acquired by the European Spatial Agency (ESA) mission Envisat has been used. Envisat was launched on

41   March 1, 2002, its payload contained ten instruments. The Advanced Synthetic Aperture Radar (ASAR) sensor onboard is the second

42   generation of SAR instrument developed by ESA , (Louet and Bruzzi, 1999). Envisat nominal life (5 years) has been doubled until the loss of

43   the satellite on April 8, 2012 (10 years).

44   The Gulf of Guinea is now one of the largest oil producing regions of the world and yet, very few studies have really analysed its

45   situation regarding oil slicks (both spills and seeps). The present study focuses on the spatial distribution of the oil slicks occurring from

46   2002 to 2012 by Exclusive Economic Zone (EEZ) throughout the Gulf of Guinea using Envisat ASAR radar images.

---

47   3. Presentation of the study area

48   *3.1. Geographic location*

49   The radar images used in this study were acquired over the Gulf of Guinea. This region is located in the Atlantic Ocean in the southwest

50   of Africa. According to the International Hydrographic Organization (Bassou, 2016), it extends from Guinea Bissau to Angola and covers the

51   EEZ of 16 countries bordering the coast (extending over 7000 km): Guinea Bissau (GNB), Guinea Conakry (GIN), Sierra Leone (SLE),

52   Liberia (LBR), Ivory Coast (CIV), Ghana (GHA), Togo (TGO), Benin (BEN), Nigeria (NGA), Cameroon (CMR), Equatorial Guinea (GNQ),

53   Sao Tome and Principe (STP), Gabon (GAB), Republic of Congo (COG), Democratic Republic of Congo (COD), and Angola (AGO)

54   (fig. 1).
fig. 1 - Location of the study area in the Gulf of Guinea and the Exclusive Economic Zones of the different countries.

3.2. Geological location

Petroleum is a natural mixture composed mainly of hydrocarbons. It is formed within certain sedimentary rocks by transformation of organic matter (plankton, plants, animals, etc.) incorporated into the deposit. It is a slow and gradual process occurring in a sedimentary basin.

Indeed, the transformation of organic matter into oil spans millions of years, and has been punctuated by several stages including the formation of an intermediate substance called kerogen. A given layer of sediment sinks and is buried under other layers of sediment. Depending on the filling of the basin, the heat flow and pressure induced by geologic processes, organic matter may change from kerogen to petroleum. Oil being less dense than water, it tends to migrate to the upper layers of the sedimentary strata. These sedimentary strata have a certain geometric configuration defined by the tectonic structure of the basin. During this structuring, different areas may have risen higher (anticlines) or have sunk lower (synclines) relatively to the rest of the stratum. When these upper zones are topped by a cover allowing the oil to escape through faults or fractures, they constitute oil deposits exploited nowadays in offshore or onshore areas.

The Gulf of Guinea is located in a passive zone resulting from the opening of the South Atlantic Ocean initiated during the Lower Cretaceous, breaking up south-west Gondwana. The climate during this period was hot, humid and stable, which favours chemical weathering of the mainland. Eroded material brought chemical elements to the Gulf of Guinea; in particular, the Niger Delta transported sediments rich in hydrocarbons. These numerous characteristics make this area a source of natural seepages also called oil seeps (Lawrence et al., 2002)

73   *3.3. Oil exploration in the Gulf of Guinea*

74   The Gulf of Guinea region has entered the global oil landscape comparatively quite recently. In 1982, the signing of the Montego Bay

75   convention extended the maritime territories of riparian countries over their EEZ, 200 nautical miles (≈ 370 km) off their coasts, which

76   encouraged offshore exploration (Bassou 2016). The Gulf of Guinea is now one of the largest oil producing regions in the world.

77   Indeed, since the installation of its first oil platforms (anchored and floating platforms) between 1960 and 1970 (Favennec et al., 2003),

78   the Gulf of Guinea has become one of the favourite destinations of international oil investors (Tull, 2008). The good quality of its oil justifies

79   the attractiveness of foreign countries to the region (Ngodi, 2005). Since the 2000s, it has supplied more than 55 billion barrels, i.e. 5% of

80   world oil production (Mfewou et al., 2018) and 60% of total daily crude oil production in sub-Saharan Africa. Offshore is the default mode

81   of oil extraction in the Gulf of Guinea (Favennec et al., 2003). The depletion of coastal water resources (shallow water; $\leq$ 200 m) means that

82   the relative share of deep water exploration (Deep water; 450 m - 1800 m), or even in ultra-deep water (1800 m - 3000 m) is increasing. This

83   is the case, for example, off the coast of Angola or Gabon.

84   *3.4. Oil pollution and environmental impacts*

85   The Gulf of Guinea is a very active area in oil exploration. The oil spills found in the region are unparalleled in frequency and their

86   toxicity induces serious repercussions both on the marine environment and on the ecosystem (Bagby et al., 2017; Chalghmi, 2015; Khanna et

87   al., 2018; Langangen et al., 2017; Li et al., 2019; Li and Johnson, 2019; NAE-NRC, 2012; Reuscher et al., 2020).

88   Several cases of accidents caused by the exploitation of offshore oil are documented. Apart from that, several accidents have occurred

89   following the exploitation of offshore oil fields. The frequency of oil spills in the Gulf of Guinea is said to be due, among other factors to oil

90   production operations, inadequate production equipment leading to corrosion of pipelines and tanks, to disasters, sabotage and vandalism

91   (Adelana and Adeosun, 2011).

92   Environmental consequences include the loss of habitat for corals and seagrass, the destruction of flora (reduction of mangroves and

93   certain species of algae) and that fauna (extinction of sea turtles) (Scheren et al., 2002). Oil slicks have a devastating effect on fishing

94   activity. Many Nigerian fishermen can no longer practice their profession, especially off the Niger Delta.

95   4. Dataset and Method

96   *4.1. Radar data*

97   Several spaceborne SAR systems have been widely used for marine pollution monitoring and mapping (Brekke and Solberg, 2008; Del

98   Frate et al., 2000; Dong et al., 2022; Espedal, 1999; Fiscella et al., 2000; Gade et al., 1998; Garcia-Pineda et al., 2008; Kanaa et al., 2003; Li

99   and Johnson, 2019; Liu et al., 1997; Marghany, 2015; Solberg et al., 1999; Suresh et al., 2015). In this study, we used SAR images acquired

100   by Envisat ASAR from 2002 to 2012. Envisat ASAR operated at the radar frequency of 5.331 GHz in C-Band (4.20 – 5.75 GHz) in various

101   modes including WSM (Wide Swath Medium-resolution). WSM ASAR images were acquired along swaths 400 km wide at a spatial

102   resolution of approximately 150 m by 150 m. WSM products are delivered with a ground pixel spacing of 75 m by 75 m. Envisat ASAR

103   operated in one of two polarizations types, either HH (horizontal transmission / horizontal reception) or VV (vertical transmission / vertical

104   reception). ASAR WSM operated according to the ScanSAR principle, using five predetermined overlapping antenna beams (also called sub-

105 swaths) which covered the wide swath. The ScanSAR principle consists in achieving swath widening by the use of an antenna beam which is

106 electronically steerable in elevation (Miranda et al., 2013).

107 On a radar image, the areas covered by oil appear as smooth dark regions with low backscattering. This is due to the damping effect that

108 the oil produces on capillary waves and small waves of gravity. On a oil-free surface, a significant part of the energy will be backscattered

109 towards the radar making it appear lighter (Alpers et al., 2017). The backscatter of the radar signal is also influenced by environmental

110 conditions such as: wind speed and sea state (Fingas and Brown, 2017; Zhang et al., 2014). The ideal wind speed for the detection of oil

111 slicks is in an interval that depends on the authors: - 2 m/s to 10 m/s (MacDonald et al., 2015), -1.5 m/s to 6.5 m/s (Jatiault et al.,

112 2017), -2.09 m/s to 8.33 m/s (Najoui, 2017)... Vertical polarization (VV) is the most effective mode for detecting oil spills on the sea surface

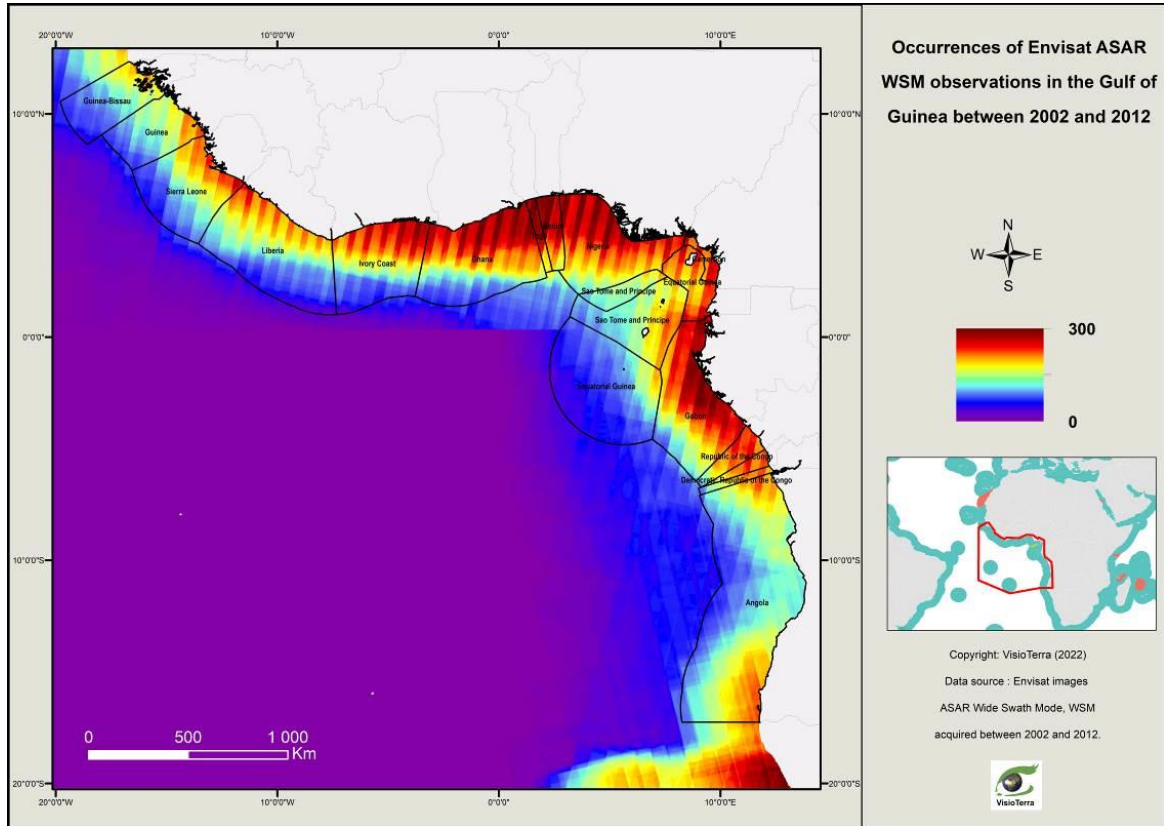
113 (Brekke and Solberg, 2008; Jatiault et al., 2017; Najoui et al., 2018a, 2018b).

114
115
116
117
118
119 *fig. 2 - Backscattering of the radar signal in the presence and absence of oil (Najoui, 2017).*

120 All the Envisat ASAR WSM scenes available in the study area have been processed leading to an amount of **3,644** scenes after

121 eliminating redundant products. The fig. 3 illustrates the spatial distribution of the occurrences of Envisat ASAR WSM observations between

122 2002 and 2012 in the Gulf of Guinea. The number of WSM observations is noticeably higher near the coasts.

123


124 *fig. 3 - Occurrences of Envisat ASAR WSM observations between 2002 and 2012.*

125 ### 4.2. Image preprocessing

126   The database of 3,644 images has been georeferenced in the geographic coordinate reference system over the WGS84 ellipsoid, datum

127 WGS84. A land mask has been applied and the images have been radiometrically corrected. The radiometric correction consists in correcting

128 the brightness variations due to SAR peculiarities. Indeed, the radar backscattering on the offshore area is dominated by non-Lambertian

129 reflections (the surface does not reflect the radiation uniformly in all directions). This non-Lambertian reflection leads to heterogeneity of the

130 brightness in the radar image: brighter along the near-range (closest to the NADIR line) and darker along the far-range. The input images

131 have a 16-bits Digital Number (DN) dynamic which requires reduction to 8-bits to be displayable on a usual screen. The applied

132 preprocessing consists in applying a local stretching with an average of 140 and a standard deviation of 60 on a sliding window of 301 pixels

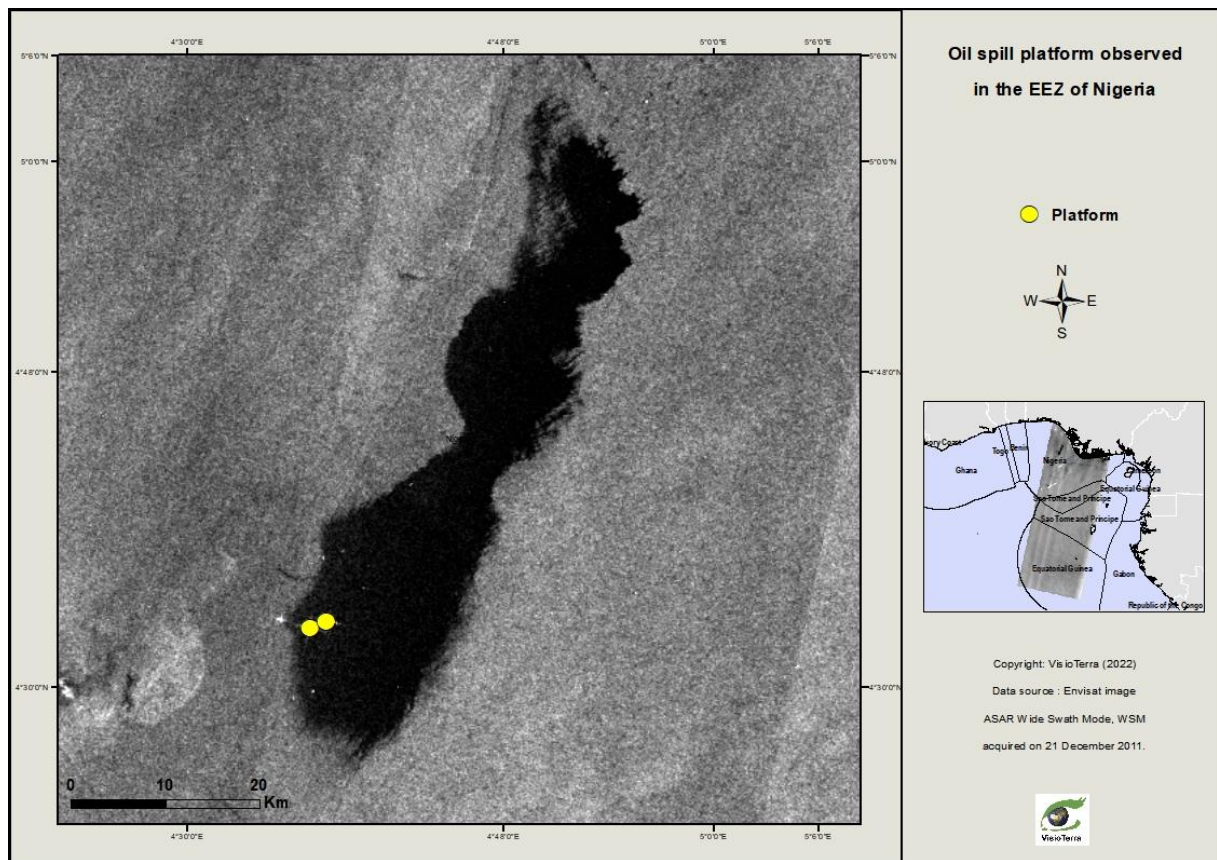
133 in order to optimize the detectability of the oil slicks (fig. 4) (Najoui, 2017; Najoui et al., 2018b).
fig. 4 - ASAR WSM images (21/12/2011) before (left) and after (right) local stretching showing a leak from an oil platform (see fig. 5).


fig. 5 - Oil spill platform observed in the EEZ of Nigeria (21/12/2011). The platforms are represented by the yellow dots (see hyperlook http://visioterra.org/VtWeb/hyperlook/504c7208cc184c12b42ed036bc9912f3).

153   *4.3. Manual detection*

154   Oil slicks appear as dark patches on radar images because they flatten the surface of the sea. However, in addition to oil slicks, many

155   phenomena also may appear as dark. Non-oil dark patches are termed as look-alikes features that include upwelling, eddies, rainfalls, wind

156   shadows, bathymetry, internal waves, current shear zones, etc. (Brekke and Solberg, 2005; Espedal, 1999; Xu et al., 2015).

157   The detection of oil slicks has been performed using a reliable manual detection approach as explained in (Najoui et al., 2018a, Jackson

158   et al., 2004). In fact, the 3,644 radar images used in this publication have been manually interpreted. The detection of oil slicks and their

159   categorisation were carried out following three stages of analysis: 1) interpretation based on morphological and textural criteria, 2) multi-date

160   analysis of repetitive oil slicks, and 3) validation using auxiliary data.

161   According to the morphological and textural criteria oil slicks may be subdivided into two major classes: biogenic and mineral. Biogenic

162   oil slicks are organic films made of substances produced by plankton and other marine organisms. The mineral oil slicks can be subdivided

163   between natural seeps (fig. 6), emitted naturally from the sea bottom, and anthropogenic oil spills that originate from ships (fig. 7), refineries,

164   oil terminals, industrial plants, oil platforms (fig. 8) and pipelines (Espedal, 1999). For instance, oil spills from platforms or ships induce

165   significant slicks (Johannessen et al., 2000; Leifer et al., 2012; Trivero and Biamino, 2010). If biogenic oil slicks appear as shiny diffracting

166   points on SAR data, oil seeps are characterized by curvilinear shapes due to short-term changes of the strength and orientation of the wind

167   and of the surface currents (Espedal, 1999).

168   Thereafter, a multi-date analysis has been performed. We use all the interpretations at different dates in order to assess the manual

169   interpretation. Indeed, repetitive slicks are, more likely, due to leaks from static sources: a geological feature for oil seeps, a platform or

170   pipeline for oil spills, for instance. The shape of these oil slicks from static sources is induced by the strength and orientation of the short-

171   term changes of both wind and sea surface current. Usually, this type of slicks from natural oil seeps and oil spills from oil platforms

172   constitutes forms of "astroseeps" or "flower structures" (fig. 9). In general, ships that discharge oily effluents do it in route, leaving behind

173   them linear-shaped spills or trails. When oil is discharged in a current-free and calm sea, the resulting overall spill geometry will follow the

174   route of the ship. This linearity is used to identify such oil spills. However, when a deballasting ship maneuvers or when a non-uniform

175   surface current is present, then, the contour of the spill can deviate significantly from linearity. When oil is discharged from a moving ship, it

176   also spreads laterally, resulting in oil trail which width increases with distance from the ship. In many cases, a white dot ahead of the

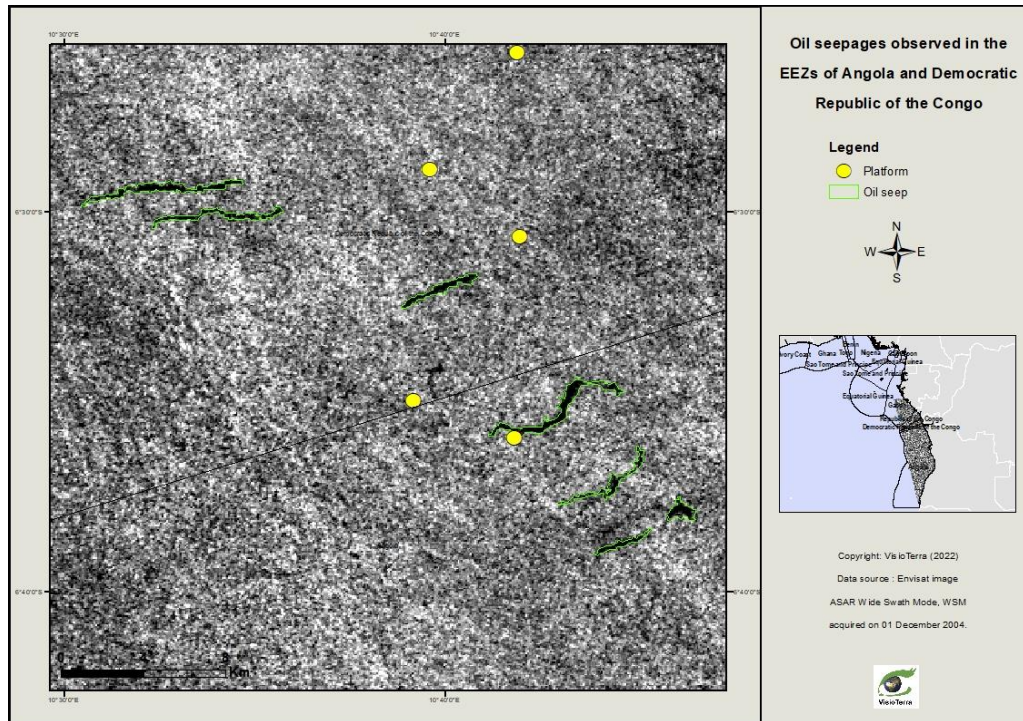
177   deballasting testifies to the metal structure of the ship and the size, or even the shape, of the dot can be an indicator of the size of the vessel.

178   Finally, the validation of the analysis has been performed by the integration of the manual detection output in a Geographic Information

179   System (GIS) with other auxiliary data. These auxiliary data include the location of oil platforms, oil and gas fields, available bathymetric,

180   geological and structural data, marine traffic, wind and current field direction… This work has led to the constitution of a dataset with 18,063

181   interpreted oil slicks (Najoui, 2022).

182


183 *fig. 6 - Oil seeps (1ˢᵗ December 2004) observed in the EEZ of Angola and Democratic Republic of the Congo. The*

189   *yellow dots.*
fig. 9 - Example of multitemporal analysis with astroseeps structure observed in the Lower Congo basin. Images a, b, c, d, e, f and g are Envisat ASAR images acquired at different dates with observed seeps. Image h shows an Envisat ASAR image with interpreted seeps. Image i shows the Envisat ASAR minimum image (i.e. each pixel is the minimum observed for the 7 dates) with an "astroseep" structure.

4.4. Mean area covered in oil

The image-interpretation described in the previous section results in the delimitation of closed polygons corresponding to the oil slicks. These polygons are "embedded" in a raster image to perform the statistical study. Since each location within the area of interest has not been observed an equal number of times by the Envisat satellite, an "observation occurrence map" has been produced (fig. 3). In fact, each location has not been equally observed because of the partial overlap of neighbouring swaths and the use of both ascending and descending orbits. Hence, it was necessary to locally normalize the oil slicks number distribution by dividing the number of oil slick occurrences by the number of observations made by Envisat ASAR over the study area which gives the relative frequency of the presence of oil per pixel.

The **probability of presence of oil X per pixel ($P_X(l,p)$)** is equal to the number of occurrences of oil X in a pixel ($S_X(l,p)$) divided by the number of observations ($O(l,p)$) of the same pixel (eq.1).

$$P_X(l,p) = \frac{S_X(l,p)}{O(l,p)} \qquad (\text{eq. 1})$$

205 Where :

206 • $S_X(l,p)$ is the number of occurrences of the presence of oil X detected on a pixel by image-
207 interpretation,

208 • X is the type of oil. It can be natural leaks (oil seepages), pollution by boats (oil spill ships) and
209 pollution by platforms (oil spill platforms),

210 • (l,p) are the coordinates (l, p) of the current pixel representing the rows and columns of the image,

211 • O(l,p) are the number of observations as they appear in the footprints of the processed images Envisat
212 ASAR WSM,

213 • $P_X(l,p)$ is the normalized occurrence also called probability of oil presence at pixel (l, p).

214 For each class X of oil slick among (e) "seepage", (s) "spill from ship", and (p) "spill from platform", the generic definition given in

215 (eq.1) becomes the ones given in (eq.2).

$$P_e(l,p) = \frac{S_e(l,p)}{O(l,p)} \; , \; P_s(l,p) = \frac{S_s(l,p)}{O(l,p)} \; , \; P_p(l,p) = \frac{S_p(l,p)}{O(l,p)} \qquad (\text{eq. 2})$$

216 Where :

217 • $S_e(l,p)$, $S_s(l,p)$ et $S_p(l,p)$ are the number of occurrences of oil presence detected on a pixel by image-interpretation
218 of -natural leaks (oil seepages), -pollution of boats (oil spill ships) and -pollution of platforms
219 (oil spill platforms) respectively,

220 • (l,p) are the coordinates (l, p) of the current pixel representing the rows and columns of the image,

221 • O(l,p) are the number of observation as they appear in the footprints of the processed images Envisat
222 ASAR WSM,

223 The total probability of presence of oil X per pixel ($P_t(l,p)$) is equal to:

$$P_t(l,p) = \frac{S_e(l,p)}{O(l,p)} + \frac{S_s(l,p)}{O(l,p)} + \frac{S_p(l,p)}{O(l,p)} \qquad (\text{eq. 3})$$

224 Thus, we denote by $\hat{A}_X$ the mean area covered in oil of origin X in the Gulf of Guinea between 2002 and 2012. This mean area is given

225 by (eq.4).

$$A_X = \sum_{GG}^{l} \sum_{GG}^{p} (P_X(l,p) \times A(l,p)) \approx \sum_{GG}^{l} \sum_{GG}^{p} (P_X(l,p)) \times \overline{A} \qquad (\text{eq. 4})$$

226 Where:

227 • A(l,p) is the area of the pixel (l,p),

228 • $\overline{A}$ is the mean area of a pixel. Due to the chosen geographic coordinate reference system (CRS),
229 the variation of the area of the pixel (75 m x 75 m) is less than 2.5 % over the Gulf of Guinea
230 (GG).

231   For a given year Y, the mean area covered in oil of origin X ($\hat{A}_{X,Y}$) is given by (eq.5).

$$A_{X,Y} = \sum_{GG}^{l} \sum_{GG}^{p} (P_{X,Y}(l,p)) \times \overline{A} \qquad (\text{ eq. 5 })$$

232   Where:

233   • $P_{X,Y}(l,p)$ is the probability of presence of oil of origin X for a given year Y for a given pixel (l,p).

234   For a given year Y and for a given EEZ, the mean area covered in oil of origin X ($\hat{A}_{X,Y,EEZ}$) is given by (eq.6).

$$A_{X,Y,EEZ} = \sum_{EEZ}^{l} \sum_{EEZ}^{p} (P_{X,Y}(l,p)) \times \overline{A} \qquad (\text{ eq. 6 })$$

235   *4.5. Mean fraction covered by oil for a given EEZ*

236   For each country's EEZ over a given period of time, we estimated the mean fraction covered in oil of origin X and for a given year Y

237   ($P_{X,Y,EEZ}$) by dividing the mean area covered in oil of origin X for a given year Y for a given EEZ ($\hat{A}_{X,Y,EEZ}$) by the area of the country's

238   EEZ A_{EEZ} (eq.7). When presenting the results, the term EEZ was replaced by the country's ISO code.

$$P_{X,Y,EEZ} = \frac{A_{X,Y,EEZ}}{A_{EEZ}} \qquad (\text{ eq. 7 })$$

239   5. Results and discussion

240   *5.1. Spatial distribution of oil slicks in the Gulf of Guinea*

241   The spatial and temporal analysis on the Gulf of Guinea allowed the image-interpretation of 18,063 oil slicks. The database of the 18,063

242   identified objects includes two classes of mineral oil. On the one hand, anthropogenic pollution that come from oil spill platforms and

243   recurring deballasting of oil spill ships. On the other hand, natural oil seepage resurgences which are hints of the presence of hydrocarbon

244   reservoirs in the sub-surface of the Gulf of Guinea.

245   The fig. 10 illustrates the spatial distribution of the 18,063 oil slicks that have been detected and then mapped in the Gulf of Guinea over

246   the period 2002-2012. For each of the N slicks, a point has been designated as the source, forming a discrete dot map. In order to obtain a

247   continuous density map, each source point of this dot map has been convoluted by a 2-D kernel function. In fact, the density map is the sum

248   of each of these N kernel functions The fig. 11, fig. 12, and fig. 13 respectively show the density maps of oil seepages, spill from ships and

249   spill from platforms. The kernel function that has been used is:

        $K(r)=(1-(r/0.7)^2)^2$ if $r \le 0.7$

$$(\text{ eq. 8 })$$

        $K(r)=0$ if $r>0.7°$

250   Where r is the Euclidian distance to the source point in degrees.
fig. 10 - Spatial distribution of oil slicks in the Gulf of Guinea between 2002 and 2012.

The fig. 11 shows that oil seepages are distributed over all the EEZs in the Gulf of Guinea. This large amount of oil seepages from the Gulf of Guinea could be partly explained by its geology resulting from the opening of the South Atlantic domain initiated in the Lower Cretaceous and by the significant sediment supply from the Niger Delta (Grimaud et al., 2018).

The proximity of the main maritime routes to the coasts contributes to the concentration of discharges in these places. This phenomenon is especially noticed along the coasts of Nigeria which is one of the main shipping routes and occupies a place in maritime piracy (see fig. 12). Thus, there are significant spills of ships there, despite the international convention for the prevention of pollution from ships (MARPOL 73/78), which came into force in 1983. Illegal dumping operations include deballasting and cleaning of ship tanks.

Offshore oil platforms have been found all along the coasts of the EEZs of the top oil producing countries (Nigeria, Angola, Republic of Congo, Ghana...) in the Gulf of Guinea (see fig. 13). The oil spills coming from platforms that have been observed in our study are very well correlated with offshore installations.

263

271   **5.2. Mean area covered in oil (Â$_{X,Y,EEZ}$)**

272   5.2.1. Mean area covered in oil in the Gulf of Guinea (Â$_{X,Y}$)

273   The fig. 14 shows the mean area covered in oil in the Gulf of Guinea by year. One may notice that:

274   •   the mean area covered in oil slicks from natural origin (oil seeps) remains more or less stable during the period 2002-
275   2012,

276   •   the mean area covered with oil slicks from oil spill platforms seems to have increased significantly during 2008 and
277   then returned to normal in 2009 until the end of the study period,

278   •   the mean area covered in oil slicks from ships seems to have increased after 2004 with a peak between 2007 and 2008,
279   then have fallen in 2009 and remained stable until the end of the study period.

280   The mean area covered with oil slicks over the entire Gulf of Guinea (GG) between 2002 and 2012 is 145 km² for oil seeps, 111 km² for

281   oil spills from platform and 308 km², oil spills from ship and 547 km² for all oil slicks (table 1). That means that we have detected an oil slick

282   area of 574 km² for a per "full-coverage observation" during 2002-2012. This result is very similar to the one obtained by Dong et al. (2022)

283   that detects an oil slick area of 568 km² for a per "full-coverage observation" during 2014-2019 using Sentinel-1 data.

284
285 *fig. 14 - Mean area covered in oil in the Gulf of Guinea by year ($\hat{A}_{X,Y}$).*

Oil slicks	Mean area covered in oil in GG
Oil seep	154 km²
Oil spill from platform	111 km²
Oil spill from ship	308 km²
Total	**574** km²

286   *table 1 – Temporal mean of the yearly mean area covered in oil in the Gulf of Guinea between 2002 and 2012.*

287   5.2.2. Mean area covered in oil by EEZ of country ($\hat{A}_{X,Y,EEZ}$)

288   The fig. 15 shows the mean area covered in oil by EEZ of countries between 2002 and 2012. The fig. 16 shows the mean area covered in

289   oil by EEZ of countries by year. One may notice that the most polluted EEZ are Nigeria followed by Angola, Republic of Congo and

290   Cameroon.

291   The analysis by EEZ shows that the decrease in oil spills observed between 2008 and 2009 (fig. 14) was driven by the major oil

292   producing countries: Angola, Nigeria and Republic of Congo (fig. 16).

293   The fall in the mean area covered in oil from platforms and ships may be explained by the economic crisis of 2008. In fact, 2008 world crisis

294   had led to the falling in oil prices inducing deficit in the budget of oil companies and governments. For instance, Angola oil production

295   decreased in 2009 following the post-2008 slowdown in global economic activity and the subsequent glut of oil on the global market

296   (Mikidadu, 2018).

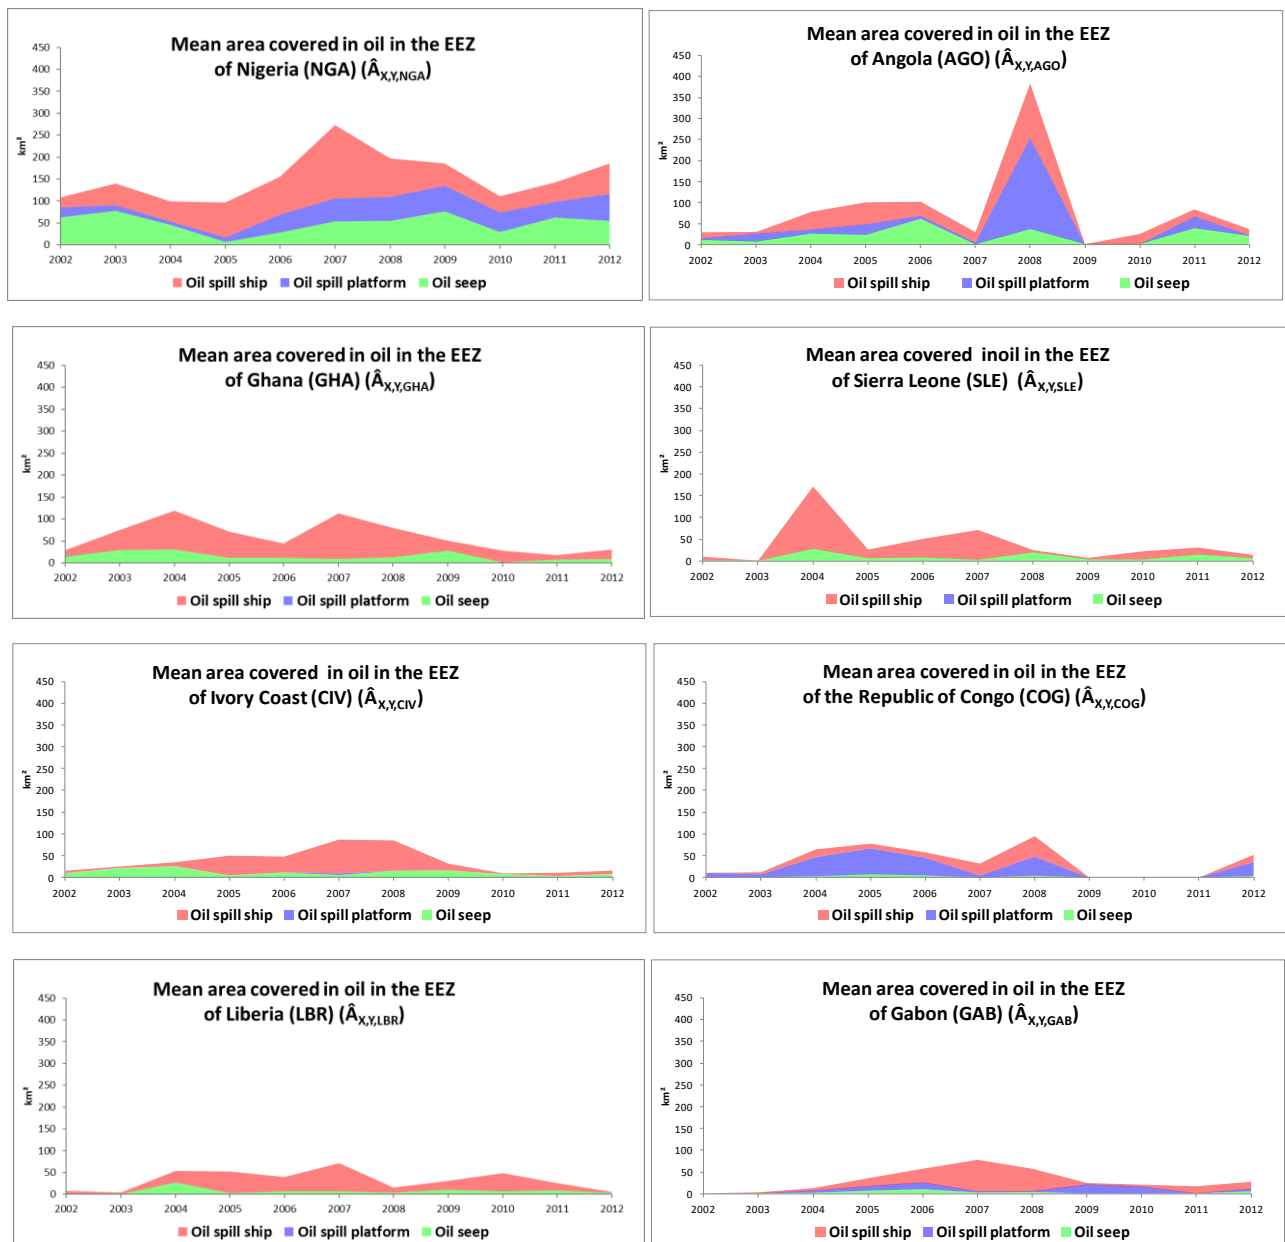
²18

297
298   fig. 15 - Mean area covered in oil by EEZ of country (Â_{X,Y}) between 2002 and 2012.

299

300

301

302


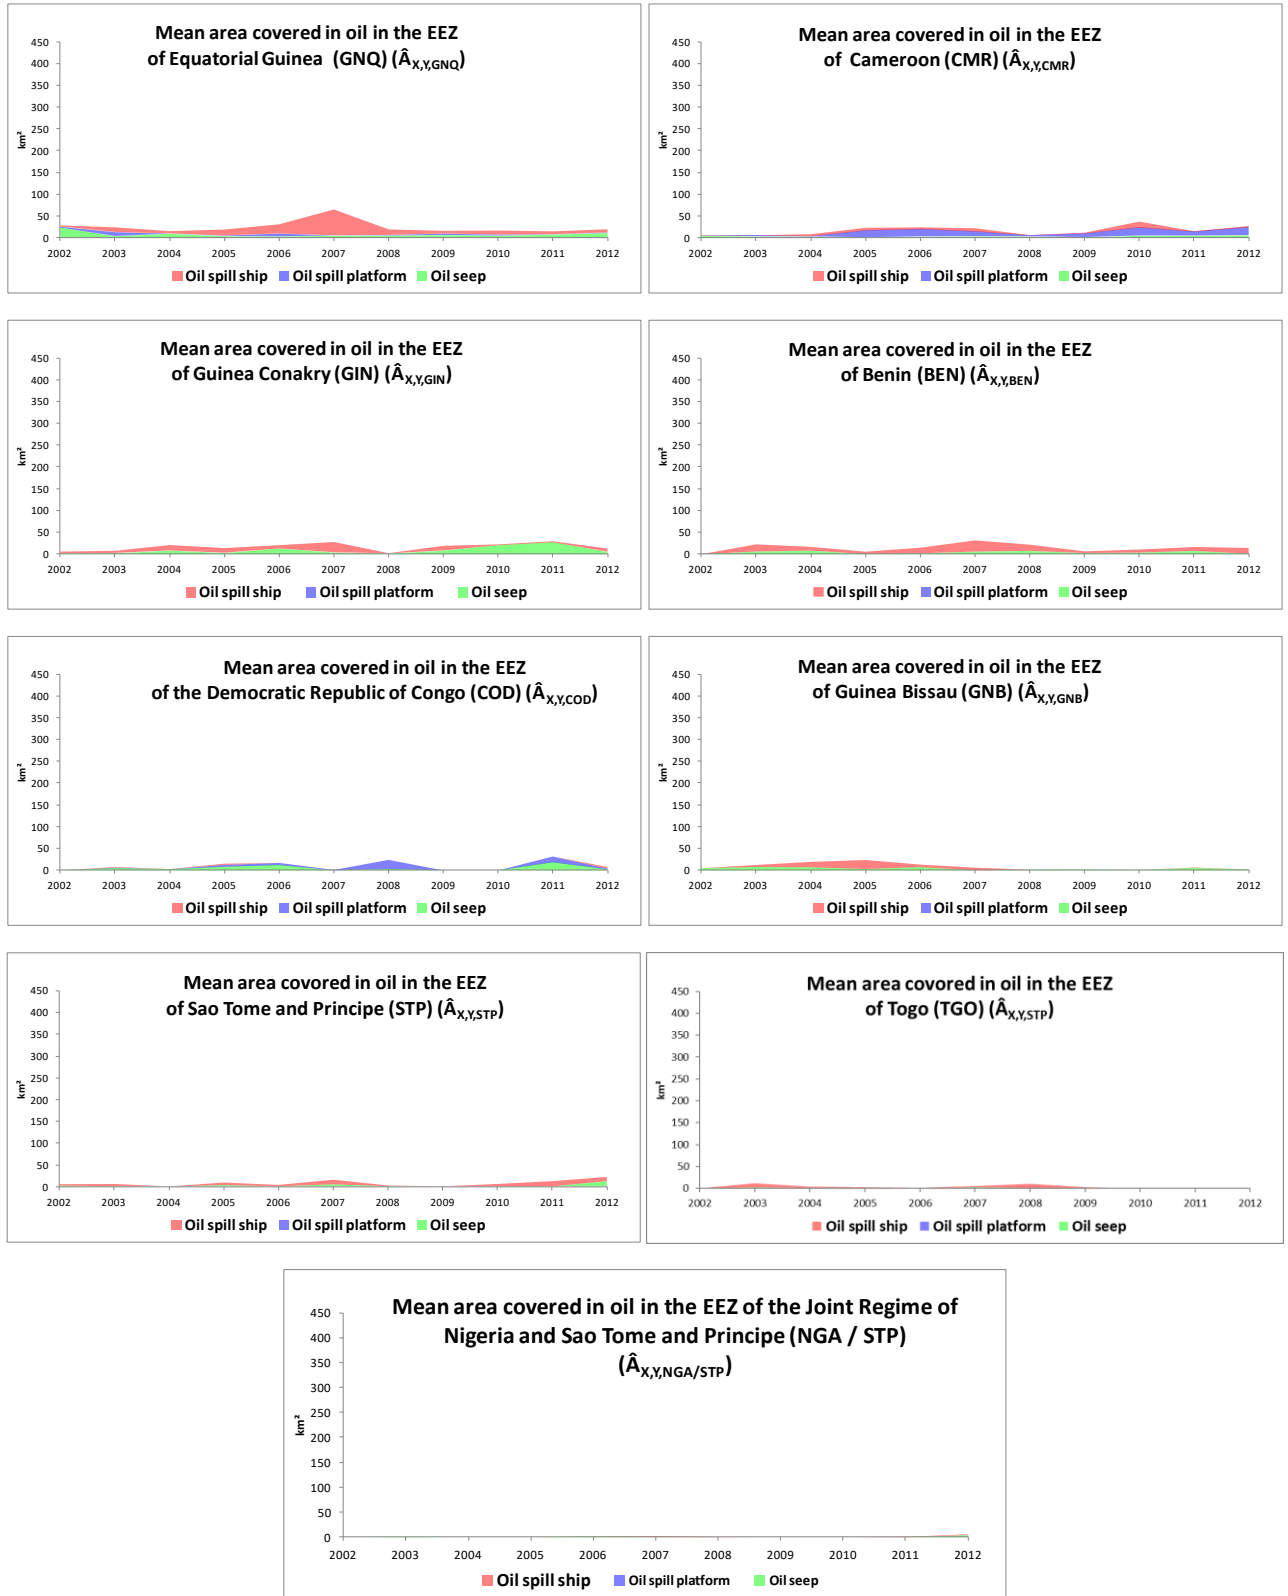


fig. 16 - Mean area covered in oil by EEZ of countries per year ($\hat{A}_{X,Y,EEZ}$).

309   *5.3. Mean fraction covered by oil by EEZ ($P_{X,Y,EEZ}$)*

310   As shown in fig.15, Nigeria holds the record for pollution by platforms and also by boats. These data incorporated the pollution observed

311   throughout its whole EEZ. But isn't it also because Nigeria has an extended EEZ? To make the analysis independent of the size of the EEZ,

312   we calculate the "Mean fraction covered by oil by EEZ".

313   The fig. 17 shows the mean fraction covered by oil by EEZ of countries between 2002 and 2012. The fig. 18 shows the mean fraction

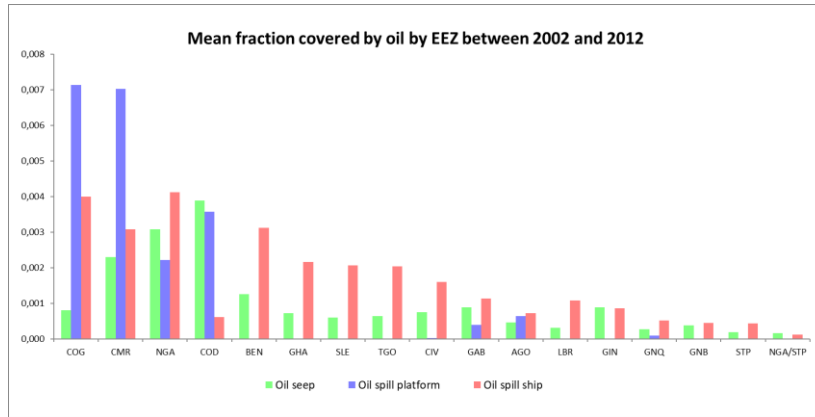
314   covered by oil by EEZ of countries by year.

315   The country mean fraction covered by oil which divides the mean area covered in oil by the country EEZ area (eq.7) gives an idea of the

316   mean probability to be covered by oil by EEZ. Thus, the largest the mean fraction is, the more the area is likely to be covered by it. One may

317   see that the probability that an oil spill occurs is high for the Republic of Congo, Cameroon and Nigeria while the probability that an oil seep

318   occurs is high for the Democratic Republic of the Congo, Nigeria and Cameroon.

319


320   *fig. 17 - Mean fraction covered by spilled oil by EEZ between 2002 and 2012.*

321

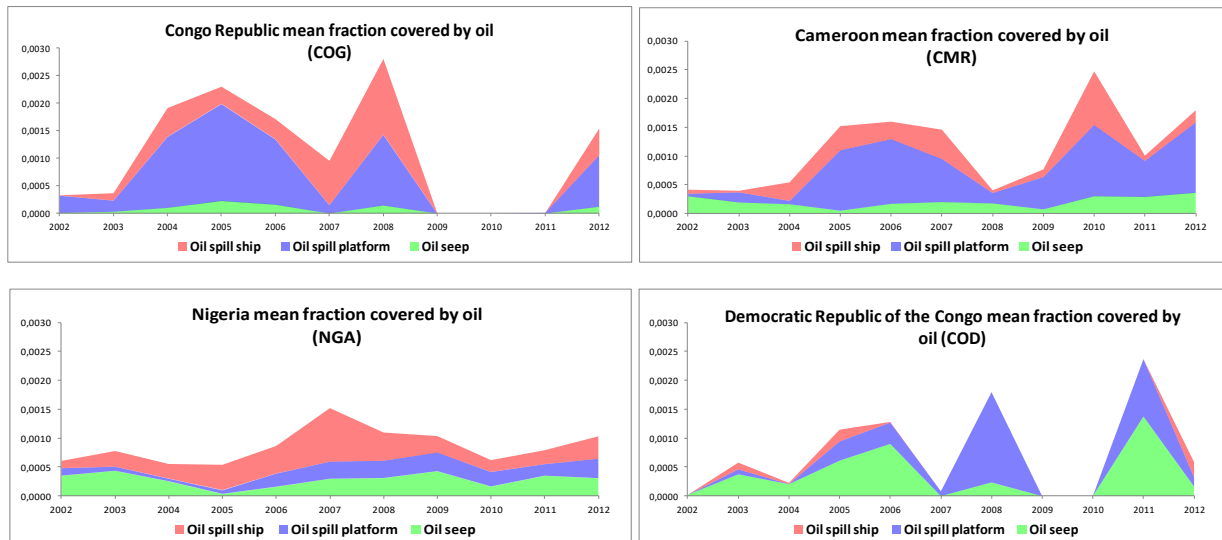
322


fig. 18 - Mean fraction covered by oil by EEZ by year.

6. Data availability

All the Envisat ASAR images (2002-2012) used in this study are available at ESA website https://eocat.esa.int/sec/#data-services-area. These data can also be viewed on the HEDAVI (Heritage Data Visualization) portal managed by VisioTerra at the address http://hedavi.esa.int/. The spatial distribution of the oil slicks in the Gulf of Guinea between 2002 and 2012 is available at ZENODO: https://doi.org/10.5281/zenodo.6470470 (Najoui, 2022).

A set of 100 georeferenced oil spills is available at ZENODO: https://doi.org/10.5281/zenodo.6907743.

7. Conclusion and perspectives

An unprecedented database of oil spills has been generated over the EEZ of the Gulf of Guinea using the 11 years of acquisitions of SAR images at C-band by ASAR in wide-swath mode (150 m of spatial resolution) contained in the archive of the Envisat mission. This database has been achieved using a manual approach. The present study shows that all of the countries EEZ are sites of natural oil seepages due to the extensive geological context of the Gulf of Guinea. It shows also that oil spills from ships are well correlated to the shipping routes along the coasts of the 17 EEZ of the Gulf of Guinea while oil spills coming from oil platforms are concentrated along the coasts of oil-producing countries like Nigeria, Republic of Congo, Angola, and Ghana. The temporal analysis during 10 years (2002-2012) shows a decrease in the mean area covered by oil between 2008 and 2009. This decreasing is likely to be due to the post-2008 global economic slowdown.

Oil seepages and oil spills monitoring will benefit from Sentinel-1 mission, launched in 2014, owing to its higher spatial resolution (10 m), its temporal resolution (6 days), and its longer period of acquisitions (beyond 2032). This dataset will offer more reliable and timely information for emergency and mitigation policies.

Acknowledgments

The authors would like to thank the ESA (European Spatial Agency) for providing the SAR scenes used in this study.
