9 **Abstract.** Global land cover (GLC) information with fine spatial resolution is a fundamental data input  
10 for studies on biogeochemical cycles of the Earth system and global climate change. Although there are  
11 several public GLC products with 30 m resolution, considerable inconsistencies were found among them  
12 especially in fragmented regions and transition zones, which brings great uncertainties to various  
13 application tasks. In this paper, we developed an improved global land cover map in 2015 with 30 m  
14 resolution (GLC-2015) by fusing multiple existing land cover products based on the Dempster-Shafer  
15 theory of evidence (DSET). Firstly, we used more than 160,000 global point-based samples to locally  
16 evaluated the reliability of the input GLC products for each LC class within each 4°×4° geographical  
17 grid for the establishment of the basic probability assignment (BPA) function. Then, the Dempster's rule  
18 of combination was used for each 30 m pixel to derive the combined probability mass of each possible  
19 land cover class from all the candidate maps. Finally, each pixel was determined with a land cover class  
20 based on a decision rule. Through this fusing process, each pixel is expected to be assigned with the land  
21 cover class that contributes to achieve a higher accuracy. We assessed our product separately with 34,711  
22 global point-based samples and 201 global patch-based samples. Results show that, the GLC-2015 map  
23 achieved the highest mapping performance globally, continentally, and eco-regionally compared with the  
24 existing 30 m GLC maps, with an overall accuracy of 79.5% (83.6%) and a kappa coefficient of 0.757  
25 (0.566) against the point-based (patch-based) validation samples. Additionally, we found that the GLC-  
26 2015 map showed substantial outperformance in the areas of inconsistency, with an accuracy

27 improvement of 19.3%-28.0% in areas of moderate inconsistency, and 27.5%-29.7% in areas of high  
28 inconsistency. Hopefully, this improved GLC-2015 product can be applied to reduce uncertainties in the  
29 research on global environmental changes, ecosystem service assessments, and hazard damage  
30 evaluations, etc. The GLC-2015 map developed in this study is available at  
31 <https://doi.org/10.6084/m9.figshare.22358143.v2> (Li et al., 2022).

## 32 **1. Introduction**

33 Land cover (LC), influenced by both nature and human activities (Running, 2008; Gong et al., 2013;  
34 Song et al., 2018; Liu et al., 2021a), is a significant component of the Earth system (Yang and Huang,  
35 2021). Global land cover (GLC) products can serve as fundamental data for various studies, such as  
36 climate and environmental changes (Bounoua et al., 2002; Foley et al., 2005; Grimm et al., 2008; Yang  
37 et al., 2013; Schewe et al., 2019), food security (Verburg et al., 2013; Ban et al., 2015), carbon cycling  
38 (Moody and Woodcock, 1994; Defries et al., 2002; Gómez et al., 2016), biodiversity conservation  
39 (Chapin et al., 2000; Giri et al., 2005) and land management (Mayaux et al., 2004; Verburg et al., 2011).  
40 Therefore, there is a pressing need for detailed, accurate, and high-quality GLC product to support global  
41 change research and sustainable development.

42 In the preliminary stage, LC mapping mainly relied on visual interpretation, which is time-  
43 consuming, labor-intensive and difficult to be applied at the global scale (Gong, 2012). In recent decades,  
44 satellite remote sensing data, which can provide information of large area coverage and long-term  
45 monitoring, has been adopted to generate GLC products. With coarse resolution satellite data such as  
46 Advanced Very High Resolution Radiometer (AVHRR), Moderate Resolution Imaging  
47 Spectroradiometer (MODIS), Medium Resolution Imaging Spectrometer (MERIS), and Global Land  
48 Surface Satellite (GLASS), a variety of GLC products have been developed at 5 km to 300 m  
49 resolution (Loveland et al., 2000; Hansen et al., 2000; Bartholomé and Belward, 2005; Friedl et al., 2010;  
50 Defourny et al., 2018; Liu et al., 2020a). Although these GLC products have been widely applied to many  
51 applications, it has been proved that the differences between sensors, classification systems, and  
52 considerably low accuracies in areas prevent harmonization of these products (Herold et al., 2008;  
53 Verburg et al., 2011; Grekousis et al., 2015). Also, these products are far from providing enough fine  
54 spatial details of LC due to their relatively coarse spatial resolution, which does not meet the demand of

55 many studies (Giri et al., 2013; Yang et al., 2017). To allow researches which can capture most human  
56 activity, finer-resolution (e.g., 30 m) GLC products are demanded (Giri et al., 2013).

57 With the free accessibility of high-resolution satellite remote sensing data, GLC mapping at fine  
58 resolution has been successfully conducted. Using Landsat imagery, there has been a milestone  
59 achievement that the two GLC products are generated with fine resolution of 30 m, namely Finer  
60 Resolution Observation and Monitoring of Global Land Cover product (FROM\_GLC)(Gong et al.,  
61 2013)and Globeland30 (Chen et al., 2015). After that, a 30 m-resolution GLC mapping in 2017 was  
62 achieved using the first all-season sample set (Li et al., 2017). More recently, Zhang et al. (2021) used  
63 both Landsat time series imagery and high-quality training data from the Global Spatial Temporal Spectra  
64 Library (GSPECLib) to produce a 30 m GLC map in 2015 (GLC\_FCS30) with a two-level classification  
65 scheme. Several attempts have been made to improve accuracy of 30 m GLC products which are  
66 prevail in the generation of GLC mapping task over the last few years. FROM\_GLC was created by  
67 employing four classification algorithms to classify the Landsat images and choosing time series of  
68 MODIS EVI data for training and test. Globeland30 was created by proposing a pixel-object-knowledge-  
69 based (POK) method to assure consistency and accuracy. GLC\_FCS30 was generated by adopting local  
70 adaptive random forest models with high-quality training samples derived from GSPECLib. [The](#)  
71 [Globeland30, FROM\\_GLC, and GLC\\_FCS30 are excellent and indispensable GLC products which have](#)  
72 [contributed much to various researches, such as biodiversity conservation \(Wu et al., 2020; Meng et al.,](#)  
73 [2023\), climate change \(Kim et al., 2016; Xue et al., 2021; Zheng et al., 2022\), and land management](#)  
74 [\(Shafizadeh-Moghadam et al., 2019\).](#)

75 Despite the great efforts in producing more accurate products, the existing 30 m GLC products still  
76 show unstable performance in certain LC classes and some specific areas (Sun et al., 2016; Kang et al.,  
77 2020). Furthermore, the existing 30 m products showed great agreement in overall spatial distribution  
78 patterns but significant spatial inconsistency in some specific areas (heterogeneous areas and transition  
79 zones) and spectrally similar classes (forest and shrubland, cropland and grassland) (Gao et al., 2020;  
80 Liu et al., 2021b). The spatial inconsistency between the existing 30m GLC products are resulted from  
81 differences in their classification systems, classification techniques employed, source data, and spatial  
82 distribution and size of training samples (Yang et al., 2017; Gao et al., 2020). Due to the aforesaid  
83 limitations, users of GLC products still have difficulties in an appropriate selection of data for their

84 specific application. Ultimately, this situation leads to uncertainties in outcomes of related researches  
85 when different 30 m GLC products are used. For GLC mapping with fine spatial resolution, more efforts  
86 should be focused on improving the mapping in heterogenous and fragmented landscape (Herold et al.,  
87 2008; Liu et al., 2021b). Therefore, it is pressing to generate a more accurate and reliable GLC product  
88 with high classification accuracy, especially for spatially inconsistent regions and low-accuracy LC  
89 classes.

90 According to Gong et al. (2016), inconsistencies between LC products indicate available  
91 complementary information and more robust and reliable data can be generated by integrating the input  
92 maps with the data fusion method. Given that different maps have disagreement and provide accurate  
93 information in different locations, we can make a best choice for the class label assigned to each pixel  
94 by weighting the credibility of all the available information and combining them through a decision rule  
95 (Clinton et al., 2015). In this way, the output map of integration on input maps can reduce the overall risk  
96 of assigning a wrong class label to a pixel and at least achieve the average performance of input maps.  
97 Several attempts have been made to produce an accurate and consistent LC map using various methods,  
98 such as majority voting (MV), fuzzy agreement and Bayesian theory. Iwao et al. (2011) created a GLC  
99 map based on a simple majority voting method. Jung et al. (2006) generated a 1km GLC map by  
100 combination of MODIS, GLC2000 and GLCC data based on fuzzy agreement scoring. Subsequently,  
101 Fritz et al. (2011) extended the synergy method of Jung et al. (2006) by ranking LC maps and mapped  
102 the cropland extent in Sub-Saharan Africa. See et al. (2015) generated two GLC products by integrating  
103 medium resolution LC products with geographically weighted regression (GWR). Gengler and Bogaert  
104 (2018) proposed a Bayesian data fusion method and applied it to the LC mapping for a specific region in  
105 Belgium. All these researches have demonstrated that fusion method can create an integrated LC product  
106 where the mapping accuracy is greatly improved by combing the best of candidate maps. However, the  
107 MV method is sensitive to the quality of the candidate maps and has significant uncertainties when the  
108 input products exhibit great disagreement(Chen and Venkataramanan, 2005). The fuzzy agreement is  
109 highly subjective since it depends on expert assessment, while the Bayesian theory requires a prior  
110 knowledge or conditional probabilities and fails to handle the states of ignorance(Liu and Xu, 2021).

111 The Dempster-Shafer theory of evidence (DSET) is an evidence-based approach to reason with  
112 uncertainties. Unlike the majority voting, the DSET method can discount evidence from inaccurate

113 information with a probability mass that reflects the degree of belief rather than a binary decision (Razi  
114 et al., 2019). In contrast to the Bayesian theory, the DSET can integrate evidence from a variety of sources  
115 without the requirement of prior knowledge (Chen and Venkataramanan, 2005). Moreover, the reliability  
116 of the final fused results is measured the DSET method with a total degree of belief. Although previous  
117 literature focused on the application of the DSET method in multisource data aggregation, very little  
118 research has been conducted at a global scale due to the lack of accurate and sufficient samples and the  
119 demand for adequate computing resources.

120 In this research, we propose a multi-source product fusion approach on the Google Earth Engine  
121 (GEE) platform to produce an improved GLC product in 2015 (GLC-2015) with 30 m resolution. The  
122 fusion approach we proposed aims to deal with the inconsistency between previous 30 m GLC products  
123 and generate a map which has better mapping performance than any of the candidate maps by evaluating  
124 the mapping accuracy of these existing products at the local scale and choosing the most credible LC  
125 class. To fulfill the purpose, we first performed reliability evaluation, where the accuracy of each GLC  
126 product for each LC class in each  $4^\circ \times 4^\circ$  geographical grid is regarded as the evidential probability to  
127 create the basic probability assignment (BPA) function. Then, the BPA values of all the LC classes from  
128 different GLC products are fused according to the Dempster's rule of combination. Finally, the GLC-  
129 2015 map was integrated after a final accepted LC class with the maximum combined probability mass  
130 was assigned to each 30 m pixel. Our GLC-2015 map was separately validated with two different  
131 validation sets, namely global point-based samples and global patch-based samples, and compared with  
132 three existing multiple-class GLC products. Moreover, we provided an analysis for mapping  
133 improvement of the GLC-2015 compared to other products in areas of high mapping inconsistency. The  
134 GLC-2015 map is proved to be accurate and credible and can significantly improve the mapping accuracy  
135 in areas of high inconsistency between previous products.

## 136 **2. Datasets**

### 137 **2.1 Multiple-class GLC products**

138 Three existing 30m GLC products with multiple classes, including GlobeLand30, FROM\_GLC and  
139 GLC\_FCS30, were employed as input maps in the fusion based on DSET. A summary of their detailed  
140 information is shown in Table 1.

141 GlobeLand30, a widely-used global geo-information product, was produced by the POK-based  
142 method using Landsat and HJ-1 satellite images. Globeland30 products are freely accessible online at  
143 the website (<http://www.globalland30.org>) for 2000 and 2010. From the accuracy assessment, the  
144 Globeland30 for the year 2010 had an overall accuracy exceeded 80% using large samples (Chen et al.,  
145 2015). Although the data time of GlobeLand30 is 2010, which has a five-year gap with other products,  
146 it was used in our project for the following reasons: (1) The changed areas of LC caused by the time  
147 interval are tiny compared to the global land area. In addition, there is relatively less uncertainty due to  
148 LC changes than due to inaccurate classification (Xu et al., 2014). Most spatial disagreements between  
149 the existing maps are about classification errors rather than LC changes over the time interval (Mccallum  
150 et al., 2006; See et al., 2015); (2) We used a global point-based sample set for the year 2015 to evaluate  
151 the reliability of the input products in all  $4^\circ \times 4^\circ$  grids. At locations where land cover changed between  
152 2010 and 2015, the Globeland30 was more likely to have low accuracy based on the validation and less  
153 likely to contribute to the fusion using the DSET approach. In this way, the errors due to land cover  
154 changes can be largely avoided.

155 FROM\_GLC was first generated using numerous Landsat images, which has a fine classification  
156 system with a two-level structure. It achieved an OA of 64.5% through validation with the complete test  
157 samples and 71.5% with a subset of test samples in homogeneous areas (Gong et al., 2013). We used the  
158 version of 2015 for the fusion.

159 GLC\_FCS30 was developed using Landsat time series data and large training samples from the  
160 GSPECLib. It has a two-level classification scheme that contains 16 global LCCS LC classes and 14  
161 detailed regional LC classes. The overall accuracy of the GLC\_FCS30 according to LCCS level-1  
162 validation scheme reached 71.4% (Zhang et al., 2021).

163 Land cover products which focus on a national scale are more likely to possess higher accuracy  
164 because they were produced by experts who have good knowledge of land cover classes nationally. Thus,  
165 the National Land Cover Database 2016 (NLCD 2016) for the year 2016 (Yang et al., 2018), China's  
166 land-use/cover datasets (CLUDs) (Liu et al., 2014) for 2015, and the annual China land cover dataset  
167 (CLCD) (Yang and Huang, 2021) for 2015 were also included in the fusion. NLCD 2016 database, which  
168 provides continuous and accurate information about land cover and change from 2001 to 2016 at an  
169 interval of 2 or 3 years, was produced based on a pixel- and object-based approach and an effective post-

170 classification process (Yang et al., 2018). The level-1 and level-2 overall accuracy of NLCD 2016  
 171 database for 2016 was 90.6% and 86.4%, respectively (Wickham et al., 2021). CLUDs, developed by the  
 172 digital interpretation method using Landsat images, provide land cover information over China from  
 173 1980s to 2015. The overall accuracy of CLUDs reached 94.3% and 91.2% for level-1 and level-2 land  
 174 cover classes, respectively (Liu et al., 2014). CLCD was generated with stable training samples derived  
 175 from CLUDs and Landsat time series. Assessed with 5463 validation samples, CLCD obtained an overall  
 176 accuracy of 79.31% (Yang and Huang, 2021).

## 178 2.2 Single-class GLC products

179 To improve the quality of the fusing result, a set of highly qualified GLC products with single class at 30

180 m fine resolution were also used. Compared to the multiple-class GLC products, these single-class GLC  
181 products are more likely to provide accurate information since they usually focus on promoting mapping  
182 performance of specific LC class. These products include Global Forest Change (GFC) (Hansen et al.,  
183 2013), Global Annual Urban Dynamics (GAUD) (Liu et al., 2020b), Joint Research Centre's Global  
184 Surface Water (JRC GSW) (Pekel et al., 2016), and Global Mangrove Watch (GMW) (Bunting et al.,  
185 2018). While these single-class products are either annual or multi-epoch, we only selected these  
186 products in the target year of 2015. The background information of these single-class products was  
187 considered as another land cover class (e.g., non-water) participating in the fusion. The accuracy of the  
188 background information was defaulted to 0 since it did not provide information about any of the other  
189 nine categories in our classification system. Table 1 also describes the information of these selected  
190 single-class GLC products.

191 GFC was resulted from a time-series analysis of growing season Landsat scenes, aiming to provide  
192 information about global tree cover extent, gain, and loss at a 30m spatial resolution. The accuracy  
193 assessment was performed at global and climate domain scales and the forest gain reached an overall  
194 accuracy of 99.6% and forest loss reached 99.7% across the globe (Hansen et al., 2013). Up to now, it  
195 has a temporary coverage from 2000 to 2020.

196 GAUD, which provides 30m annual urban extent for the time period of 1985 to 2015, was generated  
197 using numerous Landsat images with both data fusion approach and temporal segmentation approach on  
198 the GEE platform. Validation was conducted across different urban ecoregions and the globe by the  
199 product developer. The accuracy of mapping urbanized year was 76% for the period of 1985 to 2000 and  
200 82% for the period of 2000 to 2015 at humid regions worldwide (Liu et al., 2020b).

201 JRC GSW dataset provides a monthly presentation of global surface water changes from 1984 to  
202 2015 at a fine 30 m resolution. Expert systems, visual analytics and evidential reasoning were exploited  
203 to detect water extent and changes. Based on 40,124 validation points over the globe and across the 32  
204 years, commission accuracies were determined with overall accuracies of 99.45% (TM), 99.35% (ETM+)  
205 and 99.54% (OLI) and omission accuracies were reflected in overall accuracies of 97.01% (TM), 95.79%  
206 (ETM+) and 96.25%(OLI) (Pekel et al., 2016). We used the GSW Yearly Water Classification History  
207 v1.1 in the GEE catalog. A single 'waterClass' band is present in each image that provides the water's  
208 seasonality throughout the year with four types: no data, no water, seasonal water, and permanent water.

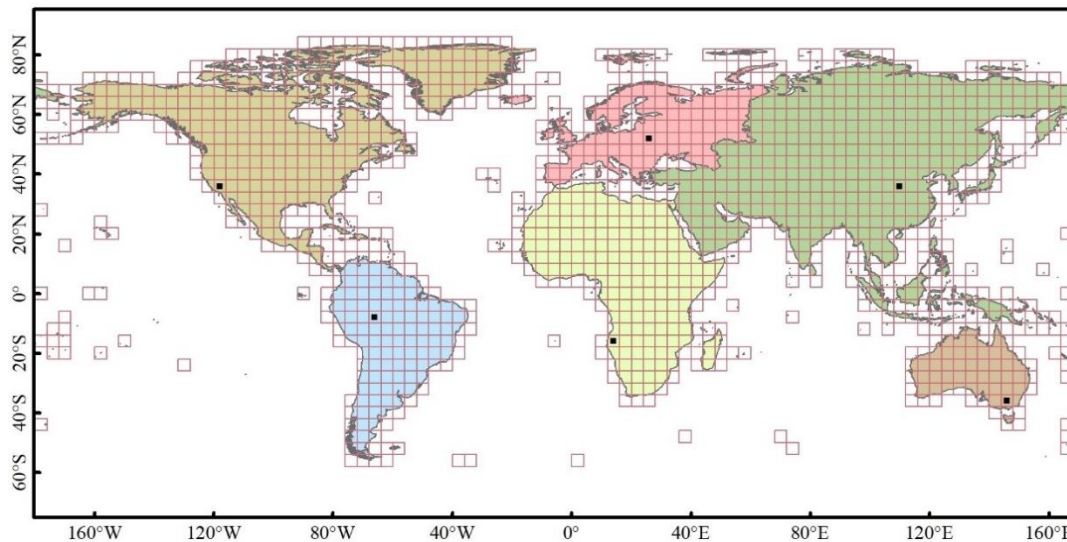

209 Since the seasonal water in GSW data is not as reliable as the permanent water (Meyer et al., 2020), we  
210 selected permanent water bodies and excluded seasonal water bodies.

211 GMW dataset was produced as a result of the GMW initiative, which aims to provide consistent  
212 information of mangrove extent. The global mangrove map in 2010 was generated as a baseline map  
213 employing the Extremely Randomized Trees classifier to classify ALOS PALSAR and Landsat imagery.  
214 Assessed by a total of 53,878 sample points globally, the overall accuracy of the baseline map reached  
215 95.3% and the producer's accuracy achieved 94.0% (Bunting et al., 2018). Based on the baseline in 2010,  
216 mangrove extent maps for six epochs between 1996 and 2016 have been established and annual change  
217 monitoring from 2018 and onwards are undertaken.

### 218 2.3 Global point-based and patch-based samples

219 In this study, we collected two sets of global samples, namely the global point-based samples and the  
220 global patch-based samples. To collect representative and sufficient samples efficiently, we divided the  
221 world's terrestrial area into  $4^\circ \times 4^\circ$  geographical grids. A total of 1,507 grids are distributed evenly across  
222 the globe, shown as Figure 1.

223  
224 **Figure 1. Spatial distribution of the  $4^\circ \times 4^\circ$  geographical grids over the world. Six black rectangle tiles with**  
225 **size of  $0.25^\circ$  were used for visual comparison between our product and other three products.**

226 To derive the global point-based samples, we adopted stratified random sampling in each grid. The  
227 stratified random sampling depends on area ratio of LC classes from a LC product. We used the  
228 FROM\_GLC as prior knowledge rather than the Globeland30 and GLC\_FCS30 with two considerations:

229 (1) the FROM\_GLC has the same data time as our target map (GLC-2015) while the Globeland30 has a  
230 5-year interval from our samples, which affects the size of samples for each LC class; (2)the 10 level-1  
231 land cover classes of the FROM\_GLC is similar to that in the classification system of the GLC-2015,  
232 while the GLC\_FCS30 has differences with the GLC-2015 in the classification scheme and definition of  
233 land cover classes. First, the FROM\_GLC product was used to calculate the area ratio of each LC class.  
234 Then, points were randomly extracted from the FROM\_GLC according to the area ratio and spatial  
235 location of each class. Finally, more than 200,000 global samples were collected. Through the sampling  
236 method mentioned above, the global point-based samples were even across the globe and sufficient for  
237 each LC class in each grid. Therefore, more than 50 points could be easily derived for LC classes with a  
238 small area ratio in the  $4^{\circ} \times 4^{\circ}$  grid. The FROM\_GLC shows low accuracy for some LC classes, especially  
239 for cropland and forest (Gao et al., 2020; Liu et al., 2021b; Zhang et al., 2021; Zhang et al., 2022). If the  
240 global samples were extracted with LC class label from the FROM\_GLC, there would be inevitable  
241 errors. Therefore, the FROM\_GLC was only used to determine the size and location of samples for each  
242 LC class. Instead, all the points were manually labeled according to Google Earth high-resolution images.  
243 The whole sample set was randomly split into two subsets: 80% of the global samples were used to assess  
244 the accuracy of each GLC product for various LC classes at the global scale and in each grid. The  
245 remaining 20% were used for the validation of the GLC-2015 map and data inter-comparison between  
246 different GLC products. Figure 2 presents the distribution of the whole global point-based samples and  
247 the subset for accuracy assessment and data inter-comparison.

To verify the consistency between the GLC-2015 and the actual pattern of the landscape at the local scale, we also established the global patch-based samples. Simple random sampling was used to derive 5 km × 5 km blocks over the world's terrestrial area and across different ecoregions because it is easy to perform and capable to augment the sample size from target areas (Pengra et al., 2020). Since inconsistency between current GLC maps tends to appear in those heterogeneous areas, such as fragmented regions and transition zones, we slightly increased the sample size for areas with the heterogeneous landscape to better evaluate our mapping results. In total, there were 201 blocks selected as the global patch-based samples, as displayed in Figure 3a. Then, for each block in the patch-based samples, we used ArcGIS 10.5 software to derive polygons (patches) of various sizes which captured the real landscape on the high-resolution images. Meanwhile, each polygon was manually labeled with a LC class. Four examples of producing patch-based samples are shown in Figure 3b, c.

**Figure 3. Spatial distribution and selected examples of the global patch-based samples. The location of 5 km × 5 km patch-based samples are shown as panel (a), the locations of four selected samples are remarked by red dash circles. Panels (b) and (c) illustrate the production of global patch-based samples on manual interpretation. The red lines in high-resolution images circa 2015 are results after vectorization using ArcGIS 10.5 software. Four corresponding patch-based samples are shown as (c).**

### 269 3. Methods

270 In this study, we proposed a multi-source product fusion method to produce the GLC-2015 map. The  
271 procedure mainly comprised the fusion based on the Dempster-Shafer theory of evidence (DSET),  
272 accuracy assessment and data inter-comparison (Figure 4). The basic of this study is the fusion of multi-  
273 source GLC products based on DSET. The fusion method was performed at the pixel level and it involves  
274 the following three main steps: (1) Construct the basic probability assignment (BPA) function of each  
275 pixel that belongs to each LC class considering the accuracy assessment of different GLC products; (2)  
276 calculate the combined probability mass for each class per pixel using the Dempster’s rule of combination;  
277 and (3) determine the finally accepted LC class per pixel by a decision rule. Afterwards, pixels with a  
278 determined LC class were integrated to generate a new map. For large-scale or global land cover mapping,

279 previous researchers divided the study area into a lot of sub-regions and conducted classification in each  
 280 sub-region on GEE (Gong et al., 2020; Liu et al., 2020b; Huang et al., 2021; Jin et al., 2022; Zhang et  
 281 al., 2021; Zhao et al., 2021). The shape and size of sub-region vary in previous work, such as hexagons  
 282 with a side length of  $2^\circ$ , geographical grids with a size of  $1^\circ \times 1^\circ$ ,  $3.5^\circ \times 3.5^\circ$ ,  $5^\circ \times 5^\circ$ , or  $10^\circ \times 10^\circ$ . When  
 283 deciding on the size of sub-regions, two important factors should be considered. The size of samples in  
 284 each sub-region should be sufficient so that the rare land cover classes will not be missed. On the other  
 285 hand, it is impossible to implement mapping work at a sub-region as larger as we want due to memory  
 286 constraints. To determine the appropriate size, we tested different sizes of the sub-region (see Table S1).  
 287 Result shows that dividing the study area into  $4^\circ \times 4^\circ$  grids performed best. Therefore, we split the world's  
 288 terrestrial area into 1507  $4^\circ \times 4^\circ$  geographical grids. The entire framework was implemented in all  $4^\circ \times 4^\circ$   
 289 geographical grids on the GEE platform.

290  
 291 **Figure 4. The framework for generating the GLC-2015 map using a multi-source product fusion approach**  
 292 **based on DEST.**

293 **3.1 Definition of the classification system**

294 In this study, we adopted the classification system with 10 LC classes, including cropland, forest,  
 13

295 grassland, shrubland, wetland, water bodies, tundra, impervious surfaces, bare land, and permanent snow  
 296 and ice (Chen et al., 2015), as listed in Table 2. Due to the applications for different social needs, the  
 297 existing GLC products and national-scale LC products were produced with different classification  
 298 systems (Tables S2-S3). The GlobeLand30 used a simple classification system that only contained 10  
 299 first-level classes. Unlike the GlobeLand30, the FROM\_GLC and GLC\_FCS30 were classified with a  
 300 two-level classification scheme. Through analysis of these systems, we found that the classification  
 301 systems are not the same, but they have some agreements. There are both 10 major classes in the  
 302 GlobeLand30 and FROM\_GLC despite that the definition of some classes differs. Additionally, in  
 303 contrast to the GlobeLand30 and FROM\_GLC, the level-0 classification system of the GLC\_FCS30  
 304 lacks tundra. However, in the level-2 detailed LC classes of the GLC\_FCS30, lichens and mosses has  
 305 little distinction with tundra.

306 **Table 2. Classification system adopted in this paper.**

Id	LC class	Definition
10	Cropland	Land areas used for food production and animal feed.
20	Forest	Land areas dominated by trees with tree canopy cover over 30%, and sparse trees with tree canopy cover between 10%-30%.
30	Grassland	Land areas dominated by natural grass with a cover over 10%.
40	Shrubland	Land areas dominated by shrubs with a cover over 30%, including mountain shrubs, deciduous shrubs, evergreen shrubs and desert shrubs with a cover over 10%.
50	Wetland	Land areas dominated by wetland plants and water bodies.
60	Water bodies	Land areas covered with accumulated liquid water.
70	Tundra	Land areas dominated by lichen, moss, hardly perennial herb and shrubs in the polar regions.
80	Impervious surfaces	Land areas covered with artificial structures.
90	Bare land	Land areas with scarce vegetation with a cover lower than 10%.
100	Permanent snow and ice	Land areas dominated by permanent snow, glacier and icecap.

307 According to the classification system adopted in the study, the original LC classes of FROM\_GLC  
 308 and GLC\_FCS30, CLUD for 2015, and NLCD 2016 for 2016 were converted into the 10 target land  
 309 cover classes based on the similarity of LC definition. Note that cropland in our classification system  
 310 was defined as land areas for food production and animal feed. Therefore, pasture in level-2 classes of

311 the FROM\_GLC was converted into cropland rather than grassland. In addition, lichens/mosses in the  
312 level-2 detailed LC classes of GLC\_FCS30 was converted into tundra.

### 313 3.2 A multi-source product fusion for the GLC-2015 mapping

314 The DSET is an effective method widely applied for the fusion of multi-source data. To generate a new  
315 high-quality GLC map, a multi-source product fusion method using DSET was proposed. In the  
316 remainder of the section 3.2, We introduced the overview on the theory and presented the application of  
317 DSET in our mapping process.

#### 318 3.2.1 Dempster-Shafer theory of evidence

319 The DSET is developed by Dempster and Shafer, which is an extension of Bayesian probability theory.  
320 This theory treats information from different data sources as independent evidence and integrated these  
321 evidences with no requirements regarding the prior knowledge. In the fusion, we assume a classification  
322 process in which all the input data are to be classified into mutually exclusive classes. Let the set  $\Omega$  of  
323 these classes be a frame of discrimination.  $2^\Omega$  is the power set of  $\Omega$  that includes all the classes and  
324 their possible unions. We defined the function  $m: 2^\Omega \rightarrow [0,1]$  as the basic probability assignment (BPA)  
325 function if and only if it satisfies  $m(\emptyset) = 0$  and  $\sum_{A \in 2^\Omega} m(A) = 1$  with  $\emptyset$  denotes an empty set. For  
326 each class  $A \subseteq 2^\Omega$ ,  $m(A)$  is called the basic probability mass which can be computed from the BPA  
327 function and represents the degree of support for class A or confidence in class A.

328 The purpose of fusion is to evaluate and integrate information from multiple sources. In the DSET,  
329 these multi-source data are regarded as different evidence and provide different assessments. To generate  
330 all the evidences, Dempster-Shafer theory of evidence offers a rule. Suppose  $m_i(B_j)$  is the basic  
331 probability mass computed from the BPA function for each input data  $i$  with  $1 \leq i \leq n$  for all classes  
332  $B_j \in 2^\Omega$ . Dempster's rule of combination is provided to calculate a combined probability mass from  
333 different evidences. The fusion rules are given in equation (1) and (2).

$$334 \quad m(C) = \frac{\sum_{B_1 \cap B_2 \dots \cap B_n = C} \prod_{1 \leq i \leq n} m_i(B_j)}{1 - k} \quad (1)$$

335

$$336 \quad k = \sum_{B_1 \cap B_2 \dots \cap B_n = \emptyset} \prod_{1 \leq i \leq n} m_i(B_j) \quad (2)$$

337 Where  $k$  represents the basic probability mass associated with conflicts among the sources of evidence.

338  $C$  is the intersection of all classes  $B_j$  and carries the joint information from all the input data. After the  
 339 combination, we took a decision rule to decide the class we finally accept. There are several ways to  
 340 decide the final class by simply choosing the class with the maximum belief, plausibility, support, or  
 341 commonality.

### 342 3.2.2 Mapping based on DSET

343 Here, we presented our implementation for the GLC-2015 mapping in the framework of DSET. All the  
 344 multiple-class and single-class GLC products described in Sect. 2 were selected as input maps to be  
 345 combined. In the integration of multi-source GLC products, since all the LC classes in our classification  
 346 system are known, the frame of discrimination was defined to be our classification system:

$$347 \quad \Omega = \left\{ \begin{array}{l} \text{cropland, forest, grassland, shrubland, wetland, water bodies,} \\ \text{tundra, impervious surfaces, bare land, permanent snow and ice} \end{array} \right\} \quad (3)$$

348 The definition of BPA function is the critical point in applying DSET (Rottensteiner et al., 2005).  
 349 In the fusion, we wanted to achieve a per-pixel classification into one of ten LC classes: cropland, forest,  
 350 grassland, shrubland, wetland, water bodies, tundra, impervious surfaces, bare land, and permanent snow  
 351 and ice. For each single-class or multiple-class GLC product, the accuracy for each LC class was  
 352 calculated and used as evidential probability to construct the BPA. Given that the local accuracy for a  
 353  $4^\circ \times 4^\circ$  grid was not able to adequately reflect the actual land cover landscape, especially for the rare LC  
 354 classes, the global accuracy was incorporated into the construction of the BPA to avoid uncertainties from  
 355 a local point of view. Since the assessment based on local samples plays a more critical role in BPA  
 356 construction for a local grid, a higher weight should be assigned to the local accuracy. **To identify the  
 357 best weight, we tested different weights of the local accuracy (see Figure S1). The result shows that using  
 358 75% performed robustly and obtained relatively higher overall accuracy. Therefore, we chose 75% as  
 359 the weight for local accuracy and 25% for global accuracy.** Here, we defined the BPA function as follow:

$$360 \quad m_i(T_j) = \frac{PA_{local(ij)} + UA_{local(ij)}}{2} \times 75\% + \frac{PA_{global(ij)} + UA_{global(ij)}}{2} \times 25\% \quad (4)$$

361 Where  $m_i(T_j)$  represents the BPA function of evidence source  $i$  for the LC class  $T_j$ ;  $PA_{local(ij)}$ ,  
 362  $UA_{local(ij)}$  denote producer's accuracy and user's accuracy of evidence source  $i$  for the LC class  $T_j$  for  
 363 each  $4^\circ \times 4^\circ$  geographical grid, respectively;  $PA_{global(ij)}$ ,  $UA_{global(ij)}$  denote producer's accuracy and  
 364 user's accuracy of evidence source  $i$  for LC class  $T_j$  at the global scale.

365 To estimate the exact values of  $PA_{local(ij)}$ ,  $UA_{local(ij)}$ ,  $PA_{global(ij)}$  and  $UA_{global(ij)}$ , we used 80%

366 of the global point-based samples more than 160,000 points derived in Sect 2.3. As soon as we obtained  
 367 the measurements of  $m_i(T_j)$ , the combined probability masses  $m(T_j)$  were evaluated based on  
 368 Dempster's rule of combination for each pixel classified as the LC class  $T_j$  by fusing BPA values of all  
 369 the evidence sources:

$$370 \quad m(T_j) = \frac{1}{1-k} \sum_{T_{1j} \cap T_{2j} \dots \cap T_{nj} = T_j} m_i(T_j) \quad (5)$$

$$371 \quad k = \sum_{T_{1j} \cap T_{2j} \dots \cap T_{nj} = \emptyset} m_i(T_j) \quad (6)$$

372 Where  $k$  represents the basic probability mass associated with conflict;  $m_i(T_j)$  represents the basic  
 373 probability mass of a certain pixel belonging to the LC class  $T_j$  from different GLC products.

374 Additionally, a belief measure (Bel) was given to measure the degree of credibility that a pixel  
 375 labeled as the finally accepted LC class when combining all the available evidences. The belief measure  
 376 was determined by

$$377 \quad Bel(T_j) = \sum_{T_{ij} \in T_j} m_i(T_j) \quad (7)$$

378 To determine the finally accepted LC class per pixel, we took the rule of maximum combined  
 379 probability mass as our decision rule and the LC class with the maximum combined probability mass is  
 380 assigned to the 30 m pixel. Pixels labeled with the LC class were integrated to generate the GLC-2015  
 381 product.

### 382 3.3 Accuracy assessment

383 To assess the accuracy of the GLC-2015 map, we utilized two validation methods: validation with the  
 384 global point-based samples and the global patch-based samples. Since the global point-based sample set  
 385 is distributed evenly across the world and its sample size for each LC class is relatively sufficient and  
 386 balanced, even for the rare classes, it can provide a representative and credible basis for estimation of the  
 387 GLC-2015 map globally. Furthermore, we used the global patch-based samples to conduct accuracy  
 388 assessment from the local landscape scale. Although the global patch-based sample set provide an  
 389 inadequate sample size for rare LC classes, it can take advantage of the spatial context information and  
 390 efficiently reflect the actual pattern of the landscape.

391 The [confusion matrix](#) was produced to evaluate and analyze the GLC-2015 mapping result. The  
 392 error matrix is composed of entry  $A_{ij}$ , which represents the number of samples with reference LC class

393  $j$  being classified as LC class  $i$ . The overall accuracy (OA), kappa coefficient, producer's accuracy (PA),  
 394 and user's accuracy (UA) were generated from [confusion matrix](#) to describe the quality of the GLC-2015  
 395 map. They are defined as follows:

$$396 \quad OA = \frac{\sum_i A_{ii}}{\sum_i \sum_j A_{ij}} \quad (8)$$

$$397 \quad P_o = OA \quad (9)$$

$$398 \quad P_e = \sum_k \frac{\sum_i A_{ik}}{\sum_i \sum_j A_{ij}} \times \frac{\sum_j A_{kj}}{\sum_i \sum_j A_{ij}} \quad (10)$$

$$399 \quad kappa = \frac{P_o - P_e}{1 - P_e} \quad (11)$$

$$400 \quad PA^i = \frac{A_{ii}}{\sum_k A_{ki}} \quad (12)$$

$$401 \quad UA^i = \frac{A_{ii}}{\sum_k A_{ik}} \quad (13)$$

402 Where  $UA^i$  and  $PA^i$  represent UA and PA of the LC  $i$ , respectively;  $P_o$  is the agreement between the  
 403 reference and the classified data;  $P_e$  is the hypothetical probability of chance agreement.

#### 404 **3.4 Data inter-comparison**

405 To better reflect the quality of the GLC-2015 map, we intercompared the GLC-2015 map with LC  
 406 products at multiple scales. In the accuracy assessment of different products, two global validation sets  
 407 described earlier were employed.

408 To figure out whether the GLC-2015 map promotes accuracy in the areas with high classification  
 409 difficulty and how much the improvement is compared to the other products, we conducted the spatial  
 410 consistency analysis between the GlobeLand30, FROM\_GLC, and GLC\_FCS30 and compared the  
 411 mapping performance of the GLC-2015 with others in the areas of low inconsistency, moderate  
 412 inconsistency, and high inconsistency. To visually present the spatial consistency between three existing  
 413 GLC maps, we employed the spatial superposition method to obtain the spatial correspondence pixel-  
 414 by-pixel between different maps. Based on the times of all the GLC products agreed for the same LC  
 415 class, the degree of consistency for a pixel was identified as three levels with the agreement value equal  
 416 to 3, 2, or 1. The areas of low inconsistency were regarded as pixels that classified as the same LC class  
 417 in all three GLC maps (labeled as 3). The moderate inconsistency areas were regarded as pixels that were  
 418 consistent in only two GLC maps (labeled as 2). The high inconsistency areas were regarded as pixels  
 419 that were totally inconsistent in these three GLC maps (labeled as 1). For a visual comparison, all these

420 GLC maps were aggregated to  $0.05^\circ$ , in which the LC class with the largest proportion determined the  
421 class in each  $0.05^\circ$  grid.

### 422 **3.5 Assessment on mapping performance of DSET and other methods**

423 In addition to inter-comparison between the GLC-2015 map and three existing GLC products, we  
424 compared the DSET method with two existing commonly used fusion methods, including the majority  
425 voting (MV) and spatial correspondence (SC) based on two global validation sets including 20% of the  
426 global point-based samples and the whole global patch-based samples. MV is a fusion approach that  
427 combines input maps and adopts the LC class favored by the majority of the candidate maps. In the MV  
428 method, we compared the GlobeLand30, FROM\_GLC, and GLC\_FCS30 at each pixel and chose the  
429 class that two or three LC products agreed for. For pixels where three LC products were different, the  
430 LC class of the product with the highest accuracy was adopted. SC method produces an integrated land  
431 cover map by selecting the LC class of the input map that has the highest spatial correspondence with  
432 the reference data. In this study, 80% of the global point-based samples were used as the reference data  
433 to obtain the SC map of each global LC product. If the class of a product agreed with that of the point-  
434 based sample, a value equal to 1 was assigned to that sample. On the contrary, a value equal to 0 was  
435 assigned to the sample if the class of the product differed from that of the sample. In each  $4^\circ \times 4^\circ$  grid,  
436 we used the Kriging method to obtain spatial correspondence maps which have the correspondence value  
437 ranging from 0 to 1 for three products. Then, the class of the product with the highest spatial  
438 correspondence was chosen for each pixel.

439 Furthermore, we compared the mapping performance of DSET with Random Forest (RF) which is  
440 considered one of the most popular algorithms for land cover mapping. In the land cover classification  
441 using the FR classifier, all available Level-2 Tier 1 surface reflectance (SR) data of Landsat 8 OLI  
442 (Operational Land Imager) sensors from the year 2015 and two adjacent years on GEE was employed.  
443 All Landsat images have been atmospherically corrected. The following six bands were used as input  
444 features: blue, green, red, NIR, SWIR1, and SWIR2. To improve the mapping performance, several  
445 important spectral indices, including DNVI, NDWI, and NDBI were also used as auxiliary data to the  
446 RF classifier. The RF classifier was trained on 80% of the global point-based samples since those samples  
447 were of high quality after manual visual interpretation of high-resolution images. As the global land cover  
448 mapping based on the RF classifier is a tough task, we randomly selected a total of 300 grids with the

449 size of 4° (Figure S2) and applied corresponding local RF classifiers to these grids. Then, the mapping  
450 results were validated by the remaining 20% of the point-based samples.

## 451 4. Results and discussion

### 452 4.1 Mapping result of the GLC-2015 map

453 Using a multi-source product fusion method based on the DSET, we generated an improved 30m global  
454 land cover map in 2015 (GLC-2015). Figure 5 illustrates the GLC-2015 map. The GLC-2015 map can  
455 accurately describe the spatial distribution of various LC classes. For example, cropland areas are mostly  
456 located in Central America, the region from the Hungarian plain to the Siberian plain, the eastern and  
457 southern parts of China, and the most of India. In addition, forest, which is one of the easily  
458 distinguishable classes from the map, is concentrated in the eastern part of North America, the Amazon  
459 basin of South America, the northern part of Eurasia and the equatorial region of Africa.

460

461 **Figure 5. Global land cover map in 2015 with 30 m resolution (GLC-2015).**

### 462 4.2 Accuracy assessment of the GLC-2015 map

#### 463 4.2.1 Accuracy assessment with the global point-based samples

464 The accuracy of the GLC-2015 map was first tested via the global point-based samples, and the results  
465 of assessment are listed in Table 3. The GLC-2015 map achieved an OA of 79.5% and kappa coefficient  
466 of 0.757 at the global scale, demonstrating the good performance of our map. Among all the LC classes,  
467 permanent snow and ice possessed the best mapping performance, with PA and UA achieving 89.1% and

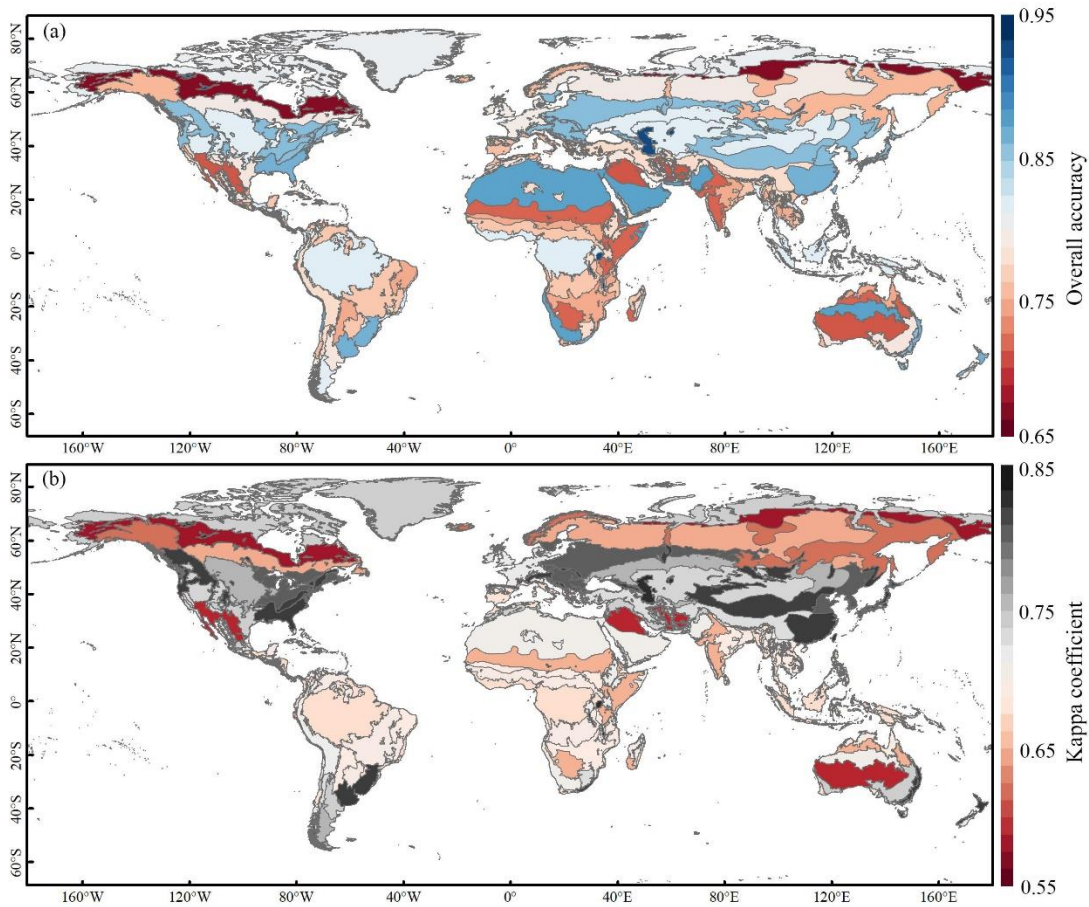

468 93.7%. The accuracy of water bodies, forest and impervious surfaces was also high, where PA and UA  
 469 exceeded 80.0%. Grassland, shrubland, and wetland had relatively low accuracy, with PA below 75.0%.  
 470 Among them, grassland and shrubland were mainly confused with forest, which might be because these  
 471 classes are both vegetation, thus causing difficulty in recognition by spectral information. Due to the  
 472 complex spectral characteristics, wetland is often mixed with vegetation (Ludwig et al., 2019).

473 **Table 3. The confusion matrix for the GLC-2015 map based on the global point-based samples.**

	Cropland	Forest	Grassland	Shrubland	Wetland	Water bodies	Tundra	Impervious surfaces	Bare land	Permanent snow and ice	Total	PA
Cropland	3623	387	356	61	27	48	2	71	81	0	4656	0.778
Forest	155	8813	186	141	232	16	43	43	53	3	9685	0.910
Grassland	10	337	1920	19	24	13	47	36	184	9	2599	0.739
Shrubland	155	438	656	1469	39	29	70	78	442	4	3380	0.435
Wetland	47	287	82	14	1067	64	22	18	110	4	1715	0.622
Water bodies	27	90	15	1	73	1936	17	10	44	3	2216	0.874
Tundra	1	242	119	6	29	19	1411	2	269	17	2115	0.667
Impervious surfaces	74	41	11	3	8	11	1	1295	45	0	1489	0.870
Bare land	36	59	237	32	44	91	55	60	4909	38	5561	0.883
Permanent snow and ice	0	11	8	0	4	18	13	1	86	1154	1295	0.891
Total	4128	10705	3590	1746	1547	2245	1681	1614	6223	1232	34711	
UA	0.878	0.823	0.535	0.841	0.690	0.862	0.839	0.802	0.789	0.937		
OA						0.795						
Kappa						0.757						

474 The regional accuracies are presented in Figure 6. The OA of the GLC-2015 ranged from 66.4% to  
 475 93.4%, and kappa coefficient from 0.552 to 0.813. From the perspective of OA, Water regions lead,  
 476 followed by Tropical desert, Temperate continental forest, and Polar. These are areas with homogeneous  
 477 land cover and have low difficulty in mapping. Boreal tundra woodland, Tropical dry forest, Tropical  
 478 shrubland, and Subtropical desert are the regions with low OA. The first one may be related to the high  
 479 latitudes. The followed two may be because they belong to areas with complicated and mixed LC classes  
 480 which is not easily classified. The last one may be the consequence of sparse vegetation in desert areas.

481 For the kappa coefficient, the ranking was similar with those for OA.

482  
483 **Figure 6. Regional accuracy of the GLC-2015 map according to ecoregions. (a)overall accuracy, (b) kappa**

485 **Nations (FAO).**

#### 486 4.2.2 Accuracy assessment with the global patch-based samples

487 The accuracy assessment of the GLC-2015 map was also conducted with the global patch-based samples.  
488 Table 4 summarizes the results for accuracy assessment of each LC class in the GLC-2015 map. From  
489 the assessment results, it can be found that the OA of the GLC-2015 map reached 83.6%, which was  
490 higher than 79.5% tested with the global point-based samples. The kappa coefficient of the GLC-2015  
491 map was 0.566, which was 0.191 lower than the result calculated with the global point-based samples.  
492 In both accuracy assessment results based on two different validation data sets, water bodies, forest, and  
493 permanent snow and ice were validated to have high accuracy, and grassland, shrubland, and wetland  
494 were validated to have low accuracy. Nevertheless, the ranking of accuracy for each LC class had a slight  
495 difference. For example, in assessment based on the global point-based samples, impervious surfaces  
496 and permanent snow and ice ranked higher than that based on the global patch-based samples. This may

497 be because a LC map can easily show where one LC class is distributed but hardly describe its actual  
 498 shape. In addition to the accuracy assessment on a pixel scale, validation on a patch scale is equally  
 499 important because it can reflect the shape consistency between the GLC-2015 map and the actual  
 500 landscape, even if the size of global patch-based samples is relatively small. Overall, no matter from the  
 501 perspective of the global point-based samples or the global patch-based samples, the mapping accuracies  
 502 of the GLC-2015 map are satisfactory.

503 **Table 4. Mapping accuracy via the global patch-based samples for the GLC-2015 map**

	Cropland	Forest	Grassland	shrubland	Wetland	Water bodies	Tundra	Impervious surfaces	Bare land	Permanent snow and ice
PA	0.887	0.895	0.629	0.589	0.301	0.939	0.701	0.757	0.682	0.825
UA	0.916	0.844	0.617	0.714	0.511	0.917	0.872	0.713	0.599	0.767
OA							0.836			
Kappa							0.566			

504 **4.3 Inter-comparison with other GLC products**

505 **4.3.1 Inter-comparison based on the global point-based samples**

506 Based on the global point-based samples, the inter-comparison of the GLC-2015 map with the  
 507 GlobeLand30, FROM\_GLC, and GLC\_FCS30 were conducted. Since the three products used different  
 508 classification systems, LC classes were transformed to the classification system we adopted in this paper  
 509 to achieve consistent accuracy assessment. The accuracy assessment results for all GLC maps are listed  
 510 in Table 5. It can be found that the GLC-2015 map achieved the highest OA of **79.5%** compared with  
 511 GlobeLand30 of **65.3%**, FROM\_GLC of **61.7%**, and GLC\_FCS30 of **65.5%**, respectively. The accuracy  
 512 gap between the GLC-2015 map and other existing ones was **14.0%-17.8%**. Also, the GLC-2015 map  
 513 possessed a better kappa coefficient than other products. For each LC class, the GLC-2015 map  
 514 outperformed the other three maps in terms of PA **except for tundra**. For cropland, grassland, shrubland,  
 515 wetland, and tundra, the GLC-2015 map also exhibited better performance for UA than the GlobeLand30,  
 516 FROM\_GLC and GLC\_FCS30. Overall, for the PA or UA, the GLC-2015 map ranked first or second in  
 517 nearly all LC classes, which demonstrated that the GLC-2015 map had smaller omission and commission  
 518 errors against the other three products.

519 **Table 5. Mapping accuracy of the GLC products with the global point-based samples.**

		Cropland	Forest	Grassland	Shrubland	Wetland	Water bodies	Tundra	Impervious surfaces	Bare land	Permanent snow and ice	OA (Kappa coefficient)
GLC-2015	PA	0.778	0.910	0.739	0.435	0.622	0.874	0.667	0.870	0.883	0.891	0.795
	UA	0.878	0.823	0.535	0.841	0.690	0.862	0.839	0.802	0.789	0.937	(0.757)
Globeland30	PA	0.752	0.719	0.713	0.245	0.540	0.680	0.769	0.688	0.609	0.821	0.653
	UA	0.786	0.818	0.255	0.428	0.573	0.869	0.577	0.809	0.868	0.905	(0.598)
FROM_GLC	PA	0.389	0.694	0.707	0.411	0.307	0.607	0.712	0.732	0.731	0.881	0.617
	UA	0.671	0.859	0.278	0.422	0.289	0.742	0.686	0.661	0.761	0.773	(0.558)
GLC_FCS30	PA	0.757	0.775	0.452	0.399	0.455	0.604	0.228	0.777	0.809	0.726	0.655
	UA	0.616	0.816	0.384	0.405	0.515	0.808	0.688	0.774	0.645	0.947	(0.591)

520 Further quantitative accuracy assessments of different GLC products were performed in  $4^{\circ} \times 4^{\circ}$   
521 grids using the global point-based samples, and box plots were produced for each product for all grids  
522 within different ecoregions, as shown in Figure 7. It can be found that the GLC-2015 map outperformed  
523 other existing products with the best OA and kappa coefficient across different ecoregions. Also, the  
524 mean overall accuracy of the GLC-2015 map exceeded 65.0% in all ecoregions, showing the high quality  
525 of our mapping results. It is worth noting that the GLC-2015 map showed shorter boxes except in  
526 Subtropical dry forest and Subtropical desert, which means the GLC-2015 map had relatively small  
527 fluctuation than other ones. In Subtropical desert, Tropical dry forest, and Boreal tundra woodland, the  
528 OA and kappa coefficient of the four products were relatively low. However, the GLC-2015 map  
529 exceeded the highest of others and greatly improved the mean OA in these regions.

530  
531 **Figure 7. The box-plot of the accuracy for twenty-one ecoregion zones. (a) overall accuracy, (b)kappa**  
532 **coefficient. Ecoregion abbreviation and corresponding ecoregion is described in Table S4.**

533 **4.3.2 Inter-comparison based on the global patch-based samples**

534 Although the global point-based samples are adequate and even across the globe, the distribution of  
 535 points in each  $4^\circ \times 4^\circ$  geographical grid is too sparse to reflect the actual spatial pattern of the landscape.  
 536 Focusing on LC pattern at the local scale, we also used the global patch-based samples which can provide  
 537 spatial context information to conduct the accuracy assessment of the GLC-2015 map and compare  
 538 difference GLC products. Table 6 lists the accuracies of the GLC-2015 map and the other three GLC  
 539 products. Obviously, the GLC-2015 map achieved the best OA and kappa coefficient among these four  
 540 GLC maps. The overall accuracy gap between the GLC-2015 product and others was 5.9%-24.5%, which  
 541 presented a more significant variation compared with the result based on the global point-based samples.  
 542 In terms of PA and UA, the GLC-2015 map was higher than the other three ones in most LC classes.  
 543 Specifically, all the products had lower accuracy for grassland, shrubland, and wetland, similar to that in  
 544 the accuracy assessment based on the global point-based samples. It is evident that the FROM\_GLC had  
 545 the lowest mapping accuracy for grassland, shrubland, and wetland, implying that the classification  
 546 method of FROM\_GLC is not robust for these three LC classes.

547 **Table 6. Mapping accuracy of the GLC products with the global patch-based samples**

		Cropland	Forest	Grassland	Shrubland	Wetland	Water bodies	Tundra	Impervious surfaces	Bare land	Permanent snow and ice	OA
GLC-2015	PA	0.887	0.895	0.629	0.589	0.301	0.939	0.701	0.757	0.682	0.825	0.836
	UA	0.916	0.844	0.617	0.714	0.511	0.917	0.872	0.713	0.599	0.767	(0.566)
Globeland30	PA	0.896	0.698	0.765	0.539	0.455	0.824	0.752	0.643	0.492	0.831	0.777
	UA	0.891	0.906	0.444	0.527	0.157	0.893	0.500	0.703	0.829	0.705	(0.437)
FROM_GLC	PA	0.485	0.714	0.640	0.254	0.032	0.904	0.760	0.506	0.681	0.501	0.591
	UA	0.872	0.809	0.193	0.139	0.186	0.884	0.696	0.808	0.496	0.703	(0.360)
GLC_FCS30	PA	0.865	0.779	0.398	0.565	0.363	0.869	0.051	0.648	0.658	0.742	0.748
	UA	0.857	0.832	0.509	0.330	0.132	0.942	0.573	0.643	0.462	0.752	(0.418)

548 Accuracy assessment was calculated in each patch-based sample, and box plots were produced for  
 549 each GLC product at the continental scale, as shown in Figure 8. The GLC-2015 map showed a robust  
 550 performance in each continent, with the highest OA and kappa coefficient among all the maps. Also, in  
 551 all continents, the GLC-2015 map had the shortest boxes in terms of OA, which denoted that it had a

552 more minor variation in accuracy at the continental scale. Among four products, the GLC\_FCS30 and  
 553 Globeland30 achieved similar accuracies in most continents. Obviously, the FROM\_GLC showed lowest  
 554 accuracy across different continents, especially in Oceania, where the OA of most patch-based samples  
 555 was below 40.0%, namely most of the pixels in Oceania were incorrectly classified. We further compared  
 556 mapping accuracies for each LC class in different continents (Figures S3-S4). Since tundra and  
 557 permanent snow and ice are rare and only existent in certain regions, they were not included in the  
 558 comparison. As for PA across different continents, the GLC-2015 map outperformed other maps in forest,  
 559 water bodies, and bare land. As for UA across different continents, the GLC-2015 map outperformed  
 560 other maps in cropland, grassland, shrubland and wetland, and achieved similar accuracies with the  
 561 GLC\_FCS30 and Globeland30 in forest. Overall, the GLC-2015 map outperformed others regarding  
 562 mapping accuracy at continental scale. In addition, all GLC products showed significant variation and  
 563 low mean accuracy in grassland, shrubland, and wetland over most continents.

564  
 565 **Figure 8. The box-plot of the accuracy for different continents. (a) overall accuracy, (b) kappa coefficient.**

566 Furthermore, to compare the OA of the GLC-2015 map with other GLC products, scatter plots were  
 567 used to describe the relationship between the overall accuracy of the GLC-2015 map and one other  
 568 product in each patch-based sample, as displayed in Figure 9. Most of the points were above the 1:1 line,  
 569 implying that the GLC-2015 map surpassed other GLC products in terms of OA. The distribution of  
 570 points was more dispersed from the 1:1 line in the plot of the GLC-2015 map against FROM\_GLC  
 571 compared to other plots. It indicated that these two products had a more significant difference, which  
 572 was also proved in Table 6.

573

574

575

576

### 4.3.3 Areal comparison for individual classes

577

To assess the similarities and discrepancies between the GLC-2015 and other GLC products, we compared the area of various LC classes at multiple scales, including global, continental, national, and ecoregional scales.

578

579

580

The areal comparison for various classes of different GLC products over the globe is shown in Figure 10. Generally, the areas of water bodies and permanent snow and ice of four GLC products were very similar, which may be related to the similar LC definitions. In contrast, the areas of cropland, forest, grassland, and shrubland in GLC-2015 differed significantly from those in other GLC products. The area of forest in GLC-2015 is much higher than other products. This may be because FROM\_GLC and GLC\_FCS30 defined forest with tree cover over 15%, while GLC-2015 used a threshold of over 10%. The cropland areas in GLC-2015 and Globeland30 were close, higher than FROM\_GLC but lower than GLC\_FCS30. Moreover, the FROM\_GLC underestimated the cropland area as it had a low producer's accuracy for cropland (see Table 5), which was also demonstrated in previous researches (Liu and Xu, 2021; Zhang et al., 2021). FROM\_GLC and Globeland30 shared similar grassland areas since a similar accuracy for grassland was found in these two products (see Table 5). However, the FROM\_GLC and Globeland30 significantly overestimated grassland extent, with much bare land misclassified as grassland (Hu et al., 2014). The GLC\_FCS30 showed the smallest area for grassland, which might be related to its higher threshold in vegetation cover for grassland. For shrubland, the area difference between GLC-2015 and Globeland30 was minimal, and the areas in FROM\_GLC and GLC\_FCS30 were similar. Furthermore, the wetland area in FROM\_GLC was the lowest among all the products, with a total area of 0.168 million km<sup>2</sup>. In contrast, the Globeland30 and GLC\_FCS30 exhibited greater wetland extent than GLC-2015 since these two products classified non-wetlands sensitive to water as wetlands

581

582

583

584

585

586

587

588

589

590

591

592

593

594

595

596

597

598 (Zhang et al., 2023). In particular, the tundra area in GLC\_FCS30 was much smaller than other products.  
 599 This is mainly because only lichens/mosses in the original classification system of GLC\_FCS30 was  
 600 converted into tundra in the classification system we used, which leads to the omission of tundra. The  
 601 areas of impervious surfaces in GLC-2015, Globeland30, and GLC\_FCS30 were very close and higher  
 602 than FROM\_GLC. For bare land, there was large difference between Globeland30 and other products,  
 603 while the area in GLC-2015 and GLC\_FCS30 was very close.

604  
 605 **Figure 10. Areal comparison of various land cover classes among GLC products at the global scale. Class IDs**  
 606 **10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 denote cropland, forest, grassland, shrubland, wetland, water bodies,**  
 607 **tundra, impervious surfaces, bare land, and permanent snow and sea ice, respectively.**

608 The area similarity and difference for various classes of different GLC products were also compared  
 609 over six continents, the top 40 countries ranked by area, and 21 ecoregions (Figures S5-S7). Overall, the  
 610 four products showed a similar distribution trend of different classes. For most LC classes, the continental,  
 611 national, and ecoregional rankings of four products agreed with their ranking at the global scale. Whereas,  
 612 for grassland and shrubland, the area ranking of four products varied at three different regional scales.

#### 613 4.3.4 Visual inter-comparison for individual classes

614 The visual comparison of cropland in GLC-2015, Globeland30, FROM\_GLC, GLC\_FCS30, GSFAD30  
 615 (Xiong et al., 2017; Teluguntla et al., 2018), and other national-scale maps was conducted in three local  
 616 regions (Figure S8). In the Egyptian agricultural area, GLC-2015, FROM\_GLC, and GLC-FCS30 shared  
 617 similar delineation of the cropland and had a good representation of cropland with fine spatial details.  
 618 Since the date time of the Google Earth image is 2015, Globeland30 missed the newly cultivated cropland.  
 619 GFASD30 had the largest cropland area among five products but misclassified bare land as cropland. In  
 620 the agricultural area of Southeastern China, GLC-2015 had an agreement with GFSAD30 and CLCD.

621 Globeland30 and GLC\_FCS30 overestimated the area of cropland. As for FROM\_GLC, it failed to depict  
622 the spatial distribution of cropland and had many omissions. In cropland-dominated areas of the United  
623 States, FROM\_GLC significantly underestimated the extent of cropland. The other five products  
624 exhibited a similar delineation of cropland, but there were little differences in some small areas. For  
625 example, Globeland30 misclassified some grassland into cropland, and NLCD 2016 had a good ability  
626 to distinguish the farm rack.

627 We also compared the performance in the forest of different products in three forest-prevalent  
628 regions of Congo, China, and the United States (Figure S 9). Overall, GLC-2015 and Globeland30  
629 showed accurate delineation in three regions. FROM\_GLC also had good performance for the forest in  
630 Congo and USA but overestimated the forest in China, mislabeling shrubland and grassland as forest.  
631 Furthermore, GFC tended to miss sparse trees in China, and GLC\_FCS30 underestimated the extent of  
632 forest in both three regions. As for national-scale products, CLCD and NLCD 2016 had a good ability to  
633 identify the details of forest, while CLUD dramatically missed both dense and sparse woodlands.

634 Furthermore, to compare the performance in the wetland of GLC-2015 with other global and  
635 national-scale products, three wetland regions in South-central Canada, coastal America, and Sundarbans  
636 were selected. It can be found that GLC-2015 and Globeland30 had similar representation and performed  
637 well in identifying the wetland over three regions (Figure S10). Unexpectedly, FROM\_GLC performed  
638 poorly in each region, with almost no wetlands captured. GLC\_FCS30 also showed unstable quality in  
639 three regions. For example, it highly underestimated the wetland area in coastal America and completely  
640 mislabeled the mangroves as cropland in Sundarbans. NLCD 2016 and GMW accurately demonstrated  
641 the spatial pattern of the wetland, while the CA\_wetlands map underestimated the wetland extent because  
642 it defined wetlands by wetland frequency of no less than 80% from 2000 to 2016 (Wulder et al., 2018).

643 To understand the spatial distribution of impervious surfaces in different products, a comparison of  
644 mapping results for three megacities, including Tokyo, Shanghai, and New York, was shown in Figure  
645 S11. In Tokyo, a high consistency was found between GLC-2015, FROM\_GLC, and GAUD, and both  
646 successfully captured the impervious surfaces in peri-urban areas. GLC\_FCS30 showed the largest area  
647 for impervious surfaces because it misclassified many croplands into impervious surfaces. In Shanghai,  
648 GLC\_FCS30 underestimated the central city, and CLUD lost the details of impervious surfaces because  
649 it was developed using the visual interpretation method. Other products generally had the similar

650 representation and accurately demonstrated the spatial distribution of the city. For New York, the  
651 FROM\_GLC, GLC\_FCS30, and GAUD agreed well with GLC-2015, while Globeland30 and NLCD  
652 2016 had high impervious areas than others.

#### 653 **4.3.5 Visual inter-comparison at the local scale**

654 Except for visual comparison for individual classes among various products, we selected six typical  
655 geographical tiles covering six continents and different landscape environments to further present the  
656 mapping performance of the GLC-2015 map, Globeland30, FROM\_GLC, and GLC\_FCS30, as shown  
657 in Figure 11. Overall, from a local point of view, the GLC-2015 map tended to be more diverse in LC  
658 classes and had better identification performance in various classes. In flattened cropland areas (Figure  
659 11a and Figure 11b), the GLC-2015 map revealed diverse LC classes and accurately distinguished  
660 impervious surfaces; however, the Globeland30 exaggerated the extent of impervious surfaces, and the  
661 FROM\_GLC failed to delineate impervious surfaces with small size. In addition, the FROM\_GLC  
662 misclassified some cropland pixels as grassland (Figure 11a) and had an abnormal “stamp” (Figure 11b).  
663 As for mountain areas (Figure 11c and Figure 11d), the GLC-2015 map uncovered the spatial pattern of  
664 natural and planted forest, cropland, and grassland. There were large confusions between cropland and  
665 grassland in the results of the FROM\_GLC and GLC\_FCS30, and some impervious surfaces and  
666 cropland areas were wrongly labeled as bare land by the FROM\_GLC. The areas (Figure 11c), which  
667 were classified as forest, were misidentified as cropland and grassland in three other products. For the  
668 rainforest areas where a large number of trees were reclaimed for cropland (Figure 11e), the GLC-2015  
669 map, Globeland30, and GLC\_FCS30 had similarities in cropland areas; but the FROM\_GLC recognized  
670 some reclaimed areas as grassland. Additionally, the GLC-2015 map accurately presented the spatial  
671 distribution of impervious surfaces while other products had omission or commission errors. In the  
672 cropland-dominated areas (Figure 11f), the GLC-2015 map and Globeland30 showed a higher agreement,  
673 and both of them mapped the undulating areas as grassland. Unlike the aforementioned two products, the  
674 FROM\_GLC misclassified large tracts of croplands as grasslands, and the GLC\_FCS30 did not capture  
675 the grassland in undulating areas. Figure 11 also shows the belief measure of the fused result in different  
676 geographical tiles. Although it does not directly evaluate the mapping accuracy, it serves as a degree of  
677 support for the hypothesis of an accepted LC class being true, it can still reflect the quality of the GLC-  
678 2015 map. Overall, Bel of the GLC-2015 map exceeded 80% in most areas of each tile, demonstrating

679 the credibility and high quality of our mapping result.

680

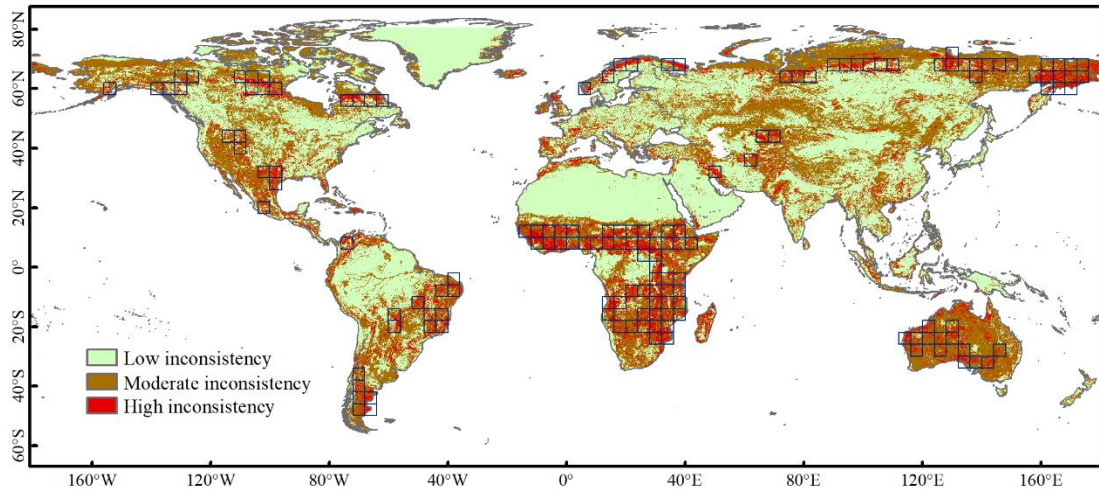

681 **Figure 11. Visual comparison between the GLC-2015 map and three other products for different continents.**

682 **(a) to (f) are examples for Europe, Asia, Africa, North America, South America, and Oceania, respectively.**

683 **4.4 Improvement of the GLC-2015 map compared to other GLC products**

684 The spatial distribution of inconsistency between three GLC products at the global scale is illustrated in  
 685 Figure 12. From the inconsistency map, we found that areas of low inconsistency mainly corresponded  
 686 to homogeneous regions with simple LC classes. For example, the northern part of Africa was mainly  
 687 classified as bare land, the northern part of South America was mainly classified as forest, and the  
 688 Greenland was classified as permanent snow and ice. On the contrary, areas of high inconsistency were  
 689 located in regions with complicated LC classes, especially in mixed vegetation regions or sparse  
 690 vegetation regions, such as northern Asia, South Africa, Sahel region, Australia, northern and southern

691 North America, and eastern and southern South America.

692  
 693 **Figure 12. Distribution of inconsistency between the Globeland30, FROM\_GLC, and GLC\_FCS30.**The blue  
 694 **rectangles are high-inconsistency grids that the area of pixels with value equal to 1 account for more than 20%**  
 695 **of the total area.**

696 Based on the global point-based samples, we assessed the accuracies of the GLC-2015 map,  
 697 Globeland30, FROM\_GLC, and GLC\_FCS30, in the aforementioned areas of low inconsistency,  
 698 moderate inconsistency, and high inconsistency, as shown in Table 7. Overall, the GLC-2015 map had  
 699 the highest accuracies against the other three ones in three areas. For each product, areas of low  
 700 inconsistency obtained the highest accuracies, followed by areas of moderate inconsistency and then high  
 701 inconsistency, which demonstrated that inconsistency of the existing products could indicate the quality  
 702 of maps. In areas of low inconsistency, the overall accuracy gap between the GLC-2015 map and  
 703 previous ones was as small as 0.1%-0.6%. However, for areas of moderate and high inconsistency, the  
 704 comparison accuracy gap expanded to 19.3%-28.0% and 27.5%-29.7%, respectively. It proved the  
 705 [outperformance](#) of the GLC-2015 map over the other three products in the areas of high identification  
 706 difficulty.

707 **Table 7. Accuracy assessments of the GLC products in three areas.**

	GLC-2015		Globeland30		FROM_GLC		GLC_FCS30	
	OA	Kappa	OA	Kappa	OA	Kappa	OA	Kappa
Areas of low inconsistency	0.951	0.938	0.945	0.929	0.950	0.936	0.951	0.937
Areas of moderate inconsistency	0.760	0.723	0.561	0.498	0.480	0.411	0.567	0.495
Areas of high inconsistency	0.567	0.498	0.292	0.204	0.286	0.198	0.270	0.160

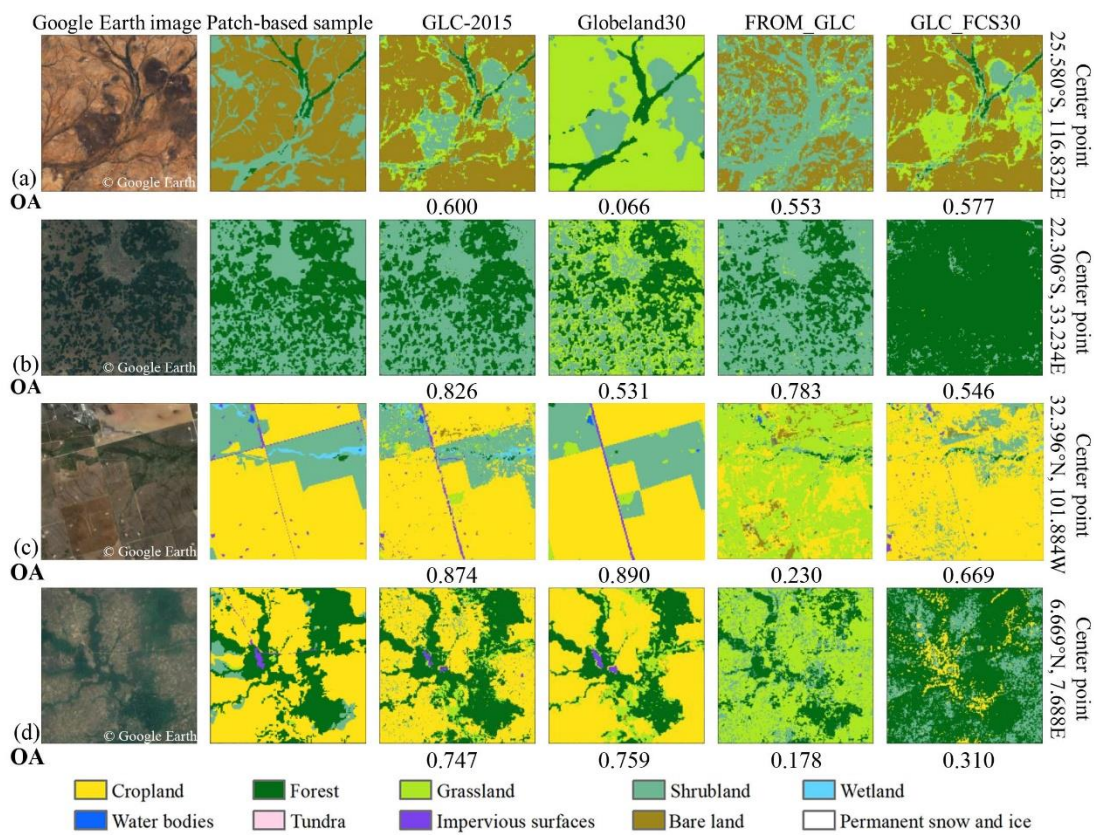

708 We further provided a comparative analysis of three previous GLC products and the GLC-2015 map  
 709 in areas of high inconsistency. We calculated the area of pixels with a value equal to 1 in  $4^\circ \times 4^\circ$  grids.  
 710 The grids that the area of pixels with a value equal to 1 account for more than 20% of the total area was  
 711 selected as grids of high inconsistency. Finally, a total number of 147 grids were selected (Figure 13). To  
 712 compare the accuracy of the GLC-2015 map and other ones, we utilized scatter plots to represent the  
 713 relationship between the overall accuracy of one previous product and the GLC-2015 map in each grid  
 714 of high inconsistency based on the global point-based samples (Figure 13). Most of the points were above  
 715 the 1:1 line, namely the values of y-axes corresponding to those points were larger than the values of x-  
 716 axes, which demonstrated that the GLC-2015 map performed better than other GLC products in most  
 717 grids of high inconsistency. It can be found that the fitting line in each scatter plot had the intercept  
 718 exceeding 0.40, the slope less than 0.55, and the  $R^2$  less than 0.35, showing that the GLC-2015 map had  
 719 a large difference with other ones.

720  
 721 **Figure 13. Overall accuracy relationship between the GLC-2015 map and other products in grids of high**  
 722 **inconsistency.**

723 To intuitively compare the mapping result of the GLC-2015 map and three existing ones in areas of  
 724 high inconsistency, we focused on visual inspection in various areas based on four  $5\text{ km} \times 5\text{ km}$  patch-  
 725 based samples and conducted accuracy statistics, as shown in Figure 14. In the detailed display, it is  
 726 apparent that three previous products had a large difference in four areas. As can be seen from the four  
 727 visual cases, the typical confusions between LC classes in areas of high inconsistency were as follows:  
 728 (1) shrubland was easily misclassified as forest and grassland; (2) cropland, grassland, and shrubland  
 729 were heavily confused with each other; (3) bare land was likely to be mixed with shrubland and grassland.  
 730 Overall, the GLC-2015 map surpassed other products in the local accuracy assessment. In Western  
 731 Australian mulga shrublands (Figure 14a), the GLC-2015 map and GLC\_FCS30 showed similar spatial  
 732 distribution and shape of bare land and forest, which was consistent with the real landscape. While the

733 Globeland30 classified bare land as grassland and the FROM\_GLC under-classified bare land. As for  
 734 Zambezian and mopane woodlands (Figure 14b), the GLC-2015 map performed best with OA reaching  
 735 82.6%, followed by the FROM\_GLC. In contrast, other products mixed shrubland with forest or  
 736 grassland. In agricultural land of Western United States (Figure 14c), the GLC-2015 and Globeland30  
 737 exhibited similar mapping results with the ground truth while the FROM\_GLC had large difference with  
 738 other products. When it comes to Guinean forest-savanna mosaic (Figure 14d), the GLC-2015 map and  
 739 Globeland30 showed high spatial consistency, and both had accurate classification profile for cropland,  
 740 forest, and impervious surfaces, while other products misidentified cropland as other LC classes.

741

742 **Figure 14. Visual comparison between the GLC-2015 map and three other products based on 5km × 5km**  
 743 **patch-based samples and Google Earth images for four areas of high inconsistency (a-d). The OA for each**  
 744 **product was calculated by the corresponding patch-based sample.**

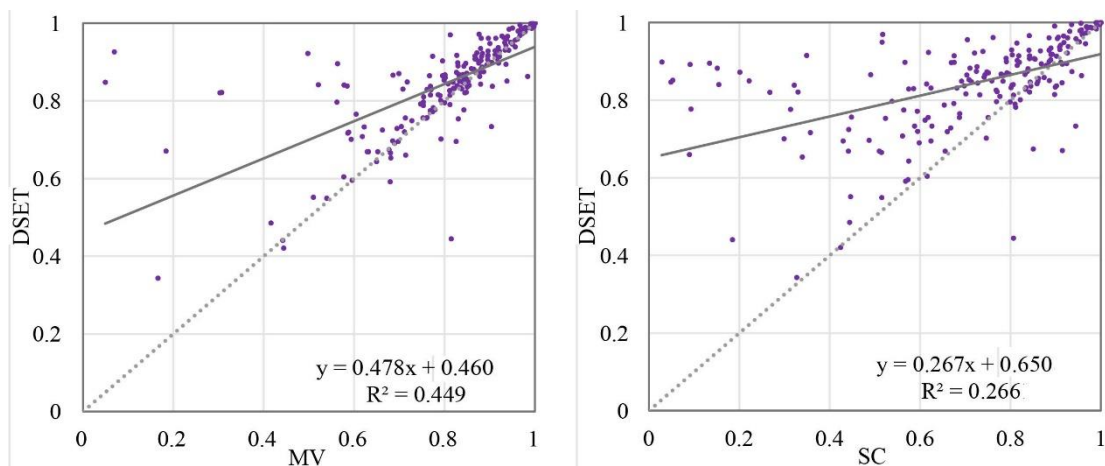

745 **4.5 Comparison between DSET and other methods**

746 **4.5.1 Inter-comparison with other data fusion methods**

747 The accuracy assessments on GLC-2015 obtained by DSET and global mapping results from two other  
 748 data fusion methods were conducted based on two global validation sample sets. The confusion matrices

749 with the global point-based samples are shown in Table S5 and S6. The OA of the global land cover  
750 classification obtained by the MV and SC was 72.1% and 71.8%, respectively. As shown in Table 3, the  
751 OA of the GLC-2015 map obtained by the DSET method was 79.5%, which had an improvement of 7.4%  
752 and 7.7% compared to mapping results from the MV and SC. In addition, the GLC-2015 map obtained  
753 higher PA and UA for most LC classes.

754 When evaluating GLC maps obtained by different data fusion approaches using the global patch-  
755 based samples, the DSET method obtained the highest OA of 83.6% and kappa coefficient of 0.566,  
756 compared with 80.1% and 0.497 for MV, and 71.8% and 0.391 for SC (Table S7). Here, the DSET method  
757 achieved an accuracy improvement of 3.5% and 11.8%. Compared to the two other methods, the DSET  
758 improved the accuracy for nearly all the LC classes, especially for grassland, shrubland, and wetland.  
759 We also compared the overall accuracy relationship between the DSET and other methods. From the  
760 scatter plots (Figure 15), we found that the majority of points were above the 1:1 line, implying DSET  
761 had better mapping performance than others in most regions across the globe.

762  
763 **Figure 15. Scatter plots between the DSET and other data fusion methods based on the global patch-based**  
764 **samples.**

765 Land cover mapping results from the DSET and other methods were also visually illustrated in six  
766 tiles with size of the 0.25° covering different continents, as displayed in Figure S12. Despite that mapping  
767 results from the DSET and MV depicted similar spatial distribution of LC classes in all tiles except the  
768 tile in North America, the DSET more accurately delineated the impervious surfaces of small size which  
769 scattered in cropland-dominated (Figure S12a) or arid areas (Figure S12c). Notably, the mapping results  
770 from the SC method presented significant differences from that obtained by the DSET and MV. For  
771 example, the SC method failed to capture scattered rural residential areas (Figure S12b) and misclassified

772 grassland as cropland (Figure S12d). Overall, the DSET method possessed better recognition  
773 performance in various LC classes than the other two methods.

#### 774 **4.5.2 Inter-comparison with the Random Forest**

775 Based on the validation data from 20% of the global point-based samples, we evaluated the quality of  
776 the GLC-2015 map obtained by the DSET method and mapping results classified by the RF classifier for  
777 a total of 300 grids. The DSET method obtained a mean OA of 80.9% across six continents, while the  
778 RF achieved a lower accuracy of 69.9%. From the scatter plots which compared the OA and kappa  
779 coefficient between the DSET and RF grid by grid, it was found that the DSET possessed higher accuracy  
780 in most grids (Figure S13). Especially, the points were clustered in the upper right corner of the plot  
781 (Figure S13a), which indicated that the RF classifier trained with the global point-based samples  
782 performed well in those selected grids though it was inferior to the DSET method. Figure S14 shows the  
783 OA of the DSET and RF across six continents. We found that the DSET method outperformed RF  
784 classifier for each continent. Especially, the mapping results of both two methods presented the lowest  
785 accuracy in Oceania. It may be because the selected grids are located in regions with heterogeneous  
786 landscape. As for the box plot for the RF classifier, the low hinge exceeded 60.00% in all continents  
787 except Oceania, demonstrating the reliability of the RF classifier trained by the global point-based  
788 samples. Nevertheless, the performance of the RF classifier was worse than the DSET method. This  
789 highlights the feasibility of the DSET method in integrating the existing maps for a better one.

#### 790 **4.6 Advancement and Limitations**

791 To address the problem that current 30m GLC products have great inconsistency in heterogeneous  
792 areas and low mapping accuracy for spectral similar LC classes, this study adopted a multi-source  
793 product fusion approach based on DSET to create an improved global land cover map (GLC-2015). The  
794 results show that the GLC-2015 had good mapping performance with OA reaching 79.5% and 83.6%  
795 based on two different validation sets. Compared with those existing products, the GLC-2015 greatly  
796 improved the accuracy across the globe, especially in areas of high inconsistency with a significant  
797 improvement of 27.5%-29.7%. Compared with other commonly used data fusion methods, the adopted  
798 DSET approach provided higher OA and kappa coefficient which showed the benefit of the DEST in  
799 integrating various land cover data. No matter from the respective of the global point-based samples or

800 the global patch-based samples, the GLC-2015 showed relatively low accuracy for grassland, shrubland,  
801 and wetland compared to other LC classes. Those LC classes are challenging to map at the global scale  
802 due to their spectral similarity to other classes, ambiguous definitions, or variety with regions. However,  
803 compared to other existing 30m GLC products, the GLC-2015 map performed better with the PA and OA  
804 ranking first or second for grassland, shrubland, and wetland, which indicated the improvement of the  
805 GLC-2015 in poorly-mapped LC classes. It was found that the GLC-2015 map had worse performance  
806 in areas with more disagreements (Table 7). However, the GLC-2015 map surpassed other products in  
807 the areas with different agree of inconsistency. Moreover, the accuracy gap between the GLC-2015 map  
808 and other ones in areas of high inconsistency was larger than that in areas with fewer disagreements,  
809 implying that the GLC-2015 map provides a more accurate characterization of land cover in poorly-  
810 mapped areas. Although the GLC-2015 map was not capable of avoiding all the wrong mapping results  
811 caused by the disagreements from the candidate GLC products, it outperformed the existing products  
812 from the aspects of mapping accuracy for the easily misclassified classes and areas with great  
813 inconsistency.

814 Although the GLC-2015 map can evidently improve mapping accuracy in inconsistent areas, there  
815 are still some uncertainties. First, we used three multiple-class GLC maps and four single-class GLC  
816 maps as the source data for integration. Since those products provided information of land cover at the  
817 global scale, classification errors inevitably exist in some specific regions. The multisource product  
818 fusion method based on DEST depends highly on the quality of those candidate maps such that the  
819 inconsistency between those source maps might lead to incorrect classification. Second, the date time of  
820 the GlobeLand30 is different from that of other maps. Because of the five-year time interval, there are  
821 changes in land cover, which inevitably distort the fusion results. However, the changed areas are tiny  
822 compared to the world's terrestrial area. The uncertainties caused by the LC changes are minor than those  
823 from classification errors. In addition, the global point-based samples were used to evaluate the reliability  
824 of each product. The accuracy of GlobeLand30 was lower than the other products for areas with LC  
825 changes. In this case, the fusion depended more on other maps to avoid the errors caused by LC changes.  
826 [Third, due to the different LC definitions, uncertainties in classification system conversion are inevitable](#)  
827 [\(Zhang et al., 2017\), which might cause problems for the fusion based on the DSET method. However,](#)  
828 [we conducted a reliability evaluation of the candidate maps to reduce the influence of uncertainties in](#)

829 classification system conversion on the fusion. The point-based samples used for reliability evaluation  
830 were labeled referring to the LC definitions in our classification system so that all the maps were  
831 evaluated under the criterion of the classification system we used. By the reliability evaluation, the  
832 candidate maps were assessed to have lower accuracy for areas with mismatched information. When  
833 integrating all the maps grid by grid, the mismatched information would contribute less to the fusion.  
834 Lastly, most candidate LC products used a simple classification system without a level-2 classification  
835 system, so they made no contributions to a more detailed classification system when they served as source  
836 data for data fusion. Although some maps provided detailed LC classification results, such as the  
837 GLC\_FCS30 and FROM\_GLC for 2015, there might be several challenges in the standardization and  
838 uniformity of level-2 classification systems due to the large discrepancies in the definition and criteria.  
839 Therefore, the GLC-2015 adopted a simple classification system containing 10 major LC classes. In  
840 future work, measures will be taken to meet the expectation of a more detailed classification system for  
841 GLC mapping. An improved GLC product with a detailed classification system rather than a simple one-  
842 level classification system can be further developed based on the highly applicable and general DSET  
843 method whenever more products with diverse LC classes are available. Additionally, a feasible  
844 framework for the conversion of different level-2 classification systems into a uniform system should be  
845 developed.

## 846 **5. Data availability**

847 The improved global land cover map in 2015 with 30 m resolution is available at  
848 <https://doi.org/10.6084/m9.figshare.22358143.v2> (Li et al., 2022). The GLC-2015 product is organized  
849 by a total of  $1507\ 4^{\circ} \times 4^{\circ}$  geographical grids in GeoTIFF format across the world's terrestrial area. Each  
850 image of the GLC-2015 product is named as "GLC-2015\_lon\_lat" (lon and lat represent the longitude  
851 and latitude and of the grid's lower left corner, respectively).

## 852 **6. Conclusions**

853 GLC information at fine spatial resolution is vital for the global environment and climate studies which  
854 can capture *the footprint of human activity*. Resulting from the differences in classification scheme,  
855 satellite sensor data, classification algorithms and sampling strategies, the existing GLC products have

856 high inconsistency in some parts of the world, especially in fragmented areas and transition zones. More  
857 accurate and reliable data with accuracy improved in areas of high mapping inconsistency is very  
858 desirable. In this study, with the help of the GEE platform, we developed the GLC-2015 map by  
859 integrating multiple existing GLC maps based on the DSET. The GLC-2015 map can significantly  
860 increase the mapping accuracy and possess good recognition performance in various LC classes.

861 The GLC-2015 map was validated by both the global point-based samples and the global patch-  
862 based samples. Accuracy assessments show that the GLC-2015 map achieved an OA of 79.5%, a kappa  
863 coefficient of 0.757 using a total of 34,117 global point-based samples, and an OA of 83.6%, a kappa  
864 coefficient of 0.566 using a total of 201 global patch-based samples. Data inter-comparison indicated  
865 that the GLC-2015 map surpassed other three products both visually and quantitatively, by OA  
866 improvement of 14.0%-17.8% validated with the global point-based samples and 5.9%-24.5% with the  
867 global patch-based samples. Compared to other products, there are fewer misclassifications in the GLC-  
868 2015 map for most LC classes, such as forest, cropland, shrubland, and water bodies. Meanwhile, the  
869 GLC-2015 map outperformed others in terms of OA and kappa coefficient across different ecoregions  
870 and different continents. Notably, the GLC-2015 map showed better performance than others by an  
871 increment of 0.1%-0.6% in overall accuracy for areas of low inconsistency, 19.3%-28.0% for areas of  
872 moderate inconsistency, and 27.5%-29.7% for areas of high inconsistency. In addition, the mapping  
873 results obtained by the DSET surpassed other data fusion methods with OA improvement of 7.4%-7.7%  
874 via the global point-based samples and 3.5%-11.8% via the global patch-based samples. Therefore, it can  
875 be concluded that the GLC-2015 map is a robust and reliable map that can significantly improve mapping  
876 accuracy compared to previous GLC products and mapping results from other common data fusion  
877 methods.

#### 878 **Author contributions**

879 XL and XX conceived the research. BL and XX designed and carried out the experiments. QS and DH  
880 provided data. BL wrote the original manuscript. XX, HZ and YC reviewed the writing.
