Abstract: Thermal state of permafrost in the present and future is fundamental to ecosystem evolution, hydrological processes, carbon release, and infrastructure integrity in cold regions. In 2011 we initiated a permafrost monitoring network along the China-Russia Crude Oil Pipelines (CRCOPs) route at the eastern flank of the northern Da Xing'anling Mountains in Northeast China. We compiled an integrated dataset of the ground thermal state along the CRCOPs route, consisting of meteorological data near the southern limit of latitudinal permafrost, ground temperature data in 20 boreholes with depths of 10.0–60.6 m, soil volumetric liquid water contents and 2-dimensional electrical resistivity tomography (ERT) data at different sites. Results demonstrate a permafrost warming during 2011–2020 in the vicinity of the southern limit of latitudinal permafrost, as manifested by rising ground temperatures at almost all depths in response to climate warming. Local thermal disturbances triggered by the construction and operation of CRCOPs have resulted in significant permafrost warming and subsequent thawing on the right-of-way (ROW) of the pipelines. This permafrost thaw will persist, but it can be alleviated by adopting mitigative measures, such as an insulation layer and thermosyphons. The *in-situ* observational dataset is of great value for assessing the variability of permafrost under the linear disturbances of the CRCOPs and related environmental effects, for understanding hydro-thermal-mechanical interactions between the

31 buried pipelines and permafrost foundation soils, and for evaluating the operational and structural integrity of the
32 pipeline systems in the future. The dataset is available at the National Tibetan Plateau/Third Pole Environment Data
33 Center (<http://doi.org/10.11888/Cryos.tpsc.272357>; Li, 2022).

34 **1 Introduction**

35 As a major component of the Earth's cryosphere, permafrost is sensitive to climate change, surface disturbances
36 and human activities (Smith et al., 2022). Over the last few decades, the warming and thawing of permafrost have
37 been observed in most permafrost regions (e.g., Ran et al., 2018; Biskaborn et al., 2019; O'Neill et al., 2019;
38 Etzelmüller et al., 2020; Liu et al., 2021; Noetzli et al., 2021; Smith et al., 2022), and permafrost degradation will
39 continue in response to a warming climate (Koven et al., 2013; Burke et al., 2020). Permafrost degradation affects
40 the geomorphological characteristics, carbon release, hydrological process, ecosystem, climate system, and
41 integrity of infrastructure (Cheng and Jin, 2013; Beck et al., 2015; Hjort et al., 2018, 2022; Turetsky et al., 2020; Jin
42 and Ma, 2021; Jin et al., 2021, 2022; Luo et al., 2021; Jones et al., 2022; Liu et al., 2022; Miner et al., 2022).

43 Permafrost occurs extensively in the Da and Xiao Xing'anling mountains in Northeast China (referred to as the
44 Xing'an permafrost). Its distribution displays both latitudinal and altitudinal zonation and is strongly influenced by
45 local environmental factors (Jin et al., 2008; Guo et al., 2018; He et al., 2021). The Xing'an permafrost has also
46 experienced significant degradation under a warming climate, wildfires, and human activities, such as
47 deforestation, urbanization, mining and linear infrastructure construction (Guo and Li, 1981; Jin et al., 2007; Wang
48 et al., 2019a; Mao et al., 2019; Li et al., 2021; Serban et al., 2021), as evidenced by rising ground temperature (GT),
49 thickening active layer, shrinking permafrost extent, and increasing thaw-related hazards, such as ground surface
50 subsidence, settlement of foundation soils and development of taliks and thermokarst. Multiple studies on future
51 changes in Xing'an permafrost have been conducted based on different modeling approaches and climate warming
52 scenarios (e.g., Ran et al., 2012; Zhang et al., 2021). Research results indicate that persistent permafrost
53 degradation is likely to occur during the next few decades (Jin et al., 2007; Wei et al., 2011). However, there are
54 great uncertainties in the prediction of the magnitude and timing of these changes (Smith et al., 2022). For example,
55 the estimated areal extent of existing permafrost in Northeast China ranges from 2.4×10^5 to 3.1×10^5 km² (Ran et al.,

56 2012; Zhang et al., 2021). Field observations of meteorological variables and permafrost thermal states have
57 substantially contributed to the understanding of the responses of GTs to climate change and to hydrothermal
58 processes in the active layer and permafrost, facilitating the evaluation and/or validation of predictive permafrost
59 models, and thus they are of great importance (Zhao et al., 2021; Wu et al., 2022). However, in Northeast China,
60 long-term and continuous datasets of permafrost thermal state are scarce, especially at the eastern flank of the Da
61 Xing'anling Mountains, due to the harsh periglacial environment, inconvenient access, and expensive installation
62 and maintenance costs (Jin et al., 2007; He et al., 2021; Li et al., 2021).

63 Since 2008, extensive permafrost investigations for the construction of the China-Russia Crude Oil Pipelines
64 (CRCOPs) I and II were conducted in the permafrost zones on the eastern slopes of the Da Xing'anling Mountains.
65 As a result, a permafrost monitoring network along the CRCOPs route was gradually established **by referring to the**
66 **experiences and lessons learned from other oil and gas pipelines (e.g., Norman Wells to Zama crude oil pipeline in**
67 **Canada, Alyeska crude oil pipeline in the U.S., and Nadym–Pur–Taz natural gas pipeline in Russia) in permafrost**
68 **regions (Burgess and Smith, 2003; Johnson and Hegdal, 2008; Smith and Riseborough, 2010; Oswell, 2011).**
69 **Boreholes were instrumented to measure GTs in the active layer and near-surface permafrost on and off the right-**
70 **of-way (ROW) of the CRCOPs and electrical resistivity tomography (ERT) surveys were used to delineate frozen**
71 **and unfrozen ground in the vicinity of the CRCOPs (Kneisel et al., 2008; Farzamian et al., 2020).**

72 We firstly present the integrated dataset of permafrost thermal state along the CRCOPs route on the eastern
73 slopes of the northern Da Xing'anling Mountains **in** Northeast China. This dataset includes meteorological data,
74 GTs, soil volumetric liquid water content, and subsurface electrical resistivity (ER) on and off the ROW of the
75 pipeline. Detailed information for the integrated dataset is provided so that this dataset can be easily understood,
76 **readily** accessed and **properly** applied by potential users.

77 **2 Site description**

78 Five permafrost observation sites, named as Xing'an (XA), Xin-tian (XT), Jin-song (JS), Song-ling (SL), and
79 Jagdaqi Bei (North) (JB), respectively, were established along the CRCOPs route in Northeast China (50.4710°–
80 53.3328°N, 123.9875°–124.3132°E) (Fig.1) through the joint efforts of the State Key Laboratory of Frozen Soil
81 Engineering (SKLFSE), Northwest Institute of Eco-Environment and Resources (the former Cold and Arid Regions
82 Environmental and Engineering Research Institute), Chinese Academy of Sciences and the Jagdaqi Division of the
83 PetroChina Pipeline Company. Site selection was primarily based on engineering geological conditions of
84 permafrost (Jin et al., 2010). According to the meteorological data of 1972–2017, the study area is characterized of
85 a frigid-temperate continental monsoon climate with mean annual air temperatures (MAAT) of –4.0 to –0.4 °C,
86 with annual precipitation of 447 to 525 mm, which falls mostly as summer rain. Snow cover generally occurs at the
87 end of September–beginning of October and disappears in late April and early May of next year. The snow depth
88 ranges from 5 to 35 cm. Between 1972 and 2017, MAAT increased at a rate of 0.32 °C per decade while annual
89 precipitation increased at a rate of 14.6 mm per decade (Wang et al., 2019a).

90 Table 1 summarizes the geographical information and permafrost characteristics of monitoring sites.
91 Permafrost is warm with mean annual ground temperature (MAGT) at the depth of zero annual amplitude (D_{ZAA})
92 ranging from –1.8 to –0.4 °C. The permafrost thickness exceeds 60 m, and the observed active layer thickness
93 (ALT) ranges from 1.0 to 2.7 m (Wang et al., 2019b). Along the CRCOP route, the XA site, located in a permafrost
94 wetland, is the most northern and has the lowest air temperature, while the JB site, near the southern limit of the
95 latitudinal permafrost in Northeast China, has the highest air temperature, where permafrost occurs in isolated
96 patches. The XT and JS sites are located in the transition zone between isolated patches of permafrost and sporadic
97 permafrost, making them the ideal locations for examining permafrost dynamics. The SL site is located in a wetland
98 underlain by ice-rich permafrost, where seasonal frost mounds, sometimes migratory, with a maximum height of 2
99 m are developed (Wang et al., 2015), and monitoring devices are prone to be destroyed due to significant frost

100 mound-related ground deformation.

101

102 Figure 1. Location of permafrost monitoring sites along the route of **China-Russia Crude Oil Pipelines (CRCOPs)**.
 103 **Permafrost zone from Jin et al., (2007, 2010)**. The red dash line represents the paralleling CRCOPs I and II (the inter-
 104 pipeline distance is generally limited to approximately 10 m).

105 Table 1. Permafrost characteristics for monitoring sites along the route of **China-Russia Crude Oil Pipelines**.

Site	Lat. (°N)	Long. (°E)	Elev. (m a.s.l.)	Permafrost zone	Vegetation	Ice content	MAGT (°C)	ALT (cm)
XA	53.3328	123.9875	318	Sporadic permafrost	<i>Carex tato</i> swamp	Ice-saturated	-1.8	130
XT	51.2444	124.2096	621	Sporadic permafrost	Shrub meadow	Ice-saturated	-1.8	100
JS	51.1619	124.1943	508	Sporadic permafrost	<i>Carex tato</i> swamp	Ice-rich	-0.7 to -0.4	200~270
SL	50.6868	124.3132	398	Isolated patches permafrost	<i>Carex tato</i> swamp	Ice-saturated /ice-rich	-0.9	130
JB	50.4710	124.2257	484	Isolated patches permafrost	<i>Carex tato</i> swamp	Ice-rich	-0.8 to -0.5	178~200

106 Notes: MAGT, mean annual ground temperature, and ALT, active layer thickness.

107

108 3 Data description

109 3.1 Meteorological data

110 In October 2017, a small automated weather station (AWS, Fig. B1) was installed at the JB site for measuring air
 111 temperature, relative humidity, wind speed and direction, and total solar radiation. Details of the sensors used are
 112 listed in Table 2. All meteorological data were recorded every two hours by a CR3000 data logger (Campbell
 113 Scientific, Inc., USA) with a relay multiplexer (TRM128, China), powered by a battery cell and solar panel
 114 regulated by a solar charge controller (Phocos ECO (10 A), Germany). The collected data have been transferred
 115 automatically to the specified server by the wireless transmission module (HKT-DTU, Campbell Scientific, Inc.,
 116 USA). Using such technology, it would be possible to check collected data in real-time and identify possible sensor
 117 failures.

118 Table 2 List of sensors, measuring range and accuracy for meteorological data, ground temperature, soil water content,
 119 and ground electrical resistivity.

Variable	Sensor/measurement device	Measuring range (operating temperature)	Accuracy/Resolution
Meteorological data			
Air temperature	HMP155A Vaisala Finland	-80 to 60 °C	(0.226-0.0028×T)°C (-80 to 20°C), (0.055+0.0057×T)°C (20 to 60 °C)
Relative humidity (RH)	HMP155A Vaisala Finland	0 to 100% RH	(1.4+0.032×RH)% (-60 to -40°C), (1.2+0.012×RH)% (-40 to -20°C, 40 to 60°C), (1.0+0.008×RH)% (-20 to 40°C)
Wind speed/direction	Model 05103 R.M. Young Company	0 to 100 m/s (-50 to 50°C)	±0.3 m s ⁻¹ , ±3°
Total solar radiation	LI200X Pyranometer Campbell Scientific, Inc.	0~1000 W/m ² (-40 to 65°C)	±5% (absolute error in natural daylight), ±3% typical
Permafrost monitoring			
Soil temperature	Thermistor cable SKLFSE, China	-30 to 30 °C	±0.05°C
Soil volumetric liquid water content	CS616 Campbell Scientific, Inc.	0% to saturation (0 to 70°C)	±2.5%
Ground electrical resistivity	SuperSting R8 system Advanced Geosciences, Inc.	-10 to 10 V	≤30nV

120 The AWS was regularly maintained and repaired, resulting in data collection with satisfactory quality and
 121 continuity. Between 15 October 2017 and 10 August 2020, less than 5% of the data were missing. However, the
 122 meteorological data had been discontinued since 10 August 2020 due to the failure of the online data transmission

123 module and lack of essential on-site maintenance for equipment under the influence of the COVID-19 pandemic.

124 Air temperature and relative humidity were measured at a height of 1.5 m every two hours using the Vaisala
125 HMP155A sensor protected by a radiation shield. The accuracy of temperature and relative humidity measurements
126 decreased along with lowering temperatures. For example, the accuracy for the HMP155A sensor was as good as
127 ± 0.17 °C at an ambient environment of 20 °C, but it worsened up to ± 0.34 °C at -40 °C. At the JB permafrost site,
128 the annual range of daily air temperature was approximately 56 °C. The recorded maximum air temperature was
129 24.7 °C on 25 July 2020, and the minimum, -33.7 °C on 27 December 2019 (Fig. 2a). The seasonal variation in
130 relative humidity followed similar patterns with the seasonal variability in air temperature (Fig. 2b).

131
132 Figure 2. Time series of meteorological variables at the JB site from October 2017 to August 2020.

133 Total solar radiation was measured at a height of 1.5 m above the ground surface by the LI200X Pyranometer
134 with an accuracy of $\pm 3\%$ to $\pm 5\%$). Although the sensors were regularly checked (e.g., checking the level of the
135 instrument and removing dust) during the site visits and re-calibrated after two years of installation, the instruments
136 were largely unattended and their accuracy was therefore likely to worsen up to $\pm 5\%$. It is worth noting that the
137 LI200X may read negative solar radiation during the night, which is later set to zero in the data processing. The
138 total solar radiation reached its maximum in summer (June to August) and was lowest in winter (December to next
139 February), with a similar pattern with seasonal variations in air temperature (Fig. 2c).

140 The wind speed and direction were measured at a height of 2 m above the ground surface by a propeller
141 anemometer (Model 05103, R.M. Young Company). The standard error of wind direction was also calculated using
142 a specific algorithm provided by the CR3000 data logger. The recorded maximum wind speed of 9 m s⁻¹ occurred
143 on 28 May 2019. The average monthly wind speeds ranged from 0.9 to 2.6 m s⁻¹ and reached their maximum in
144 April–May (Fig. 2d).

145 **3.2 Ground temperature and soil water content data**

146 In total, 20 boreholes were drilled and instrumented for GT monitoring both on the ROW of the CRCOPs at
147 varying distances from the pipe centerline/axis-lines and in nearby undisturbed terrains (off the ROW, 2.6 to 90 m
148 from the ROW edge) between 2011 and 2021 (Table 3). Generally, the ROW is approximately 20 m wide. The
149 depths of boreholes range from 10.0 to 60.6 m, although most of them are 15 to 20 m deep. *In-situ* temperature
150 monitoring in the borehole JB-B-II (6.6 m from the ROW edge) was deployed starting in November 2011, and ten
151 boreholes (JB-B-1 to JB-B-10) were drilled on the ROW between 2 and 4 m from the centerline of pipe in 2014 and
152 2015 at the JB site. Besides, a new borehole (JB-B-I) was drilled down to 60.6 m near the above-mentioned AWS in
153 March 2017. At the SL site, two on-ROW boreholes (SL-B-1 and SL-B-2, 3 and 5.9 m from the centerline of
154 CRCOP II, respectively) and one off-ROW borehole (SL-B-I, 2.6 m from the edge of the CRCOP I ROW) were
155 drilled in March 2017 and instrumented in September 2017. At the JS site, two boreholes (JS-B-1 and JS-B-2, 2 and
156 5 m from the pipe centreline, respectively) were established on the CRCOP II ROW in 2017, and an additional
157 borehole (JS-B-I) was drilled 14.8 m from the ROW edge of CRCOP I in 2018. A borehole (XT-B-I) at the XT site,
158 10 km north of the JS site, was drilled in 2019 to evaluate the spatial differentiation of permafrost distribution
159 influenced by local geo-environmental factors. At the XA site, a borehole with a depth of 60.5 m (XA-B-I) was
160 drilled 7 km south of the first pump station of the CRCOPs in Xing'an Village of Mo'he County, Heilongjiang
161 Province, where there was previously no GT data.

162
163
164

Table 3 Summary of monitoring information of ground temperature boreholes, water content monitoring pits, and electrical resistivity tomography (ERT) profiles along the China-Russia Crude Oil Pipelines (CRCOPs) in Northeast China.

Variable	Borehole/ ERT profile	Maximum monitoring depth (m)	Distance from pipe centreline (m)	Data logger	Measuring interval	Operation period

* Boreholes were drilled on the ROW of CRCOP II. The width of ROW along the pipeline is about 20 m.

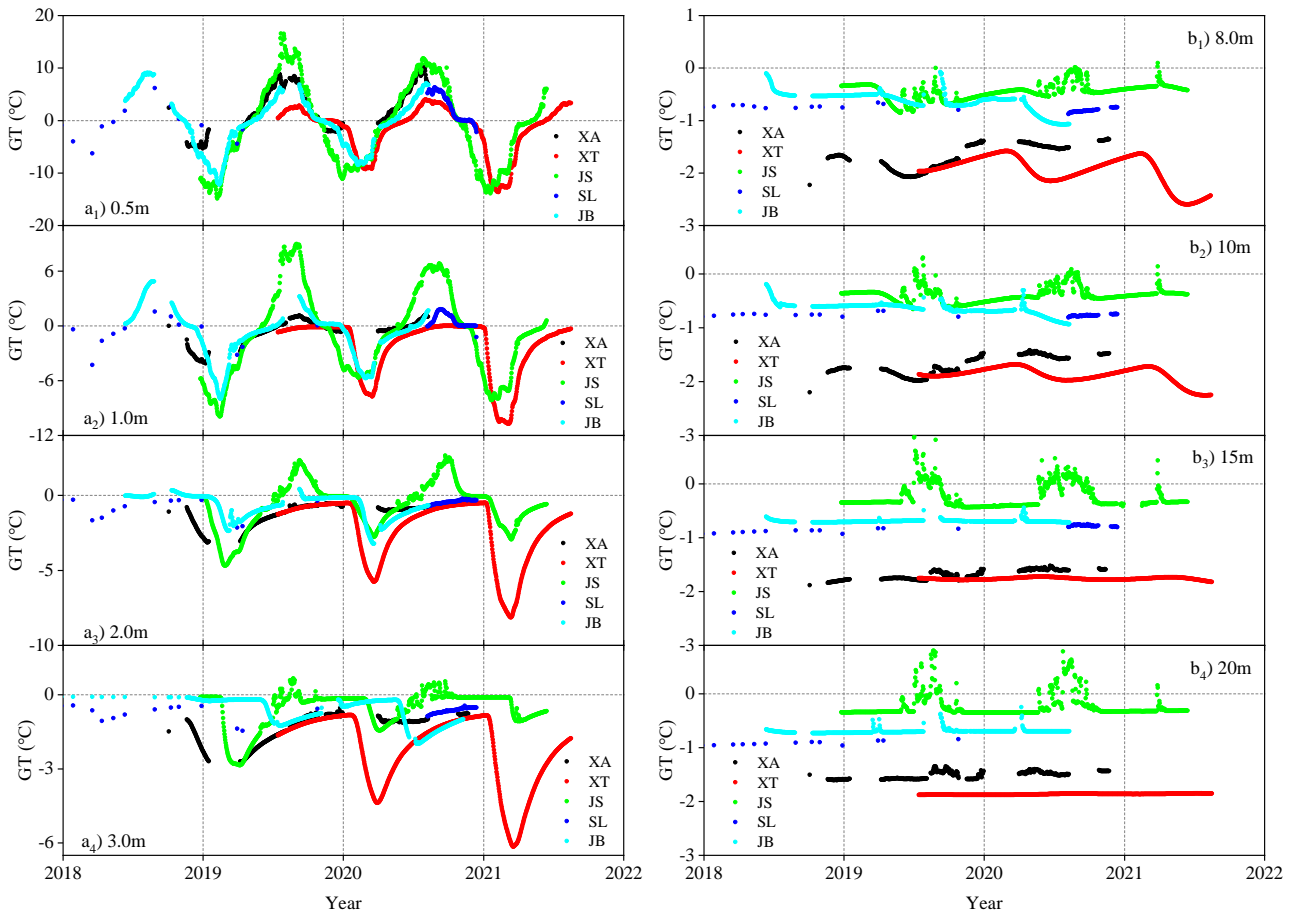

165 The GT measurement was carried out by installing a thermistor cable protected by a steel tube into the
166 borehole (Wang et al., 2019b). The thermistor cable was assembled by the SKLFSE, with thermistors at the
167 designed intervals. Manual temperature reading using Fluke 87/89 was made in five boreholes (SL-B-I, SL-B-1,
168 SL-B-2, JB-B-II, and JB-B-1) for some earlier time (Table 3). The accuracy of the manual readings is estimated to
169 be ± 0.1 °C (Juliussen et al., 2010). Two types of data loggers, which are connected to the thermistor cables, are now
170 used for automatic and continuous GTs monitoring in boreholes at 2 h intervals. They are CR3000 data loggers and
171 miniature temperature data loggers (RTB37a36V3, jointly developed by Northwestern Polytechnical University and
172 SKLFSE). The latter generally has a lower resolution than the CR3000 data logger (± 0.05 °C), but allows more
173 widely used due to its lower cost. The GT in boreholes at the SL site has been recorded by this miniature data
174 logger. Besides, the soil volumetric liquid water content (VWC) was measured by the Campbell Scientific CS616
175 water content reflectometer probe (Table 2) by connecting to a CR3000 data logger. Three pits were excavated on
176 the ROW of the CRCOP I at the JB site and three probes were embedded horizontally at depths of 0.5, 1.5, and 2.5
177 m in each pit (Table 3).

178 Quality control of data was carried out by manually checking to detect missing data and obvious erroneous
179 recordings in the GT and VWC data. All the missing or abnormal data were replaced with null values. Then, daily
180 averages were calculated from hourly values at 2-hour intervals if at least 10 values (~ 83 %) were available within
181 1 day.

182 **3.2.1 Ground temperature at the undisturbed sites**

183 To analyze the spatial distribution of GT, we chose GTs between 2018 and 2021, when GT data series of all five
184 permafrost sites were available (Fig. 3). The average daily GTs at depths of 0–3 m showed seasonal dynamic
185 variations, but the changing amplitudes of GTs weakened progressively with increasing depth and varied
186 significantly from one site to another (Fig. 3a). For example, the JS site with a high permafrost temperature had the
187 maximum variation amplitude of GT at the depth of 0.5 m (from -14.9 to 16.6 °C) among all the five sites, while at

188 the depth of 3 m, the XT site had the maximum variation amplitude of GT, which was mainly related to the local
 189 topography, vegetation, soils and geology (Table 1). Zero-curtain effects were evident at a particular depth in these
 190 five sites, but the duration time of zero curtains at the same depth varied greatly with location, which was mainly
 191 related to *in situ* soil water/ice content of these permafrost sites.

192
 193 Figure 3. Variability of ground temperatures at depths of 0–3 m (a) and 8–20 m (b) at the undisturbed sites along the
 194 route of China-Russia Crude Oil Pipelines (CRCOPs) in Northeast China, 2018–2021.

195 Seasonal changes in GTs at depths ≥ 15 m are negligible at all sites, except for the JS site, which indicates that
 196 zero annual amplitude (ZAA) is located below 15 m in depth (Fig.3b). At the JS site, abnormal positive
 197 temperatures were observed in the summers of 2019 and 2020, probably due to the thermal disturbance of supra-
 198 and/or intra-permafrost groundwater. GTs at depths of 8, 10, 15, and 20 m showed that permafrost temperature
 199 decreased with the increasing northern latitude. Overall, the relationship between GT and latitude is not linearly
 200 dependent (Fig. 4).

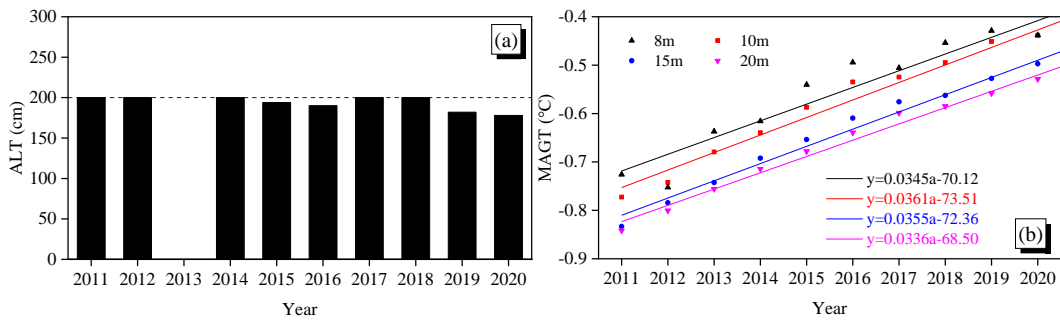

201
202 **Figure 4. Relationship between latitude and GT along the route of China-Russia Crude Oil Pipelines (CRCOPs).**

203 A decade record (2011–2020) of GTs in the active layer and **near-surface** permafrost in borehole JB-B-II
 204 allows for assessment of the inter-annual trend of permafrost under a warming climate. As displayed in Fig. 5, the
 205 monthly average GTs in 2018 at depths from 1 to 2 m were fluctuating in proximity to 0 °C without an obvious
 206 geothermal gradient (termed as the zero curtain layer), decreased with a geothermal gradient of 0.08 °C m⁻¹ at
 207 depths from 2 to 7 m, and remained unchanged below 7 m. The ALT (the maximum depth of 0 °C isotherm from
 208 linear interpolation of the daily average GTs) **in this borehole varied slightly** between 178 and 200 cm from 2011 to
 209 2020, mainly due to the damping effect of the zero curtain layer (Fig. 6a), while the **near-surface** permafrost at
 210 depths of 8-20 m was warming at an average rate of 0.035 °C yr⁻¹ in this 10-year observation period (Fig. 6b). At
 211 the D_{ZZA} of 15 m, MAGT increased by 0.3 °C (from -0.8 to -0.5 °C) during 2011-2020.

212
213 **Figure 5. Monthly average ground temperatures at depths of 0-20 m recorded in the JB-B-II borehole at the JB site in**

214 2018.

215

216 Figure 6. Variations in the active layer thickness (ALT) (a) and mean annual ground temperature (MAGT) (b) in borehole
217 JB-B-II at the JB site along the China-Russia Crude Oil Pipeline (CRCOP) I in northern part of Northeast China from
218 2011 to 2020.

219 3.2.2 Ground temperature on the ROW of pipeline

220 Boreholes on the ROW along the CRCOPs were drilled and instrumented for GT monitoring at three permafrost
221 sites (JS, SL, and JB) to evaluate the thermal disturbances of the insulated or uninsulated CRCOPs on the
222 surrounding permafrost (Table 3). At the JS and SL sites, the pipelines were insulated and initially buried at depths
223 of 2-3 m, while they were uninsulated and buried at about 1.6-2.4 m in depth at the JB site. The warm oil (with the
224 maximum recorded temperature of 28 °C at the first/northernmost pump station of the CRCOPs in China) flowing
225 in the pipeline brought substantial heat into the underlying and ambient permafrost, resulting in the rising GTs,
226 even though the pipelines were wrapped by an insulation layer (Fig. 7). However, temperature differences on and
227 off the ROW of pipeline were substantially reduced by an insulation layer at the JS and SL sites compared to those
228 at the JB site without insulation. Besides, GTs in the borehole 5 m (perpendicular to the CRCOP I) away from the
229 pipe centerline were also greater than those at the nearby undisturbed site, indicating the lateral thermal disturbance
230 range of the pipeline may have extended beyond a horizontal distance of 5 m.

231 The time-series of the depths of the permafrost table and maximum frost penetration in borehole JB-B-1,
232 horizontally 2 m away from the uninsulated pipe centerline at the JB site shows that since the official operation of
233 CRCOP I starting in 2011, the depth of the permafrost table has been increasing with an average rate of 0.9 m yr⁻¹
234 and depth of seasonal frost penetration decrease rapidly and then varies little (0.4-0.8 m) during 2010–2021 (Fig. 8).

235 Therefore, a thawed interlayer between permafrost table and the bottom of seasonal frost (i.e., supra-permafrost
 236 subaerial talik, SST) formed and developed with an average rate of 1.1 m yr^{-1} in the same period. This has
 237 demonstrated that the pipeline has triggered an intensive and quick permafrost degradation at a local scale. This
 238 deepening of the permafrost table and thickening of the SST have exposed the pipelines to thawed low-bearing
 239 foundation soils, resulting in potential pipeline damage. For example, the excavation at the JB site in 2015 revealed
 240 that the CRCOP I had locally settled down by 1.4 m during 2010–2015.

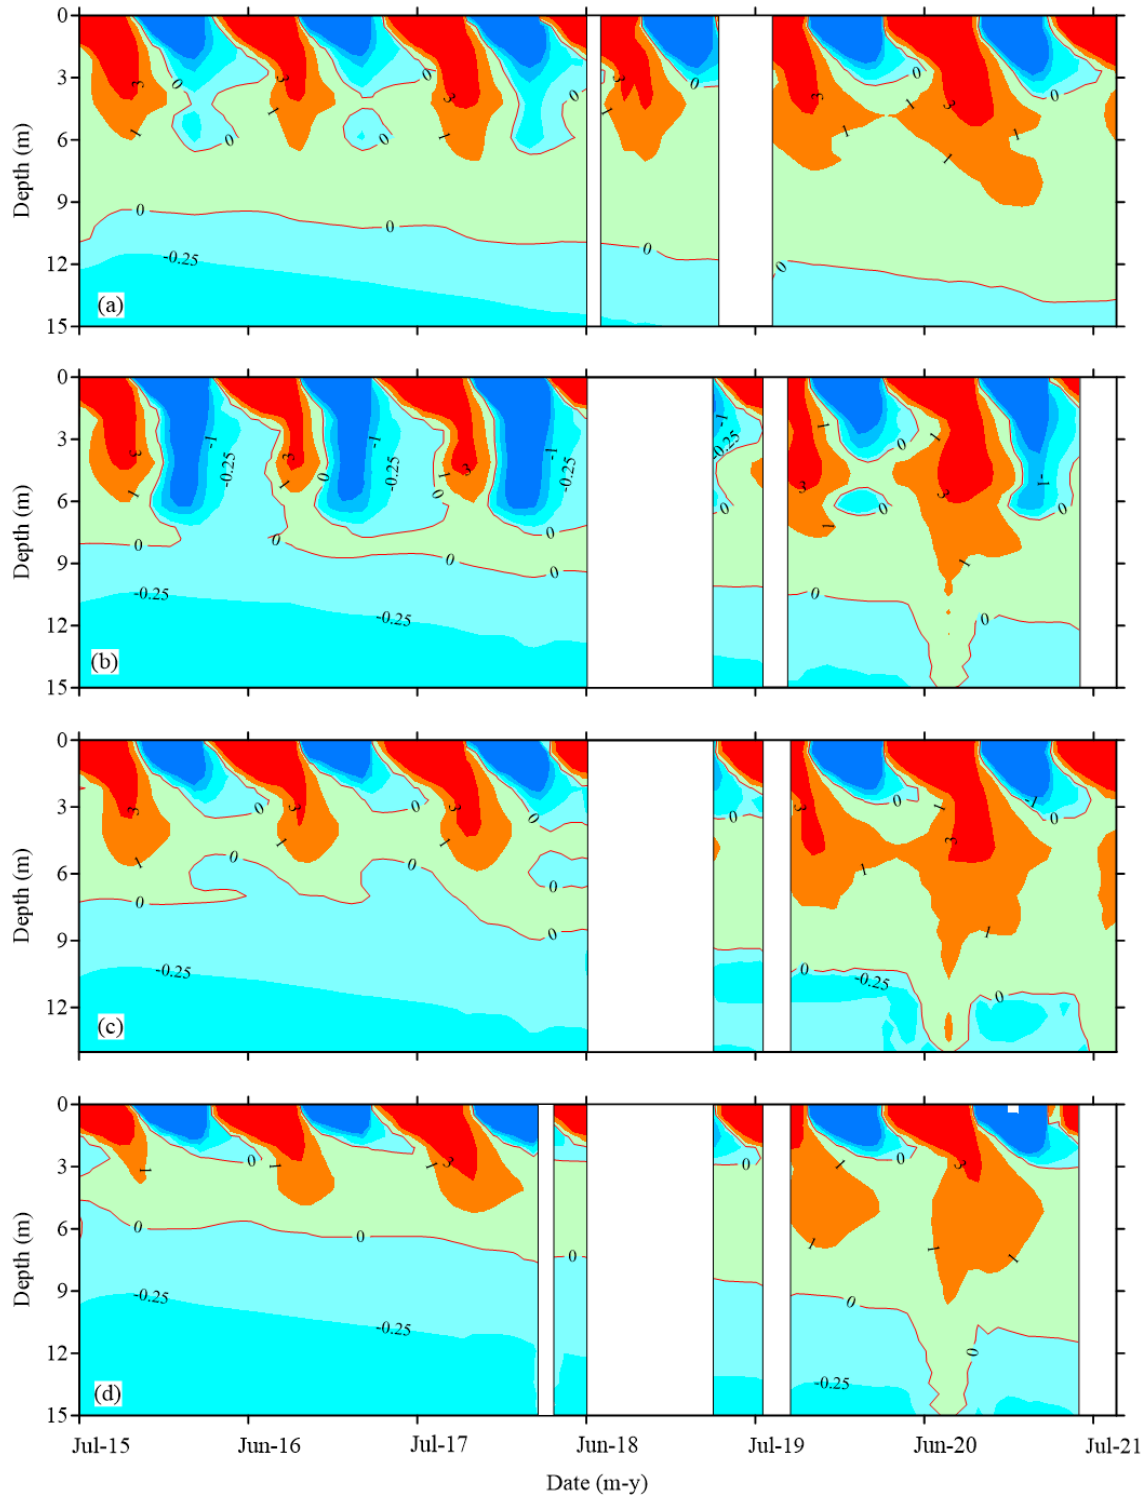

241
 242 Figure 7. Variations in ground temperatures at the depth of 3 m on the right-of-way (ROW) at the JS (a), SL (b), and JB
 243 (c) sites along the China-Russia Crude Oil Pipeline (CRCOP) I in northern part of Northeast China during 2017–2021.

244
 245 Figure 8. Variations in the depths of permafrost table and seasonal frost, and thickness of supra-permafrost subaerial talik
 246 during 2010–2021 in borehole JB-B-1, 2 m away from the centerline of the uninsulated China-Russia Crude Oil Pipeline
 247 (CRCOP) I at the JB site in northern part of Northeast China.

248 Thermosyphons, a widely-used mitigative measure for permafrost thaw in cold region engineering, can

249 **effectively** change the temporal and spatial variations of **local** GT distribution. Figure 9 shows the time series of
250 temperature contours in boreholes of JB-B-2, JB-B-3, JB-B-6, and JB-B-9 from July 2015 to August 2021 (the
251 period with high-quality GT data series). Borehole JB-B-2 is located 2 m away from the pipeline centerline with
252 one pair of thermosyphons, while boreholes JB-B-3, JB-B-6, and JB-B-9 are set 2, 3, and 4 m, respectively, away
253 from the centerline of the CRCOP I, **but** with two pairs of thermosyphons. During the cold season, **the artificial**
254 **permafrost table (APT)** remains unchanged due to the cooling effect of thermosyphons, but it deepens when the
255 thermosyphons stop working during the warm season. Overall, APT has been increasing slowly over the
256 observational decade (Fig.9a). The cooling performance of the thermosyphons on pipeline foundation soils has
257 been enhanced with an increased number of thermosyphons, as characterized by a **lower** rate of APT deepening and
258 a wider vertical cooling extent **in winter or the cold season** (Fig.9b). Besides, GTs in boreholes of JB-B-6 and JB-B-
259 9 indicate a greater-than-1.5-m cooling range of thermosyphons, and a greater-than-4-m lateral extent on the
260 ground surface of thermal disturbance of the warm pipeline (CRCOP I) (Figs.9c and 9d). During June–August
261 2020, abnormal changes in 0 °C isotherm **shown** in Figures 9b, 9c, and 9d are likely related to the infiltration of
262 surface **waters and supra- and/or intra-permafrost waters**. The above results show that the vertically-inserted
263 thermosyphons are unable to completely **prevent** the thawing of **the underlying** permafrost. The unexpectedly
264 warmer oil temperature, thermal erosion of surface water ponding on the ROW, **lowering** thermosyphon
265 performance, as well as climate warming are responsible for the unsatisfactory cooling effect of thermosyphons on
266 the pipeline foundation soils.

267

268 Figure 9. Time series of temperature contours (°C) with thermosyphons from the ground surface (0 m) to a depth of 15 m,
 269 derived from the boreholes JB-B-2 (a), JB-B-3 (b), JB-B-6 (c), and JB-B-9 (d) at the JB site along the China-Russia
 270 Crude Oil Pipeline (CRCOP) I in the northern part of Northeast China. The blank gap indicates the missing data.

271 **3.2.3 Soil water content on the ROW of pipeline**

272 The variations in VWC at depths of 0.5 m (peaty soil) and 1.5 m (silt clay) are controlled by the freeze-thaw

273 processes of soil layers. In the ground thawing season, VWC is $0.55 \text{ m}^3 \text{ m}^{-3}$ at 0.5 m in depth and reaches 0.64 m^3
 274 m^{-3} at 1.5 m. While the VWC at 2.5 m (silt clay) is less changed with an average of $0.45 \text{ m}^3 \text{ m}^{-3}$ (Fig.10), offering
 275 indirect evidence to the presence of the SST around the warm-oil pipe (Li et al., 2018). All these findings
 276 undoubtedly confirm that the construction and operation of the buried warm pipeline have resulted in locally
 277 intensive thermal disturbances on the underlying permafrost in the ROW along CRCOPs, although spatially
 278 confined.

279
 280 **Figure 10. Temporal history of soil volumetric liquid water content at depths of 0.5, 1.5, and 2.5 m at the JB site along**
 281 **the China-Russia Crude Oil Pipeline (CRCOP) I in the northern part of Northeast China during 2015-2021.**

282 **3.3 Subsurface electrical resistivity data**

283 The electrical resistivity (ER) is dependent on many parameters including lithology, soil water/ice content, and soil
 284 temperature. The ER distribution in the ground can be visualized by ERT, which provides a continuous transect of
 285 the characteristics of the active layer and near-surface permafrost to delineate the shape and size of talik or
 286 permafrost islands along the CRCOPs route. We performed ERT surveys in April 2018 with the SuperSting R8
 287 system (Advanced Geosciences, Inc., Table 2) using the Wenner-Schlumberger configuration due to its high signal-
 288 to-noise ratio (Dahlin and Zhou, 2014). In addition to the fourth ERT profile at the JB site (P-JB-4), other profiles
 289 were done using stainless electrodes spaced by 2 m along the 120-m-long profile, reaching a maximum penetration
 290 depth of 24 m (Table 3). The smoothness-constrained least-squares method was employed for ERT inversion.

291 The inverted ERT results, i.e., distribution of apparent ER within the subsurface, can provide information
 292 regarding the spatial distribution of permafrost and talik (unfrozen ground in permafrost regions) (Zhang, 2011).
 293 The configurations of talik around the CRCOPs can be seen in Figure 11. Here, an ER value of 300 Ωm was used
 294 as the critical value to identify the boundary between frozen and unfrozen zones combined with the profile
 295 characteristics of resistivity, GT, water/ice content, and lithology (obtained from borehole drilling) (Fig.12). There
 296 was a significant difference in the sizes of taliks around the CRCOPs in April 2018, suggesting that pipeline
 297 operation-related thermal disturbances had accelerated permafrost thaw (Fig. 11). Besides, the shallow soil layer
 298 beneath the vegetation cleared pipeline ROW had lower ER values, compared to those in the adjacent undisturbed
 299 site at the same time (Fig. 11), indicating that the clearing of the ROW has also contributed to permafrost warming
 300 and thawing.

301

4 Data availability

The data sets presented herein can be freely downloaded from the National Tibetan Plateau/Third Pole Environment Data Center at <http://doi.org/10.11888/Cryos.tpcdc.272357> (Li, 2022).

5 Conclusions

For this study, an *in-situ* monitoring network for the ground thermal state of permafrost was established along the CRCOP route, at the eastern flank of the northern Da Xing'anling Mountains in Northeast China. The resulting dataset fills the gaps in the spatial coverage of mid-latitude mountain permafrost databases with and without warm pipeline disturbances. This dataset consists of daily ground temperatures at depths of 0-20 m in 20 boreholes (10.0 to 60.6 deep, spanning a range of latitudes from 50.47 to 53.33°N), soil volumetric liquid water contents, meteorological variables, and ERT data. The harsh environmental conditions and inaccessibility to the field sites during the COVID-19 pandemic have resulted in some missing data, but we will continue to update the dataset by overcoming these difficulties in subsequent years.

318 The dataset presented herein shows permafrost at the eastern flank of the northern Da Xing'anling Mountains
319 is controlled by latitude and strongly influenced by the local geo-environmental factors. The MAGT at 15 m **depth**
320 ranges from -1.8 to -0.4 °C, and the ALT varies from 100 to 270 cm from north to south in permafrost **terrains**.
321 The record from 2011 to 2020 of GT measurements indicates an **extensive ground warming** in the vicinity of the
322 southern limit of latitudinal permafrost. **Permafrost temperatures at depths of 8–20 m have** been rising at a rate of
323 0.035 °C yr⁻¹, but there is no significant change in ALT, varying between 178 and 200 cm in the 10-year
324 observation period. The GT measurements on the ROW of the pipeline and **the** ERT results show that the
325 construction and operation of the CRCOP have brought strong thermal disturbances to the underlying and ambient
326 permafrost foundation soils, leading to a talik with a maximum depth of 11.5 m around the pipeline, although
327 laterally much confined to the ROW of the CRCOP I. This permafrost disturbance is still in rapid expanding.
328 Thawing of permafrost on the ROW of the pipelines cannot be completely prevented by installing the insulation
329 layer or thermosyphons, but its rate can be reduced significantly. This dataset provides a **solid** basis for assessing
330 the spatiotemporal variability of **ground hydrothermal states of the active layer and near-surface (generally ≤ 20 m)**
331 permafrost under the linear **disturbances** of the buried warm pipeline and related environmental effects, for
332 revealing hydro-thermal-mechanical interactions between buried pipeline and the ambient permafrost environment,
333 for evaluating the integrity of the pipeline systems, and for offering **crucial and badly needed data on the design,**
334 **construction and maintenance** of similar pipelines in permafrost regions.

335 **Author contribution**

336 GY, WM and HJ designed this study and obtained the financial support for establishing and maintaining the
337 monitoring sites. FW and GY compiled the dataset, performed the analysis, and wrote the manuscript. FA, YH, and
338 DC improved the writing. GW, YP, YZ, YC, JZ, KG, RH, XJ, XL, and YL participated in the fieldwork and editing
339 of manuscripts at various stages.

340 **Competing interests**

341 The authors declared no conflicts of interest in this work.

342 **Special issue statement**

343 This article is part of the special issue “*Extreme Environment Datasets for the Three Poles*”. It is not associated
344 with a conference.

345 **Acknowledgments**

346 This work was financially supported by the Strategic Priority Research Program of Chinese Academy of Sciences
347 (Grant No. XDA2003020102), the National Natural Science Foundation of China (Grant No. 42101121), and the
348 Research Projects of the State Key Laboratory of Frozen Soil Engineering (Grant Nos. SKLFSE-ZY-20 and
349 SKLFSE202010).

459 **route in the northern Da Xing'anling Mountains, Northeast China.** Notes: Photo was taken on April 2018. The rain gauge
460 sensor has been installed but is ineffective. The photo shows the location of the Jagdaqi pump station. The CR3000 data
461 logger, multiplexer, battery cell, solar charge controller, and wireless transmission module are placed in the white box
462 with a solar panel (*i.e.*, insulated box). All monitoring devices are protected by an aluminum alloy fence.

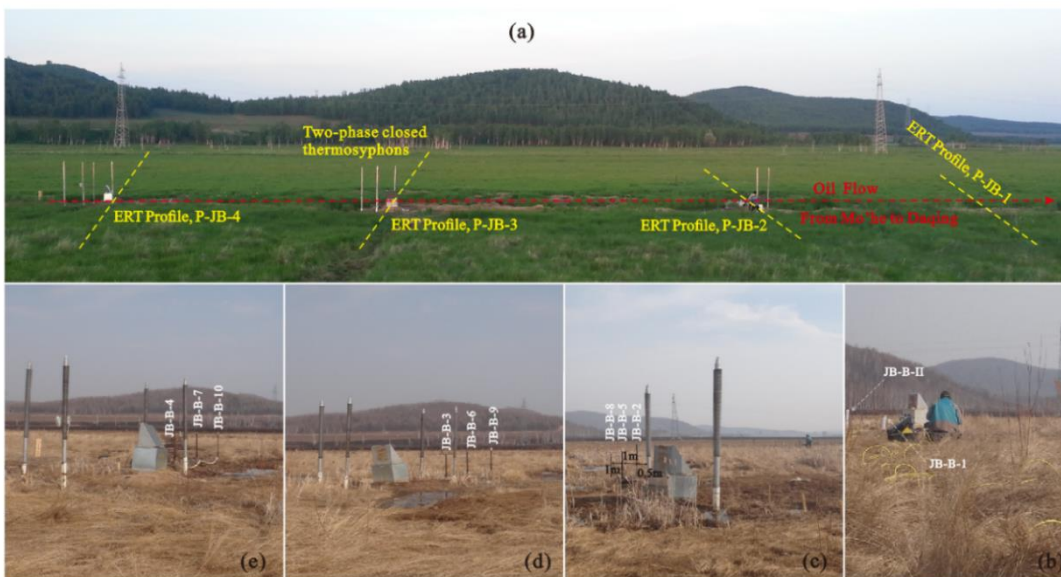

463 **Appendix C: Relative position of boreholes and automatic collection instrumentation for ground temperatures at**
 464 **permafrost monitoring sites**

465
 466 Figure C1. Position of boreholes drilled on and off the pipeline ROW and the ERT profile at the JS permafrost site. Photo
 467 was taken on 29 June 2021. Ground temperatures are measured using thermistor chains connected to the CR3000 data
 468 logger. Notes: (a) Wireless transmission module (HKT-DTU, Campbell Scientific, Inc., USA), (b) CR3000 data logger
 469 with a TRM128 multiplexer, (c) Solar charge controller (Phocos ECO (10 A), Germany), (d) Battery cell, a part of the
 470 power supply device.

471
 472 Figure C2. Position of boreholes drilled on and off the pipeline ROW and the ERT profile at the SL permafrost site.
 473 Notes: (a). Photo was taken on 30 March 2018. The ground surface within the trench is completely covered with ice and
 474 snow. (b) Miniature temperature data loggers were installed in August 2020. Photo was taken on 17 April 2021. The
 475 surface vegetation was destroyed by a controlled burn.

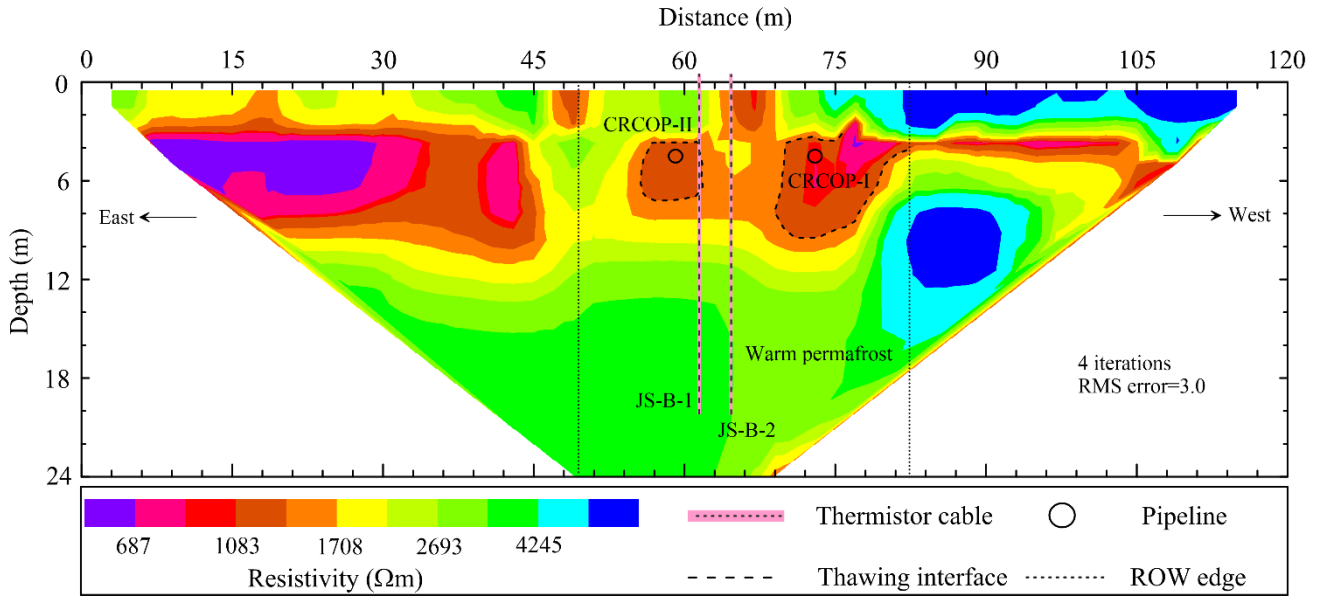

476

477 Figure C3. Picture of the monitored cross-sections, perpendicular to the pipeline at 20 m intervals, at the JB permafrost
 478 site. Notes: (a) Plane view, (b) Section 1, without thermosyphon, (c) Section 2, one pair of thermosyphons, (d) Section 3,
 479 two pairs of thermosyphons at a longitudinal spacing of 1.3 m, and (e) Section 4, two pairs of thermosyphons at a
 480 longitudinal spacing of 1.4 m. The data acquisition device is the same as that at the JS site.

481 **Appendix D: ERT results along P-JS, P-SL, P-JB-2, P-JB-3, and P-JB-4 profiles**

482

483 Figure D1. Inversion results of electrical imaging along P-JS profile at the JS site, carried out in April 2018.

484

485 Figure D2. Inversion results of electrical imaging along P-SL profile at the SL site, carried out in April 2018.

486

487 Figure D3. Inversion results of electrical imaging along monitored cross-sections with thermosyphons at the JB site,
 488 carried out in April 2018. Notes: (a) P-JB-2 profile, one pair of thermosyphons, (b) P-JB-3 profile, two pairs of
 489 thermosyphons at a longitudinal spacing of 1.3 m, and (c) P-JB-4 profile, two pairs of thermosyphons at a longitudinal
 490 spacing of 1.4 m.
