**Abstract.** Because of the large diversity of case 2 waters ranging from extremely absorbing to extremely scattering waters and the complexity of light transfer due to external terrestrial inputs, retrieving main biogeochemical parameters such as chlorophyll-a or suspended particulate matter concentration in these waters is still challenging. By providing optical and biogeochemical parameters for 180 sampling stations with turbidity and chlorophyll-a concentration ranging from 1 to 700 FNU and from 0.9 to 180 mg m<sup>-3</sup> respectively, the HYPERMAQ dataset will contribute to a better description of marine optics in optically complex water bodies and can help the scientific community to develop algorithms. The HYPERMAQ dataset provides biogeochemical parameters (i.e. turbidity, pigment and chlorophyll-a concentration, suspended particulate matter), apparent optical properties (i.e. water reflectance from above water measurements) and inherent optical properties (i.e. absorption and attenuation coefficients) from six different study areas. These study areas include large estuaries (i.e. the Rio de la Plata in Argentina, the Yangtze Estuary in China and the Gironde Estuary in France), inland (i.e. the Spuikom in Belgium and Chascomús lake in Argentina) and coastal waters (Belgium). The dataset is available from Lavigne et al (2022), <https://doi.pangaea.de/10.1594/PANGAEA.944313>.

## 1 Introduction

In marine optics, certain water properties such as the concentration of chlorophyll-a ([Chl-a] hereafter) or suspended particulate matter (SPM hereafter) are inferred from water leaving reflectance allowing a powerful satellite-based monitoring. However, although algorithms are well matured in clear case 1 waters (Morel and Prieur, 1975; Morel and Maritorena, 2001), it is not the case in optically complex case 2 waters where apparent optical properties (AOPs) and inherent optical properties (IOPs) are influenced not only by [Chl-a] but also by terrestrial

38 optically-active substances such as suspended sediments and colored dissolved organic matter (CDOM) that do  
39 not covary with [Chl-a]. Given the complexity of light transfer in these waters and the large diversity of case 2  
40 waters, algorithm definition is much more challenging (Odermatt et al., 2012) and requires datasets covering the  
41 extreme variability of case 2 water conditions. Hence, additional data obtained in optically complex waters are  
42 valuable to the scientific community as they will help to better understand marine optics in such waters and to  
43 design ocean color algorithms.

44 The present dataset (Lavigne et al., 2022; <https://doi.pangaea.de/10.1594/PANGAEA.944313>) has been collected  
45 as part of the HYPERMAQ project. During this project, different types of optically complex waters with turbidity  
46 ranging from moderate to extreme (1 to 700 FNU) and [Chl-a] ranging from low to very high (0.9 to 180 mg m<sup>-3</sup>)  
47 have been sampled in various locations around the world. Their main optical and biogeochemical parameters  
48 are shared in this dataset, including measurements of water-leaving reflectance, turbidity, non-water light absorp-  
49 tion and attenuation coefficients as well as SPM, [Chl-a] and other pigment composition. In the next sections,  
50 study areas, sampling methodology and final HYPERMAQ datasets are described.

## 51 **2 Sites**

52 Contrary to case-1 waters, optical properties of case-2 waters are impacted by terrestrial inputs of sediments and  
53 CDOM with concentrations ranging from low to extreme values. Hence, in these waters, the retrieval of water  
54 properties from bio-optical algorithms is extremely complex. As case-2 waters are generally highly connected to  
55 land-ocean interaction and human activities (estuaries, coastal and inland waters), it becomes critical to collect  
56 enough in situ data to help for the development of specific algorithms. Given the large diversity of case-2 waters,  
57 Hieronymi et al. (2016) defined four main groups: case-2 scattering (C2S), case-2 extremely scattering (C2SX),  
58 case-2 absorbing (C2A) and case-2 extremely absorbing (C2AX), suggesting that specific efforts in algorithm  
59 development should be given to each group. For instance, Hieronymi et al. (2017) proposed a multi-neural net-  
60 works algorithm for case-2 waters atmospheric correction, but the algorithm was mostly trained and validated with  
61 synthetic datasets. In this context, the HYPERMAQ dataset provides bio-optical data from C2S and C2SX waters  
62 by sampling a very large diversity of waters affected by additional sediments inputs (see sample sites on Figure  
63 1). Sample sites allow obtaining a large range in SPM and turbidity (1 to 700 FNU) by sampling Belgian coastal  
64 waters which are extremely turbid locally close to the coast and less turbid further offshore. In addition, three  
65 estuaries known to be extremely turbid have been sampled (the Gironde (France), the Yangtze (China) and the Rio  
66 de la Plata (Argentina) estuaries). Since they are affected by tides, a gradient of turbidity could be sampled along  
67 the day with diverse influences of oceanic waters. These three estuaries, located on different continents, carry  
68 suspended particles with their own mineral properties, enriching then the database. Finally, two terrestrial lagoons  
69 were sampled. One with low to moderate concentrations in suspended sediments (Spuikom in Belgium) and one  
70 with extreme concentrations of both algae and non-algal suspended particles (Chascomùs in Argentina). This large  
71 diversity of sampled sites should then help to improve our knowledge of case-2 moderately to extremely scattering  
72 waters. A detailed description of each site is provided below.

73

## 74 **2.1 Belgian coastal waters**

75 The Belgian coastal waters (latitudes: 51.27° to 51.59°N; longitudes: 2.50° to 3.15°E) have been sampled in April  
76 2018 and July 2018 from the RV Simon Stevin (Table 1). Belgian coastal waters are dominated by Atlantic waters  
77 which enter from the English Channel (Lacroix et al., 2004) and experience very strong along shore tidal currents  
78 which cause sediment resuspension leading to high turbidity. SPM concentrations range from less than 1 g m<sup>-3</sup> in  
79 offshore and deeper waters to more than 100 g m<sup>-3</sup> in very shallow waters. Phytoplankton blooms, characterized  
80 by high [Chl-a] concentration (more than 10 mg m<sup>-3</sup>), develop in spring from March to May. During summer, the  
81 biomass remains rather high (5 to 10 mg m<sup>-3</sup>) compared to winter when phytoplankton growth is mostly limited  
82 by light (Lancelot et al., 2005). The blooming season is mostly dominated by two taxa: diatoms in early spring and  
83 summer and *Phaeocystis globosa* in April-May (Muylaert et al., 2006).

## 84 **2.2 Spuikom lagoon**

85 The Spuikom lagoon (latitude: 51.23°N, longitude: 2.95°E) is an artificial basin that is connected to Ostend harbor  
86 (Belgium) by a lock system. The Spuikom has a surface area of 0.82 km<sup>2</sup> and an average depth of 1.5 m. In the  
87 past, it has been used as a flushing basin to flush sediments from the harbor channel. Today it is used for leisure  
88 and commercial activities like sailing and shellfish farming. The Spuikom can experience events of phytoplankton  
89 blooms, of high turbidity (when strong winds cause the resuspension of bottom sediments), and of clear waters,  
90 which allow the development of microphytobenthic biofilms and macroalgae in the bottom (Castagna et al., 2022).  
91 The system was sampled during the growth season of 2018 (April and July, Table 1). Measurements were  
92 performed from inflatable boats provided by Ghent University and VLIZ (Zeekat).

## 93 **2.3 Gironde Estuary**

94 The Gironde Estuary, southwest France, is a good example of sediment-dominated case 2 waters influenced by  
95 river inputs. The Gironde Estuary has been sampled between 17-20 September 2018 in two locations: Pauillac  
96 (latitude: 45.1975°N, longitude: -0.7422°E) close to the maximum turbidity zone and Le Verdon (latitude:  
97 45.5438°N, longitude: -1.042°E) close to the river mouth. In the Gironde Estuary, the origin of the particles is  
98 twofold: inputs from rivers Garonne and Dordogne and erosion of recently settled sediments by tidal currents  
99 (Castaing and Allen, 1981). The suspended matter is a mixture of organic and mineral composites, where the  
100 organic fraction represents less than 2% of the total material (Doxaran et al. 2002). The mineral fraction is com-  
101 posed of micas (63%) and quartz (25%), while clay phases contain four minerals: montmorillonite (30%), illite  
102 and interstratified minerals (40%), kaolinite (15%), chlorite and interstratified minerals (15%). [Chl-a] and CDOM  
103 concentrations are low, with [Chl-a] ranging from 1 to 3 mg m<sup>-3</sup> (Irigoiien & Castel, 1997), and dissolved organic  
104 carbon (DOC) ranging from 1 to 7 mgC L<sup>-1</sup> (Abril et al., 1999; Castaing and Allen, 1981). The Gironde Estuary  
105 has well-developed turbidity maximum zones, with both tidal asymmetry and density residual circulation involved  
106 in their formation (Castaing and Allen, 1981). It is characterized by SPM concentrations ranging from 10 to 1000  
107 g m<sup>-3</sup> within surface waters (Doxaran et al. 2009a).

## 108 **2.4 Chascomús lake**

109 Chascomús lake, located in the Pampa Plain in the Buenos Aires Province in Argentina (latitude: -35.5828°N,  
110 longitude: -58.0202°E), with a surface area of ~ 30 km<sup>2</sup>, is a highly turbid, shallow lagoon (average depth of ~ 1.9  
111 m), permanently mixed due to intense and persistent winds (Torremorell et al., 2007). Total suspended matter  
112 varies widely from 66.3 to 614 g m<sup>-3</sup> with a mean value of 227.3 ±133.7 g m<sup>-3</sup> (Diovisalvi et al. 2014) and on  
113 average the inorganic content represented ~65%. Nephelometric turbidity also widely ranged from 76.46 to 509.74  
114 NTU, with a mean value of 209.18±112.76 NTU. Turbidity was highly correlated to SPM while no significant  
115 correlation with [Chl-a] was found (Pérez et al. 2011). Total [Chl-a] concentration ranged from 50.6 to 856.3 mg  
116 m<sup>-3</sup> (mean = 328.5 ±173.4 mg m<sup>-3</sup>) during the 2005-2009 sampled period (Diovisalvi et al. 2014). The lake is  
117 characterized by high primary production (Torremorell et al., 2009) and a rich and diverse phytoplankton commu-  
118 nity, mostly composed of cyanobacteria. In terms of biovolume, cyanobacteria contribute 50% to total phytoplank-  
119 ton biovolume and 75% to total C in the water column (Diovisalvi et al. 2010). Despite the high CDOM absorption  
120 ( $a_{CDOM}$ , mean  $a_{CDOM}(440)=4.65 \pm 0.91 \text{ m}^{-1}$ ), absorption by particulate fraction ( $a_p$ ) has a prominent role in light  
121 absorption, for which both phytoplankton pigments ( $a_{phy}$ ) and non-pigmented particles ( $a_{NAP}$ ) contribute similarly  
122 to total particulate absorption (Pérez et al. 2011). Both SPM (especially the inorganic part) and [Chl-a] (less pro-  
123 nounced) show seasonal variation with increasing values in spring and summer (Mid-September to Mid-March),  
124 while the dissolved fraction did not show a significant seasonal difference (Pérez et al. 2011). The HYPERMAQ  
125 field campaign in Chascomús lake took place on 9-10 April 2018. Radiometric, in-water measurements as well as  
126 samples were collected at the end of a 164 m long pier.

## 127 **2.5 Río de la Plata**

128 The Río de la Plata is a large and shallow funnel shaped estuary with high values SPM, ranging from 100 to 300  
129 g m<sup>-3</sup> (Framiñan and Brown, 1996) and reaching 940 g m<sup>-3</sup> in the maximum turbidity zone (Dogliotti et al. 2014).  
130 Turbidity values widely vary between 2 and 680 FNU (Dogliotti et al. 2016). SPM, turbidity and [Chl-a] spatial  
131 distribution and temporal variability is highly variable. In the upper estuary, a freshwater with tidal regime area,  
132 turbidity increases from January to April/May (with higher values along the southern Argentinian coast compared  
133 to the northern Uruguayan coast), and decreases from June to September (Dogliotti et al. 2016). In turn [Chl-a]  
134 also show high spatial variability, in the upper estuary higher values are generally found in the northern part (Uru-  
135 guay) compared to the southern part (Argentina). In particular, high [Chl-a] have been recorded during spring-  
136 summer months related to cyanobacteria blooms both along the Uruguay (Aubriot et al. 2020) and Argentine  
137 (Dogliotti et al. 2021) coasts, when [Chl-a] values as high as 13.6 and 153 mg m<sup>-3</sup> have been recorded, respectively.  
138 Measurements in the Rio de la Plata were performed from a fixed 500 m long pontoon at the Palermo Pescadores  
139 Club in Buenos Aires (latitude: -34.5609°N, longitude: -58.3988°E) on 4 and 5 April 2018.

## 140 **2.6 Yangtze Estuary**

141 The Yangtze Estuary is located on the east coast of China and close to East China Sea (Figure 1). Influenced by  
142 the Yangtze River, the largest river in China and the third largest in the world due to its enormous runoff, which  
143 discharges an annual average of  $9 \times 10^{11} \text{ m}^3$  of freshwater and  $4 \times 10^8$  tons of sediment into the estuary from 1950s

144 to 2000 (Chen et al., 2003), the Yangtze Estuary is an extremely turbid area (Shen et al., 2010a). Taking 2009 as  
145 example, the annually averaged of SPM in surface waters varied from  $58 \text{ g m}^{-3}$  at the upstream limit of the estuary  
146 to about  $600 \text{ g m}^{-3}$  at the mouth area, and fell again to  $57 \text{ g m}^{-3}$  at the seaward limit of fresh water diffusion (Li et  
147 al., 2012). Due to the different river discharges, the SPM of the Yangtze Estuary exhibits seasonal variations (Shen  
148 et al., 2013), with SPM in the upper estuary (lower estuary) during flood season significantly higher (lower) than  
149 that during the dry season. Over the past 37 years, SPM in the Yangtze Estuary demonstrated an overall declining  
150 pattern (Luo et al., 2022), with SPM in the inner estuary responding most promptly (40.3% reduction) after the  
151 operation of Three Gorges Dam. [Chl-a] also shows seasonal variations in the Yangtze Estuary, ranging from 0.03  
152 to  $3.10 \text{ mg m}^{-3}$  and from 0.88 to  $31.5 \text{ mg m}^{-3}$  during spring and summer seasons of 2008, respectively (Shen et al.,  
153 2010b). In addition, the Yangtze Estuary is an area with frequent outbreaks of algal blooms, with diatoms being  
154 the most frequently reported group (Shen et al., 2019; Zhu et al., 2019).

155 Two Hydrological Stations in Chongming Island, Shanghai, China, namely Chongxi (longitude:  $121.193^\circ\text{E}$ , lati-  
156 tude:  $31.759^\circ\text{N}$ ) and Baozhen (longitude:  $121.609^\circ\text{E}$ , latitude:  $31.520^\circ\text{N}$ ) have been sampled from 30 May to 8 June  
157 in 2018 (Table 1).

158

### 159 **3. Data collection**

160 The dataset contains measurements of the turbidity and, if available, concomitant SPM, absorption and attenuation  
161 coefficients, [Chl-a] and reflectance measurements are also included (Lavigne et al., 2002; [https://doi.pan-  
162 gaea.de/10.1594/PANGAEA.944313](https://doi.pangaea.de/10.1594/PANGAEA.944313)). An overview of the dataset, with the number of observations after quality  
163 control for each site and parameter, is provided in Table 2. The measurement methodology for each parameter is  
164 described below.

#### 165 **3.1 Water-leaving reflectance**

166 Above-water reflectance was determined using three TriOS/RAMSES hyperspectral spectroradiometers, two spec-  
167 troradiometers measure radiance and one irradiance. The same TriOS instruments from RBINS institute were used  
168 for all campaigns except the ones which occurred in Argentina where only instruments from IAFE institute were  
169 available. The spectrometers measure in the 350-950 nm range with a sampling interval of 3.3 nm and effective  
170 spectral resolution of 10 nm. The instruments were mounted on a frame and placed in the bow of the vessels  
171 (Belgian coastal zone and Spuikom) or fixed to a rail when measurements were made from pontoons (Gironde,  
172 Chascomús and Rio de la Plata). Zenith angles of the sea- and sky-viewing radiance sensors were set to  $40^\circ$ . Prior  
173 to each measurement, the azimuth angle of the sensors was adjusted to obtain a relative azimuth angle with respect  
174 to the sun of  $90^\circ$ , either left or right to get the best unobstructed view of the water and minimize structure pertur-  
175 bation when measuring from pontoons. Simultaneous upwelling water radiance ( $L_u$ ), downwelling sky radiance  
176 ( $L_{sky}$ ) and downwelling irradiance ( $E_d$ ) were collected every 10 s for 10 min. Data was acquired using MSDA-XE  
177 software and radiometrically calibrated using the latest calibration update from annual laboratory calibration. Wa-  
178 ter reflectance ( $\rho_w$ ) was calculated following

179 
$$\rho_w(\lambda) = \frac{L_u(\lambda) - \rho_{sky}L_{sky}(\lambda)}{E_d(\lambda)}\pi$$

180 Where  $\rho_{sky}$  is the air-sea interface reflection coefficient which is calculated based, when available, on wind speed  
 181 as in Ruddick et al. (2006) or set to a fixed value of 0.0256 when measured in estuaries from fixed pontoon con-  
 182 sidering that surface waves are fetch-limited and not related to wind speed. The data processing, including quality  
 183 control, are described in Ruddick et al. (2006).

### 184 **3.2 Turbidity**

185 Turbidity was measured with two handheld HACH 2100P/Q ISO turbidimeters from RBINS and IAFE institutions.  
 186 In the HYPERMAQ dataset, turbidity data measured with the instrument from IAFE were provided by default as  
 187 they cover the most of the campaigns. However, when turbidity data from IAFE instrument were not available  
 188 (Belgian coastal waters, April 2018 and Spuikom April 2018), the values obtained with the instrument of the  
 189 RBINS were used. Figure 2 shows the good consistency of both instruments ( $r^2=0.99$ ). Water samples were col-  
 190 lected from the surface with a bucket or from subsurface with a NISKIN bottle for measurements in coastal waters.  
 191 A 10 mL vial was filled and turbidity was determined in Formazin Nephelometric Unit (FNU) with the ratio of  
 192 light scattered at  $90^\circ$  compared to the transmitted light at 860 nm. Turbidity was recorded in triplicates and the  
 193 median value was used. Turbidimeters were controlled with standards STABCAL Stabilized Formazin Turbidity  
 194 of 0.1, 20, 100 and 800 FNU before and after each campaign.

195 In water turbidity was also measured with an OBS501 (OBS hereafter) using a CR200 data logger. Turbidity  
 196 measurements are derived from back-scattering with a field-of-view ranging from 125 to 170 degree and 90-degree  
 197 side-scattering of a signal emitted at 850 nm and data are provided in Formazin Backscatter Unit (FBU) and in  
 198 Formazin Nephelometric Unit (FNU), respectively. When deployed from a pier, OBS was continuously recording  
 199 data at subsurface throughout the whole day and values corresponding to specific stations were extracted from the  
 200 time-series in a time-window of 10 minutes centered on the timing of the radiometric measurement and water  
 201 sampling. When deployed from a boat, the OBS was maintained at subsurface (1 m depth) for at least 5 minutes.  
 202 Then, from a visual check, leading and trailing data of each time-series were removed and the central values were  
 203 averaged to obtain a final value.

### 204 **3.3 *In situ* absorption, beam attenuation and scattering coefficients**

205 The underwater absorption- and attenuation-meter (AC-9, WETLabs, Inc.) used was modified to cover the visible  
 206 and near-infrared (NIR; 700 to 900 nm) spectral regions. It was designed with three visible (centered at 440 nm,  
 207 555 nm and 630 nm) and six NIR (centered at 715 nm, 730 nm, 750 nm, 767 nm, 820 nm and 870 nm) spectral  
 208 channels, and a short pathlength (10 cm) appropriate for turbid coastal waters. At the sampling sites, the AC-9  
 209 sensor was either deployed within the water column using an electrical water pump (SBE, SeaBird, Inc.) or used  
 210 as a bench photometer passing the water samples right after collection through the tubes by gravimetry. The AC-  
 211 9 data recorded just below the water surface were averaged over the last minute of acquisition to obtain the mean  
 212 attenuation and absorption spectra for each station. Temperature and salinity corrections were applied as recom-  
 213 mended by the manufacturer. As in Doxaran et al. (2007), the residual scattering effects on absorption

214 measurements were corrected by applying the “proportional” method using 870 nm as the reference wavelength.  
215 The scattering coefficient was calculated as the difference between the measured beam attenuation coefficient,  $c_{nw}$ ,  
216 corrected for temperature and salinity effects, and the absorption coefficient,  $a_{nw}$ , corrected for temperature, salin-  
217 ity and scattering effects. Those attenuation and absorption coefficients were referenced to pure water (non-water,  
218 subscript “nw”), so that the scattering coefficient obtained by difference corresponds to the scattering coefficient  
219 of marine particulates,  $b_p$  in  $m^{-1}$ . Small bubbles can contribute to the measured attenuation and scattering, but in  
220 turbid systems particles dominate the signal. One of the main issues encountered when sampling highly turbid  
221 waters was the saturation of the measured absorption and/or attenuation coefficients, which sometimes occurred  
222 at short visible wavelengths and even in near-infrared bands in the case of extremely turbid waters. This saturation  
223 was easily detected and the corresponding spectra were systematically removed from the dataset.  
224 When possible, after AC-9 data measurements, the water sample collected was directly filtered through disc filters  
225 (pore size 0.2  $\mu m$ , Whatman). As in Doxaran et al. (2009b), the tube was rinsed twice with Milli-Q water and once  
226 with the filtrate, and then filled with the filtrate. The absorption signal of the filtrate was measured, providing  
227  $a_{CDOM}$  in  $m^{-1}$  after applying corrections for temperature and salinity. The absorption coefficient of suspended par-  
228 ticles ( $a_p$ , in  $m^{-1}$ ) was finally calculated by subtracting the signal from the non-water absorption coefficient.

### 229 **3.4 Concentration of Suspended Particulate Matter and Suspended Inorganic Particulate Matter**

230 SPM concentration was determined gravimetrically following the protocol of Tilstone et al. (2002) which is based  
231 on Van der Linde (1998). Water was sampled from the surface (maximum 2m depth) with a NISKIN bottle on  
232 board the RV Simon Stevin or with a bucket in estuarine and inland waters. A sufficient volume of water was  
233 filtered on a pre-ashed GF/F filter and conserved at  $-20^{\circ}C$  before analysis. The volume filtrated was determined  
234 as a function of the turbidity following recommendations of Neukermans et al. (2012). Inorganic suspended par-  
235 ticulate matter (SPIM) was also calculated in all campaigns except in the Yangtze river. All the SPM measurements  
236 have been conducted with 3 replicates to assess variability except for the campaigns in the Yangtze Estuary where  
237 only one sample has been measured per each station. Filters were dried at  $75^{\circ}C$  for 24 hours and weighed in order  
238 to determine the suspended matter concentration (SPM, in  $g m^{-3}$ ). For SPIM measurements, filters were then  
239 burned at  $450^{\circ}C$  for 4 hours to remove the organic part, and weighed again to estimate the suspended inorganic  
240 particulate concentration (SPIM, in  $g m^{-3}$ ).

### 241 **3.5 Chlorophyll-*a* and other pigment concentrations**

242 Phytoplankton pigments including [Chl-*a*] were determined using High Performance Liquid Chromatography  
243 (HPLC) following the protocol of Van Heukelem and Thomas (2001) in campaigns in the Belgian coastal waters,  
244 the Spuikom and the Gironde. In Belgian coastal waters, measurements were provided by the LifeWatchBE  
245 sampling campaigns (Mortelmans et al., 2019, Flanders Marine Institute, 2021) of VLIZ. Pigment standards were  
246 acquired from the Danish Hydrographic Institute (DHI). In the Gironde, the analysis of pigments were performed  
247 by the SAPIGH analytical platform of the “Institut de la Mer de Villefranche” (CNRS-France). In the Argentinian  
248 campaigns [Chl-*a*] was determined spectrophotometrically using hot ethanol ( $60-70^{\circ}C$ ) (Jespersen and

249 Christoffersen 1987). As for turbidity and SPM, water samples have been collected from surface water with a  
250 bucket in inland waters or subsurface waters with a NISKIN in sea water.

## 251 **4. Results and discussions**

### 252 **4.1 SPM and turbidity results**

253 In the HYPERMAQ dataset SPM ranges between  $1 \text{ g m}^{-3}$  and  $474 \text{ g m}^{-3}$  (Table 3) and turbidity measured from  
254 HACH and OBS (side-scattering measurements) ranges between 0.9 and 771 FNU and between 0.2 and 632 FNU  
255 respectively. A very good relationship is observed between SPM and turbidity which almost follows the 1:1 line  
256 for both instruments (Figure 3). A linear model between both parameters gives very good coefficients of determi-  
257 nation ( $R^2 = 0.98$  for HACH and  $R^2 = 0.95$  for OBS) and slopes (0.92 for HACH and 0.86 for OBS). However, we  
258 can notice that for very high turbidity ( $> 500$  FNU), turbidity values measured by HACH tends to be slightly higher  
259 than SPM values (Figure 3A) but not OBS turbidity values. As expected from previous results, when comparing  
260 side scattering turbidity obtained from OBS and turbidity measured by HACH, a good relationship is retrieved  
261 (Figure 4A) with a  $R^2$  of 0.96 and a slope of 0.84. Despite larger variability for very high turbidity, these results  
262 confirm that OBS is a good tool for continuous measurements of turbidity in turbid environments.

263 The ratio of the side scattering versus the back scattering derived from OBS measurements has a particular interest  
264 as it can provide information on the size and properties of the particles, e.g. higher ratio could be explained by  
265 larger particles (Nechad et al., 2016). In the HYPERMAQ dataset this ratio (Figure 4B) displayed a very high  
266 variability in low turbidity environments and an increasing slope for high turbidity environments (i.e. Pauillac) as  
267 also observed by Nechad et al. (2016). The very high variability when turbidity is low is explained by the strong  
268 impact of uncertainty on low back scattering values in the ratio calculation. In Figure 4B, it can be observed that  
269 the side scattering versus back scattering ratio varies significantly between and within sampled sites. For instance,  
270 this ratio is higher in the Gironde Estuary at Le Verdon than in the Spuikom lagoon. It seems also to be higher in  
271 the Río de la Plata and in the Gironde at Pauillac than in the Chascomús lake, though the Río de la Plata showed  
272 high variability. Finally, the median ratio of the whole dataset is 1.77 which is close to the mean value of 1.72  
273 found in Nechad et al. (2016) in turbid waters.

### 274 **4.2 Chl-a and other pigments concentrations**

275 [Chl-a] are extremely variable within HYPERMAQ test sites with values ranging between  $0.91 \text{ mg m}^{-3}$  in the  
276 Gironde Estuary at Le Verdon and  $180.7 \text{ mg m}^{-3}$  in the Chascomús lake, although most of the observations are  
277 within the range of  $3 \text{ mg m}^{-3}$  to  $10 \text{ mg m}^{-3}$  (Table 4). In addition, very high variability is observed within Belgian  
278 waters and Spuikom, with [Chl-a] values ranging by a factor 10. This variability is mainly due to the fact these  
279 study areas have been sampled in two different seasons (i.e. spring and summer).

280 Phytoplankton pigments derived from HPLC analysis were available in the Gironde Estuary, in the Belgian coastal  
281 waters and in the Spuikom. The relative contribution of some key pigments for phytoplankton groups identification  
282 (Uitz et al., 2006; Mackey et al., 1996) are represented on Figure 5. In the Gironde Estuary, at Le Verdon, signif-  
283 icant concentration of fucoxanthin, peridinin and chlorophyll-b are observed suggesting that diatoms, dinoflagellates

284 and chlorophytes are co-existing at similar levels. However, at Pauillac where phytoplankton biomass is higher  
285 (Table 4), the high concentration of fucoxanthin suggests that planktonic assemblages were dominated by diatoms.  
286 In Belgian waters, high value of fucoxanthin is also observed. This pattern was expected as fucoxanthin charac-  
287 terized the two phytoplankton groups which are dominant during spring and summer in the Southern North Sea:  
288 diatoms and the prymnesiophyte *Phaeocystisglobosa* (Lancelot et al., 2005). The last one is also characterized by  
289 the presence of chlorophyll-c<sub>3</sub>. In the Spuikom, fucoxanthin and chlorophyll-b show high concentrations indicating  
290 an important proportion of diatoms and chlorophytes.

#### 291 **4.3 Absorption and attenuation coefficients**

292 Very wide ranges of light absorption and attenuation coefficients were measured as representative of low to ex-  
293 tremely turbid waters. As expected in CDOM- and sediment-rich waters, the spectral variations of the non-water  
294 absorption coefficients were closely following an exponential function, with decreasing values from short visible  
295 to near-infrared wavelengths (Figure 6A). The respective contributions of CDOM and suspended particles to light  
296 absorption at 440 nm (Figure 7) were observed to vary from 20 % to 40% for CDOM and hence from 60 % to 80%  
297 for suspended particles, which could be expected in productive waters strongly influenced by sediment inputs from  
298 rivers and resuspension effects.

299 The spectral variations of the non-water attenuation coefficients ( $c_{nw}$ , Figure 6B) showed a smooth decrease with  
300 increasing wavelengths, closely following the power-law function with varying slopes. These variations of the  
301 spectral slope are expected to be representative of different particle size distributions due to the combined influ-  
302 ences of wind-driven and tidal currents, and to the mixing between mineral-rich (sediments) and organic-rich  
303 (phytoplankton) particles.

#### 304 **4.4 Water reflectance**

305 The large diversity of water-leaving reflectance spectra is displayed in Figure 8. Maximum reflectance in each  
306 spectrum varies from less than 0.02 on some spectra of the Belgian coastal waters to more than 0.15 in the Gironde  
307 Estuary at Pauillac. Shapes of the spectra are also very variable. The mark of strong chlorophyll-a absorption  
308 around 670 nm is well observed in the Chascomús and Spuikom lakes as well as in some spectra of the Belgian  
309 coastal waters. The two extremely turbid sampling stations, the Rio de la Plata and the Gironde at Pauillac, show  
310 some similarities in their spectral shapes although a large variability is observed at Pauillac due to a larger impact  
311 of tides.

312 The relationship of water reflectance at 645 and 860 nm and turbidity (Figure 9) shows expected patterns with a  
313 saturation of the reflectance at 645 nm when turbidity is higher than 200 FNU (Luo et al., 2018). Indeed, for these  
314 extreme turbidity values the band at 860 nm shows a more linear relationship.

#### 315 **5. Conclusion**

316 Coastal and inland waters strongly interact with human activities. Some of these activities, like fisheries or tourism,  
317 rely on a good ecological status whereas the same activities but also others like farming, industry or urbanization

318 tend to affect water quality. Hence, monitoring these waters is extremely important and for that optical remote  
319 sensing is a valuable tool as it allows a large spatial and temporal coverage. However, it is still challenging to  
320 retrieve biogeochemical parameters in complex case 2 waters (Odermatt et al., 2012) because the transfer of light  
321 in water is affected by temporally and spatially variable inputs of CDOM and terrestrial sediments. To help the  
322 scientific community to build comprehensive database for the development of algorithms, the HYPERMAQ da-  
323 taset provides data for six different studies areas with SPM and [Chl-a] ranging from moderate to extremely turbid  
324 and productive, and located over three continents (i.e. Europe, South America and Asia). The HYPERMAQ dataset  
325 includes big river estuaries characterized by high turbidity, inland lagoons with productivity ranging from moder-  
326 ate to extreme and finally Belgian coastal waters in the North Sea characterized by the high spatio-temporal vari-  
327 ability of optical properties (Vantrepotte et al., 2012). The parameters shared in the HYPERMAQ dataset include  
328 descriptors of biogeochemical conditions (i.e. [Chl-a], SPM, turbidity) as well as AOPs (i.e. water reflectance) and  
329 IOPs ( $a_{nw}$  and  $c_{nw}$ ). Although this dataset does not aim to cover the whole variability of case 2 waters, it provides  
330 valuable information to describe turbid and even extremely turbid waters and has the potential to help the devel-  
331 opment of remote sensing algorithms. It can also contribute to the production of a larger optical database, based  
332 on in situ measurements for a comprehensive description of case 2 waters.

333

#### 334 **Data availability**

335 Data is available from Lavigne et al. (2022), hosted at PANGAEA (<http://www.pangaea.de>) under the doi:  
336 <https://doi.pangaea.de/10.1594/PANGAEA.944313>. The HYPERMAQ dataset is subdivided into 10 sub-datasets  
337 with their own DOI: absorptions and attenuation data (<https://doi.pangaea.de/10.1594/PANGAEA.944361>), Chl-  
338 a concentration, turbidity and organic and inorganic sediments concentrations (<https://doi.pan->  
339 [gaea.de/10.1594/PANGAEA.944364](https://doi.pangaea.de/10.1594/PANGAEA.944364)), pigment concentrations ([https://doi.pan-](https://doi.pangaea.de/10.1594/PAN-)  
340 [GAEA.944321](https://doi.pangaea.de/10.1594/PANGAEA.944321)), spectral downwelling irradiance (<https://doi.pangaea.de/10.1594/PANGAEA.944311>) and its  
341 standard deviation (<https://doi.pangaea.de/10.1594/PANGAEA.944312>), downwellingsky radiance  
342 (<https://doi.pangaea.de/10.1594/PANGAEA.944380>) and its standard deviation (<https://doi.pan->  
343 [gaea.de/10.1594/PANGAEA.944385](https://doi.pangaea.de/10.1594/PANGAEA.944385)), water downwelling radiance (<https://doi.pangaea.de/10.1594/PAN->  
344 [GAEA.944369](https://doi.pangaea.de/10.1594/PANGAEA.944369)) and its standard deviation (<https://doi.pangaea.de/10.1594/PANGAEA.944371>) and finally water  
345 reflectance (<https://doi.pangaea.de/10.1594/PANGAEA.944474>) and its standard deviation (<https://doi.pan->  
346 [gaea.de/10.1594/PANGAEA.944475](https://doi.pangaea.de/10.1594/PANGAEA.944475)).

#### 347 **Author contributions**

348 HL, AD, DD, FS, AC, XS, JIG, RP, MB, QV and KR participated to one or more field campaigns. Data processing  
349 has been made by HL, AD and JIG (turbidity), DD (absorption), KR, MB, QV, RP, AD (water reflectance), AC,  
350 AD, DD, FS, KS (chlorophyll-a, pigments and SPM). HL, DD, AD have compiled data and created the final  
351 dataset. All authors participated to manuscript redaction and revision.

352 **Competing interests.**

353 The authors declare that they have no conflict of interest.

354 **Acknowledgements**

355 This work has been founded and promoted by the Research programme for earth observation 580 STEREO III  
356 HYPERMAQ project (contract nr SR/00/335).Flemish LifeWatch BE programme, funding by FWO, is thanks for  
357 its contribution to the water sampling in the Belgian Coastal Zone.We thank VLIZ for providing the Zeekat and  
358 shiptime on the RV Simon Stevin and her crew for their support during sampling. Inland water sampling in  
359 Belgium was also founded by the Belspo PONDER (SR/00/325) project. The SAPIGH analytical platform of the  
360 “Institut de la Mer de Villefranche” (CNRS-France) is thanks for having performed the analysis of pigments in the  
361 Gironde. NASA, USGS, ESA and EUMETSAT are thanks to offer a free access to Landsat 8 and Sentinel 2  
362 images.

487 **Table 1: Date, location and platform of the campaigns.**

488

Campaign	Date	Platform	Latitude (deg)	Longitude (deg)
Spuikom	19 April 2018, 23,24 and 27 July 2018	Inflatable boat	51.23	2.95
Belgian Coastal waters	23-25 April 2018, 25-26 July 2018	RV Simon Stevin	51.18-51.59	2.50-3.15
Gironde (Pauillac)	17 and 19 Sept. 2018	Harbor	45.1975	-0.7422
Gironde (Le Verdon)	18 and 20 Sept. 2018	Pier	45.5438	-1.042
Chascomús	9-10 April 2018	Pier	-35.5828	-58.0202
Rio de la Plata (Buenos Aires)	4-5 April 2018	Pier	-34.5609	-58.3988
Yangtze (Chongxi)	31 May, 1 and 3 June 2018	Pier	31.759	121.193
Yangtze (Baozhen)	4-8 June 2018	Pier	31.520	121.609

489

490 **Table 2: Number of observations for each sampling site. \*also include pigments concentrations from HPLC.**

Campaign / Site	TriOS	TUR (HACH)	TUR (OBS)	$a_{nw} - c_{nw}$ AC-9	SPM	[Chl-a]
Spuikom	27	27	23	11	17	17*
Belgian coastal waters	18	19	17	10	19	18*
Gironde - Pauillac	25	26	26	23	13	13*
Gironde - Le Verdon	21	25	25	24	12	12*
Chascomús	5	5	5	5	5	3
Rio de la Plata- BA	16	22	22	18	10	10
Yangtze - Chongxi	-	16	-	-	16	-
Yangtze - Baozhen	-	37	-	29	37	-

491

492

493 **Table 3: Distribution of SPM ( $g m^{-3}$ ) in each sampling site.**

Campaign / Site	SPM ( $g m^{-3}$ )			
	min	median	mean	max
Spuikom	2.06	3.16	3.93	8.40
Belgian coastal waters	1.02	4.49	9.63	62.04
Gironde - Pauillac	22.5	181	177	474
Gironde - Le Verdon	5.85	7.80	10.2	23.5
Chascomús	81.0	175	141	189
Rio de la Plata	49.3	71.7	74.0	93.8
Yangtze - Chongxi	27.2	42.2	44.8	66.4
Yangtze - Baozhen	23.6	52.8	53.6	138.4

494

495

496

497 **Table 4: Distribution of Chl-a concentration (mg m<sup>-3</sup>) in each sampling site.**

498

Campaign / Site	Chl-a (mg m <sup>-3</sup> )			
	min	median	mean	max
Spuikom	2.40	9.16	10.64	22.70
Belgian coastal waters	1.99	6.33	7.49	17.36
Gironde - Pauillac	2.49	3.82	3.88	6.85
Gironde – Le Verdon	0.91	1.63	1.67	2.79
Chascomús	141.5	141.5	154.6	180.7
Rio de la Plata-BA	2.17	3.27	3.72	8.71
Yangtze - Chongxi	-	-	-	-
Yangtze - Baozhen	-	-	-	-
