Abstract. We present a database from substantial collections of macronutrient data made on 20 oceanographic cruises, primarily from around the island of South Georgia and the Scotia Sea. This sector of the Southern Ocean was studied comprehensively during the Discovery Investigations between ~1920 and 1950 and resulted in the hugely influential Discovery Reports. Following this pioneering research period, there was a lull of several decades prior to the British Antarctic Survey's (BAS) initiation of an offshore biological programme to study the ecology of the South Atlantic sector of the Southern Ocean. These studies began in the late 1970s and have continued until the present day. Between 1980-2009, the programme included macronutrient measurements as part of an integrated ecosystem analysis. In addition to South Georgia and the Scotia Sea, measurements were also made in the Bellingshausen Sea and the waters to the west of the Antarctic Peninsula. Data were collected during all months of the year with the exceptions of May and June and compiled into a database. Vertical profile samples were taken from water bottles while data along transects were collected through monitoring the ship's non-toxic seawater supply. Nutrients measured were silicate, $\text{Si(OH)}_4\text{-Si}$; phosphate, $\text{PO}_4\text{-P}$; nitrate, $\text{NO}_3\text{-N}$; ammonium $\text{NH}_4\text{-N}$; and nitrite, $\text{NO}_2\text{-N}$. Our database includes nutrient data along with contemporaneous temperature and salinity data where available. Further background and supporting information are included for context.

1 Introduction

25 1.1 Geography and physical oceanography

The island of South Georgia lies on the Scotia Ridge, a submarine arc in the southwest Atlantic sector of the Southern Ocean that extends eastwards from South America to the South Sandwich Islands, returning westwards to the Antarctic Peninsula. The arc forms the northern, eastern and southern boundary of the Scotia Sea with Drake Passage forming the western boundary.

30 South Georgia and its broad continental shelf lie within the Antarctic Zone (AAZ) of the predominantly eastward flowing Antarctic Circumpolar Current (ACC). The AAZ is bounded by the Polar Front (PF) to the north and the Southern Antarctic Circumpolar Current Front (SACCF) to the south (see Fig. 1; Nowlin and Klinck, 1986; Orsi et al., 1995). In the Scotia Sea, the ACC is deflected northeastward by the local bathymetry. The SACCF approaches South Georgia from the southwest and is inflected around the eastern and northern continental shelf of the island before retroreflecting eastwards at the Northwest
35 Georgia Rise (Orsi et al., 1995; Thorpe et al., 2002; Meredith et al., 2003; Boehme et al., 2008). The oceanic circulation at South Georgia has been studied with Eulerian and Lagrangian observations, and modelled at increasingly higher resolutions. These studies demonstrate a northwestward flow along the island's northern shelf edge, cross-shelf exchange and areas of retention on the island's continental shelf (Hardy and Gunther, 1935; Maslennikov, 1979; Priddle et al., 1986; Latogursky et al., 1990; Trathan et al., 1997; Brandon et al., 1999, 2000; Young et al., 2014). Recent fine-scale ocean models not only
40 reconstruct the larger-scale circulation features but also resolve eddy-scale processes, and suggest the existence of coastal upwelling jet structures that have yet to be physically observed (Young et al., 2011, 2014; Matano et al., 2020).

The long-term mean positions of the ACC fronts mask the degree of large- and mesoscale variability. Meandering and eddy shedding have been described for ACC fronts (e.g. Lutjeharms and Baker, 1980; Bryden, 1983). In areas of irregular bottom
45 topography such as the northeastern Scotia Sea, the fronts are particularly variable (e.g. Gordon et al., 1977; Peterson and Whitworth, 1989; Boehme et al., 2008). The positions of fronts and eddies influence the waters and plankton communities around South Georgia. There is some evidence, for example, that warm water eddies of Polar Frontal Zone origin (i.e. from north of the PF) influence the South Georgia region from the west (Atkinson et al., 1990; Whitehouse et al., 1996b).

1.2 Research history

50 South Georgia has been commercially exploited for centuries from the sealing of the late 1700s (Bonner, 1984; Headland, 1984) to the whaling industry in the early 20th century (Harmer, 1931; Kemp and Bennett, 1932) and the current krill fishery in the Southern Ocean (Everson and Goss, 1991; Trathan et al., 1998).

The Discovery Investigations were initiated in the 1920s to provide an ecosystem approach to managing whaling. Multi-ship
55 surveys were undertaken to understand the causes of the region's high primary productivity and how it supported the fisheries. The resulting Discovery Reports covered many topics from oceanography to whales, and the report on the plankton by Hardy and Gunther (1935) linked the environment and higher trophic levels using some very modern concepts. For example, they suspected that micronutrients controlled phytoplankton productivity. Later Discovery Investigations broadened their coverage to include South Georgia as part of the Scotia Sea-Antarctic Circumpolar Current system (e.g. Foxton, 1956; Marr, 1962;
60 Mackintosh, 1973).

The Discovery Investigations laid the foundations for our understanding of phytoplankton growth and nutrient use at South Georgia. Hardy and Gunther (1935) and Hardy (1967) correlated locally reduced phosphate concentrations with elevated phytoplankton biomass, suggesting that phosphate depletion provided a time-integrated “memory” of primary production. 65 Clowes (1938) showed summer silicate and phosphate reductions, and possible year-to-year variation in phytoplankton utilisation, and suggested that silicate concentrations may, in some years, limit phytoplankton growth. A wider scale context was provided by Hart (1934, 1942) who noted the general failure of Antarctic marine phytoplankton to deplete fully the abundant pools of macronutrients in the surface waters: now known as the High-Nutrient-Low-Chlorophyll paradox (HNLC).

70

Between 1940 and 1970, much less scientific work was undertaken in the vicinity of South Georgia. However, from the late 1970s to the present-day, attention has been renewed with work being undertaken by the British Antarctic Survey (BAS). Altogether, offshore, ecological studies have been conducted sporadically around South Georgia and in the Scotia Sea for about a century.

75 **1.3 Phytoplankton productivity and nutrient controls**

The AAZ’s open ocean is generally considered to be a zone of low productivity. However, the South Georgia region is characterised by high biomass and productivity of phytoplankton, zooplankton and vertebrate predators.

Although the AAZ is characterised by HNLC conditions (maximum chlorophyll *a* ~1 mg m⁻³), parts of the Scotia Sea may be 80 more productive (but still usually <2.5 mg chlorophyll *a* m⁻³, Rönner et al., 1983; Jacques, 1989; Tréguer and Jacques, 1992; Korb et al., 2005). However, during a series of cruises across the Scotia Sea, concentrations of chlorophyll *a* >3 mg m⁻³ were found at ~58°S in spring (Korb et al., 2012). Phytoplankton blooms >0.75 mg m⁻³ chlorophyll *a* persisted for >6 months during the 2006/2007 season in this mid-Scotia Sea zone. Similarly, a large-scale bloom investigated during the 2011/2012 season 85 downstream of South Georgia revealed chlorophyll *a* concentrations of >3 mg m⁻³, peaking in December, with the bloom persisting (chlorophyll *a* > 0.5 mg m⁻³) until mid-March. Furthermore, in comparison to those in the open ocean, the South Georgia bloom was characterised by higher chlorophyll *a*-specific carbon fixation, indicative of high photosynthetic efficiency (Hoppe et al., 2017).

With decades of both field observations and remotely sensed ocean colour data available to investigate spatial and temporal 90 variability, there is clear evidence that phytoplankton blooms are more frequent and more intense downstream of South Georgia and into the Georgia Basin relative to upstream (e.g. Borrione and Schlitzer; 2013). High phytoplankton concentrations (>20 mg chlorophyll *a* m⁻³) may be linked to enhanced supplies of iron (up to 4 nmol m⁻³, de Baar et al., 1995; Whitehouse et al., 2000; Korb et al., 2004; Nielsdottir et al., 2012; Schlosser et al., 2018) or reduced forms of nitrogen (up to 3 mmol ammonium m⁻³, Owens et al., 1991; Priddle et al., 1997; Whitehouse et al., 1999). Although macronutrients are generally non-limiting in

95 the AAZ, silicate concentrations limit growth ($<1 \text{ mmol m}^{-3}$) at South Georgia in some summers (Whitehouse et al., 1996a,
2008). During trans-Scotia Sea cruises from $\sim 61\text{-}50^\circ\text{S}$, substantial latitudinal gradients were found for silicate, nitrate and
phosphate (Whitehouse et al., 2012). Surface ammonium concentrations were substantially higher to the north of the North
Scotia Ridge although a peak in values was measured around the southern boundary of the ACC, coincident with increased
mid-Scotia Sea chlorophyll *a* concentrations. These transects crossed multiple oceanographic features that may each contribute
100 to increased productivity and nutrient depletion. However, silicate was the only macronutrient to be found at limiting
concentrations and only north of 56°S (Whitehouse et al., 2012).

Observations, together with coupled hydrodynamic and biogeochemical models, support a strong supply of iron downstream
of South Georgia, sourced from shallow shelf sediments ($<20 \text{ m}$ water depth), glacial meltwaters and particulates, upwelling
105 deep waters transported by the ACC and topographic steering, and a lesser contribution from dust (Nielsdottir et al., 2012;
Borrione et al., 2014; Hoppe et al., 2017; Schlosser et al., 2018; Matano et al., 2020). The alleviation of iron limitation not
only drives the bloom initiation, but also has the potential to shift the uptake ratio of macronutrients, impacting regional
stoichiometry (Borrione et al., 2014; Hoppe et al., 2017). However, the lateral advection of iron alone cannot explain the
variability in duration of downstream blooms near South Georgia (Robinson et al., 2016). Mixed-layer depths and
110 phytoplankton-zooplankton interactions will also likely play a role in nutrient stoichiometry; grazing pressure plays an
important role in bloom dynamics and rapid, shallow nutrient cycling and effectively traps nutrients in the surface mixed layers
of the downstream waters (Robinson et al., 2016; Schlosser et al., 2018; Cavan et al., 2019).

Although there is intensive recycling in the surface mixed layer, the high summer primary productivity to the north of South
115 Georgia is reflected in organic carbon export and inorganic carbon uptake. For example, in austral summer 2012, the flux of
particulate organic carbon (POC) collected in sediment traps downstream and upstream of South Georgia (1500-2000 m water
depth) were $46\text{-}904$ and $38\text{-}205 \mu\text{mol m}^{-2} \text{ d}^{-1}$ respectively (Rembauville et al., 2016). That study also found downstream export
to have a relatively low Si:C ratio, due to a lower proportion of empty diatom frustules, with over 40% of the sinking POC
associated with diatom resting spores. The extensive summer blooms around South Georgia also deplete dissolved inorganic
120 carbon (DIC), acting as a strong sink for atmospheric CO_2 , although this is countered in the winter due to strong mixing (Jones
et al., 2012).

Despite some retention over the continental shelf of South Georgia, the high productivity of phytoplankton is widespread
extending into deep waters to the north of the island and to the PF ($>8 \text{ mg chlorophyll } a \text{ m}^{-3}$, Fryxell et al., 1979; El-Sayed and
125 Weber, 1982; Whitehouse et al., 1996b, 2000; Korb et al., 2004, 2008; Korb and Whitehouse, 2004; Hoppe et al., 2017). Such
high productivity can also be sustained for thousands of kilometres downstream (Korb et al., 2004), in part due to the supply
of nutrients by meandering mesoscale structures that form during interactions between the oceanic fronts and topographic
features (Smith et al., 2010; Jones et al., 2017). Indeed, the large spatial extent and long growth season (Korb et al., 2004;

130 Hoppe et al., 2017) mean that the South Georgia blooms are associated with the strongest predicted carbon sink in the Southern Ocean (Schlitzer, 2002).

In this paper we present a multi-year nutrient dataset along with concurrent temperature and salinity measurements. We detail methods, consider preliminary data evaluation, and summarise previous data management and utilisation. In addition to data availability, we consider their potential use and also catalogue supporting cruise report information.

135 2 Methods

The present macronutrient database has been collated from direct measurements made by BAS scientists (principally MJW) as part of sampling campaigns conducted from scientific research vessels to the respective regions of the Southern Ocean. Samples were collected via two principle collection methods: CTD water bottles or the underway non-toxic ship's seawater supply. Initial measurements were made at sea and concentrations calculated post-cruise. These data were initially published in a number of different sources which have been compiled as part of the present exercise (see Whitehouse et al., 2022). Furthermore, we have carried out additional quality control of these measurements and added supplementary data fields to the database that we are now making externally accessible (Whitehouse et al., 2022).

2.1 Sampling sites

The current dataset was collected between 1980 and 2009 (Table 1).

145

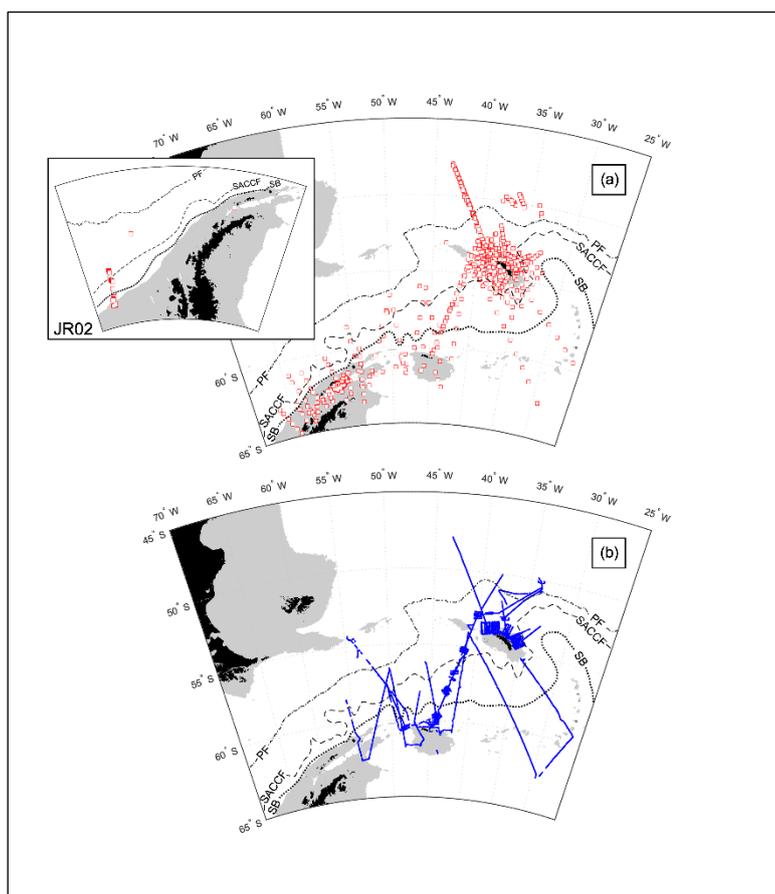

Table 1. Cruise, duration, region and nutrients measured at CTD stations (●) and during transects (●). *MEB - Maurice Ewing Bank transect between 48°S, 44°W and 54°S, 39°W. Concurrent temperature and salinity values are presented for all CTD profiles and for cruises JR161, JR177 and JR200 transect measurements.

150 Measurements were made predominantly around the island of South Georgia and across the wider Scotia Sea with additional sampling to the west of the Antarctic Peninsula and in the Bellingshausen Sea (Fig. 1a and 1b).

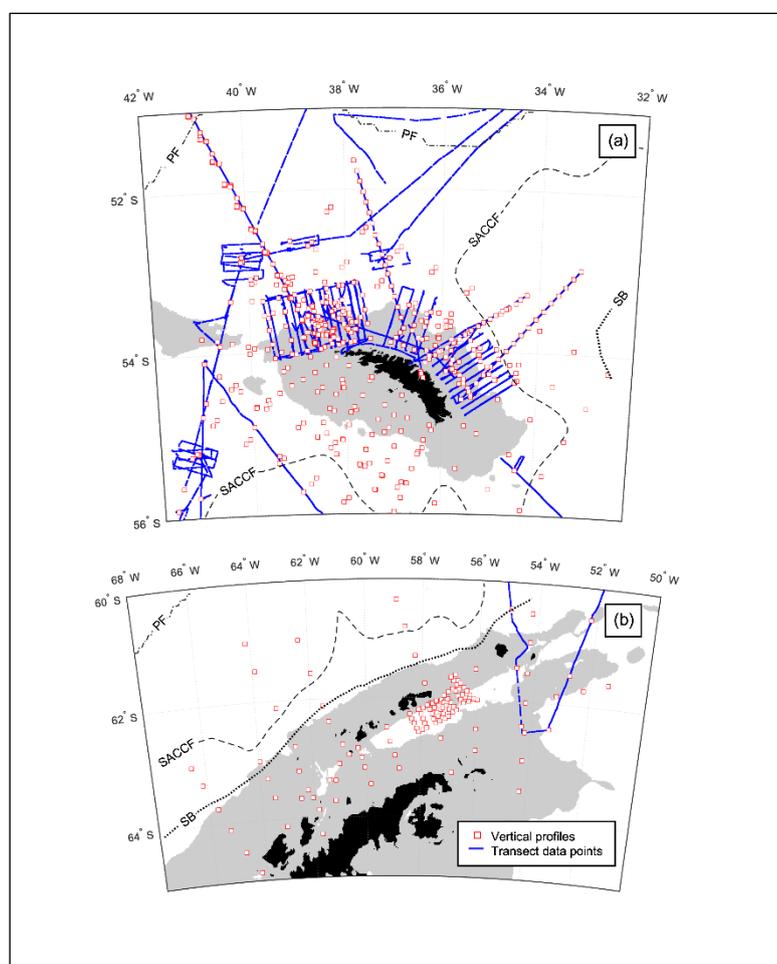

155 **Figure 1.** Sample locations of (a) CTD vertical profiles with inset to show stations sampled in the Bellingshausen Sea during cruise JR02; (b) transect data points. Southern Ocean fronts are shown in each panel: PF, Polar Front; SACCF, Southern Antarctic Circumpolar Current Front; and SB, Southern Boundary of the Antarctic Circumpolar Current (Orsi et al., 1995; Moore et al.,

1999; Thorpe et al., 2002; Orsi and Harris, 2019). Pale grey areas show water depths <1000 m (Amante and Eakins, 2009; NOAA National Geophysical Data Center 2009). Coastline following GSHHG, version 2.3.7.

160 During nearly 30 years of sampling, some sites were repeatedly visited. Two monitoring areas termed the Eastern Core Box (ECB) and the Western Core Box (WCB) to the north of South Georgia have been studied intensively with a set of repeat
transects oriented across the northeastern and northwestern shelf break to sample on- and off-shelf waters (Fig. 2a).

165 **Figure 2. Smaller-scale detail of sampling around (a) South Georgia; (b) Antarctic Peninsula. Southern Ocean fronts, pale grey areas and coastline are as in Figure 1.**

A series of stations spanning >700 km from the western end of South Georgia to the northwest crossed the PF and a number of bathymetric features including the Maurice Ewing Bank (50.667°S, 43.5°W) after which the transect was named. Three
170 cruises crossed the Scotia Sea from south to north in consecutive years and covered spring, summer and autumn periods (see

Tarling et al., 2012). These cruises along with the Core Box surveys to the north of South Georgia included extensive underway sampling (see Section 2.2), while surveying near the Antarctic Peninsula comprised predominantly station grids (Fig. 2b).

2.2 Chemistry instrumentation and methods

In 1979, a segmented-flow analyser (SFA) was built in-house to analyse macronutrient measurements for the BAS offshore programme. It was based on Chemlab colorimeters and Ismatec proportioning pumps (Whitehouse and Woodley, 1987). Originally, data were logged to paper chart and processed manually. In the mid-80s, data extraction was automated and processing was managed with a digitising tablet and associated PC (Woodley, 1989).

During 1993, the analyser was completely remodelled around Technicon colorimeters, the Ismatec proportioning pumps were updated, the chemistry manifolds were re-built and data were logged to a PC (Whitehouse, 1997). Data acquisition and subsequent processing was achieved with custom-built software (see Whitehouse and Preston, 1997).

All data were collected during BAS or other Natural Environment Research Council cruises aboard the RRS John Biscoe (cruises prefixed JB) or the RRS James Clark Ross (cruises prefixed JR). The macronutrients analysed are described fully in Whitehouse and Woodley (1987). They agree with the internationally accepted conventions for silicic acid ($\text{Si(OH)}_4\text{-Si}$), orthophosphate ($\text{PO}_4\text{-P}$), nitrate ($\text{NO}_3\text{-N}$), nitrite ($\text{NO}_2\text{-N}$), and ammonium ($\text{NH}_4\text{-N}$). All concentrations are expressed as mmol m^{-3} . A statistical analysis of the chemistry methods was documented in Whitehouse and Woodley (1987) but we present a summary for this analysis in Table 2.

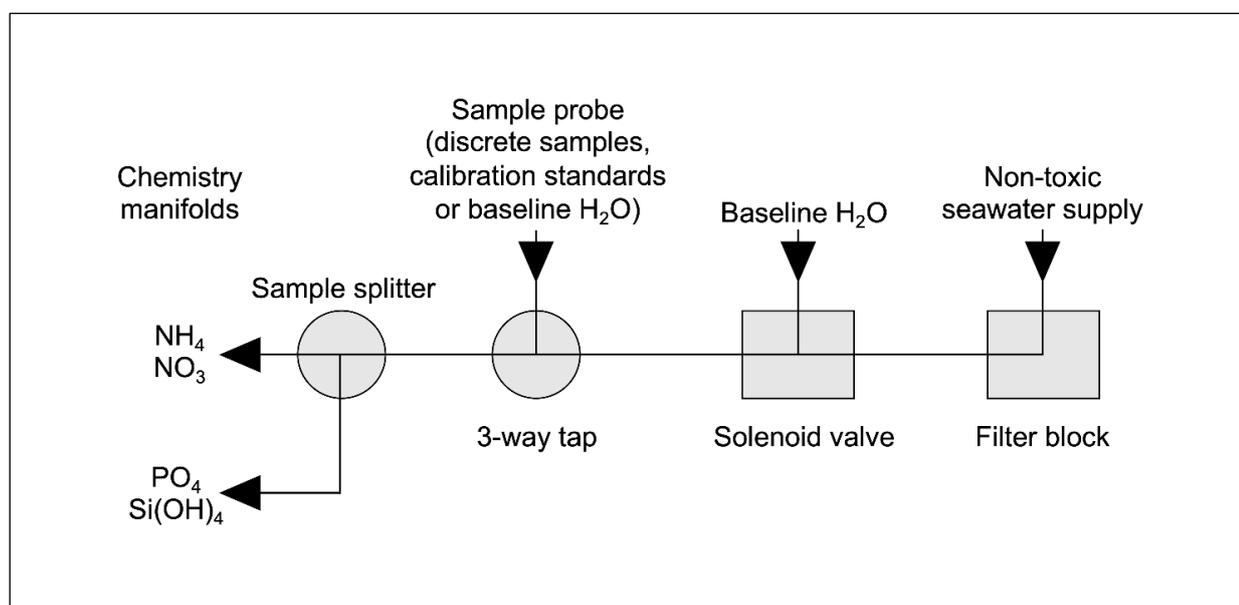

Table 2. Replication and limits of detection measured for chemistry methods (Whitehouse and Woodley, 1987).

	$\text{Si(OH)}_4\text{-Si}$	$\text{PO}_4\text{-P}$	$\text{NO}_3\text{-N}$	$\text{NH}_4\text{-N}$	$\text{NO}_2\text{-N}$
Replication (<i>n</i>)	9	20	12	9	12
Concentration (mmol m^{-3})	71	3.2	0.7	3.6	8.9
Standard deviation of replicates (% of mean)	0.14	0.47	0.75	0.42	0.8
Limit of detection (mmol m^{-3})	0.28	0.05	0.28	0.01	0.01

Data were collected by means of two sampling methods. First of all, sub-samples were taken from CTD (conductivity, temperature, depth) rosette water bottles that provide the conventional vertical profiles. Water samples were taken from CTD upcasts, in which bottles were fired at depths ranging from 0.5 m to 5500 m. Secondly, samples were analysed continuously from the ship's non-toxic seawater supply while the vessel was underway to provide high-resolution horizontal coverage of near-surface conditions during transects. Here we document further details of the sample handling regime.

The ship's non-toxic seawater inlet was at ~6-7m and forward of the bows to avoid contamination. The time-lag between seawater entering the ship's non-toxic inlet and reaching the chemistry laboratory was ~60 seconds (S. Wright, Deck Engineer, pers. comm., 31 December 1996). On arrival at the chemistry laboratory, the stream of seawater passed through a tangential flow filter block (Morris et al., 1978) fitted with a filter membrane (pre-1990 Whatman GF/C, pore size 1.2 μm , and then a mixed ester Whatman WME, pore size 0.45 μm) (Fig. 3).

205 **Figure 3. Sample handling schematic for flow of samples, standards and baseline blanks between ship's non-toxic seawater supply and the chemistry manifolds of the segmented-flow analyser.**

A sub-sample was then pumped through a solenoid valve controlled with an electric timer. Typically, a 5 min baseline check was automatically introduced once per hour while the ship was underway and horizontal profiles were being measured. The sample stream then passed through a 3-way tap before arriving at a sample stream splitter followed by introduction to the chemistry manifolds. The 3-way tap allowed manual interruption of the sample stream to introduce discrete samples from the CTD water bottles along with calibration standards and blank solutions for the calculation of baselines, refractive index compensation and flow-through times.

215 The time-lag between the sample entering the laboratory and passing through the analyser to the detector varied between the different nutrient analyses depending on the complexity of the chemistries used. Therefore, underway measurements were time and date stamped at the analyser's detector by referencing the ship's central clock to enable integration with navigation and other underway measurements such as physical oceanography and phytoplankton-related information (see Whitehouse and Preston, 1997). The underway data were originally logged at a 10 second interval. However, given the time-lag between

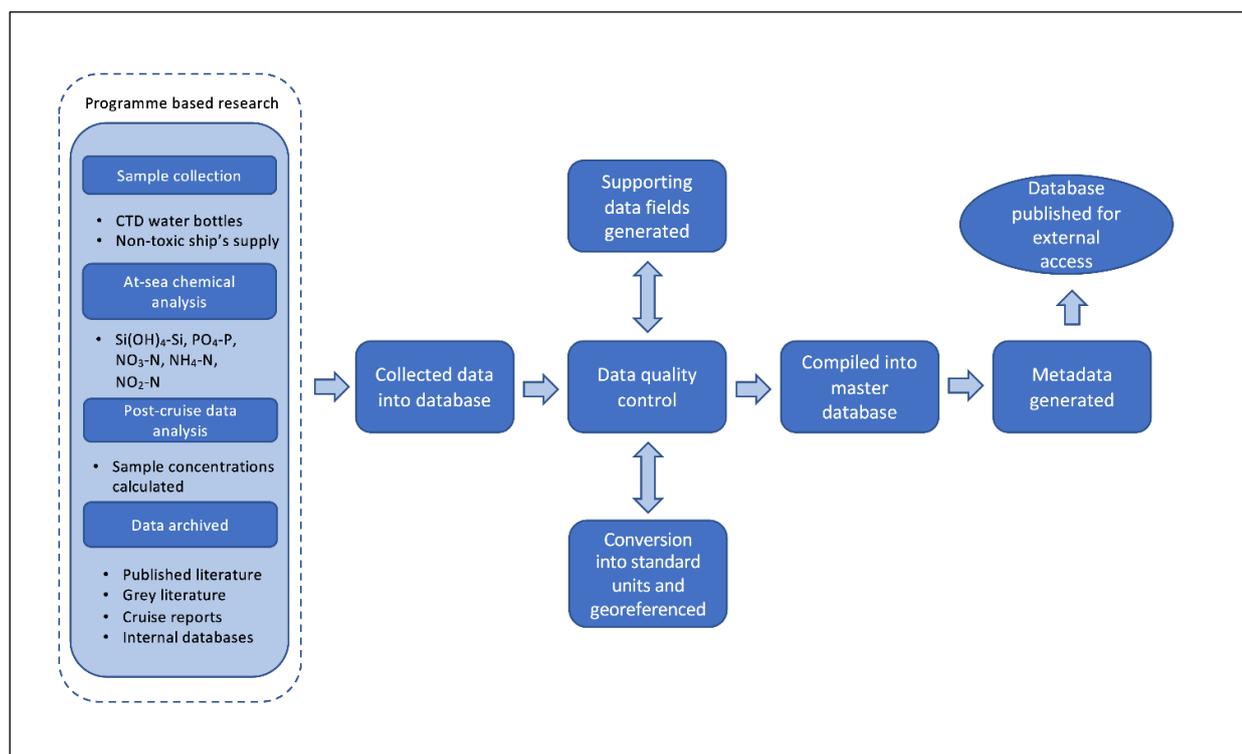

220 seawater entering the ship's non-toxic inlet and reaching the chemistry laboratory (~60 seconds), the detector's output was averaged over one-minute intervals during post-cruise processing to give a more realistic sampling sensitivity.

2.3 Temperature and conductivity measurements

225 Temperature and conductivity measurements were taken during CTD vertical profiles and with a thermosalinograph as part of the underway system that sampled from the ship's non-toxic seawater supply. During most cruises, the vertical profile conductivity measurements were calibrated against samples drawn from the CTD water bottles. Temperature and salinity data from the profile upcast were averaged onto the depth and time of the bottle firing for most nutrient samples taken from the CTD water bottles but, where this was not possible, the downcast profile data were binned onto the depth (± 2 metres) of the nutrient sample. Further details are provided in the respective cruise reports (Appendix 1). For this dataset, the underway temperature and conductivity measurements have not been calibrated against sample measurements but were averaged over a 230 60 second interval to smooth the data.

2.4 Dataset compilation

The compilation of the dataset is summarised in Fig. 4.

235 **Figure 4. Flowchart of dataset compilation including sample collection, data processing and utilisation.**

CTD water bottle data were compiled with ship, ship identification information, cruise number, event number, geographic location and depth. Temperature and salinity data were extracted and matched with profile nutrient data from each cruise using latitude and depth as primary selector variables, with event numbers and timestamps used as secondary checks.

240

The non-toxic ship's seawater supply data were compiled with ship, ship identification information, cruise number, geographic location, temperature and salinity, and each timestamp reformatted as a date vector, a serial date number, and a datetime string (DD-MMM-YYYYThh:mm:ssZ). The serial date numbers were ordered temporally, converted into a datetime string (DD-MMM-YYYYThh:mm:ssZ), and converted to a table with minute intervals and corresponding arithmetic means of concentrations of each nutrient, temperature and salinity.

245

The profile and underway sample data have been deposited at the UK Polar Data Centre and are publically available in the NetCDF and CSV formats as of the date of publication (Whitehouse et al., 2022).

All available cruise reports (17 in total) that provide cruise and individual projects as well as additional background information on the current dataset have been compiled (Appendix 1).

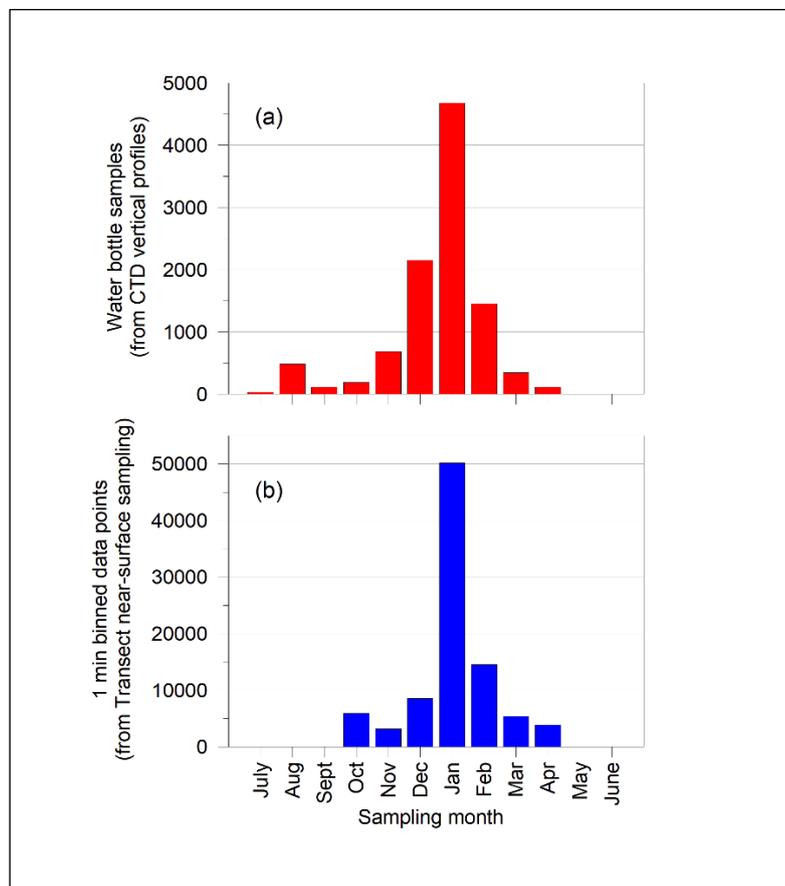

250

3. Results

3.1 Data evaluation

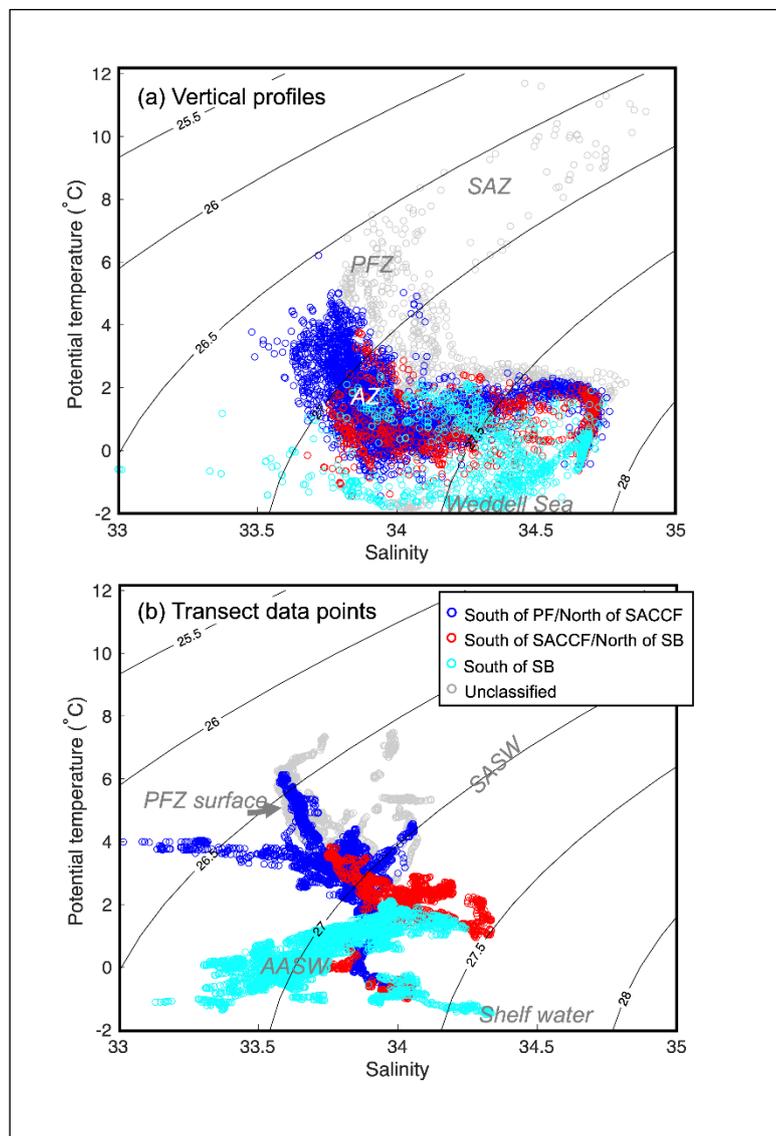

In all, ~10,000 CTD water bottles were sampled and analysed, and ~900,000 one-minute bins of data were recorded from the underway sampling over the period 1980-2009. As with other high latitude marine sampling projects, logistics and ice conditions dictated when surveys could be conducted. January was the most frequent month of collection although sampling occurred in all months apart from May and June (Fig. 5).

255

260 **Figure 5. Monthly totals for nutrient samples from CTD water bottles and transect data points.**

Oceanographically, the profile data spanned the SB, SACCF, PF and SAF (Fig. 6a). Antarctic Surface Water, Polar Frontal Zone surface water, and shelf waters were evident in the underway data (Fig. 6b).

265

Figure 6. Potential temperature-salinity plots for (a) CTD vertical profiles and (b) transect data points. Data have been colour coded according to their location relative to the long-term mean positions of the PF, SACCF and SB (see Fig. 1). SAZ – Subantarctic Zone, PFZ – Polar Frontal Zone, SASW – Subantarctic Surface Water, AASW – Antarctic Surface Water.

270 On repeated transects to the north of South Georgia (cruises JR17, JR28 and JR38) and across the Scotia Sea (JR161, JR177 and JR200), near-surface nutrient values (0 – 7 m) were compared with a mean value derived from CTD water bottle data (0 – 50 m) to assess whether surface values were representative of deeper parts of the water column (Table 3).

275 **Table 3. Relationship between mean surface (0 to 7 m) nutrient data with those averaged over 0 to 50 m using linear regressions. All available data from 6 cruises were examined during 2 studies: (a) to the north of South Georgia with 50% of stations on-shelf (Whitehouse et al., 2009); (b) repeated transects across the Scotia Sea sampling deep oceanic waters (Whitehouse et al., 2012).**

Parameter	(a) Cruises JR17, JR28, JR38			(b) Cruises JR161, JR177, JR200		
	n	R ²	p	n	R ²	p
SiOH ₄ -Si	29	98%	<0.001	31	100%	<0.001
PO ₄ -P	31	94%	<0.001	29	93%	<0.001
NO ₃ -N	31	96%	<0.001	31	98%	<0.001
NH ₄ -N	31	87%	<0.001	29	69%	<0.001

280 Linear regressions for all comparisons were highly significant ($p < 0.001$). For Si(OH)₄-Si, PO₄-P, and NO₃-N, R² values were
≥93%. For NH₄-N, R² values were lower and a difference was observed between the South Georgia cruises (87%) and those
in the Scotia Sea (69%). This was doubtless due to the different water column characteristics sampled during the two studies.
The South Georgia cruises include many on-shelf stations to the north of the island where NH₄-N is biologically generated and
constrained bathymetrically to the surface waters. Whereas for the offshore Scotia Sea stations, NH₄-N concentrations were
285 relatively low, pycnoclines were deeper and the upper mixed-layer frequently extended below 50 m (Korb and Whitehouse,
2004; Korb et al., 2012).

4. Data availability

The profile and underway sample data have been deposited at the UK Polar Data Centre and are publicly available in the
NetCDF and CSV formats as of the date of publication, [https://doi.org/10.5285/4014370F-8EB2-492B-A5F3-
290 6DC68BF12C1E](https://doi.org/10.5285/4014370F-8EB2-492B-A5F3-6DC68BF12C1E) (Whitehouse et al., 2022).

5. Code availability

This paper does not report original code.

6. Conclusions and potential use of the dataset

We have presented here a new macronutrient database, including depth profiles and continuous underway surface
295 measurements of silicic acid, phosphate, nitrate, ammonium, and nitrite, along with co-located temperature and salinity. Data
were collected throughout the year from a variety of biological “hotspots” within the Southern Ocean, including South Georgia
and the wider Scotia Sea, the Western Antarctic Peninsula, and the Bellingshausen Sea. One of the key challenges in
understanding carbon cycling in the Southern Ocean is disentangling long-term responses from significant spatial and temporal
variability in physical and biogeochemical parameters. As such, there is a critical need for regional long-term observational
300 datasets that are openly accessible to generate a better mechanistic understanding of the drivers of primary production. The

new data product described here provides an unprecedented view of biogeochemical cycling in biologically productive regions of the Southern Ocean across a critical period in recent climate history, and illustrates the importance of FAIR (Findable, Accessible, Interoperable, and Reusable) sharing of scientifically valuable observational datasets.

7. Appendix 1

305 Further information is available for most of the cruises during which data for the current database were collected. This includes the specific aim of each cruise, methodology and preliminary results.

Cruise reports are listed in chronological order:

310 Heywood, R. B.: RRS John Biscoe Cruise JB04: Offshore Biological Programme, BODC Cruise Inventory, 32 pp., https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/john_biscoe4_83.pdf, 1983.

Priddle, J.: RRS John Biscoe Cruise JB08: South Georgia and Bransfield Strait Marine Biology, BODC Cruise Inventory, 52 pp., https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/john_biscoe08.pdf,
315 1988.

Watkins, J. L. and Priddle, J.: RRS John Biscoe Cruise JB10: South Georgia Marine Biology, BODC Cruise Inventory, 12 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/john_biscoe10_90leg1_2.pdf, 1990.

320 Owens, N. J. P.: RRS James Clark Ross Cruise JR02: Biogeochemical Ocean Flux Study, BODC Cruise Inventory, 245 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr02_92.pdf, 1992.

White, M.: RRS James Clark Ross Cruise JR06: South Georgia and South Orkneys Marine Biology (Predator/Prey cruise), BODC Cruise Inventory, 218 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr06.pdf, 1994.
325

Priddle, J. and Swanson, C.: RRS James Clark Ross Cruise JR11: Marine Life Sciences Pelagic Ecosystem Studies, BAS Cruise Archive, 46 pp, 1996.

Priddle, J.: RRS James Clark Ross Cruise JR17: BAS Marine Life Sciences, BAS Cruise Archive, 44 pp, 1996.
330

Priddle, J.: RRS James Clark Ross Cruise JR25: Spring Processes, BAS Cruise Archive, 116 pp, 1997.

- 335 Murphy, E. J.: RRS James Clark Ross Cruise JR28: Variability of the South Georgia Marine Ecosystem, BODC Cruise Inventory, 160 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr028.pdf, 1998.
- Everson, I.: RRS James Clark Ross Cruise JR38: Variability of the South Georgia Marine Ecosystem, BODC Cruise Inventory, 55 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr38.pdf. 1999.
- 340 Ward, P.: RRS James Clark Ross Cruise JR57: Variability in the Southern Ocean, BODC Cruise Inventory, 77 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr57.pdf, 2001.
- Ward, P.: RRS James Clark Ross Cruise JR70: Flux and Marine Production Experiment, BODC Cruise Inventory, 155 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr70.pdf, 2002.
- 345 Atkinson, A.: RRS James Clark Ross Cruise JR82: Large scale distribution in the Scotia Sea, BODC Cruise Inventory, 164 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr82.pdf, 2003.
- Ward, P.: RRS James Clark Ross Cruise JR116: A study of community structure and production along the southern shelf of South Georgia and links with the Georgia Basin, BODC Cruise Inventory, 127 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr116.pdf, 2005.
- 350 Shreeve, R.: RRS James Clark Ross Cruise JR161: A study of pelagic marine food web interactions and condition factors of zooplankton across the Scotia Sea, BODC Cruise Inventory, 324 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr161.pdf, 2006.
- 355 Tarling, G.: RRS James Clark Ross Cruise JR177: Life cycles and trophic interactions of the Scotia Sea pelagic community: from ice-edge to Polar Front, BODC Cruise Inventory, 321 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr177.pdf, 2008.
- 360 Korb, R.: RRS James Clark Ross Cruise JR200: Life cycles and trophic interactions of the Scotia Sea pelagic community: from the South Orkneys to the Polar Front, BODC Cruise Inventory, 205 pp, https://www.bodc.ac.uk/resources/inventories/cruise_inventory/reports/jr200.pdf, 2009.
- For cruises JR11, JR17 and JR25, pdf files can be requested from the Polar Data Centre at PDServiceDesk@bas.ac.uk.
- 365 Cruise reports are not available for JB03, JB05 or JB06.

8. Author contributions

MJW, KRH, GAT, SET and PTH conceived the data paper and wrote the manuscript. All authors commented on the paper and contributed to the quality check.

370 9. Competing interests

The authors declare that they have no conflict of interest.

10. Acknowledgements

We are most grateful to the officers and crew of the RRS John Biscoe and the RRS James Clark Ross, along with the cruises' Principal Scientists. We are also indebted to Vince Woodley, Julian Priddle, Beki Korb and Min Gordon for their assistance
375 with chemical and data analysis, and to the numerous scientists and technicians for their assistance with CTD and underway sampling and calibration of temperature and salinity data. MJW would also like to thank Barry Heywood, Julian Priddle and Pete Ward for their advice and guidance over many years.

11. Financial support

The contributions of KRH, GAT, SET and PTH were supported by the BIPOLE National Capability Multicentre Round 2
380 funding from the Natural Environment Research Council (NE/W004933/1). GAT and SET were also supported by NC-ALI funding to the Ecosystems team at the British Antarctic Survey.
