Abstract. Here we describe the LegacyClimate 1.0, a dataset of the reconstruction of mean July temperature (T_{July}), mean annual temperature (T_{ann}), and annual precipitation (P_{ann}) from 2594 fossil pollen records from the Northern Hemisphere spanning the entire Holocene with some records reaching back to the Last Glacial. Two reconstruction methods, the Modern Analogue Technique (MAT) and Weighted-Averaging Partial-Least Squares regression (WA-PLS) reveal similar results regarding spatial and temporal patterns. To reduce the impact of precipitation on temperature reconstruction and vice versa, we also provide reconstructions using tailored modern pollen data limiting the range of the corresponding other climate variables variable. We assess the reliability of the reconstructions using information from the spatial distributions of the root-mean--squared error of prediction and reconstruction significance tests. The dataset is beneficial for climate proxy-synthesis studies of proxy-based reconstructions and to evaluate the output of climate models and thus help to improve the models themselves. We provide our compilation of reconstructed T_{July}, T_{ann}, and P_{ann} as open-access datasets at PANGAEA (https://doi.pangaea.de/10.1594/PANGAEA.930512; Herzschuh et al., 2021). R code for the reconstructions is provided at Zenodo (https://doi.org/10.5281/zenodo.5910989; Herzschuh et al., 2022b2022), including harmonized open-access modern and fossil datasets used for the reconstructions, so that customized reconstructions can be easily established.

1 Introduction

The <u>comparison</u>evaluation of climate model outputs <u>withusing</u> climate data is essential for model improvements (Eyring et al., 2019). However, the period for which observations are available is only of limited use to validate simulations because it is short and characterized by strong changes in the climate driver. Climate proxy data derived from natural archives are therefore of great value. The extratropical

Northern Hemisphere is of particular interest because it is known for complex spatial and temporal temperature and precipitation patterns. <u>However, the period for which instrumental observations are</u> available is only of limited use to validate simulations in particular when assessing climate response to <u>natural climate drivers because it is too short and because it is impacted by human-induced greenhouse</u> gas forcing. Climate proxy data derived from natural archives are therefore of great value.

-Previous proxy-based climate inferences have contributed to major debates about Holocene climate change. For example, while simulations indicate a-gradual warming of the Holocene, temperature proxy data syntheses rather support a mid-Holocene optimum which resulted in the "Holocene conundrum" debate (Liu et al., 2014). Qualitative proxy-based inferences indicate that the mid-Holocene in the Northern Hemisphere mid-latitudes was rather dry and warm compared with present-day in agreement with modellingmodeling outputs (Routson et al., 2019). Also, quantitative precipitation reconstructions from Eastern and Central Asia unveiled the complex monsoon-westerlies interactions (Chen et al., 2019; Herzschuh et al., 2019).

-Fossil pollen records are well-established in their use as a palaeoecological and palaeoclimatological proxy and of great value as indicators of past environmental and climatic change for many decades. Considerable efforts have been made to establish regional, continental and even global data repositories like the North American Pollen Database (NAPD; https://www.ncei.noaa.gov/products/paleoclimatology, last access: July 2020),(http://www.ncdc.noaa.gov/paleo/napd.html), the European Pollen Database (EPD; http://www.europeanpollendatabase.net/index.php, last access: 1 July 2020)(http://www.europeanpollendatabase.net) and the Neotoma Paleoecology Database (https://www.neotomadb.org/, last access: 1 April 2021;https://www.neotomadb.org; Williams et al., 2018). Pollen data from Regarding the prevalence of pollen archives across multiple environmental settings such as lakes, wetlands, or marine sediments, have beenfossil pollen records are widely used to quantitatively reconstruct past vegetation and climate variables (Birks, 2019; Chevalier et al., 2020). Pollen data are the only land-derived proxy data that have sufficient temporal and spatial coverage to allow for high-resolution climate model evaluation of the late Quaternary period. A number of methods have been proposed for making pollen-based climate reconstructions (Chevalier et al., 2020): among them, classification approaches like the Modern Analogue Technique (MAT) or regression approaches like Weighted-Averaging Partial-Least Squares regression (WA-PLS) are most commonly used. MAT

and WA-PLS rely on extensive collections of modern training data. Designing a robust calibration dataset from modern pollen assemblages is a crucial part of the reconstruction process. A suitable calibration dataset should cover a wide range of climatic and environmental gradients in order to represent an empirical relationship between pollen assemblages and climate (Birks et al., 2010; Chevalier et al., 2020). Like with fossil pollen records, data syntheses and repositories also exist for modern surface pollen data e.g. for North America (Whitmore et al., 2005), Eurasia (Davis et al., 2013; and 2020) and China (Cao et al., 2013; Herzschuh et al., 2019).

-For temperature reconstruction time-series, several broad-scale syntheses exist; however, either they originate from different proxies (Kaufman et al., 2020a and 2020b) or are restricted to certain continents or regions <u>or/and are poorly documented</u> (Mauri et al., 2015; Marsicek et al., 2018; Routson et al., 2019). Temperature reconstructions from the large extratropical Asia are mostly lacking. Precipitation syntheses are available from Europe (Mauri et al., 2015), North America (<u>Gajewski, 2000</u>; Whitmore et al., 2005) and China and Mongolia (Herzschuh et al., 2019) but, hitherto, no global or hemispheric syntheses of quantitative precipitation changes are available for the Holocene.

-In a recent effort, we synthesized and taxonomically harmonized pollen records available in the Neotoma Paleoecology Database (Williams et al., 2018) and additional records from China and Siberia (Cao et al., 2013 and 2020) into a global Late Quaternary fossil pollen dataset (LegacyPollen 1.0; were synthesized and taxonomically harmonized (Herzschuh et al., 2022c) and revised submitted). Furthermore, all chronologies of those these records were recently revised-using a Bayesian approach that allows for the inference of temporal uncertainties (LegacyAge 1.0; Li et al., 2022). Here, in the third part of interconnected studies, we present the pollen-based reconstruction of mean July temperature (T_{July}), mean annual temperature (T_{ann}) and annual precipitation (P_{ann}) including reconstruction and temporal uncertainties as well as quality measures from these 2594 records from the Northern Hemisphere using WA-PLS and MAT (LegacyClimate 1.0; this study).⁺

2 Methods

2.1 Input data

The objective of this study is to create a dataset of quantitative reconstructions of T_{July}, T_{ann} and P_{ann} spanning the <u>last 30 ka and beyond</u>Holocene from <u>a set of</u> fossil pollen records. <u>These variables (or</u>

variables highly correlated to them) were shown to explain most variance in the modern pollen data (T_{July}, P_{ann}) or are typically used in synthesis studies (T_{ann}). We used fossil data <u>set compiled in</u> LegacyPollen 1.0 (stored on the PANGAEA open database and presented in Herzschuh et al. (2022c) that integrates pollen records archived in from the Neotoma Paleoecology Database₁-(Williams et al., 2018; https://www.neotomadb.org; downloaded in July 2020), a dataset from Eastern and Central Asia (Cao et al., 2013; Herzschuh et al., 2019) and a dataset from Northern Asia (Cao et al., 2020). The harmonized dataset is stored on PANGAEA (LegacyPollen 1.0) and presented in Herzschuh et al. (submitted). Ages were taken from the "Bacon" (Blaauw and Christen, 2011) age-depth models presented in Li et al. (2022_), who recently provided a set of harmonized chronologies under the "LegacyAge 1.0)," framework, and for each record, we provide an ensemble of 1000 realizations of the age-depth model in applied to our data product so that it can be used to account for chronological uncertainty on the reconstructions.

We compiled the fossil data into four sub-continental datasets for Eastern North America (<104pollen synthesis. <u>°W</u>; Williams et al., 2000), Western North America, Europe and Asia. We restricted the analyses to the 70 most common taxa on each continent to reduce computational power after making sure that higher taxa number would not substantially improve model statistics in climate reconstructions. To identify the most common taxa we used Hill's N2 diversity index (i.e., the effective number of occurrences of a species in the dataset; Hill, 1973). For all analyses, square-root percentages were used if not indicated otherwise.

A modern pollen training dataset comprised of <u>15379</u>45,379 sites includes datasets from Eurasia (EMPD1, Davis et al. 2013; EMPD2, Davis et al. 2020; Herzschuh et al., 2019; Tarasov et al., 2011) and North America (Whitmore et al., 2005). <u>The In order to reduce inconsistencies in pollen identification</u>, the modern and fossil-pollen datasets were taxonomically harmonized <u>in accordance</u> ; major tree and shrub pollen were merged to genus level and most of the herbaceous taxa (except the most common ones such as *Artemisia*, *Thalictrum* or *Rumex*) to family level. We excluded aquatic pollen (with the fossil pollen dataset (see details in Herzschuh et al., 2022c).

exception of *Cyperaceae*), spores from ferns and fungi, as well as algae and calculated pollen percentages on the basis of the total number of terrestrial pollen grains. The site-specific Tann, TJuly, Pann were derived from WorldClim 2 version 2.1 (spatial resolution of <u>30 seconds</u> (~1 km2), https://www.worldclim.org1 km, https://www.worldclim.org, Fick and Hijmans, 2017) by extracting the climate data at the location of the modern sample sites using the *raster* package in R (version 3.5-11, Hijmans et al., 2021; R Core Team, 2020).

We compiled the fossil data into four sub-continental datasets for Eastern North America (<105°W; Williams et al., 2000), Western North America, Europe and Asia. For consistency with the amount of taxa in the North American training dataset, the fossil datasets were reduced to the 70 most common taxa on the respective sub-continents, according to Hill's N2 diversity index (i.e., the offective number of occurrences of a species in the dataset; Hill, 1973). The WorldClim 2 dataset provides spatially interpolated gridded climate data aggregated from weather stations as temporal averages between 1970-2000 (Fick and Hijmans, 2017). We used monthly average temperature data to extract the mean TJuly and the "bioclimatic variables" bio1 (T_{ann}) and bio12 (P_{ann}).

2.2 Reconstruction methods

Our reconstruction approach included MAT (Overpeck et al., 1985) and WA-PLS (ter Braak and Juggins, 1993) by applying the MAT and WAPLS functions from the *rioja* package (version 0.9-21, Juggins, 2019) for R (R Core Team, 2020) on our Northern Hemispheric fossil pollen synthesis. For each fossil location, we calculated the geographic distance between each modern sampling site and the fossil pollen record using the *rdist.earth* function from the *fields* R-package (version 10.3, Nychka et al., 2020) and selected a unique calibration set from modern sites within a 2000 km radius. We fixed the radius to 2000 km, instead of 1500 km as suggested from a study in Eastern Asia by Cao et al. (2017), because the modern dataset density is rather low in Northern Asia. For the reconstruction with MAT, we used the original pollen percentages of the selected fossil pollen taxa, looking for 7 analogues between the pollen data and the selected calibration dataset. The dissimilarity between the fossil samples and the modern pollen assemblages was determined by squared-chord distance of the percentage datametrics (Simpson, 2012; Cao et al., 2014).

For the reconstruction with WA-PLS, we used the square-root transformed pollen percentages in a leave-one-out cross-validation approach (Cao et al., 2014). In addition to the classic WA-PLS reconstruction, we also propose provide WA-PLS_tailored. This approach addresses the problem that

co-variation of climate variables today in space is transferred to the reconstruction even if the past temporal relationship among the climate variables mechanistically differs. In fact, this approach aims to make use of the full climate space covered by the modern pollen samples avoiding those samples in the calibration set that cause spatial covariation. This approach is based on the assumption that several climate variables can be reflected in one and the same pollen assemblage because different plant taxa have different optima in temperature and precipitation ranges and might therefore occur with different co-occurrence and abundance pattern. To reconstruct T_{July} we "tailored" our modern training dataset with respect to the Pann range. For this purpose, we identified the Pann range of the reconstructed by WA-PLSPann and extended it by 25% to both ends of the modern Pann range in order to reduce the influence of Pann on Tann and T_{July} reconstruction due to co-variation. We applied the same method to the reconstruction of Pann. Tann and <u>TJuly</u> were tailored by Pann; Pann was tailored by TJuly and, additionally, by Tann (illustrated for an example in Appendix Fig. 1). Reconstruction uncertainties are provided as root mean square errors (RMSE) derived from A statistical significance test (Telford and Birks, 2011) was performed for the outputreconstruction by using the randomTF function in the MAT and WAPLS functions. Model errors of WA-PLS and MAT are reported palaeoSig R-package (version 2.0-3, Telford, 2019). The reconstructed climate parameters were tested as single variables, as root mean square error of prediction (RMSEP) derived from leave-one-well as with partialling-out cross-validation.

We provide site- or sample-specific measures of quality in addition to the error estimates and model statistics to allow the user to assess the quality of the climate reconstruction dataset. First, werespective other variable. We applied a Canonical Correlation Analysis (CCA) to the modern training dataset in order to explore the modern relationship between the pollen spectra and the climate variables and to infer the explained variance in the modern pollen dataset by the target climate variables (ter Braak, 1988)dataset by using the *cca* function in the *vegan* R-package (version 2.5-7, Oksanen et al., 2020). The ratio between constrained (λ_1) and unconstrained (λ_2) explained variance was determined for all modern training datasets used for climate reconstructions. High values of λ_1 vs λ_2 are commonly considered as an indicator to measure how well the target environmental variable is strongly related to the variation in the modern pollen data set (e.g. Juggins, 2012).To infer the analogue quality as an indicator of no-analogue situations we calculated the minimum dissimilarity (squared chord distance) between modern pollen assemblages and fossil pollen assemblages with probability thresholds of 1%, 2.5% and 5% using the *minDC* function from the *analogue* R-package (version 0.17-6, Simpson et al., 2021). -

A statistical significance test (Telford and Birks, 2011) was applied using the *randomTF* function in the *palaeoSig* R-package (version 2.0-3, Telford, 2019). In this test, the proportion of variance in the fossil pollen data explained by the reconstructed environmental variable is estimated from redundancy analysis (RDA) and tested against a null distribution generated from a total of 999 randomly generated environmental variables from the training data. A reconstruction is considered statistically significant if the reconstructed variable explains more of the variance than 95% of the random reconstructions (Telford and Birks, 2011). The reconstructed climate parameters were tested as introducing the environmental variable as a single variable in a run, as well as with partialling out the explained variance in the pollen data by the respective other variables.

We used Plantaginaceae (mostly representing *Plantago lanceolata*-type in Europe) and *Rumex*-type to assess human influence as an indicator for intense herding (Behre, 1988). In addition, we calculated the correlation between the WA-PLS reconstruction of T_{July}, T_{ann} and P_{ann} and the pollen percentages of Plantaginaceae and *Rumex* for 9000, 3000 and 1000 years BP.

3 Dataset description LegacyClimate 1.0: input data, reconstructions and reconstruction model statistics

LegacyClimate 1.0 provides pollen-based reconstructions and sample-specific reconstruction errors of T_{ann}, T_{July} and P_{ann} for 2594 fossil pollen records (i.e., a total of <u>146067</u><u>146,067</u> single pollen samples) from three reconstruction methods (WA-PLS, WA-PLS_tailored, MAT). Furthermore, we provide the method-specific model metadata and <u>quality measures</u>statistics for each record and each climate variable (Table 1). To ease data handling, the dataset files are separated into Western North America, Eastern North America, Europe and Asia.

Table 1. Structure and content of the LegacyClimate 1.0 data with details about the information contained in the input, datasets, in the <u>climate</u> reconstructions and the reconstruction model statistics.

4 Dataset assessment

4.1 Spatial and temporal coverage of LegacyClimate 1.0

In total, we provide reconstructions for 2594 fossil pollen records. <u>Among, among</u> them 670 records <u>are</u> <u>located</u> from Eastern North America, 361 records from Western North America, 1075 records from Europe and 488 Asian records (Fig. 1). The temporal coverage of the records is rather -uneven: 119 and 289 records cover the periods before 30,000 years (Fig. 2) and -the Last Glacial Maximum, respectively. A total of 1229, 1845<u>and</u>, 2052 records -are available for 12-11 ka, 6-5 ka BP and- 2-1 ka BP, respectively.

Figure 1. <u>Topleft</u>: map indicating the spatial distribution and record lengths covered by the LegacyPollen 1.0 dataset (Herzschuh et al., <u>2022csubmitted</u>) for which climate reconstructions, <u>temporal and</u> <u>reconstruction uncertainties and reconstruction quality measures</u> are provided in LegacyClimate 1.0 with a total of 2594 records; <u>Bottomright</u>: spatial distribution of modern pollen dataset used for reconstruction with a total of <u>1537915,379</u> sites.

Figure 2. Number of records that cover certain millennia of the last 30 ka.

4.2 Modern relationships between pollen and climate assessed by constrained ordination.

Results from CCA applied to modern datasets reveal that T_{July} -constrained ordinations have high $\lambda 1/\lambda 2$ ratios, indicating a strong relationship between this climate variable and modern pollen assemblages, in Eastern North America while low ratios can be found in Central Asia. The spatial pattern of $\lambda 1/\lambda 2$ of ordinations constrained by T_{ann} is overall similar to those of $T_{July but}$ the ratios are slightly higher for T_{ann} than for T_{July} . 4.2Reconstructions for P_{ann} show low ratios in Europe and Eastern North America. Areas with high ratios are concentrated in Alaska and East Asia (Fig. 3).

Figure 3. Maps showing λ_1/λ_2 , representing the ratio of explained variance of first axis (constrained) vs. second (unconstrained) axis as revealed by applying a CCA to all modern training datasets that were used for the reconstructions. High ratios (>1) indicate a strong relationship between the modern pollen datasets and climate. Constraining variables as well as tailoring of the dataset (see methods) is indicated in the map captions.

4.3 Analogue quality

minimum dissimilarity at 3000 years

Figure 4. Analogue quality as assessed by squared chord distance between modern pollen assemblages and fossil pollen assemblages. Results identify a very good (<1%), good (<2.5%) and poor (<5%) analogues Distances >5% are considered to indicate non-analogue situations. (As percentage of all distances among pollen samples in the modern dataset used for calibration.)

The dissimilarity (squared chord distance) between modern pollen assemblages and fossil pollen assemblages was calculated and extracted for distinct time-slices at 9000, 6000 and 3000 years BP. In total, 36.4% (9000 years BP), 39.2% (6000 years BP) and 45.6% (3000 years BP) records indicate a very good (<1%) analogue quality. the central part of the North American continent, Scandinavia and Central Asia show a very good analogue quality for all time-slices investigated. Poor (<5%) analogues can be found in Western Europe, the eastern parts of the United States and along the eastern Asian coastline. Non-analogues (>5%) are found for 22.6% (9000 years BP), 20.47% (6000 years BP) and 12.5% (3000 years BP) record respectively, especially in Western Europe and at 9000 years BP in Alaska.

4.4 Prediction errors of LegacyClimate 1.0

The mean RMSEPs and their standard deviations for T_{ann} are 1.98±0.52°C (MAT), 2.61±0.53°C (WA-PLS) and 2.24±0.61°C (WA-PLS_tailored) and mean RMSEPs as a percentage of modern T_{ann} range are 7.68±1.93% (MAT), 10.09±2.05% (WA-PLS) and 10.26±2.79% (WA-PLS_tailored). The largest mean RMSEP values are located in Central Asia in Kazakhstan, Mongolia and the north-western parts of the Tibetan Plateau and are consistent across all three reconstruction methods. Other areas with large mean RMSEP values are located in Western North America, Southern and Central Europe and south-east Asia. The smallest RMSEPs can be found along the east coast of North America. Relative to the modern temperature range, the RMSEP from this region also reveals the lowest fraction. In general, MAT has the lowest mean error fraction relative to the modern temperature range of all three methods.

–The mean RMSEPs of T_{July} are 1.90±0.63°C (MAT), 2.50±0.73°C (WA-PLS) and 2.21±0.75°C (WA-PLS_tailored) and mean percentages of T_{July} range are 8.11±1.64% (MAT), 10.71±1.94% (WA-PLS) and 10.70±2.60% (WA-PLS_tailored). Thus, they are slightly smaller than those of T_{ann} but slightly larger as a percentage of the range. The spatial patterns, however, are largely similar to those of T_{ann} .

-The mean RMSEPs of P_{ann} are 176.38±51.40 mm (MAT), 244.48±75.84 mm (WA-PLS) and 232.71±98.57 mm (WA-PLS_tailored) and mean percentages of P_{ann} range are 6.78±1.48% (MAT), 9.27±1.70% (WA-PLS) and 10.26±2.67% (WA-PLS_tailored). High RMSEPs are found for Western North America, Europe and along the coastline of south-east Asia, while the lowest RMSEP values are found for Central Asia. A clear division in RMSEPs are found on the North American continent: while the western part of North America (with the exception of Alaska) has a rather high RMSEP, the eastern part of North America has a smaller RMSEP. This pattern is found for all three methods (Fig. <u>5</u>3).

RMSEP of Tann | WA-PLS

RMSEP of Tann | WA-PLS tailored

RMSEP of Tann | MAT

RMSEP as % of Tann range | WA-PLS tailored

RMSEP as % of Tann range | MAT

Figure 53. Spatial distribution of root_-mean_-squared error of prediction (RMSEP) as inferred from leave-one_-out cross-validation presented as absolute values and as a percentage of the range of mean July temperature (T_{July}), mean annual temperature (T_{ann}), mean annual precipitation (P_{ann}) in the modern pollen data used for reconstruction for the three methods applied (Weighted-Averaging Partial-Least Squares regressionweighted-averaging partial least squares (WA-PLS), WA-PLS using a training set from within a limited climate range (WA-PLS_tailored) and Modern Analogue Techniquemodern analogue technique (MAT)).

4.5 Significance test

-A significance test (p < 0.1, <u>see methods</u>) according to Telford and Birks (2011) for the whole reconstructed time period was <u>performedrun</u> for each record and for the reconstructions with WA-PLS and WA-PLS_tailored (Fig. <u>6</u>4; Table 2). For the The T_{July} reconstruction, is significant for 30.9% (WA-PLS) and 35.2% (WA-PLS_tailored) of all records passed the significance test when included as a single variable in the significance test. Partialling out precipitation as a conditional variable causes an increase in the amount of significant records to 35.5% for WA-PLS<u>of T_{July}</u>, but a decrease for WA-PLS_tailored to 33.6% of all records. <u>TheFor T_{ann} reconstruction is significant for</u>, 32.8% (WA-PLS) and 36.1% (WA-PLS_tailored) of all records pass the significance test when tested as a single variable. When partialling out precipitation, the amount of significant records decreases for both WA-PLS and WA-PLS_tailored. 32.1% (WA-PLS) and 33.4% (WA-PLS_tailored) of all records pass the significance test when testing P_{ann} as a single variable. In contrast to the significance tests for T_{ann}, partialling out the mean July temperature as a conditional variable increases the number of significant records for both WA-PLS and WA-PLS_tailored.

Figure <u>6</u>4. Maps showing mean July temperature (T_{July}) , mean annual temperature (T_{ann}) , mean annual precipitation (P_{ann}) records that passed the reconstruction significance test (p<0.1). <u>ColorsCelor</u> indicates the significance level.

Table 2. Percentage of records that pass the reconstruction significance test (p<0.1) sensu Telford and</th>
 Birks (2011).

<u>MAT</u>

T _{July}	30.9%	35.2%
T _{July} partialling out P _{ann}	35.5%	33.6%
Tann	32.8%	36.1%
Tann partialling out Pann	32.6%	34.1%
Pann	32.1%	33.4%
P_{ann} partialling out T_{July}	34.3%	36.5%

4.<u>6 Human impact</u>

We used the abundance of Plantaginaceae and *Rumex* as indicators of grazing and such intense animal husbandry. Overall weak human impact is inferred for North America and Northern Asia. The indicators indicate strong human impact only in single records at 9000 years BP in China and the Mediterranean region (Fig. 7). The percentage values of Plantaginaceae and *Rumex* were high especially in Europe for 3000 years and 1000 years BP which indicates growing human impact on that region. High Plantaginaceae correlate with low T_{July} in Central Europe indicating potential biases in the temperature reconstructions i.e. too low temperatures become reconstructed (Fig. 8).

Figure 7. Abundance of Plantaginaceae (left) and *Rumex* (right) at 9000, 3000 and 1000 years BP. Colors indicate percentage values.

Figure 8. Correlation between the percentage of Plantaginaceae (left) and *Rumex* (right) and reconstructed T_{July}, T_{ann} and P_{ann} with WA-PLS.

4.73 Assessment of major temporal patterns of LegacyClimate 1.0

To illustrate the difference between Mid- and Late Holocene climate For analyzing the temporal variation, we calculated the value for the means of all three climate variables at 6 for the time periods between 6.5 and 5.5 ka BP and between 1.5 and 0.5 ka BP, each time taking the average of the interpolated values at-and-subtracted those ages for the ensemble of 1000 realizations of the age-depth models (Li et al., 2022), means from every record in order to evaluate the changes between the reconstructed mid-Holocene conditions and those of modern times. Differences between these time-slices periods reveal warmer and drier conditions during Mid-Holocene compared with Late Holocene conditions, especially in Eastern North America but also in Central and Northern Europe. The overall patterns are in good agreement for all three methods but show differences on a regional scale, especially when comparing the reconstructions with WA-PLS and MAT. For T_{July}, the reconstruction with MAT shows greater temperature differences in Western North America and south-east Asia. Compared to the reconstruction with WA-PLS, there is a reduced cooling from 6 to 1 in Eastern Europe and a warming instead of a

cooling in the Western Mediterranean region and along the south-eastern Asian coastline in MAT.in Eastern Europe and a warming in the Western Mediterranean region and along the south-eastern Asian coastline. Comparing the reconstructions of Tann, more gradual patterns are seen in the reconstruction with WA-PLS: Western North America reveals a mid-Holocene warming, while Eastern North America shows a cooling. In Europe records that report a cooling are more concentrated in the northern and western parts of the continent. In the reconstruction with MAT, Eastern North America is divided into a reported cooling in the northern part and a warming in the southern part. In Western North America, there is a mixture of locations with a warming and a cooling since the mid-Holocene. In Europe, only France and Southern Scandinavia show a cooling; in Central and parts of Southern Europe, a warming can be found in the reconstructions. For large areas in North America and Europe, the reconstructions with WA-PLS suggest an increase in precipitation from since 6 to 1 ka BP. A shift to drier conditions can be found along the south-eastern coastline in North America, in the Mediterranean Region and especially in south-east Asia. The reconstruction with MAT reveals a gradient from increasing precipitation in south-western Europe to decreasing precipitation in north-eastern Europe. In contrast to the reconstructions with WA-PLS, records along the south-eastern Asian coastline suggest an increase in precipitation with MAT rather than a decrease (Fig. 9).5).

26

temperature difference (°C) -3 -2 -1 0 1 2 3 precipitation difference (mm) -200 -100 0 100 200 precipitation change (%) -50 -25 0 25 50

Figure 95. Difference from 6 ka to 1 ka for mean July temperature (T_{July}), mean annual temperature (T_{ann}), mean annual precipitation (P_{ann}) and P_{ann}% as reconstructed from weighted-averaging partial least squares (WA-PLS (upper panel), WA-PLS using a training set from within a limited climate range (WA-PLS tailored (middle panel) and modern analogue technique (MAT (lower panel).).

-Time-series of absolute T_{ann} reconstructions reveal temporal as well as latitudinal spatial variation on the single continents. Eastern North America and Asia show the most variation in the low latitudes. It is also Eastern North America which shows the most pronounced latitudinal gradient. In Western North America, the most variation takes place in the high latitudes, while the variation is concentrated to the mid-latitudes in Europe. Especially in North America, the warming since the last deglaciation and the beginning of the Holocene is well shown in the temporal variation of the time-series (Fig. <u>106</u>).

years BP

4.84 Assessment of consistency among reconstruction methods

Reconstructions with MAT are, in general, in good agreement with those derived from the WA-PLS. Comparing MAT with WA-PLS, 37.3% (T_{July}), 38.9% (T_{ann}) and 30.4% (P_{ann}) of all records have a positive correlation of r >= 0.6. Strong positive correlations (r >= 0.9) can mainly be identified in Eastern North America, while weak correlation can be found for large areas in central North America and most of Europe (Fig. <u>117</u>).

-180°E -120°E -60°E 0°E 60°E 120°E 180°E

Figure <u>117</u>. Correlation between time-series of the 3 different reconstruction methods used - weightedaveraging partial least squares using a global training set (WA-PLS), WA-PLS using a training set with a limited modern climate range (WA-PLS_tailored) and the modern analogue technique (MAT) for the three climate variables of mean July temperature (T_{July}), mean annual temperature (T_{ann}) and mean annual precipitation (P_{ann})

-WA-PLS_tailored used a reduced modern training dataset (illustrated for an example in Appendix Fig. 1). The tailoring successfully reduced the co-variation of temperature and precipitation in the modern dataset as indicated by the distribution of the correlation coefficient in Fig. <u>128</u>. Nevertheless, the obtained reconstructions are largely consistent between WA-PLS and WA-PLS-tailored: a correlation of r >= 0.9 is found for 59.2% of all records for T_{July}, 60.7% for T_{ann} and 56.5% for P_{ann}.

Figure <u>128</u>. Violin plot of the correlation coefficients between T_{July} and P_{ann} in the <u>15379</u><u>15</u>,379 training datasets used for the reconstructions. Left: used for WA-PLS reconstructions; middle: WA-PLS <u> T_{July} </u>tialored (used for the reconstruction of P_{ann}); WA-PLS <u> P_{ann} </u>pann-tailored (used for the reconstruction of T_{July}).

<u>A CCA was performed to infer the ratio between constrained and unconstrained explained variance</u> for all modern training datasets (λ_1/λ_2) for the modern datasets used for WA-PLS and WA-PLS_tailored. Modern datasets used for WA-PLS constrained by T_{July} reveal a concentration of high ratios in Eastern North America while low ratios can be found in Central Asia. While the spatial pattern of λ_1/λ_2 -constrained by T_{ann} is similar, the ratios are slightly higher for T_{ann} than for T_{July}. Reconstructions for P_{ann}-show low ratios in Europe and Eastern North America. Areas with high ratios are concentrated in Alaska and East Asia.

Figure 9. Maps showing λ_1/λ_2 , representing the ratio of explained variance of first axis (constrained) vs. second (unconstrained) axis as revealed by applying a CCA to all modern training datasets that were used for the reconstructions. Constraining variable as well as tailoring of the dataset (see methods) is indicated in the map captions.

5 Discussion

5.1 Impact of the fossil pollen data source on LegacyClimate 1.0 quality

LegacyClimate 1.0 contains reconstructions of climate variables from fossil pollen data derived from open-access data repositories. The fossil records were derived from multiple natural archives, most commonly, assemblages from continuous lacustrine and peat accumulations (Herzschuh et al., <u>2022csubmitted</u>). Different sizes of lakes and peat areas result in varying sizes of pollen source areas and thus the spatial representativeness of a record, <u>while</u> small lakes and peatlands are considered to provide information about the (extra-)local scale, while the regional signal is better represented in pollen assemblages from large lakes are considered as a regional signal (Jackson, 1990; Sugita, 1993). However, <u>taphonomic changes</u>such signals might be impacted by taphonomy of the <u>records</u> originatingrecord, for example, from lake level changes may impact the reconstructed climate pollen from azonal riverine vegetation might be over-represented in fluvially impacted pollen records.

-Our dataset is based on taxonomically harmonized modern and fossil pollen datasets using a restricted number of taxa. (i.e., the most common 70 taxa on each (sub-)continent). Such an approach guarantees that all records are handled consistently. Although losing taxonomic information when merging taxa together into a higher taxonomic level, it also increases the possibility of matching climate analogues in the modern and the fossil datasets. However, one needs to keep in mind that species with different ecological requirements may be merged together into one genus or family, for example, *Pinus* species that are restricted to tropical or subtropical areas in China or ones that grow in boreal forests (Cao et al., 2013; Tian et al., 2017).

-Along with the pollen assemblages, data repositories also provide chronological information for fossil records. The quality of such chronologies varies strongly with respect to dating methods, calibration and numerical algorithms for determining an age-depth relationship (Blois et al., 2011; Trachsel and Telford, 2017). Having accurate and precise chronologies is thus of pivotal importance for reconstructing past climate in order to identify temporo-spatial patterns and therefore in helping to evaluate climate model outputs. The advantage of the fossil pollen dataset used for the reconstruction presented here (i.e., LegacyPollen 1.0; Herzschuh et al., <u>2022csubmitted</u>) is that it has harmonized chronologies (LegacyAge 1.0) along with information about uncertainties as well as related metadata and scripts that allow a customized re-establishment of the chronologies (Li et al., 2022). Accordingly, we were able to provide sample specific age-This, for example, allows the calculation of the temporal uncertainties along withwhen presenting reconstruction uncertainties of a specific time-slice.

5.2 Modern pollen and climate data sources and LegacyClimate 1.0 quality

Palaeoclimate reconstruction methods such as MAT and WA-PLS rely on extensive collections of modern training data. Designing a robust calibration dataset from modern pollon accomblages is a crucial part of the reconstruction process. A suitable calibration dataset should cover a wide range of elimatic and environmental gradients in order to represent an empirical relationship between pollon accomblages and climate (Birks et al., 2010; Chevalier et al., 2020). Like with fessil pollon records, data syntheses and repositories also exist for modern surface pollon data. Most of the records in our modern dataset were compiled from well-established pollen assemblages from-North America (Whitmere et al., 2005), Eurasia (Davis et al., 2013 and 2020) and China (Cao et al., 2013; Herzschuh et al., For our study we used the, to our knowledge, largest modern dataset ever used in a pollen-based climate

reconstruction.2019). For fossil pollen records in areas with an insufficient coverage of modern surface pollen samples (e.g., Central Asia or Western Siberia), it might be difficult to create a calibration dataset that maps the required variety of environmental and climatic gradients and therefore find enough modern analogues for reconstructions with a classification approach such as MAT. This is indicated by the high <u>RMSEPs as percentages of gradient length in these areas.</u> Our routine uses the modern pollen data from within a radius of 2000 km around the site of the fossil record. The information provided in the reconstruction metadata including number of modern pollen samples and ranges of reconstructed variables, allows an assessment of the modern dataset used for reconstruction.

We a priori selected $T_{July,}$ T_{ann} and P_{ann} as target variables for our reconstructions. However, we provide λ_1/λ_2 (i.e. explained variance of the climate variable in the modern pollen data set relative to the variance explained by the unconstrained first axis; ter Braak, 1988), a commonly used proxy for the assessment of reconstructions. The higher λ_1/λ_2 in the spatial modern dataset the higher the chance that this target climate variable has also impacted vegetation over time and is thus reflected in the variation of the fossil pollen dataset. As a rule of thumb, a ratio of 1 is considered to indicate reliable reconstructions (Juggins, 2012) though useful reconstruction may also be obtained from datasets with lower values. As expected, maps of RMSEPs reveal similar spatial pattern as the results of constrained ordination. Our results indicate that in particular calibration sets from Europe have low ratios and a high RMSEP for all climate variables (despite we have a high number of modern samples), likely related to the human impact on the modern and fossil data. Some areas that are known for its sensitivity to precipitation e.g. Eastern Asia show low RMSEPs as expected for P_{ann} but on the other hand show a low sensitivity to T_{ann} and T_{July}.

5.3 Reconstruction method and LegacyClimate 1.0 quality

Overall, the three reconstruction approaches, MAT, WA-PLS and WA-PLS_tailored yield rather similar results i.e. indicated by the overall high correlation between the reconstructions of the different methods (Fig. 11). Accordingly, the major trends at global or continental scales are similar, even if the actual amplitude of change may vary locally. As each method has its own strengths and weaknesses, there is not one set of reconstructions that is absolutely superior. One advantage of our multi-method reconstruction dataset is that users can identify the methods that are likely to perform best in a selected region and/or specific reconstructions. MAT is often recommended for large-scale studies, but it is highly

sensitive to the quality of analogues (Chevalier et al. 2020). Low analogue situations can arise from two causes: climate conditions that differ strongly from today (e.g., the low atmospheric CO₂ concentration during the LGM; Jackson and Williams, 2004), or in regions with limited modern samples (e.g., extratropical Asia). We report the analogue distance for each sample to help identify such situations. From our assessments, we revealed that analogues quality is overall rather good at least for the Holocene and except for Western Europe in particularly the British Isles (Fig. 4).

In contrast MAT, WA-PLS (and most regression techniques in general) model relationships between pollen and climate and are, as such, less sensitive to the low analogue situations (Birks et al., 2010). They are, however, based on some modelling assumptions, such as the unimodality of the response of the pollen taxa to climate (ter Braak and Juggins 1993). This condition is not always met at the continental scale, primarily because of the limited taxonomic resolution of pollen data that merges several plant species with distinct climate requirements as one single pollen taxon. WA-PLS tailoring has the same limitation but it has the advantage of reducing the influence of the correlation between variables when reconstructing, for instance, temperature and precipitation. This may be particularly relevantClimate requirements all have different strengths and weaknesses. MAT and WA-PLS for regions with a temperature-moisture driven circulation system such as the East Asian Summer Monsoon (EASM) that can heavily affect precipitation patterns in certain regions (Herzschuh et al., 2019). Using WAPLS tailoring also increases the number of records that pass a significance level of p < 0.1 (Telford and Birks, 2011). Providing several reconstructions based on different assumptions also allow exploring, even if only partially, the uncertainties associated with the modelling assumptions (e.g., MAT vs WA-PLS, the number of analogues, type metric used to compare pollen samples).

<u>All reconstruction methods</u> used in this study heavily rely on extensive collections of modern assemblage data covering diverse climatic and environmental gradients and are applicable on a broad spatial scale. <u>As discussed, all the However, both</u> methods may struggle with <u>some intrinsic</u> <u>characteristics of pollen data and of pollen compilations, including</u> complex species responses, <u>sensitivityare sensitive</u> to spatial autocorrelation, <u>limited analogues that</u>ean only deal with a certain extent of non-analogous situations and may produce poor results in so-called "quantification deserts" (Chevalier, 2019), where fossil pollen is hardly preserved or nearby modern surface pollen samples are missing (Chevalier et al., 2020). <u>However, we designed our</u>Nonetheless, for reconstructions on a local or regional scale, MAT and WA-PLS are most commonly used in climate reconstructions. The format of the modern and fossil datasets <u>so that more methods can be included in ouras well as the provided</u>

scripts could also be easily adapted to apply to other reconstruction <u>scripts</u> (https://doi.org/10.5281/zenodo.5910989; Herzschuh et al., 2022b), methods-such as CREST, ane Bayesian approach that combines presence-only occurrence data from species distribution databases instead of modern pollen samples and modern climatologies to estimate the <u>responses</u>conditional response of pollen taxa to the climate variable to reconstructa given taxon to a climate variable (Chevalier et al., 2014 and 2022). CREST is, therefore, more independent from the availability of modern pollen samples. Employing the Inverse-Modelling through iterative forward modeling (IMIFM) (Izumi and Bartlein, 2016) might also be possible in such regions. Its use would be particularly interesting to reconstruct the LGM samples, because IMIFM is the only technique that can explicitly take the effect of CO₂ on plants (Chevalier et al., 2020). The inclusion of CREST and/or IMIFM in such large scale studies would complement our multi-model reconstruction ensemble by exploring a larger fraction of the "method uncertainty" space in greater details (e.g. Brewer et al, 2008).

Through numerous physical processes that vary with both location and time, temperature and precipitation are interconnected, especially within the extratropical regions (Adler et al., 2008; Trenberth, 2011) and thus temperature and precipitation may not be treated as independent variables. Due to the numerical mechanisms in the transfer function, the correlation between both climate variables may reduce the reliability of the reconstructions. This is especially true for regions with a temperature-moisture driven circulation system such as the East Asian Summer Monsoon (EASM) that can heavily affect precipitation patterns in certain regions (Herzschuh et al., 2019). With our tailoring approach we are able to reduce the influence of co-variation of these two climate variables for the reconstruction and increase the number of records that pass a significance level of p < 0.1 (Telford and Birks, 2011).

5.4 Potential use of LegacyClimate 1.0

Our LegacyPollen 1.0 fossil pollen synthesis (Herzschuh et al., 2022c) contains records from all over the Northern Hemisphere extratropics. Climate reconstruction data sets like LegacyClimate 1.0 and thus can be used to infer spatio-temporal patterns in climate reconstructions that are not only limited to a local or regional scale. Although several hemispheric or global reconstruction studies exist, they have been largely restricted to temperature or have included relatively few records (Marcott et al., 2013; Marsicek et al., 2018; Routson et al., 2019; Kaufman et al., 2020a and 2020b). Our dataset is therefore a valuable addition. It may be used in a multi-proxy approach, synthesizing marine and terrestrial records in order to assess temperature development during the Holocene and can help to highlight possible

interdependencies between oceans and land masses and such contribute to the "Holocene conundrum" debate (Liu et al., 2014). Temperature reconstructions from proxy data indicate peak temperatures during the Holocene Thermal Maximum around 6000 years BP followed by a pronounced cooling trend toward the late Holocene (KaufmanLiu et al., 2020b2014; Bova et al., 2021), which is also visible in our pollen-based reconstructions (Fig. 6). In contrast, climate models simulate a monotonic warming throughout the Holocene, which resulted in the "Holocene conundrum" debate (Liu et al., 2014). Temperature reconstructions are often derived from sea-surface temperatures as either mean annual temperatures (Birks, 2019; Bova et al., 2021) or global mean surface temperature (Marcott et al., 2013; Marsicek et al., 2018; Kaufman et al., 2020a and 2020b). However, it is argued that proxy-based climate reconstructions are seasonally biased and therefore might be the reason for the observed proxy-model divergence (Liu et al., 2014; Rehfeld et al., 2016; KaufmanBeva et al., 2020b2024). In this respect, it might help that we provide TuutyTiuty along with Tann reconstructions <u>derived from our tailoring approach</u>, which provides the opportunity to assess seasonal impacts on the reconstruction.

-So far, reconstructions of precipitation have not been implemented on a hemispheric scale. The interconnection between temperature and precipitation (Trenberth, 2011) and its spatio-temporal variation across the Northern Hemisphere is therefore an important aspect of evaluating climate models (Wu et al., 2013; Hao et al., 2019; Herzschuh et al., <u>2022asubmitted</u>). A broad-scale quantitative reconstruction of temperature and precipitation would therefore be of great value for evaluating transient model runs performed by climate model experiments models such as TraCE 21k (He, 2010).

Our assessments of the modern dataset (e.g. using CCA), the transfer function (e.g. RMSEP) and the reconstruction (e.g. the significance test) revealed also the potential biases in the pollen-based reconstruction and pointed to limitations. Further validation and assessments of the results and more comprehensive uncertainty analyses e.g. by applying forward modelling approaches (Izumi & Bartlein, 2016; Parnell et al., 2016) would be highly valuable.

6 Data and code availability

The compilation of reconstructed T_{July}, T_{ann}, and P_{ann}, is open access and available at PANGAEA (https://doi.pangaea.de/10.1594/PANGAEA.<u>930512</u>.930512; in the "*Other version*" section; Herzschuh

et al., 2021). The dataset files are stored in machine-readable data format (.CSV), which are already separated into Western North America, Eastern North America, Europe, and Asia for easy access and use.

-The R code to run the reconstructions for single sites is available at Zenodo (https://doi.org/10.5281/zenodo.5910989; Herzschuh et al., <u>2022b2022</u>) including harmonized openaccess modern and fossil pollen datasets so that customized reconstructions can be easily established.

Appendix Figures

Appendix Figure 1. Example to illustrate the effect of tailoring the modern dataset for the location <u>"Yellow Dog Pond" in Eastern North America. Upper part: reconstruction of T_{July} and P_{ann} with WA-PLS (red) and WA-PLS tailored (blue); lower part: correlation of T_{July} and P_{ann} in the modern dataset and the <u>effect of tailoring the modern dataset (indicated with the red box). Correlations are given for non-tailored</u> (red) and tailored (blue) data.</u>

Author contributions. UH designed the study design and reconstruction dataset. CL and TB compiled the metadata and the harmonized pollen dataset. TB wrote the R scripts and ran the analyses under the supervision of UH. UH, TB and MC wrote the first draft of the manuscript. All authors discussed the results and contributed to the final manuscript.

Competing interests. The <u>contact author has declared</u> authors declare that <u>none</u>they have no conflict of <u>the authors has any competing interests</u> interest.

Acknowledgements. We would like to express our gratitude to all the palynologists and geologists who, either directly or indirectly by providing their work the Neotoma Paleoecology Database, contributed

pollen data and chronologies to the dataset. The work of data contributors, data stewards, and the Neotoma community is gratefully acknowledged. We thank Andrej Andreev, Mareike Wieczorek, and Birgit Heim from AWI for providing information on pollen records and data uploads. We also thank Cathy Jenks for language editing on a previous version of the paper.

Financial support. This research has been supported by the European Research Council (ERC Glacial Legacy 772852 to UH) and the PalMod Initiative (01LP1510C to UH). TB and MC is supported by the German Federal Ministry of Education and Research (BMBF) as a Research for Sustainability initiative (FONA; https://www.fona.de/en) through the PalMod Phase II project (grant no. FKZ: 01LP1926D). CL holds a scholarship from the Chinese Scholarship Council (grant no. 201908130165). NR work was supported by the Russian Science Foundation (Grant No. 20-17-00110).

Appendix Figures

- non-tailored - tailored

Appendix Figure 1. Example to illustrate the offect of tailoring the modern dataset for the location "Yellow Dog Pond" in Eastern North America. Upper part: reconstruction of T_{July} and P_{ann} with WA-PLS (rod) and WA-PLS_tailored (blue); lower part: correlation of T_{July} and P_{ann} in the modern dataset and the offect of tailoring the modern dataset (indicated with the red box). Correlations are given for non-tailored (red) and tailored (blue) data.
