52

53 **Abstract.** Here we describe the LegacyClimate 1.0, a dataset of the reconstruction of mean July
54 temperature (T_{July}), mean annual temperature (T_{ann}), and annual precipitation (P_{ann}) from 2594 fossil
55 pollen records from the Northern Hemisphere spanning the entire Holocene with some records reaching
56 back to the Last Glacial. Two reconstruction methods, the Modern Analogue Technique (MAT) and
57 Weighted-Averaging Partial-Least Squares regression (WA-PLS) reveal similar results regarding spatial
58 and temporal patterns. To reduce the impact of precipitation on temperature reconstruction and vice
59 versa, we also provide reconstructions using tailored modern pollen data limiting the range of the
60 corresponding other climate variables. We assess the reliability of the reconstructions using information
61 from the spatial distributions of the root-mean-squared error of prediction and reconstruction significance
62 tests. The dataset is beneficial for synthesis studies of proxy-based reconstructions and to evaluate the
63 output of climate models and thus help to improve the models themselves. We provide our compilation
64 of reconstructed T_{July} , T_{ann} , and P_{ann} as open-access datasets at PANGAEA
65 (<https://doi.pangaea.de/10.1594/PANGAEA.930512>; Herzschuh et al., 2021). R code for the
66 reconstructions is provided at Zenodo (<https://doi.org/10.5281/zenodo.5910989>; Herzschuh et al.,
67 2022b), including harmonized open-access modern and fossil datasets used for the reconstructions, so
68 that customized reconstructions can be easily established.

69

70 **1 Introduction**

71 The comparison of climate model outputs with climate data is essential for model improvements (Eyring
72 et al., 2019). The extratropical Northern Hemisphere is of particular interest because it is known for
73 complex spatial and temporal temperature and precipitation patterns. However, the period for which
74 instrumental observations are available is only of limited use to validate simulations, in particular when
75 assessing climate response to natural climate drivers because it is too short and because it is impacted

76 by human-induced greenhouse gas forcing. Climate proxy data derived from natural archives are
77 therefore of great value.

78 Previous proxy-based climate inferences have contributed to major debates about Holocene climate
79 change. For example, while simulations indicate gradual warming of the Holocene, temperature proxy
80 data syntheses rather support a mid-Holocene optimum which resulted in the “Holocene conundrum”
81 debate (Liu et al., 2014). While the debate has progressed since new proxy-based syntheses can help
82 to understand regional differences and contribute further to the debate. Qualitative proxy-based
83 inferences indicate that the mid-Holocene in the Northern Hemisphere mid-latitudes was rather dry and
84 warm compared with present-day in agreement with modeling outputs (Routson et al., 2019). Also,
85 quantitative precipitation reconstructions from Eastern and Central Asia unveiled the complex monsoon-
86 westerlies interactions (Chen et al., 2019; Herzschuh et al., 2019). However, evaluating modeling
87 outputs using proxy-based reconstructions is a complex task and strongly depends on the purpose of
88 the proxy data-model comparison study (e.g. the purpose of an evaluation could either target the mean
89 or site-specific changes, or it could target relative changes or absolute values, or the purpose could be
90 to infer spatial or temporal climate variability at specific scales, etc.). All these types of evaluation require
91 a specific handling of the proxy-data and have to be considered for proxy-model comparisons.

92 Fossil pollen records are well-established in their use as a palaeoecological and palaeoclimatological
93 proxy and of great value as indicators of past environmental and climatic change for many decades.
94 Considerable efforts have been made to establish regional, continental and even global data repositories
95 like the North American Pollen Database (NAPD; <https://www.ncei.noaa.gov/products/paleoclimatology>,
96 last access: 1 July 2020), the European Pollen Database (EPD;
97 <http://www.europeanpollendatabase.net/index.php>, last access: 1 July 2020) and the Neotoma
98 Paleocology Database (<https://www.neotomadb.org/>, last access: 1 April 2021; Williams et al., 2018).
99 Pollen data from archives across multiple environmental settings such as lakes, wetlands, or marine
100 sediments, have been widely used to quantitatively reconstruct past vegetation and climate variables
101 (Birks, 2019; Chevalier et al., 2020). Among land-derived proxy data, pollen is particularly suitable for
102 temporarily and spatially high-resolution evaluation of climate model simulations of the late Quaternary
103 period. A number of methods have been proposed for making pollen-based climate reconstructions
104 (Chevalier et al., 2020): among them, classification approaches like the Modern Analogue Technique
105 (MAT) or regression approaches like Weighted-Averaging Partial-Least Squares regression (WA-PLS)

106 are most commonly used. MAT and WA-PLS rely on extensive collections of modern spectra. Hence,
107 designing a robust calibration dataset from modern pollen assemblages is a crucial part of the
108 reconstruction process. A suitable calibration dataset should cover a wide range of climatic and
109 environmental gradients in order to represent an empirical relationship between pollen assemblages
110 and climate (Birks et al., 2010; Chevalier et al., 2020). Like with fossil pollen records, data syntheses
111 and repositories also exist for modern surface pollen data e.g. for North America (Whitmore et al., 2005),
112 Eurasia (Davis et al., 2013 and 2020) and China (Cao et al., 2013; Herzschuh et al., 2019).

113 For temperature reconstruction time-series, several broad-scale syntheses exist; however, either they
114 originate from different proxies (Kaufman et al., 2020a and 2020b) or are restricted to certain continents
115 or regions or/and are poorly documented (Mauri et al., 2015; Marsicek et al., 2018; Routson et al., 2019).
116 Temperature reconstructions from extratropical Asia are mostly lacking. Precipitation syntheses are
117 available from Europe (Mauri et al., 2015), North America (Gajewski, 2000) and China and Mongolia
118 (Herzschuh et al., 2019) but, hitherto, no global or hemispheric syntheses of quantitative precipitation
119 changes are available for the Holocene.

120 In a recent effort, we synthesized and taxonomically harmonized pollen records available in the Neotoma
121 Paleocology Database (Williams et al., 2018) and additional records from China and Siberia (Cao et
122 al., 2013 and 2020) into a global Late Quaternary fossil pollen dataset (LegacyPollen 1.0; Herzschuh et
123 al., 2022c) and revised all chronologies of those records using a Bayesian approach that allows for the
124 inference of temporal uncertainties (LegacyAge 1.0; Li et al., 2022). Here, in the third part of a series of
125 interconnected studies, we present the pollen-based reconstruction of mean July temperature (T_{July}),
126 mean annual temperature (T_{ann}) and annual precipitation (P_{ann}) including reconstruction and temporal
127 uncertainties as well as quality measures from 2594 records from the Northern Hemisphere using WA-
128 PLS and MAT (LegacyClimate 1.0; this study).

129

130 **2 Methods**

131 **2.1 Input data**

132 The objective of this study is to create a dataset of quantitative reconstructions of T_{July} , T_{ann} and P_{ann}
133 spanning the last 30 ka and beyond from fossil pollen records. These variables (or variables highly
134 correlated to them) were shown to explain most variance in the modern pollen data (T_{July} , P_{ann}) or are

135 typically used in syntheses and proxy-model comparison studies (T_{ann}). Accordingly, we selected these
136 three variables. We used the fossil data set compiled in LegacyPollen 1.0 (stored on the PANGAEA
137 open data repository and presented in Herzschuh et al., 2022c) that integrates pollen records archived
138 in the Neotoma Paleoecology Database, a dataset from Eastern and Central Asia (Cao et al., 2013;
139 Herzschuh et al., 2019) and a dataset from Northern Asia (Cao et al., 2020). Ages were taken from the
140 “Bacon” (Blaauw and Christen, 2011) age-depth models presented in Li et al. (2022, LegacyAge 1.0),
141 and for each record, we provide an ensemble of 1000 realizations of the age-depth model in our data
142 product so that it can be used to account for chronological uncertainty on the reconstructions. As the
143 chronological and reconstruction errors are independent, they can be added in quadrature to obtain the
144 combined error. With this information, users can easily produce curves with all relevant uncertainties as
145 exemplary shown in Appendix Figure 1.

146 We compiled the fossil data into four sub-continental datasets for Eastern North America ($<104^{\circ}W$;
147 Williams et al., 2000), Western North America, Europe ($<43^{\circ}E$) and Asia ($>43^{\circ}E$). We restricted the
148 analyses to the 70 most common taxa on each continent to reduce computational power after making
149 sure that higher taxa number would not substantially improve model statistics in climate reconstructions.
150 The number of taxa is limited by the modern training dataset from North America, which contains 70
151 taxa after applying our taxa harmonization routine (see details in Herzschuh et al., 2022c). We therefore
152 restricted the number of taxa in all fossil datasets to keep the taxa comparable for the reconstructions.
153 To identify the most common taxa we used Hill’s N2 diversity index (i.e., the effective number of
154 occurrences of a species in the dataset; Hill, 1973). For all analyses, square-root percentages were
155 used if not indicated otherwise.

156 A modern pollen training dataset comprised of 15379 sites includes datasets from Eurasia (EMPD1,
157 Davis et al. 2013; EMPD2, Davis et al. 2020; Herzschuh et al., 2019; Tarasov et al., 2011) and North
158 America (Whitmore et al., 2005). The modern pollen datasets were taxonomically harmonized in
159 accordance with the fossil pollen dataset.

160 The site-specific T_{ann} , T_{July} , P_{ann} were derived from WorldClim 2 version 2.1 (spatial resolution of 30
161 seconds ($\sim 1 \text{ km}^2$), <https://www.worldclim.org>; Fick and Hijmans, 2017) by extracting the climate data at
162 the location of the modern sample sites using the *raster* package in R (version 3.5-11, Hijmans et al.,
163 2021; R Core Team, 2020). The WorldClim 2 dataset provides spatially interpolated gridded climate

164 data aggregated from weather stations as temporal averages between 1970-2000 (Fick and Hijmans,
165 2017). We used monthly average temperature data to extract the mean T_{July} and the “bioclimatic
166 variables” bio1 (T_{ann}) and bio12 (P_{ann}).

167

168 **2.2 Reconstruction methods**

169 Our reconstruction approach included MAT (Overpeck et al., 1985) and WA-PLS (ter Braak and Juggins,
170 1993) by applying the MAT and WAPLS functions from the *rioja* package (version 0.9-21, Juggins, 2019)
171 for R (R Core Team, 2020) on our Northern Hemispheric fossil pollen synthesis. For each fossil location,
172 we calculated the geographic distance between each modern sampling site and the fossil pollen record
173 using the *rdist.earth* function from the *fields* R-package (version 10.3, Nychka et al., 2020) and selected
174 a unique calibration set from modern sites within a 2000 km radius. We fixed the radius to 2000 km
175 instead of 1500 km as suggested from a study in Eastern Asia by Cao et al. (2017), because the modern
176 dataset density is rather low in Northern Asia. For the reconstruction with MAT, we used the original
177 pollen percentages of the selected fossil pollen taxa, looking for 7 analogues between the pollen data
178 and the selected calibration dataset. The dissimilarity between the fossil samples and the modern pollen
179 assemblages was determined by squared-chord distance of the percentage data (Simpson, 2012; Cao
180 et al., 2014).

181 In addition to the classic WA-PLS reconstruction, we also propose WA-PLS_tailored. This approach
182 addresses the problem that co-variation of climate variables today in space is transferred to the
183 reconstruction even if the past temporal relationship among the climate variables mechanistically differs.
184 In fact, this approach aims to make use of the full climate space covered by the modern pollen samples
185 avoiding those samples in the calibration set that cause spatial covariation. This approach is based on
186 the assumption that several climate variables can be reflected in one and the same pollen assemblage
187 because different plant taxa have different optima in temperature and precipitation ranges and might
188 therefore occur with different co-occurrence and abundance pattern. To reconstruct T_{July} we identified
189 the P_{ann} range reconstructed by WA-PLS and extended it by 25% to both ends of the modern P_{ann} range
190 in order to reduce the influence of P_{ann} on T_{ann} and T_{July} reconstruction due to co-variation. We applied
191 the same method to the reconstruction of P_{ann} . T_{ann} and T_{July} were tailored by P_{ann} ; P_{ann} was tailored by
192 T_{July} and, additionally, by T_{ann} (illustrated for an example in Appendix Fig. 2). Reconstruction

193 uncertainties are provided as root mean square errors (RMSE) derived from the output in the MAT and
194 WAPLS functions. Model errors of WA-PLS and MAT are reported as root mean square error of
195 prediction (RMSEP) derived from leave-one-out cross-validation.

196 We provide site- or sample-specific measures of quality in addition to the error estimates and model
197 statistics to allow the user to assess the quality of the climate reconstruction dataset. First, we applied
198 a Canonical Correlation Analysis (CCA) to the modern training dataset in order to explore the modern
199 relationship between the pollen spectra and the climate variables and to infer the explained variance in
200 the modern pollen dataset by the target climate variables (ter Braak, 1988) by using the *cca* function in
201 the *vegan* R-package (version 2.5-7, Oksanen et al., 2020). The ratio between constrained (λ_1) and
202 unconstrained (λ_2) explained variance was determined for all modern training datasets used for climate
203 reconstructions. High values of λ_1 vs λ_2 (≥ 1) are commonly considered as an indicator to measure
204 how well the target environmental variable is related to the variation in the modern pollen data set (e.g.
205 Juggins, 2013). However, most training data sets encompass multiple environmental variables that are
206 often correlated and additional requirements to such variables would be necessary to explain a
207 significant and independent portion of the variation in the training data set. While a careful design of the
208 training data set can help reduce the effect of correlated environmental gradients, it can never eliminate
209 them completely (Juggins, 2013). To infer the analogue quality as an indicator of no-analogue situations
210 we calculated the minimum dissimilarity (squared chord distance) between modern pollen assemblages
211 and fossil pollen assemblages with probability thresholds of 1% (indicating very good analogs), 2.5%
212 (good analogs) and 5% (poor analogs) using the *minDC* function from the *analogue* R-package (version
213 0.17-6, Simpson et al., 2021).

214 A statistical significance test (Telford and Birks, 2011) was applied using the *randomTF* function in the
215 *palaeoSig* R-package (version 2.0-3, Telford, 2019). In this test, the proportion of variance in the fossil
216 pollen data explained by the reconstructed environmental variable is estimated from redundancy
217 analysis (RDA) and tested against a null distribution generated by replacing the modern training dataset
218 with randomly generated surrogate fields. The surrogate fields were simulated to have realistic spatial
219 autocorrelation by fitting variograms to the WorldClim 2 temperature and precipitation data; 1000-
220 member ensembles were simulated for each variable. A reconstruction is considered statistically
221 significant if the reconstructed variable explains more of the variance than 95% of the random
222 reconstructions (Telford and Birks, 2011). The reconstructed climate variables were tested as

223 introducing the environmental variable as a single variable in a run, as well as with partialling out the
224 explained variance in the pollen data by the respective other variables.

225 We used Plantaginaceae (mostly representing *Plantago lanceolata*-type in Europe) and *Rumex*-type to
226 assess human influence as an indicator for intense herding (Behre, 1988). In addition, we calculated the
227 correlation between the WA-PLS reconstruction of T_{July} , T_{ann} and P_{ann} and the pollen percentages of
228 Plantaginaceae and *Rumex* for 9000, 3000 and 1000 years BP to assess potential biases in the dataset.

229

230 **3 Dataset description LegacyClimate 1.0: input data, reconstructions and reconstruction model** 231 **statistics**

232 LegacyClimate 1.0 provides pollen-based reconstructions and sample-specific reconstruction errors of
233 T_{ann} , T_{July} and P_{ann} for 2594 fossil pollen records (i.e., a total of 146067 single pollen samples) from three
234 reconstruction methods (WA-PLS, WA-PLS_tailored, MAT). Furthermore, we provide the method-
235 specific model metadata and quality measures for each record and each climate variable (Table 1). To
236 ease data handling, the dataset files are separated into Western North America, Eastern North America,
237 Europe and Asia.

238

239

248

249 **Table 1.** Structure and content of the LegacyClimate 1.0 data with details about the information
 250 contained in the input datasets, in the climate reconstructions and the reconstruction model statistics.

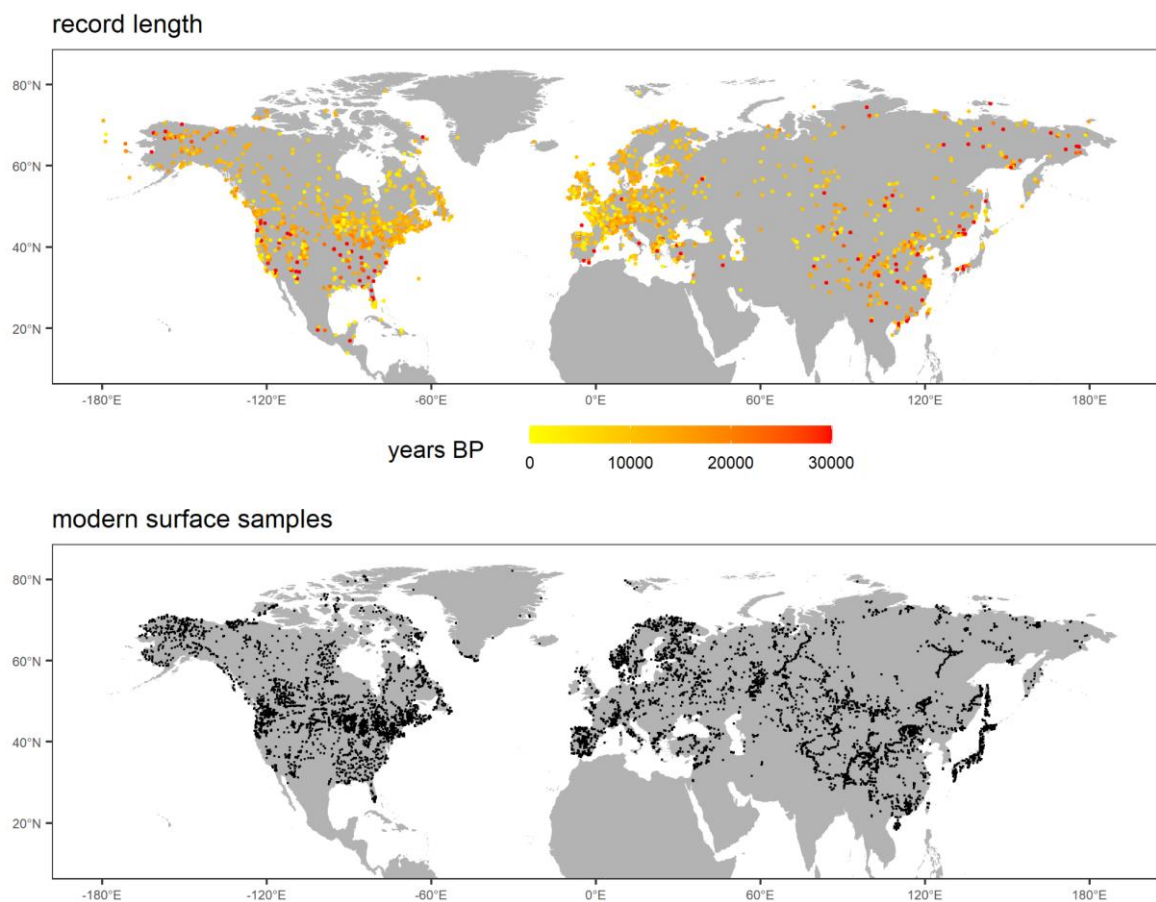

Datasets	Content
Input datasets	Modern pollen dataset of 15379 sites
	Modern dataset of T_{ann} , T_{July} , P_{ann}
	Fossil pollen data (LegacyPollen 1.0) for 2594 sites with a total of 146067 samples
LegacyClimate 1.0: Climate reconstructions	Bacon age-depth models (LegacyAge 1.0) for 2579 sites
	Reconstructions and sample-specific reconstruction errors of T_{ann} , T_{July} and P_{ann} for 2593 sites using MAT, WA-PLS and WA-PLS_tailored
LegacyClimate 1.0: Reconstruction model statistics	Ensemble of 1000 realizations of the Bacon age-depth models for 2579 sites
	Site information (Event label, Source, ID, Site name, Longitude, Latitude)
	Modern pollen dataset information (number of modern analogues, range of climate variables)
LegacyClimate 1.0: Quality Measures	Model statistics for each site for MAT, WA-PLS, WA-PLS_tailored (including r^2 observed vs. predicted, RMSEP, no. of WA-PLS components)
	Canonical Correlation Analysis (CCA) of the modern training dataset
	Minimum dissimilarities between modern pollen assemblages and fossil pollen assemblages for each record sample for MAT
	Statistical significances sensu Telford & Birks (2011) for each site for MAT, WA-PLS, WA-PLS_tailored

251 4 Dataset assessment

252 4.1 Spatial and temporal coverage of LegacyClimate 1.0

253 In total, we provide reconstructions for 2594 fossil pollen records. Among them 670 records are located
254 in Eastern North America, 361 records in Western North America, 1075 records in Europe and 488
255 Asian records (Fig. 1). Some few records are included that come from marine cores which were taken
256 from the continental shelf. They contain information from source areas from the nearby continents (e.g.
257 fluviially transported material). If users want to focus on terrestrial-only records, those marine sites could
258 be filtered out by the archive type provided in the metadata. Climate reconstructions for one fossil record
259 in the Western North American Dataset on Hawaii (Dataset-ID 17832, "Kealia Pond") could not be
260 performed as there were no modern training data available within a 2000 km area.

261 The temporal coverage of the records is rather uneven: 75 and 666 records cover the periods between
262 30-29 ka and 15-14 ka, respectively (Fig. 2).

263

264 **Figure 1.** Upper panel: map indicating the spatial distribution and record lengths covered by the
 265 LegacyPollen 1.0 dataset (Herzschuh et al., 2022c) for which climate reconstructions, temporal and
 266 reconstruction uncertainties and reconstruction quality measures are provided in LegacyClimate 1.0 with
 267 a total of 2594 records; Lower panel: spatial distribution of modern pollen dataset used for reconstruction
 268 with a total of 15379 sites.

269

270 **Figure 2.** Number of records that cover certain millennia of the last 30 ka.

271

272 4.2 Modern relationships between pollen and climate assessed by constrained ordination.

273 Results from CCA applied to modern datasets reveal that T_{July} -constrained ordinations have high λ_1/λ_2
 274 ratios, indicating a strong relationship between this climate variable and modern pollen assemblages, in
 275 Eastern North America while low ratios can be found in Central Asia. The spatial pattern of λ_1/λ_2 of
 276 ordinations constrained by T_{ann} is overall similar to those of T_{July} but the ratios are slightly higher for T_{ann}
 277 than for T_{July} . Reconstructions for P_{ann} show low ratios in Europe and Eastern North America. Areas with
 278 high ratios are concentrated in Alaska and East Asia (Fig. 3).

279

280 **Figure 3.** Maps showing λ_1/λ_2 , representing the ratio of explained variance of first axis (constrained) vs.
 281 second (unconstrained) axis as revealed by applying a CCA to all modern training datasets that were
 282 used for the reconstructions. High ratios (≥ 1) indicate a strong relationship between the modern pollen
 283 datasets and climate and can be used to determine ecologically important determinants. Constraining
 284 variables as well as tailoring of the dataset (see methods) is indicated in the map captions.

285

286 4.3 Analogue quality

287 The dissimilarity (squared chord distance) between modern pollen assemblages and fossil pollen
 288 assemblages was calculated and extracted for distinct time-slices at 9000, 6000 and 3000 years BP. In
 289 total, 36.4% (9000 years BP), 39.2% (6000 years BP) and 45.6% (3000 years BP) records indicate a
 290 very good ($< 1\%$) analogue quality. The central part of the North American continent, Scandinavia and
 291 Central Asia show a very good analogue quality for all time-slices investigated. Poor ($< 5\%$) analogues
 292 can be found in Western Europe, the eastern parts of the United States and along the eastern Asian
 293 coastline. Non-analogues ($> 5\%$) are found for 22.6% (9000 years BP), 20.47% (6000 years BP) and
 294 12.5% (3000 years BP) record respectively, especially in Western Europe and at 9000 years BP in
 295 Alaska (Fig. 4).

296

297

298 **Figure 4.** Analogue quality as assessed by squared chord distance between modern pollen
 299 assemblages and fossil pollen assemblages. Results identify very good (<1%), good (<2.5%) and poor
 300 (<5%) analogues. Distances >5% are considered to indicate non-analogue situations (as percentage of
 301 all distances among pollen samples in the modern dataset used for calibration).

302

303

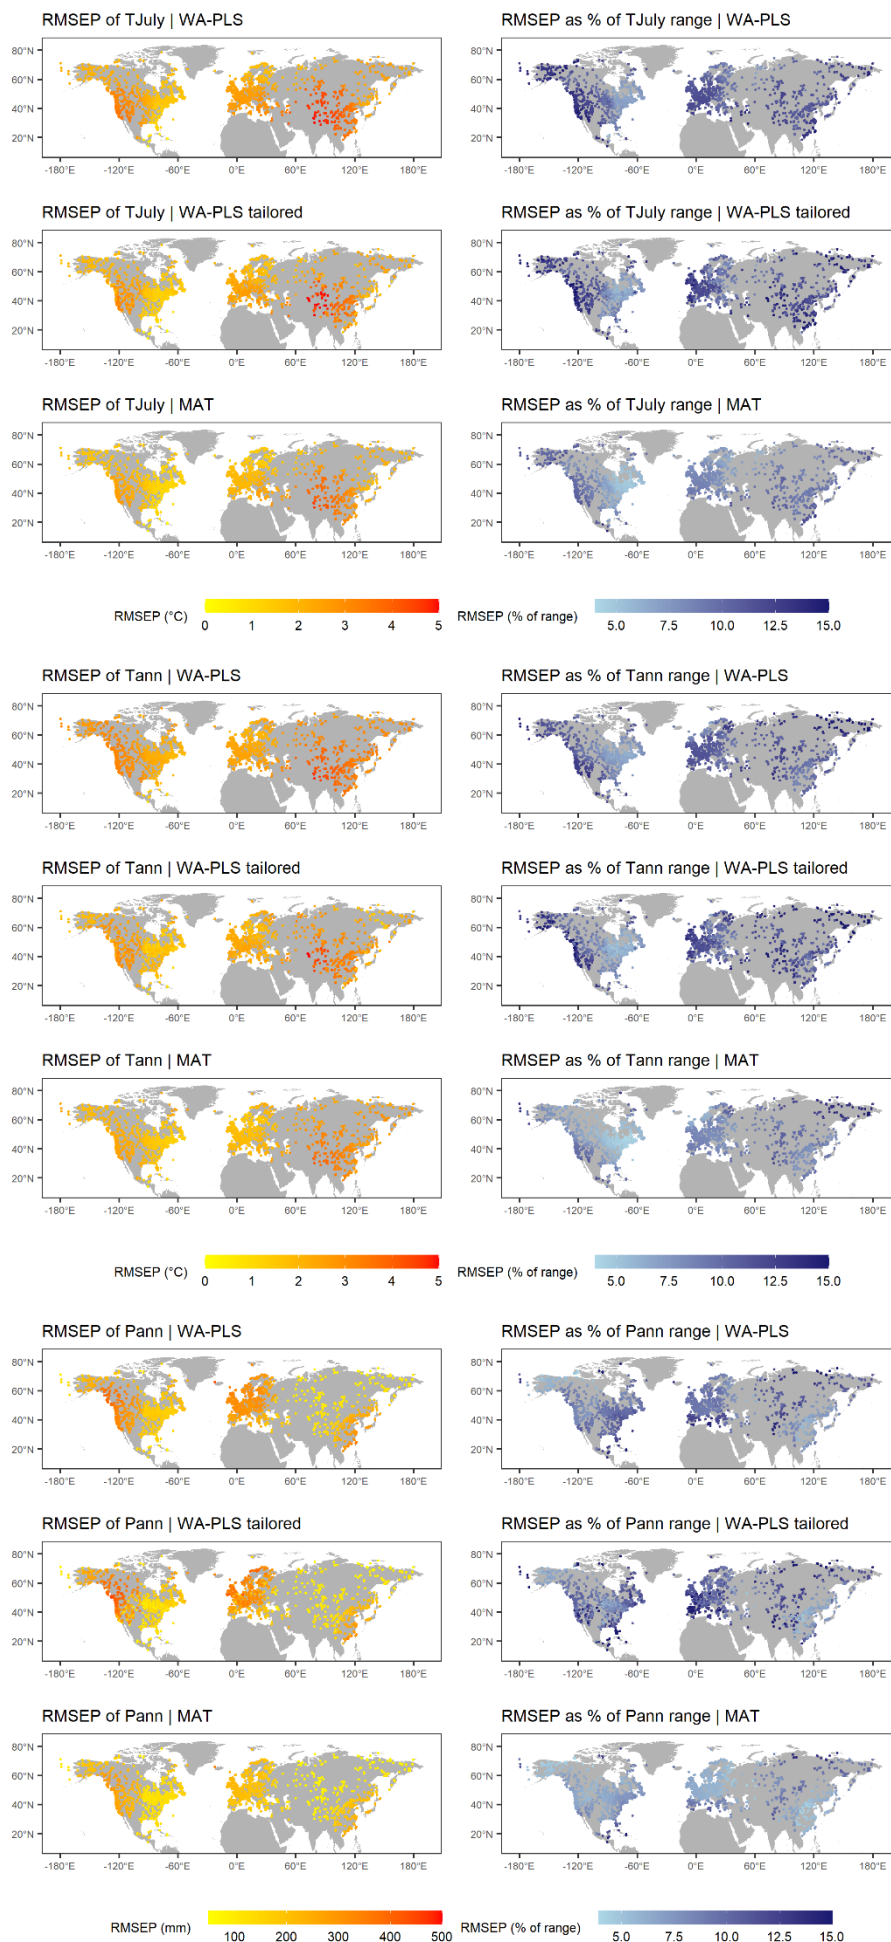

304

305 4.4 Prediction errors of LegacyClimate 1.0

306 The mean RMSEPs and their standard deviations for T_{ann} are $1.98 \pm 0.52^\circ\text{C}$ (MAT), $2.61 \pm 0.53^\circ\text{C}$ (WA-
307 PLS) and $2.24 \pm 0.61^\circ\text{C}$ (WA-PLS_tailored) and mean RMSEPs as a percentage of modern T_{ann} range
308 are $7.68 \pm 1.93\%$ (MAT), $10.09 \pm 2.05\%$ (WA-PLS) and $10.26 \pm 2.79\%$ (WA-PLS_tailored). The largest
309 mean RMSEP values are located in Central Asia in Kazakhstan, Mongolia and the north-western parts
310 of the Tibetan Plateau and are consistent across all three reconstruction methods. Other areas with
311 large mean RMSEP values are located in Western North America, Southern and Central Europe and
312 south-east Asia. The smallest RMSEPs can be found along the east coast of North America. Relative
313 to the modern temperature range, the RMSEP from this region also reveals the lowest fraction. In
314 general, MAT has the lowest mean error fraction relative to the modern temperature range of all three
315 methods.

316 The mean RMSEPs of T_{July} are $1.90 \pm 0.63^\circ\text{C}$ (MAT), $2.50 \pm 0.73^\circ\text{C}$ (WA-PLS) and $2.21 \pm 0.75^\circ\text{C}$ (WA-
317 PLS_tailored) and mean percentages of T_{July} range are $8.11 \pm 1.64\%$ (MAT), $10.71 \pm 1.94\%$ (WA-PLS)
318 and $10.70 \pm 2.60\%$ (WA-PLS_tailored). Thus, they are slightly smaller than those of T_{ann} but slightly larger
319 as a percentage of the range. The spatial patterns, however, are largely similar to those of T_{ann} .

320 The mean RMSEPs of P_{ann} are 176.38 ± 51.40 mm (MAT), 244.48 ± 75.84 mm (WA-PLS) and
321 232.71 ± 98.57 mm (WA-PLS_tailored) and mean percentages of P_{ann} range are $6.78 \pm 1.48\%$ (MAT),
322 $9.27 \pm 1.70\%$ (WA-PLS) and $10.26 \pm 2.67\%$ (WA-PLS_tailored). High RMSEPs are found for Western
323 North America, Europe and along the coastline of south-east Asia, while the lowest RMSEP values are
324 found for Central Asia. A clear division in RMSEPs are found on the North American continent: while
325 the western part of North America (with the exception of Alaska) has a rather high RMSEP, the eastern
326 part of North America has a smaller RMSEP. This pattern is found for all three methods (Fig. 5).

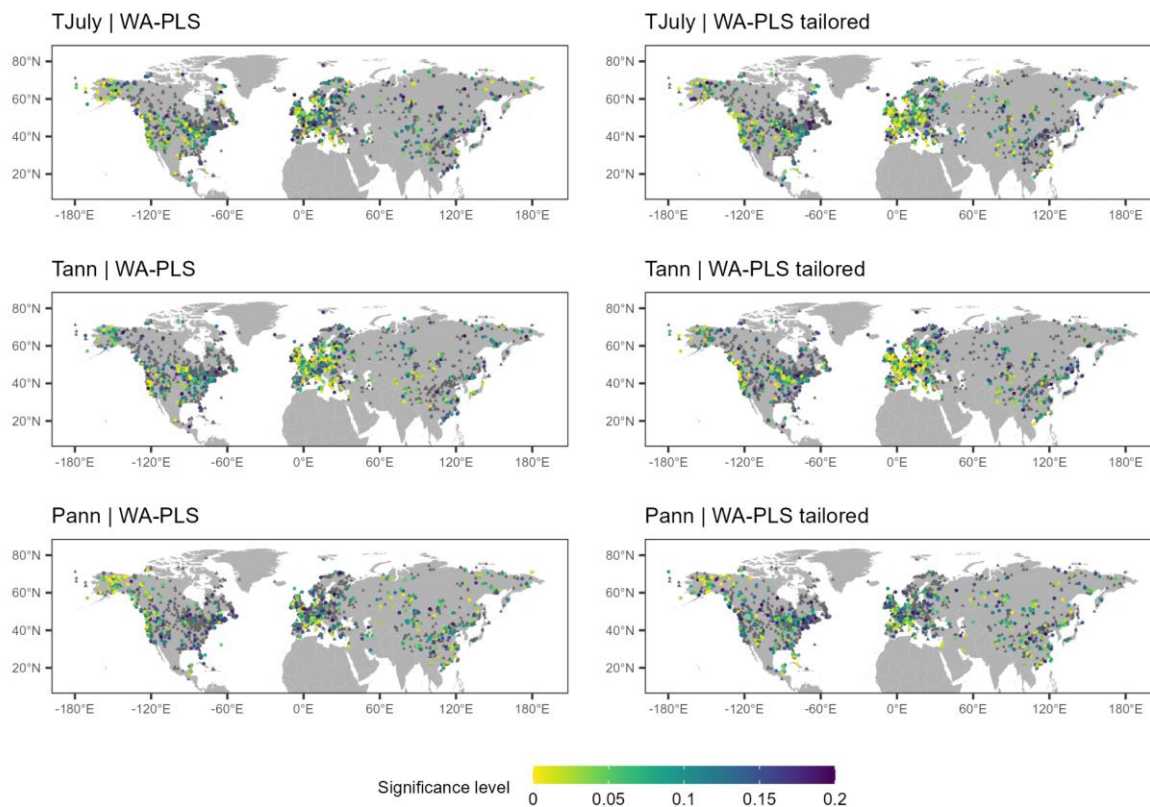

328 **Figure 5.** Spatial distribution of root-mean-squared error of prediction (RMSEP) as inferred from leave-
329 one-out cross-validation presented as absolute values and as a percentage of the range of mean July
330 temperature (T_{July}), mean annual temperature (T_{ann}), annual precipitation (P_{ann}) in the modern pollen
331 data used for reconstruction for the three methods applied (Weighted-Averaging Partial-Least Squares
332 regression (WA-PLS), WA-PLS using a training set from within a limited climate range (WA-
333 PLS_tailored) and Modern Analogue Technique (MAT)).

334

335 **4.5 Significance test**

336 A significance test ($p < 0.1$ and in addition $p < 0.2$, see methods) according to Telford and Birks (2011)
337 was performed for each record (Fig. 6; Table 2). For the T_{July} reconstruction, 16.4% [$p < 0.2$: 27.2%] (WA-
338 PLS) and 19.0% [$p < 0.2$: 29.1%] (WA-PLS_tailored) of all records passed the significance test when
339 included as a single variable in the significance test. Partialling out precipitation as a conditional variable
340 causes an increase in the amount of significant records to 19.0% [$p < 0.2$: 30.6%] for WA-PLS of T_{July} ,
341 but a decrease for WA-PLS_tailored to 16.7% [$p < 0.2$: 27.6%] of all records. The T_{ann} reconstruction is
342 significant for 16.5% [$p < 0.2$: 27.1%] (WA-PLS) and 20.0% [$p < 0.2$: 31.6%] (WA-PLS_tailored) of all
343 records when tested as a single variable. When partialling out precipitation, the amount of significant
344 records slightly increases for WA-PLS, but decreases for WA-PLS_tailored. 13.0% [$p < 0.2$: 21.8%] (WA-
345 PLS) and 14.3% [$p < 0.2$: 25.4%] (WA-PLS_tailored) of all records pass the significance test when testing
346 P_{ann} as a single variable. Partialling out the mean July temperature as a conditional variable increases
347 the number of significant records for both WA-PLS and WA-PLS_tailored.

348

349 **Figure 6.** Maps showing mean July temperature (T_{July}), mean annual temperature (T_{ann}), annual
 350 precipitation (P_{ann}) records that passed the reconstruction significance test ($p < 0.2$). Colors indicate the
 351 significance level. Records that did not pass the significance level ($p \geq 0.2$) are shown as grey
 352 rectangles.

362 **Table 2.** Percentage of records that pass the reconstruction significance test ($p < 0.1$ and $p < 0.2$) sensu
 363 Telford and Birks (2011). The values in brackets for $p < 0.1$ indicate the significance values without taking
 364 spatial autocorrelation into account.

	WA-PLS		WA-PLS_tailored		MAT	
	$p < 0.1$	$p < 0.2$	$p < 0.1$	$p < 0.2$	$p < 0.1$	$p < 0.2$
T_{July}	16.4%	27.2%	19.0%	29.1%	44.1%	56.8%
	(30.9%)		(35.2%)		(42.4%)	
T_{July} partialling out P_{ann}	19.0%	30.6%	16.7%	27.6%	48.7%	61.4%
	(35.5%)		(33.6%)		(39.9%)	
T_{ann}	16.5%	27.1%	20.0%	31.6%	46.5%	57.7%
	(32.8%)		(36.1%)		(42.4%)	
T_{ann} partialling out P_{ann}	16.7%	27.1%	18.4%	28.8%	48.1%	61.9%
	(32.6%)		(34.1%)		(39.2%)	
P_{ann}	13.0%	21.8%	14.3%	25.4%	36.5%	51.1%
	(32.1%)		(33.4%)		(36.3%)	
P_{ann} partialling out T_{July}	14.5%	24.1%	16.5%	28.2%	39.4%	53.7%
	(34.2%)		(36.5%)		(34.5%)	

365

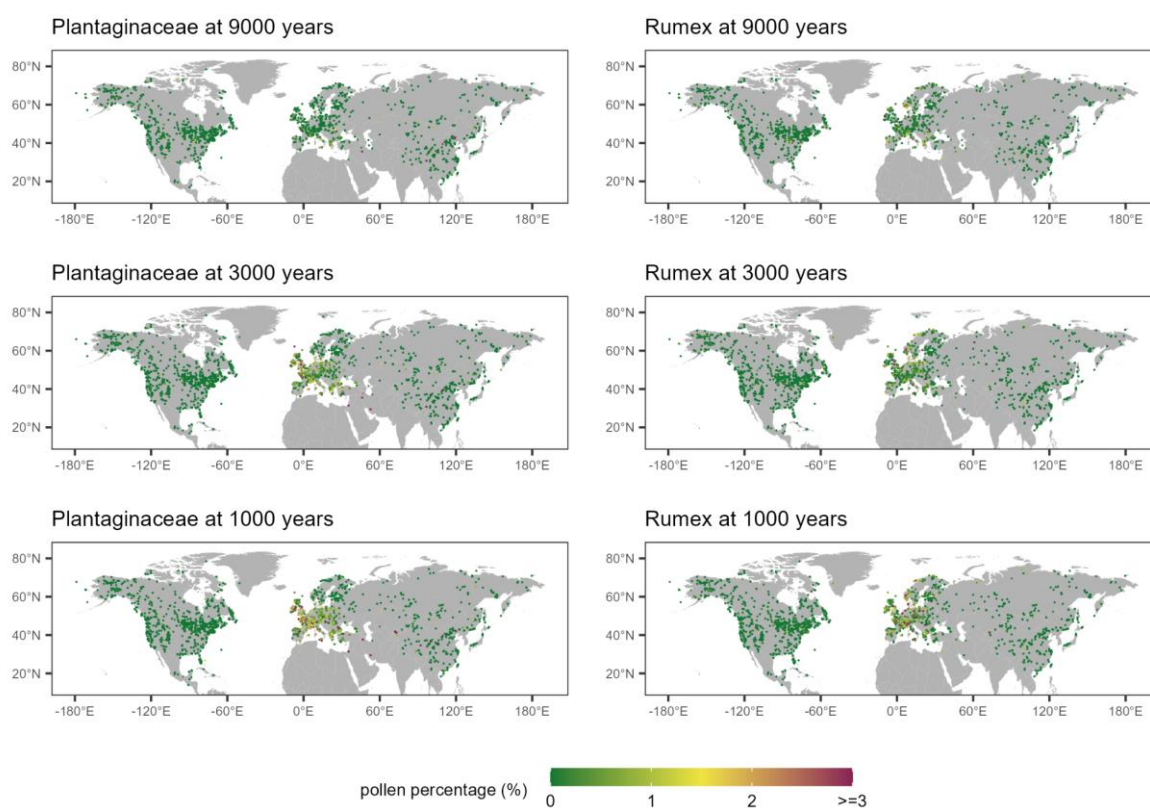

366

367

368 **4.6 Human impact**

369 We used the abundance of Plantaginaceae and *Rumex* as indicators of grazing and such intense animal
 370 husbandry. Overall weak human impact is inferred for North America and Northern Asia. The indicators
 371 show strong human impact only in individual records at 9000 years BP in China and the Mediterranean
 372 region (Fig. 7). The percentage values of Plantaginaceae and *Rumex* were high especially in Europe
 373 for 3000 years and 1000 years BP which indicates growing human impact on that region. High
 374 Plantaginaceae correlate with low T_{July} and high P_{ann} in Central Europe indicating potential biases in the
 375 temperature reconstructions i.e. too low temperatures become reconstructed. Similar correlations are
 376 found for *Rumex*, especially in Northern Europe (Fig. 8).

377

378

379 **Figure 7.** Abundance of Plantaginaceae (left) and *Rumex* (right) at 9000, 3000 and 1000 years BP.

380 Colors indicate percentage values.

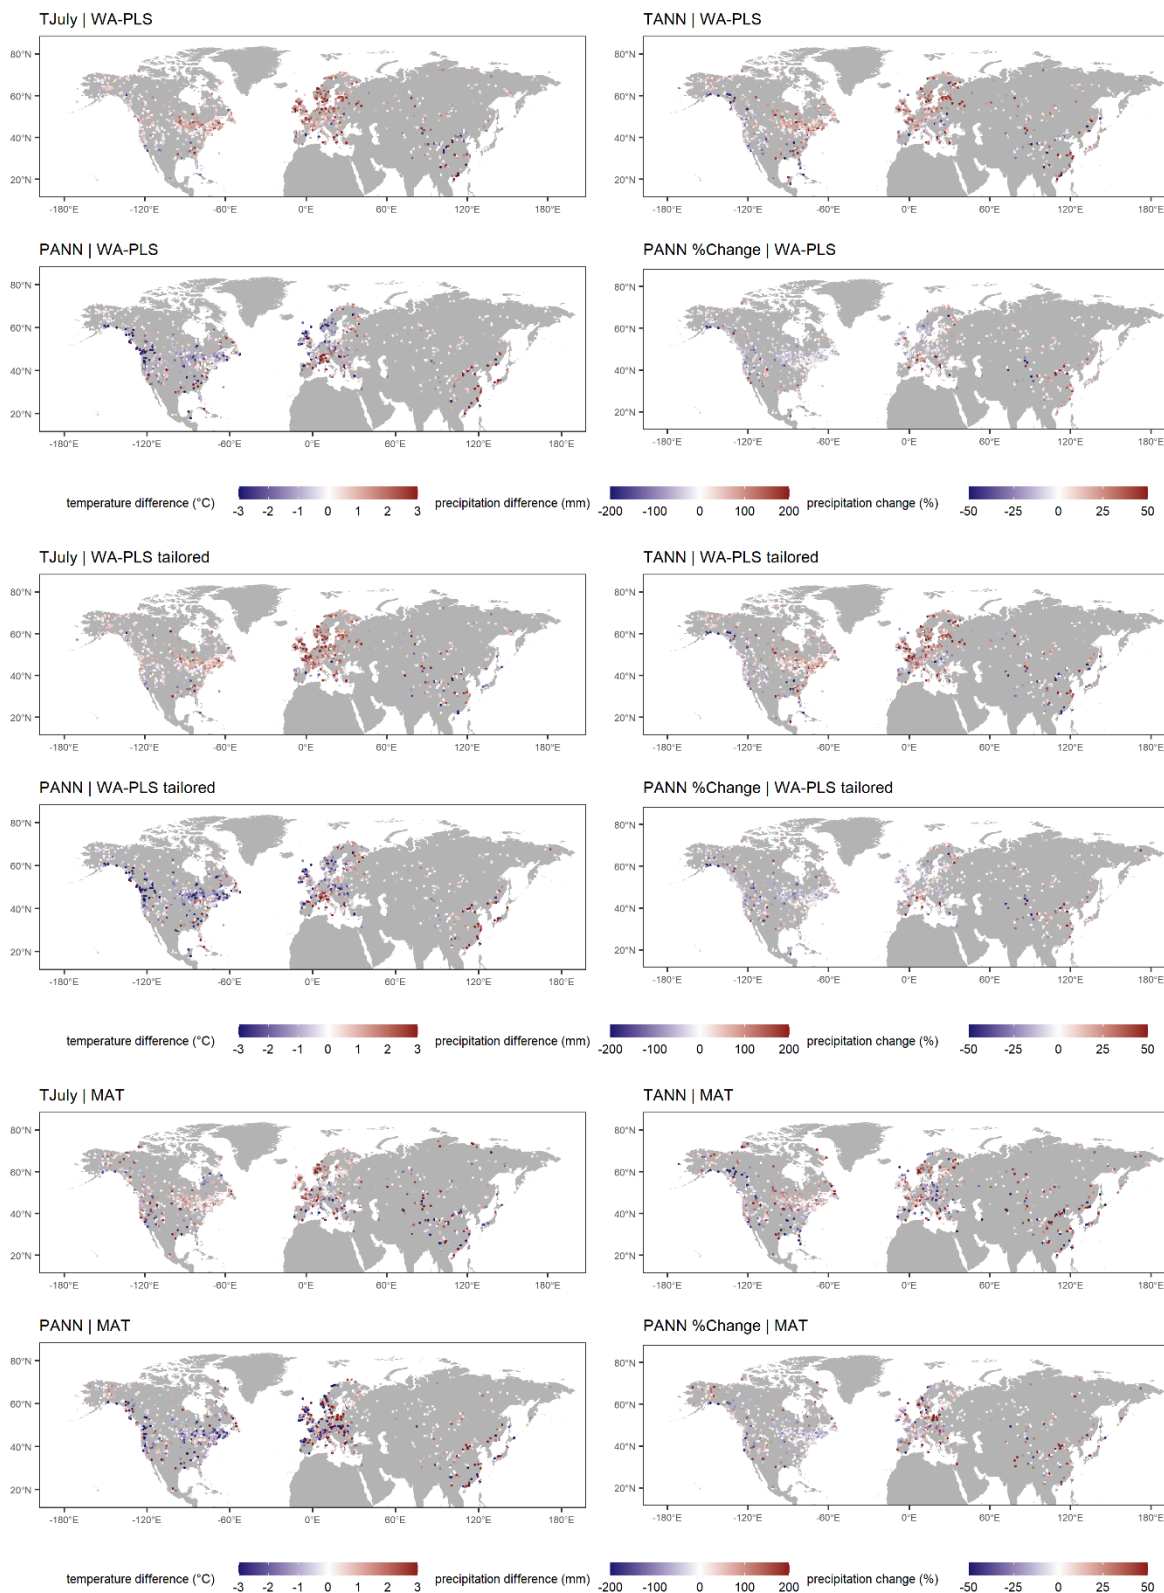

381
 382 **Figure 8.** Correlation between the percentage of Plantaginaceae (left) and *Rumex* (right) and
 383 reconstructed T_{July} , T_{ann} and P_{ann} with WA-PLS.

384

385 **4.7 Assessment of major temporal patterns of LegacyClimate 1.0**

386 To illustrate the difference between Mid- and Late Holocene climate, we calculated the value for the
 387 three climate variables at 6 ka BP and 1 ka BP, each time taking the average of the interpolated values
 388 at those ages for the ensemble of 1000 realizations of the age-depth models (Li et al., 2022). Differences
 389 between these time-slices reveal warmer and drier conditions during the Mid-Holocene compared with
 390 Late Holocene conditions, especially in Eastern North America, but also in Central and Northern Europe.
 391 The overall patterns are in good agreement for all three methods but show differences on a regional
 392 scale, especially when comparing the reconstructions with WA-PLS and MAT. For T_{July} , the
 393 reconstruction with MAT shows greater temperature differences in Western North America and south-
 394 east Asia. Compared to the reconstruction with WA-PLS, there is a reduced cooling from 6 ka to 1 ka in
 395 Eastern Europe and a warming instead of a cooling in the Western Mediterranean region and along the
 396 south-eastern Asian coastline in MAT. For large areas in North America and Europe, the reconstructions
 397 with WA-PLS suggest an increase in precipitation from 6 to 1 ka BP. A shift to drier conditions can be

398 found along the south-eastern coastline in North America, in the Mediterranean Region and especially
399 in south-east Asia. The reconstruction with MAT reveals a gradient from increasing precipitation in
400 south-western Europe to decreasing precipitation in north-eastern Europe. In contrast to the
401 reconstructions with WA-PLS, records along the south-eastern Asian coastline suggest an increase in
402 precipitation with MAT rather than a decrease (Fig. 9).

403

404 **Figure 9.** Difference from 6 ka to 1 ka for mean July temperature (T_{July}), mean annual temperature (T_{ann}),
 405 annual precipitation (P_{ann}) and $P_{ann}\%$ as reconstructed from WA-PLS (upper panel), WA-PLS_tailored
 406 (middle panel) and MAT (lower panel).

407 Time-series of absolute T_{ann} reconstructions reveal temporal as well as latitudinal spatial variation on
 408 the single continents. Eastern North America and Asia show the most variation in the low latitudes. It is
 409 also Eastern North America which shows the most pronounced latitudinal gradient. In Western North
 410 America, the most variation takes place in the high latitudes, while the variation is concentrated to the
 411 mid-latitudes in Europe. Especially in North America, the warming since the last deglaciation and the
 412 beginning of the Holocene is well shown in the temporal variation of the time-series (Fig. 10).

413

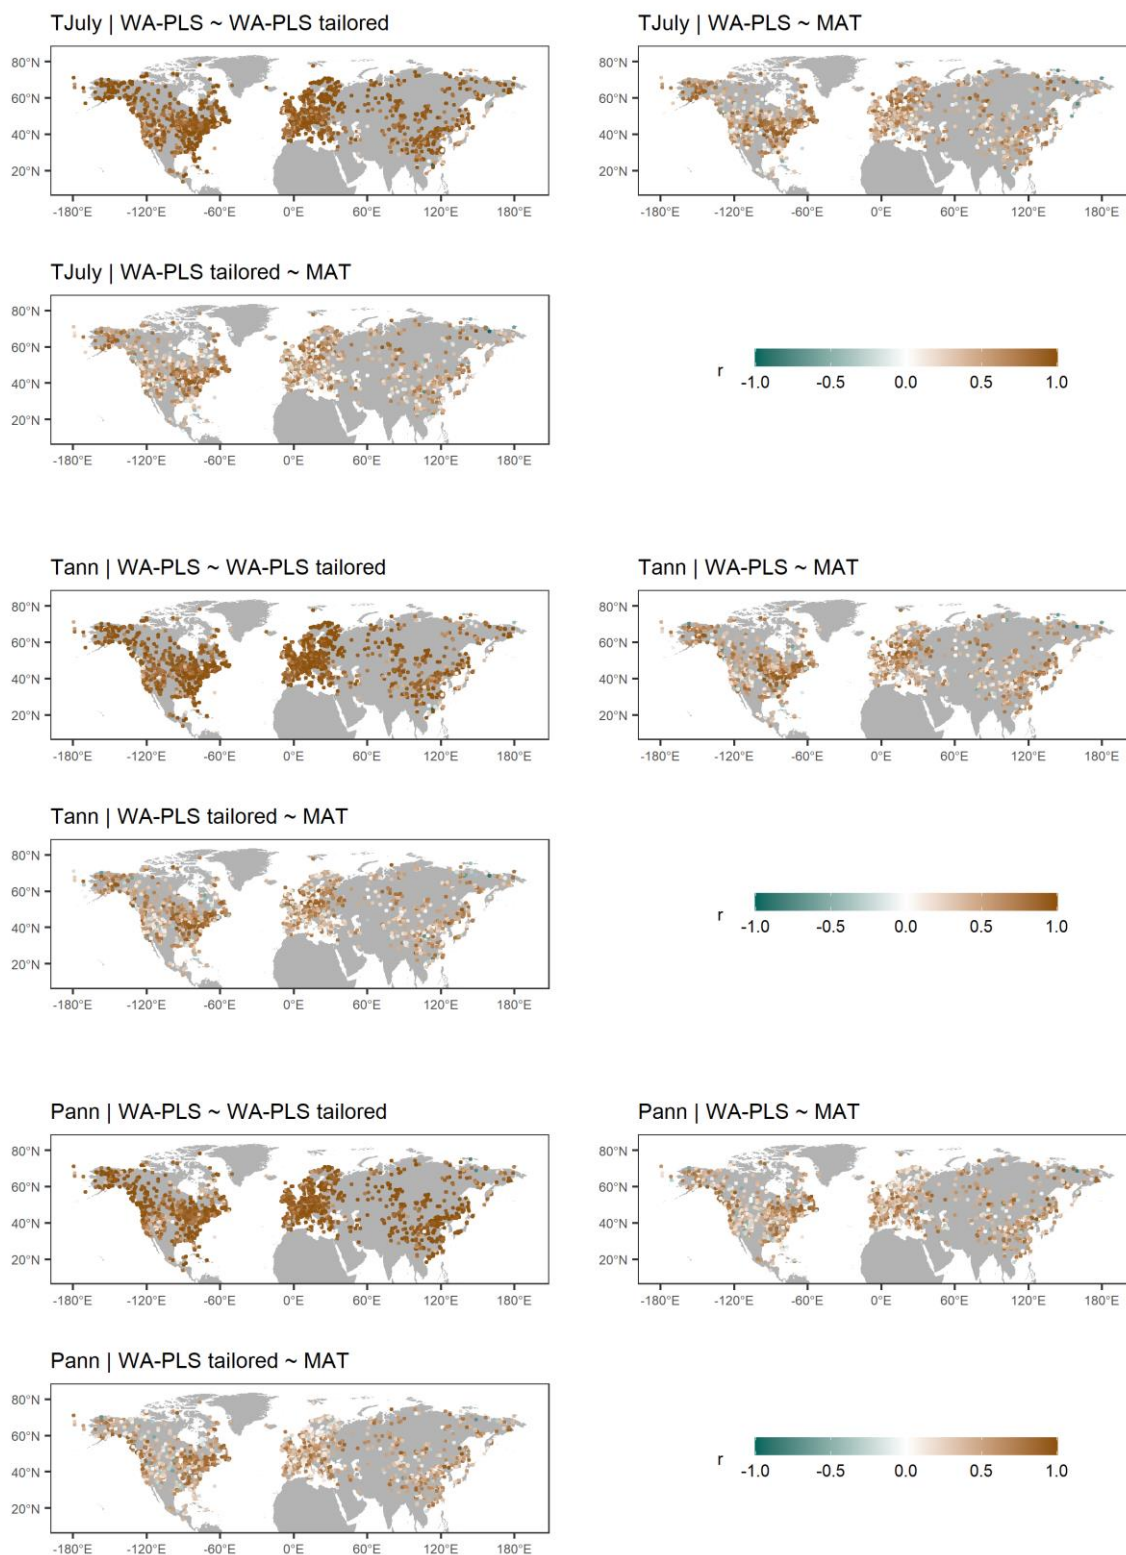

414

415 **Figure 10.** Time-series of absolute mean annual temperature (T_{ann}) reconstruction with WA-PLS for
 416 each (sub-)continent. Colors denote the latitude of record origin. Age and reconstruction uncertainties
 417 are not plotted but are available for each time-series.

418

419 **4.8 Assessment of consistency among reconstruction methods**

420 Reconstructions with MAT are, in general, in good agreement with those derived from the WA-PLS.
 421 Comparing MAT with WA-PLS, 37.3% (T_{July}), 38.9% (T_{ann}) and 30.4% (P_{ann}) of all records have a positive
 422 correlation of $r \geq 0.6$. Strong positive correlations ($r \geq 0.9$) can mainly be identified in Eastern North
 423 America, while weak correlation can be found for large areas in central North America and most of
 424 Europe (Fig. 11).

425

426 **Figure 11.** Correlation between time-series of the 3 different reconstruction methods used - weighted-
 427 averaging partial least squares using a global training set (WA-PLS), WA-PLS using a training set with
 428 a limited modern climate range (WA-PLS_tailored) and the modern analogue technique (MAT) for the

429 three climate variables of mean July temperature (T_{July}), mean annual temperature (T_{ann}) and annual
 430 precipitation (P_{ann}).

431

432 WA-PLS_tailored used a reduced modern training dataset (illustrated for an example in Appendix Fig.
 433 2). The tailoring successfully reduced the co-variation of temperature and precipitation in the modern
 434 dataset as indicated by the distribution of the correlation coefficient in Fig. 12. Nevertheless, the obtained
 435 reconstructions are largely consistent between WA-PLS and WA-PLS-tailored: a correlation of $r \geq 0.9$
 436 is found for 59.2% of all records for T_{July} , 60.7% for T_{ann} and 56.5% for P_{ann} .

437

438 **Figure 12.** Violin plot of the correlation coefficients between T_{July} and P_{ann} in the 15379 training datasets
 439 used for the reconstructions. Left: used for WA-PLS reconstructions; middle: WA-PLS T_{July} -tailored
 440 (used for the reconstruction of P_{ann}); WA-PLS P_{ann} -tailored (used for the reconstruction of T_{July}).

441

442 5 Discussion

443 5.1 Impact of the fossil pollen data source on LegacyClimate 1.0 quality

444 LegacyClimate 1.0 contains reconstructions of climate variables from fossil pollen data derived from
 445 open-access data repositories. The fossil records were derived from multiple natural archives, most
 446 commonly, assemblages from continuous lacustrine and peat accumulations (Herzschuh et al., 2022c).

447 Different sizes of lakes and peat areas result in varying sizes of pollen source areas and thus the spatial
448 representativeness of a record. While small lakes and peatlands are considered to provide information
449 about the (extra-)local scale, the regional signal is better represented in pollen assemblages from large
450 lakes (Jackson, 1990; Sugita, 1993). However, taphonomic changes of the records originating, for
451 example, from lake level changes may impact the reconstructed climate. Pollen from azonal riverine
452 vegetation might be over-represented in fluvially impacted pollen records.

453 Our dataset is based on taxonomically harmonized modern and fossil pollen datasets using a restricted
454 number of taxa. Such an approach guarantees that all records are handled consistently. Although losing
455 taxonomic information when merging taxa together into a higher taxonomic level, it also increases the
456 possibility of matching climate analogues in the modern and the fossil datasets. However, one needs to
457 keep in mind that species with different ecological requirements may be merged together into one genus
458 or family, for example, *Pinus* species that are restricted to tropical or subtropical areas in China or ones
459 that grow in boreal forests (Cao et al., 2013; Tian et al., 2017).

460 Along with the pollen assemblages, data repositories also provide chronological information for fossil
461 records. The quality of such chronologies varies strongly with respect to dating methods, calibration and
462 numerical algorithms for determining an age-depth relationship (Blois et al., 2011; Trachsel and Telford,
463 2017). Having accurate and precise chronologies is thus of pivotal importance for reconstructing past
464 climate in order to identify temporo-spatial patterns and therefore in helping to evaluate climate model
465 outputs. The advantage of the fossil pollen dataset used for the reconstruction presented here (i.e.,
466 LegacyPollen 1.0; Herzschuh et al., 2022c) is that it has harmonized chronologies (LegacyAge 1.0)
467 along with information about uncertainties as well as related metadata and scripts that allow a
468 customized re-establishment of the chronologies (Li et al., 2022). Accordingly, we were able to provide
469 sample specific age-uncertainties along with reconstruction uncertainties.

470

471 **5.2 Modern pollen and climate data sources and LegacyClimate 1.0 quality**

472 We a priori selected T_{July} , T_{ann} and P_{ann} as target variables for our reconstructions. However, we provide
473 λ_1/λ_2 (i.e. explained variance of the climate variable in the modern pollen data set relative to the variance
474 explained by the unconstrained first axis; ter Braak, 1988), a commonly used proxy for the assessment
475 of reconstructions. The higher λ_1/λ_2 in the spatial modern dataset the higher the chance that this target

476 climate variable has also impacted vegetation over time and is thus reflected in the variation of the fossil
477 pollen dataset. As a rule of thumb, a ratio of 1 is considered to indicate reliable reconstructions (Juggins,
478 2013) though useful reconstructions may also be obtained from datasets with lower values. As expected,
479 maps of RMSEPs reveal similar spatial pattern as the results of constrained ordination. Our results
480 indicate that in particular calibration sets from Europe have low ratios and a high RMSEP for all climate
481 variables (despite having a high number of modern samples), likely related to the human impact on the
482 modern and fossil data. Some areas that are known for its sensitivity to precipitation e.g. Eastern Asia
483 show low RMSEPs as expected for P_{ann} but on the other hand show a low sensitivity to T_{ann} and T_{July} .

484 For our study we used the, to our knowledge, largest modern dataset ever used in a pollen-based climate
485 reconstruction. For fossil pollen records in areas with an insufficient coverage of modern surface pollen
486 samples (e.g., Central Asia or Western Siberia), it might be difficult to create a calibration dataset that
487 maps the required variety of environmental and climatic gradients and therefore find enough modern
488 analogues for reconstructions with a classification approach such as MAT. This is indicated by the high
489 RMSEPs as percentages of gradient length in these areas. Our routine uses the modern pollen data
490 from within a radius of 2000 km around the site of the fossil record. The information provided in the
491 reconstruction metadata including number of modern pollen samples and ranges of reconstructed
492 variables, allow an assessment of the modern dataset used for reconstruction. Our assessments of the
493 modern dataset (e.g. using CCA), the transfer function (e.g. RMSEP) and the reconstruction (e.g. the
494 significance test) revealed also the potential biases in the pollen-based reconstruction and pointed to
495 limitations. Further validation and assessments of the results and more comprehensive uncertainty
496 analyses e.g. by applying forward modelling approaches (Izumi & Bartlein, 2016; Parnell et al., 2016)
497 would be highly valuable.

498

499 **5.3 Reconstruction method and LegacyClimate 1.0 quality**

500 Overall, the three reconstruction approaches, MAT, WA-PLS and WA-PLS_tailored yield rather similar
501 results i.e. indicated by the overall high correlation between the reconstructions of the different methods
502 (Fig. 11). Accordingly, the major trends at global or continental scales are similar, even if the actual
503 amplitude of change may vary locally. As each method has its own strengths and weaknesses, there is
504 not one set of reconstructions that is absolutely superior. One advantage of our multi-method
505 reconstruction dataset is that users can identify the methods that are likely to perform best in a selected

506 region and/or specific reconstructions. MAT is often recommended for large-scale studies, but it is highly
507 sensitive to the quality of analogues (Chevalier et al. 2020). Low analogue situations can arise from two
508 causes: climate conditions that differ strongly from today (e.g., the low atmospheric CO₂ concentration
509 during the LGM; Jackson and Williams, 2004), or in regions with limited modern samples (e.g.,
510 extratropical Asia). Furthermore, growing human influence on the landscape since the Middle to Late
511 Holocene especially in densely settled regions in Europe contributed to gaps within the potential
512 bioclimatic space of taxa and probably also led to extinction events, especially for disturbance-
513 dependent taxa (Zanon et al., 2018). We report the analogue distance for each sample to help identify
514 such situations. From our assessments, we revealed that analogues quality is overall rather good at
515 least for the Holocene and except for Western Europe in particularly the British Isles (Fig. 4).

516 In contrast to MAT, WA-PLS (and most regression techniques in general) model relationships between
517 pollen and climate and are, as such, less sensitive to the low analogue situations (Birks et al., 2010).
518 They are, however, based on some modelling assumptions, such as the unimodality of the response of
519 the pollen taxa to climate (ter Braak and Juggins 1993). This condition is not always met at the
520 continental scale, primarily because of the limited taxonomic resolution of pollen data that merges
521 several plant species with distinct climate requirements as one single pollen taxon. WA-PLS_tailored
522 has the same limitation but it has the advantage of reducing the influence of the correlation between
523 variables when reconstructing, for instance, temperature and precipitation. This may be particularly
524 relevant for regions with a temperature-moisture driven circulation system such as the East Asian
525 Summer Monsoon (EASM) that can heavily affect precipitation patterns in certain regions (Herzschuh
526 et al., 2019). Using WA-PLS_tailored also increases the number of records that pass a significance level
527 of $p < 0.1$ (Telford and Birks, 2011). Providing several reconstructions based on different assumptions
528 also allow exploring, even if only partially, the uncertainties associated with the modelling assumptions
529 (e.g., MAT vs WA-PLS, the number of analogues, type metric used to compare pollen samples).

530 The significance tests sensu Telford and Birks (2011) revealed a rather low percentage of
531 reconstructions to be substantial ($p < 0.1$). However, a failed significance test does not necessarily mean
532 that the reconstruction is not reliable, but the results should be treated more cautiously, as the Telford-
533 Birks test is rather conservative (Luoto et al., 2014; Hébert et al., 2022). Several reasons of possible
534 false negative errors are reported and discussed in the literature, including the test being supposed to
535 be sensitive to the size of the training data, a low magnitude of an input climate signal, the trajectory of

536 the core samples through calibration space, or poor analog situations (Luoto et al., 2014; Self et al.,
537 2015; Andr en et al., 2015, H ebert et al., 2022).

538 All reconstruction methods used in this study heavily rely on extensive collections of modern
539 assemblage data covering diverse climatic and environmental gradients and are applicable on a broad
540 spatial scale. As discussed, all the methods may struggle with some intrinsic characteristics of pollen
541 data and of pollen compilations, including complex species responses, sensitivity to spatial
542 autocorrelation, limited analogues that may produce poor results in so-called “quantification deserts”
543 (Chevalier, 2019), where fossil pollen is hardly preserved or nearby modern surface pollen samples are
544 missing (Chevalier et al., 2020). However, we designed our datasets so that more methods can be
545 included in our reconstruction scripts (<https://doi.org/10.5281/zenodo.5910989>; Herzs Schuh et al.,
546 2022b), such as CREST, an approach that combines presence-only occurrence data from species
547 distribution databases instead of modern pollen samples to estimate the responses of pollen taxa to the
548 climate variable to reconstruct to a climate variable (Chevalier et al., 2014; Chevalier, 2022). CREST is,
549 therefore, more independent from the availability of modern pollen samples. Employing the Inverse-
550 Modelling through iterative forward modeling (IMIFM) (Izumi and Bartlein, 2016) might also be possible
551 in such regions. Its use would be particularly interesting to reconstruct the LGM samples, because
552 IMIFM is the only technique that can explicitly take the effect of CO₂ on plants (Chevalier et al., 2020).
553 The inclusion of CREST and/or IMIFM in such large-scale studies would complement our multi-model
554 reconstruction ensemble by exploring a larger fraction of the “method uncertainty” space in greater
555 details (e.g. Brewer et al, 2008). Kucera et al. (2005) propose several metrics for a multi-technique
556 approach to assess the uncertainty space: correlations between the residuals (observed minus
557 reconstructed values) between pairs of techniques are used to investigate the similarity in the
558 reconstructions among different techniques. The correlation between the residuals in seasonal
559 reconstructions (e.g. summer and winter temperatures, summer and annual temperatures) can be used
560 to investigate the degree of independence of different seasonal reconstructions. Error rate estimates
561 (RMSEP) determined by cross validation of the calibration data sets and the leaving-one-out method
562 can be used to compare the calibration of individual transfer function techniques, though it should be
563 considered that error estimates may vary with the choice of the cross-validation procedure (Kucera et
564 al., 2005).

565

566 **5.4 Potential use of LegacyClimate 1.0**

567 Our LegacyPollen 1.0 fossil pollen synthesis (Herzschuh et al., 2022c) contains records from all over
568 the Northern Hemisphere extratropics. We used this synthesis to produce our LegacyClimate 1.0
569 reconstruction data set, which thus can be used to infer spatio-temporal patterns in climate
570 reconstructions that are not only limited to a local or regional scale. Although several hemispheric or
571 global reconstruction studies exist, they have been largely restricted to temperature or have included
572 relatively few records (Marcott et al., 2013; Marsicek et al., 2018; Routson et al., 2019; Kaufman et al.,
573 2020a and 2020b). Our dataset is therefore a valuable addition. It may be used in a multi-proxy
574 approach, synthesizing marine and terrestrial records in order to assess temperature development
575 during the Holocene and can help to highlight possible interdependencies between oceans and land
576 masses. Globally or hemispherically averaged temperature reconstructions from proxy data indicate
577 peak temperatures during the Holocene Thermal Maximum around 6000 years BP followed by a
578 pronounced cooling trend toward the late Holocene, which is also visible in our pollen-based
579 reconstructions (Fig. 10). Hence, spatial variability in the Holocene temperature trends (e.g. missing of
580 a pronounced maximum for certain latitudinal bands; delayed thermal maximum on land compared to
581 the ocean) indicate a more local rather than a global Holocene Thermal Maximum (Kaufman et al.,
582 2020b; Osman et al., 2021; Cartapanis et al., 2022). In contrast, climate models simulate a monotonic
583 warming throughout the Holocene, which resulted in the “Holocene conundrum” debate (Liu et al., 2014).
584 The debate has since progressed and hints to discrepancies in data-model comparisons due to
585 spatiotemporal dynamics related to heterogeneous responses to climate forcing and feedbacks (i.e. the
586 timing of a Holocene Thermal Maximum in the Northern Hemisphere extra-tropics between
587 reconstructions from continental and from marine proxy records; Cartapanis et al., 2022) and sometimes
588 poor spatial averaging due to unevenly distributed proxies. Proxy-only reconstructions often rely on
589 latitudinal binning and weighting, which makes this approach particularly sensitive to latitudinal bands
590 that contain only sparse spatial coverage and thus do not represent a true global average (Osman et
591 al., 2021). Those spatiotemporal dynamics should be considered in data-model comparison.

592 Temperature reconstructions often use either mean annual temperatures (Birks, 2019; Bova et al., 2021)
593 or global mean surface temperatures (Marcott et al., 2013; Marsicek et al., 2018; Kaufman et al., 2020a
594 and 2020b). Despite T_{ann} being more commonly used in multi-proxy comparisons, it might be useful to
595 also consider T_{July} , as on a regional scale the mean July temperature (or in general summer temperature)

596 is more important in particular in high latitudes. However, it is argued that proxy-based climate
597 reconstructions are seasonally biased and therefore might be the reason for the observed proxy-model
598 divergence (Liu et al., 2014; Rehfeld et al., 2016; Kaufman et al., 2020b). In this respect, it might help
599 that we provide T_{July} along with T_{ann} reconstructions derived from our tailoring approach, which provides
600 the opportunity to assess seasonal impacts on the reconstruction (especially in the high latitudes) in
601 addition to a consistent reconstruction synthesis.

602 So far, reconstructions of precipitation have not been implemented on a hemispheric scale. The
603 interconnection between temperature and precipitation (Trenberth, 2011) and its spatio-temporal
604 variation across the Northern Hemisphere is therefore an important aspect of evaluating climate models
605 (Wu et al., 2013; Hao et al., 2019; Herzschuh et al., 2022a). A broad-scale quantitative reconstruction
606 of temperature and precipitation would therefore be of great value for evaluating transient climate model
607 experiments such as TraCE 21k (He, 2010).

608

609 **6 Data and code availability**

610 The compilation of reconstructed T_{July} , T_{ann} , and P_{ann} , is open access and available at PANGAEA
611 (<https://doi.pangaea.de/10.1594/PANGAEA.930512>; in the “*Other version*” section; Herzschuh et al.,
612 2021). The dataset files are stored in machine-readable data format (.CSV), which are already separated
613 into Western North America, Eastern North America, Europe, and Asia for easy access and use.

614 The R code to run the reconstructions for single sites is available at Zenodo
615 (<https://doi.org/10.5281/zenodo.5910989>; Herzschuh et al., 2022b) including harmonized open-access
616 modern and fossil pollen datasets so that customized reconstructions can be easily established.

617

618 **Author contributions.** UH designed the study design and reconstruction dataset. CL and TB compiled
619 the metadata and the harmonized pollen dataset. TB wrote the R scripts and ran the analyses under the
620 supervision of UH. UH, TB and MC wrote the first draft of the manuscript. All authors discussed the
621 results and contributed to the final manuscript.

622 **Competing interests.** The contact author has declared that none of the authors has any competing
623 interests.

624 **Acknowledgements.** We would like to express our gratitude to all the palynologists and geologists who,
625 either directly or indirectly by providing their work the Neotoma Paleocology Database, contributed
626 pollen data and chronologies to the dataset. The work of data contributors, data stewards, and the
627 Neotoma community is gratefully acknowledged. We thank Andrej Andreev, Mareike Wieczorek, and
628 Birgit Heim from AWI for providing information on pollen records and data uploads. We also thank Cathy
629 Jenks for language editing on a previous version of the paper.

630 **Financial support.** This research has been supported by the European Research Council (ERC Glacial
631 Legacy 772852 to UH) and the PalMod Initiative (01LP1510C to UH). TB and MC are supported by the
632 German Federal Ministry of Education and Research (BMBF) as a Research for Sustainability initiative
633 (FONA; <https://www.fona.de/en>) through the PalMod Phase II project (grant no. FKZ: 01LP1926D). CL
634 holds a scholarship from the Chinese Scholarship Council (grant no. 201908130165). NR work was
635 supported by the Russian Science Foundation (Grant No. 20-17-00110).

921 **Appendix Figures**

922

923 **Appendix Figure 1.** Reconstruction error (shaded blue) and the chronological error (shaded red) around
924 the reconstruction smoothed by the time-uncertainty (i.e. when we interpolate at regular timesteps for
925 the 1000 realizations and average over the ensemble, dashed white). The original reconstruction with
926 the median ages is also shown for comparison (solid white); this underlines that averaging over the age
927 models only preserves the low-frequencies but (unrealistically) smooths out the high-frequencies.

928

929 **Appendix Figure 2.** Example to illustrate the effect of tailoring the modern dataset for the location
 930 “Yellow Dog Pond” in Eastern North America. Upper part: reconstruction of T_{July} and P_{ann} with WA-PLS
 931 (red) and WA-PLS_tailored (blue); lower part: correlation of T_{July} and P_{ann} in the modern dataset and the
 932 effect of tailoring the modern dataset (indicated with the red box). Correlations are given for non-tailored
 933 (red) and tailored (blue) data.
