## 35 **Abstract**

36 Quantification of large-scale leaf age-dependent leaf area index has been lacking  
37 in tropical and subtropical evergreen broadleaved forests (TEFs) despite the recognized  
38 importance of leaf age in influencing leaf photosynthetic capacity in this biome. Here,  
39 we simplified the canopy leaves of TEFs into three age cohorts (i.e., young, mature and  
40 old one with different photosynthesis capacities ( $V_{c,max}$ )) and proposed a novel  
41 neighbor-based approach to develop the first gridded dataset of monthly leaf age-  
42 dependent LAI product (**referred to as Lad-LAI**) at 0.25-degree spatial resolution over  
43 the continental scale during 2001-2018 from satellite observations of sun-induced  
44 chlorophyll fluorescence (SIF) that was reconstructed from MODIS and TROPOMI  
45 (the TROPOspheric Monitoring Instrument). The new Lad-LAI products show good  
46 performance in capturing the seasonality of three LAI cohorts, i.e., young ( $LAI_{young}$ )  
47 (the Pearson correlation coefficient,  $R=0.36$ ), mature ( $LAI_{mature}$ ) ( $R=0.77$ ) and old  
48 ( $LAI_{old}$ ) ( $R=0.59$ ) leaves at eight camera-based observation sites (four in south America,  
49 three in subtropical Asia and one in Congo) and can also represent their interannual  
50 dynamics, validated only at the Barro Colorado site with  $R$  being equal to 0.54, 0.64 and  
51 0.49 for  $LAI_{young}$ ,  $LAI_{mature}$  and  $LAI_{old}$ , respectively. Additionally, the abrupt drops in  
52  $LAI_{old}$  are mostly consistent with the seasonal litterfall peaks at 53 *in situ* measurements  
53 across the whole tropical region ( $R=0.82$ ). The LAI seasonality of young and mature  
54 leaves also agrees well with the seasonal dynamics of Enhanced Vegetation Index (EVI)  
55 ( $R=0.61$ ), a proxy of photosynthetically effective leaves. Spatially, the gridded Lad-  
56 LAI data capture a dry-season green-up of canopy leaves across the wet Amazonia areas

57 where mean annual precipitation exceeds 2,000 mm yr<sup>-1</sup>, consistent with previous  
58 satellite-based analyses. The spatial patterns clustered from the three LAI cohorts also  
59 coincide with those clustered from climatic variables over the whole TEF region.  
60 Herein, we provide the average seasonality of three LAI cohorts as the main dataset,  
61 and their time-series as a supplementary dataset. These Lad-LAI products are available  
62 at <https://doi.org/10.6084/m9.figshare.21700955.v4> (Yang et al., 2022).

63

## 64 **1. Introduction**

65 Tropical and subtropical evergreen broadleaved forests (TEFs) account for  
66 approximately 34% of global terrestrial primary productivity (GPP) (Beer et al., 2010)  
67 and 40-50% of the world's gross forest carbon sink (Pan et al., 2011; Saatchi et al.,  
68 2011). Despite a perennial canopy, TEFs shed and rejuvenate their leaves continuously  
69 throughout the year, leading to significant seasonality in canopy leaf demography (Wu  
70 et al., 2016; Chen et al., 2021). This phenological change in leaf demography is the  
71 primary cause of GPP seasonality in TEFs (Saleska et al., 2003; Sayer et al., 2011; Leff  
72 et al., 2012) and thus largely regulates their seasonal carbon sinks (Beer et al., 2010;  
73 Aragao et al., 2014; Saatchi et al., 2011).

74 A key plant trait linking canopy phenology with GPP seasonality was shown to be  
75 leaf age (Wu et al., 2017; Xu et al., 2017). At leaf scale, the newly-flushed young leaves  
76 and maturing leaves show higher maximum carboxylation rates ( $V_{c,max}$ ) than the old  
77 leaves being replaced (De Weirtdt et al., 2012; Chen et al., 2020). Such age-dependent  
78 variations in  $V_{c,max}$  are associated with changes in leaf nutritional contents (nitrogen,  
79 phosphorus and potassium, etc.) and stomatal conductance over time (Menezes et al.,  
80 2021). Xu et al. (2017) and Menezes et al. (2021) monitored *in situ* leaf age and leaf  
81 demography combined with leaf-level  $V_{c,max}$  in Amazonian TEFs and found that  $V_{c,max}$   
82 of newly-flushed leaves increases rapidly with leaf longevity, peaks at approximately  
83 2-month old, and then declines gradually as leaf grows older (leaf age > 2 months). At  
84 canopy scale, it was hypothesized that leaf demography and seasonal differences in leaf

85 age compositions of tree canopies control the GPP seasonality in TEFs (Wu et al., 2016;  
86 Albert et al., 2018). A similar mechanism was also observed from the ground-based  
87 LiDAR signals which showed an increasing trend in upper canopy leaf area index (LAI)  
88 during the dry season, whereas a decrease in lower canopy LAI (more old leaves)  
89 (Smith et al., 2019). Wu et al. (2016) classified canopy leaves of Amazonian TEFs into  
90 three leaf age cohorts (young: 1-2 months, mature: 3-5 months and old:  $\geq 6$  months).  
91 LAI of young and mature leaves increased during the dry seasons and consequently  
92 promoted dry-season canopy photosynthesis. Based on above age-dependent  $V_{c,max}$  at  
93 leaf scale (Xu et al., 2017) and LAI seasonality of different leaf age cohorts at canopy  
94 scale (Wu et al., 2016), Chen et al. (2020; 2021) developed a climate-triggered leaf  
95 litterfall and flushing model and successfully represented the seasonality of canopy leaf  
96 demography and GPP at four Amazonian TEF sites. Overall, leaf age-dependent LAI  
97 seasonality is one of the vital biotic factors in influencing the GPP seasonality in TEFs  
98 (Wu et al., 2016; Chen et al., 2020).

99 Although the leaf age-dependent LAI seasonality can be well documented at site  
100 level using phenology cameras (Wu et al., 2016), it is still rarely studied and remains  
101 unclear at the continental scale. The key causation is that leaf flushing and litterfall of  
102 TEFs in different climatic regions experience different seasonal constraints of water  
103 and light availability during recurrent dry and wet seasons (Brando et al., 2010; Chen  
104 et al., 2020; Davidson et al., 2012; Xiao et al., 2005). Thus, the seasonal patterns of LAI  
105 in different leaf age cohorts become very complex at the continental scale (Chen et al.,  
106 2020; Xu et al., 2015). Satellite-based remote sensing (Saatchi et al., 2011, Guan et al.,  
107 2015) and land surface model (LSM) technologies (De Weirdt et al., 2012; Chen et al.,  
108 2020; 2021) are two commonly used approaches for detecting the spatial heterogeneity  
109 of plant phenology at a large scale. However, for satellite-based studies, most optical  
110 signals are saturated in TEFs due to the dense covered canopies and thus fail to capture  
111 the seasonality of total LAI in TEFs, much less decomposing the LAI into different leaf  
112 age cohorts. These limitations prevent satellite-based studies from accurately

113 representing the age-dependent LAI seasonality. Moreover, most ESM models also  
114 show poor performances in simulating the LAI seasonality in different leaf age cohorts  
115 (De Weirdt et al., 2012; Chen et al., 2020). This is because the underlying mechanisms  
116 linking seasonal water and light availability with leaf flushing and litterfall seasonality  
117 are currently highly debated and remain elusive at the regional scale (Leff et al., 2012;  
118 Saleska et al., 2003; Sayer et al., 2011). This vague notion imposes a challenge for  
119 accurately modeling continental-scale GPP seasonality in most LSMs (Restrepo-Coupe  
120 et al., 2017; Chen et al., 2021).

121 To fill the research gap, this study aimed to produce a global gridded dataset of leaf  
122 age-dependent LAI seasonality product (Lad-LAI) over the whole TEF biomes from  
123 2001 to 2018. For this purpose, we first simplified that canopy GPP was composed of  
124 three parts that were produced from young, mature and old leaves, respectively. GPP  
125 was then expressed as a function of the sum of the product of each LAI cohort (i.e.,  
126 young, mature and old leaves, denoted as  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$ , respectively)  
127 and corresponding net  $CO_2$  assimilation rate ( $A_n$ , denoted as  $A_{n_{young}}$ ,  $A_{n_{mature}}$ , and  $A_{n_{old}}$   
128 for young, mature and old leaves, respectively) (**Equation 1**). Then, we proposed a  
129 novel neighbor-based approach to derive the values of three LAI cohorts. It was  
130 hypothesized that forests in adjacent four cells in the gridded map exhibited consistent  
131 seasonality in both GPP, and LAI cohorts ( $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$ ). Based on  
132 this assumption, we applied **Equation 1** to each pixel and combined the four equations  
133 of 2\*2 neighboring pixels to derive the three LAI cohorts using a linear least-squares  
134 with constrained method.  $A_n$  was calculated using the Farquhar-von Caemmerer-Berry  
135 (FvCB) leaf photochemistry model (Farquhar et al., 1980); and GPP was linearly  
136 derived from an arguably better proxy—TROPOMI (the TROPospheric Monitoring  
137 Instrument) Solar-Induced Fluorescence (SIF) based on a simple SIF-GPP relationship  
138 established by Chen et al. (2022) (see **Methods** for details). This gridded dataset of  
139 three LAI cohorts provides new insights into tropical and subtropical phenology with  
140 more details of sub-canopy level of leaf seasonality in different leaf age cohorts and

141 will be helpful for developing an accurate tropical phenology model in ESMs.

142

## 143 2. Study area and material

### 144 2.1 Tropical and subtropical evergreen broadleaved forest biomes

145 In this study, we focused on the whole tropical and subtropical evergreen broadleaf  
146 forests (TEFs). The pixels labeled TEFs according to the International Geosphere-  
147 Biosphere Program (IGBP) classification were extracted as the study area based on the  
148 0.05° spatial resolution MODIS land cover map (**Fig. 1**) (MCD12C1, Sulla-Menashe et  
149 al., 2018). The study area contains three regions: South America (30°S–18°N; 40°W–  
150 90°W), the world's largest and most biodiverse tropical rain forest, Congo (10°S–10°N;  
151 10°W–30°E), the western part of the Africa TEF region, and Tropical Asia (20°S–30°N;  
152 70°E–150°E), covering the Indo-China Peninsula, the majority of the Malay  
153 Archipelago and northern Australia.

154

157 pentangles: observed LAI cohorts at eight camera-based observation sites. Black circles:

158 observed litterfall seasonality at 53 observation sites.

159

### 160 2.2 Input datasets for calculating GPP and An parameters

161 The TROPOspheric Monitoring Instrument (TROPOMI) Solar-Induced

162 Fluorescence (SIF) data were used to derive the continent-scale GPP (denoted as

163 RTSIF-derived GPP) according to the SIF-GPP relationship established by Chen et al.

164 (2022) which used 15.343 as a transformation coefficient to covert SIF to GPP. The air

165 temperature data from ERA5-Land (Zhao, Gao et al., 2020), vapor pressure deficits  
166 (VPD) data from ERA-Interim (Yuan et al., 2019) and downward shortwave solar  
167 radiation (SW) from Breathing Earth System Simulator (BESS) (Ryu et al., 2018) were  
168 used to calculate  $K_C$ ,  $K_O$ ,  $\Gamma^*$ ,  $R_{dark}$  and  $V_{c,max}$  and thus to calculate  $A_n$  according to  
169 equations in **Table S4**. The calculation processes were illustrated in **Fig. 2**. All datasets  
170 were aggregated at the same spatial ( $0.125^\circ$ ) and temporal resolutions (month) (**Table**  
171 **S3**).

172

### 173 **2.3 Datasets for validating leaf age-dependent LAI seasonality**

174 **Ground-based seasonal LAI cohorts and litterfall data.** Top-of-canopy  
175 imageries observed by ground-based phenology cameras were used to decompose  
176 canopy LAI into  $LAI_{young}$ ,  $LAI_{mature}$  and  $LAI_{old}$ . In total, imageries from eight  
177 observation sites across the whole TEF region were used to validate the simulating  
178 results (blue pentangles in **Fig. 1**, **Table S1**). Additionally, the seasonal litterfall data  
179 from 53 *in situ* sites (black circles in **Fig. 1**, **Table S6**) spanning the TEFs were collected  
180 from globally published articles to compare with the phase of simulated  $LAI_{old}$   
181 seasonality (see **Methods** for details). The multiyear monthly litterfall data were  
182 averaged to the monthly mean to compare with the seasonality of simulated  $LAI_{old}$ .  
183 Four eddy covariance flux tower sites (red triangles in **Fig. 1**, **Table S2**) provided *in*  
184 *situ* seasonal GPP data to evaluate the seasonality of RTSIF-derived GPP.

185 **Satellite-based seasonal EVI data.** To evaluate the LAI seasonality of  
186 photosynthesis-effective leaves, i.e., young and mature leaves, this study used satellite-  
187 based MODIS Enhanced Vegetation Index (EVI) (Huete et al., 2002; Lopes et al., 2016;  
188 Wu et al., 2018) as a remotely sensed proxies alternatives of effective leaf area changes  
189 and new leaf flush, i.e.,  $LAI_{young+mature}$  (Wu et al., 2016; Xu et al., 2015). To prove the  
190 robustness of the products over a large spatial coverage, the seasonal LAI cohorts of  
191 young and mature leaves were evaluated against the enhanced vegetation index (EVI)  
192 product, which was considered as a proxy for leaf area changes of photosynthetically

193 effective leaves (Xu et al., 2015; Wu et al., 2016; de Moura et al., 2017).

194

### 195 **3. Methods**

#### 196 **3.1 Decomposing LAI cohorts (young, mature and old) from SIF-derived GPP**

197 **Figure 2** illustrates the overall framework used to generate leaf age-dependent LAI  
198 seasonality product (Lad-LAI). The majority of the tropical and subtropical EBFs retain  
199 leaves year-round and their total LAI shows marginally small spatial and seasonal  
200 changes (Wu et al., 2016) (**Figs. S3, S4**). Therefore, previous modelling studies have  
201 assumed a constant value for the total LAI in tropical and subtropical EBFs (Cramer et  
202 al., 2001; Arora and Boer, 2005; De Weirdt et al., 2012). Based on this, we collected  
203 observed seasonal LAI dynamics in tropical and subtropical EBFs from previously  
204 published literatures which showed a constant value of LAI around 6.0 (**Figs. S3, S4,**  
205 **Table S5**). Thus, in this study, we simplified to assume that the seasonal LAI was  
206 approximately equal to 6.0 in tropical and subtropical EBFs. We grouped the canopy  
207 leaves of tropical and subtropical EBFs into three leaf age cohorts, i.e., young, mature  
208 and old leaves, respectively. Then, the total GPP was defined as the sum of those  
209 produced by the young, mature and old leaves, respectively. According to the Farquhar-  
210 von Caemmerer-Berry (FvCB) leaf photochemistry model (Farquhar et al., 1980), GPP  
211 can be expressed as function of the sum of the products of each LAI cohort ( $LAI_{young}$ ,  
212  $LAI_{mature}$ , and  $LAI_{old}$ ) and corresponding net  $CO_2$  assimilation rate ( $An_{young}$ ,  $An_{mature}$ ,  
213 and  $An_{old}$ ) (**Equation 1**).

$$214 \quad GPP = LAI_{young} \times An_{young} + LAI_{mature} \times An_{mature} + LAI_{old} \times An_{old} \quad (1)$$

215 where  $LAI_{young}$ ,  $LAI_{mature}$  and  $LAI_{old}$  are the leaf area index of young, mature and old  
216 leaves, respectively;  $An_{young}$ ,  $An_{mature}$  and  $An_{old}$  are the net rate of  $CO_2$  assimilation  
217 dependent on three leaf age classes; GPP is canopy total gross primary production. The  
218 sum of  $LAI_{young}$ ,  $LAI_{mature}$  and  $LAI_{old}$  was set as a constant in this study, equaling to 6.0.

219 The gridded GPP data over the whole EBFs were derived from SIF (denoted as  
220 RTSIF-derived GPP) using a linear SIF-GPP regression model (see sect. 3.2) which was

221 established based on *in situ* GPP from 76 eddy covariance (EC) sites (Chen et al., 2022).  
222 The  $An_{\text{young}}$ ,  $An_{\text{mature}}$  and  $An_{\text{old}}$  were calculated according to the FvCB biochemical  
223 model (Farquhar et al., 1980; Bernacchi et al., 2003) (see section 3.3). As there were  
224 three unknown variables (i.e.,  $LAI_{\text{young}}$ ,  $LAI_{\text{mature}}$  and  $LAI_{\text{old}}$ ) to be solved in **Equation**  
225 **1**, we hypothesized that the adjacent four pixels exhibited homogenous EBFs and  
226 consistent leaf demography and canopy photosynthesis. Then, we used the GPP and  $An$   
227 data from adjacent four pixels to estimate their  $LAI_{\text{young}}$ ,  $LAI_{\text{mature}}$  and  $LAI_{\text{old}}$  based on  
228 **Equation 1** using a linear least-squares with constrained method. The inputs gridded  
229 datasets (i.e., RTSIF-derived GPP and  $An$  derived from  $T_{\text{air}}$ , VPD and SW) (**Table S3**,  
230 **Fig. 2**) were sampled at 0.125-degree spatial resolution; while the output maps of  
231  $LAI_{\text{young}}$ ,  $LAI_{\text{mature}}$ , and  $LAI_{\text{old}}$  were at 0.25-degree spatial resolution. Therefore, the  
232 output maps of  $LAI_{\text{young}}$ ,  $LAI_{\text{mature}}$ , and  $LAI_{\text{old}}$  were at a 0.25-degree spatial resolution.  
233 Additionally, to test the robustness of the neighbor-based decomposition approach, we  
234 increased the number of adjacent pixels from 4 ( $2*2$ ) to 16 ( $4*4$ ) to produce another  
235 version of Lad-LAI products with a spatial resolution of 0.5-degree. All our analyses  
236 were conducted using Python (version 3.7, <http://www.python.org>) and Matlab (version  
237 R2019b) software.

238

239 **Figure 2.** The workflow for mapping Lad-LAI using the LsqLin method. LsqLin is the  
240 abbreviation of Linear least-squares solver with bounds or linear constraints. All the  
241 abbreviations were described in supplementary **Tables S4**.

242

### 243 3.2 Calculating the GPP (RTSIF-derived GPP) from TROPOMI SIF

244 Satellite-retrieved solar-induced chlorophyll fluorescence (SIF) is a widely used  
245 proxy for canopy photosynthesis (Yang et al., 2015; Dechant et al., 2020). Here, we  
246 used a long-term reconstructed TROPOMI SIF dataset (RTSIF) (Chen et al., 2022) to  
247 estimate GPP seasonality. Previous analyses showed that RTSIF was strongly linearly  
248 correlated to eddy covariance (EC) GPP and used 15.343 as a transformation coefficient

249 to convert RTSIF to GPP (Fig. 8a in Chen et al., 2022). In this study, we followed  
250 previously published literatures to set a constant value of LAI around 6.0 for the whole  
251 tropical and subtropical EBFs (Figs. S3, S4, Table S5). We collected seasonal GPP data  
252 observed at four EC sites from the FLUXNET 2015 Tier 1 dataset (Table S2; Pastorello  
253 et al., 2020) and validated the Chen's simple SIF-GPP relationship (Fig. S1). Results  
254 confirmed the robustness of Chen's simple SIF-GPP relationship in estimating the GPP  
255 seasonality in tropical and subtropical EBFs ( $R > 0.49$ ). Despite potential overestimation  
256 (Fig. S1 b) or underestimation (Fig. S1 h) of the magnitudes, RTSIF-derived GPP  
257 mostly captured the seasonality of the EC GPP at all four sites ( $d_{\text{phase}} < 0.26$ ).

258

### 259 3.3 Calculating the net rate of CO<sub>2</sub> assimilation (An)

260 We calculated the net CO<sub>2</sub> assimilation (An) using the FvCB biochemical model  
261 (Farquhar et al., 1980). In this model, the parameter An was calculated as the minimum  
262 of Rubisco ( $W_c$ ), RuBP regeneration ( $W_j$ ) and TPU ( $W_p$ ) to minus dark respiration ( $R_{\text{dark}}$ )  
263 (Bernacchi et al., 2013). The formulas for calculating An,  $W_c$ ,  $W_j$ ,  $W_p$ ,  $R_{\text{dark}}$  and  
264 corresponding intermediate variables were listed in Tables S4.

265 **Calculation of  $W_c$ .**  $W_c$  is expressed as a function of internal CO<sub>2</sub> concentration ( $c_i$ ),  
266 Michaelis-Menton constant for carboxylase ( $K_c$ ), Michaelis-Menton constant for  
267 oxygenase ( $K_o$ ), CO<sub>2</sub> compensation point ( $\Gamma^*$ ) and maximum carboxylation rate ( $V_{c,\text{max}}$ )  
268 (Table S4-part1) (Lin et al., 2015; Bernacchi et al., 2013; Ryu et al., 2011; Medlyn et  
269 al., 2011; June et al., 2004; Farquhar et al., 1980). The  $K_c$ ,  $K_o$ ,  $\Gamma^*$  and  $V_{c,\text{max}}$  are  
270 temperature-dependent variables. Thus, we used Equation 2 to calculate their values at  
271  $T_k$  by converting from those at 25°C. Then, we used the Medlyn's stomatal conductance  
272 model (Medlyn et al., 2011) to estimate internal CO<sub>2</sub> concentration ( $c_i$ ) (Equation 3),  
273 which is expressed as a function of vapor pressure deficit (VPD) rather than relative  
274 humidity (Lin et al., 2015). The method for calculating the  $V_{c,\text{max}}$  of each LAI cohort  
275 was introduced in section 3.4. The formulas for calculating corresponding intermediate  
276 parameters were presented in Table S4.

277  $Para = Para_{25} \times \exp\left(\frac{(T_k - 298.15) \times \Delta H_{para}}{R \times T_k \times 298.15}\right)$  (2)

278 where  $Para$  denotes a correction factor arising from the temperature dependence of  
 279  $V_{c,max}$ ;  $Para_{25}$  are values of the temperature-dependent parameters ( $K_c$ ,  $K_o$ ,  $\Gamma^*$  and  $V_{c,max}$ )  
 280 at the temperature 25°C;  $T_k$  denotes temperature in Kelvin;  $\Delta H_{para}$  is the activation  
 281 energy for temperature dependence;  $R$  is the universal gas constant.

282  $c_i = c_a \times \left(1 - \frac{1}{1.6 \times \left(1 + \frac{g_1}{\sqrt{VPD}}\right)}\right)$  (3)

283 where  $c_a$  is atmospheric CO<sub>2</sub> concentration, 380 ppm; VPD was calculated from air  
 284 temperature and dew point temperature of the global ERA-Interim reanalysis dataset  
 285 (Dee et al., 2011) using the method of Yuan et al. (2019). The calculation formula of  
 286 VPD was described in supplementary files. In this study, we used the value of 3.77 for  
 287 the stomatal slope ( $g_1$ ) in the stomatal conductance model according to Lin et al. (2015).

288 **Calculation of  $W_p$ .**  $W_p$  was calculated as the function of  $V_{c,max}$ , which was given  
 289 different values for different LAI cohorts based on multiple *in situ* observations (section  
 290 3.4).

291 **Calculation of  $W_j$ .**  $W_j$  was calculated from  $V_{c,max}$ ,  $c_i$  and the rate of electrons  
 292 through the thylakoid membrane ( $J$ ) (Bernacchi et al., 2013). The parameter  $J$  was  
 293 calculated from the maximum electron transport rate ( $J_{max}$ ) and the rate of whole  
 294 electron transport provided by light ( $J_e$ ) (Bernacchi et al., 2013).  $J_{max}$  was expressed as  
 295 a temperature dependence function of maximum electron transport rate ( $J_{max,25}$ ) at 25°C  
 296 and temperature ( $T_{air}$ ) and  $J_e$  was expressed as a function of total PAR absorbed by  
 297 canopy ( $PAR_{total}$ ) that was the sum of active radiation in beam ( $PAR_{b,0}$ ) and diffuse  
 298 ( $PAR_{d,0}$ ) light firstly (Weiss et al., 1985), which were calculated from downward short-  
 299 wave radiation (SW) (Ryu et al., 2018). The formula for  $PAR_{total}$  was given in **Equation**  
 300 **4** and formulas for other intermediate parameters (i.e.,  $PAR_{b,0}$ ,  $PAR_{d,0}$ ,  $\rho_{cb}$ ,  $\rho_{cd}$ ,  $k'_b$ ,  $k'_d$ ,  
 301 and  $CI$ ) were listed in **Table S4**.

302  $PAR_{total} = (1 - \rho_{cb}) \times PAR_{b,0} \times (1 - \exp(-k'_b \times CI \times LAI_{total})) + (1 - \rho_{cd}) \times$   
 303  $PAR_{d,0} \times (1 - \exp(-k'_d \times CI \times LAI_{total}))$  (4)

304 where  $PAR_{total}$  is total PAR absorbed by canopy;  $PAR_{b,0}$  is the active radiation;  $PAR_{d,0}$   
305 is diffuse radiation;  $LAI_{total}$  is a total LAI. Here, we used a constant value of 6.0  
306 according to De Weirdt et al. (2012).

307

### 308 **3.4 Classifying three LAI cohorts with different $V_{c,max}$**

309 In this study, we collected *in situ* samples of  $V_{c,max25}$  data against different leaf age  
310 across tropical and subtropical EBFs from previous publications. Mature leaves (leaf  
311 age: 70-160 days) show the highest  $V_{c,max25}$  than those of newly flushed leaves (leaf age:  
312 <60 days) and old leaves(leaf age: >200 days) as Menezes et al. (2021). Therefore, in  
313 this study, we classified the canopy leaves into three cohorts: young (leaf age: <2  
314 months), mature (leaf age: 3-5 months) and old cohorts (leaf age: >6 months) as Wu et  
315 al. (2016). The  $V_{c,max25}$  for young, mature and old cohorts were set as 60, 40 and 20  
316  $\mu\text{mol m}^{-2} \text{s}^{-1}$ , respectively, according to previous ground-based observations by Chen et  
317 al. (2020).

318

### 319 **3.5 Decomposing camera-based LAI into three leaf age cohorts**

320 We classified the canopy leaves into young, mature and old age cohorts based on  
321 the green-color band from the top-of-canopy imageries observed by RGB camera. It is  
322 because the brightness of different leaf age leaves differs greatly in the values of the  
323 green-color band. Raster density slicing is a useful classification method for detecting  
324 the attributes of various ground objects (Kartikeyan et al., 1998). Therefore, we set three  
325 brightness thresholds to divide young (blue), mature (green), old (yellow) leaves and  
326 background (gray) for the same canopy extent in each month (**Fig. S2**). This analysis  
327 was conducted in ENVI5.3 software.

328

### 329 **3.6 Evaluating the $LAI_{young+mature}$ seasonality and its spatial patterns using** 330 **satellite-based EVI products**

331 To compare the seasonality of  $LAI_{young+mature}$  with those of EVI, we calculate mean

332 squared deviation (MSD) and their three components— $d_{\text{bias}}$ , which denotes the  
333 differences about absolute value,  $d_{\text{var}}$ , which denotes the differences of seasonal  
334 fluctuations, and  $d_{\text{phase}}$ , which denotes the differences of peak phase to evaluate this  
335 consistency, comprehensively (see section 3.8). Additionally, we compared the spatial  
336 patterns of the wet- minus dry-season differences ( $\Delta$ ) between observed and simulated  
337 variables, following the work of Guan et al. (2015). To determine the wet and dry  
338 seasons in each grid cell, we defined a month as dry one when its monthly average  
339 precipitation was smaller than the potential evapotranspiration (PET) computed using  
340 the method of Maes et al. (2019); other months were classified as wet ones. The wet-  
341 minus dry-season  $\text{LAI}_{\text{young+mature}}$  (denoted as  $\Delta\text{LAI}_{\text{young+mature}}$ ) was calculated for each  
342 grid cell as the wet-season average  $\text{LAI}_{\text{young+mature}}$  value minus the dry-season average  
343 value of  $\text{LAI}_{\text{young+mature}}$ .

344

### 345 **3.7 Evaluating the $\text{LAI}_{\text{old}}$ seasonality using ground-based litterfall data**

346 Litterfall is closely related to the seasonal dynamics of old leaves, i.e.,  $\text{LAI}_{\text{old}}$  (Chen  
347 et al., 2020; Yang et al., 2021). Previous analyses indicated that, in general, a sharpening  
348 decrease in  $\text{LAI}_{\text{old}}$  corresponded to a peak in litterfall (Pastorello et al., 2020; Midoko  
349 Iponga et al., 2019; Ndakara, 2011; Barlow et al., 2007; Dantas and Phillipson, 1989).  
350 Based on this causal relationship between litterfall and  $\text{LAI}_{\text{old}}$ , we compared the time  
351 of seasonal litterfall peak with the time of abrupt drops in  $\text{LAI}_{\text{old}}$ , to indirectly evaluate  
352 the simulated  $\text{LAI}_{\text{old}}$  seasonality. To accurately detect the onset date of old leaves  
353 shedding and the day of litterfall peak, we used a least-square regression analysis  
354 method developed by Piao et al. (2006) to smoothen  $\text{LAI}_{\text{old}}$  and litterfall seasonal curves.  
355 The sixth-degree polynomial function ( $n=6$ ) was applicable to the regression (**Equation**  
356 **5**).

$$357 \text{LAI}_{\text{old}} = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \quad (5)$$

358 where  $x$  is the day of a year.

359 The slope of seasonal LAI ( $\text{LAI}_{\text{old, ratio}}$ ) was calculated in **Equation 6**. The date of

360 abrupt drops in  $LAI_{old}$  was defined as the time with most negative values of  $LAI_{old, ratio}$ .

$$361 \quad LAI_{old, ratio}(t) = (LAI_{old(t+1)} - LAI_{old(t)}) / (LAI_{old(t)}) \quad (6)$$

362 where  $LAI_{old, ratio}$  is the slope of seasonal  $LAI_{old}$  curve.  $LAI_{old(t+1)}$  and  $LAI_{old(t)}$  are the  
363 corresponding monthly LAI at time t+1 and t, respectively.

364

### 365 **3.8 Evaluation Metrics**

366 Two metrics were chosen to evaluate the seasonality of Lad-LAI against the that of  
367 other proxies: the Kobayashi decomposition of the Mean Square Difference between  
368 model and observation (Kobayashi and Salam, 2000) and the Pearson correlation  
369 coefficient (Pearson, 1896) for gridded fields.

370 **Mean squared deviation (MSD).** The mean squared deviation (MSD) was given  
371 by Kobayashi and Salam (2000):

$$372 \quad MSD = \frac{1}{n} \sum_{i=1}^n (x_i - y_i)^2 \quad (7)$$

$$373 \quad SB = (\bar{x} - \bar{y})^2 \quad (8)$$

$$374 \quad SD_s = \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \quad (9)$$

$$375 \quad SD_m = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \bar{y})^2} \quad (10)$$

$$376 \quad SDDS = (SD_s - SD_m)^2 \quad (11)$$

$$377 \quad LCS = 2SD_s SD_m (1 - r) \quad (12)$$

378 where mean squared deviation is the square of RMSD; i.e.,  $MSD = RMSD^2$ ; and  $x_i$  is  
379 the simulated data at time t, and  $y_i$  is the observed one at time t (month). The lower the  
380 value of MSD, the closer the simulation is to the measurement. MSD can be  
381 decomposed into the sum of three components: the squared bias ( $d_{bias}$ ),  $d_{bias}=SB$ ; the  
382 squared difference between standard deviations (variance-related difference,  $d_{var}$ ),  
383  $d_{var}=SDDS$ ; and the lack of correlation weighted by the standard deviations (phase-  
384 related difference,  $d_{phase}$ ),  $d_{phase}=LCS$ ;  $r$  indicates the correlation coefficient between  $x$   
385 and  $y$ .

386 **Pearson correlation coefficient (R).** The Pearson correlation coefficient is a

387 measure of linear correlation between two variables (Merkl and Waack, 2009). The  
388 correlation coefficient between X and Y was as:

$$389 \rho_{X,Y} = \frac{cov(X,Y)}{\sigma_X\sigma_Y} = \frac{E((X-\mu_X)(Y-\mu_Y))}{\sigma_X\sigma_Y} \quad (13)$$

390

### 391 **3.9 The quality control (QC) for the Lad-LAI product**

392 We provided information of data quality control (QC) along with the Lad-LAI  
393 product (**Fig. S5**). In the QC system (**Table S7**), data quality was divided into four  
394 levels: level 1 represents the highest quality; level 2 and level 3 represent good and  
395 acceptable quality, respectively; and level 4 warns to be used cautiously. This QC  
396 product was generated according to residual sum of squares (RSS) (Melgosa et al., 2008)  
397 and the root mean square error (RMSE) (Chen et al., 2020), obtained from the  
398 constrained least-squares method that was used to estimate derive monthly Lad-LAI  
399 data.

400

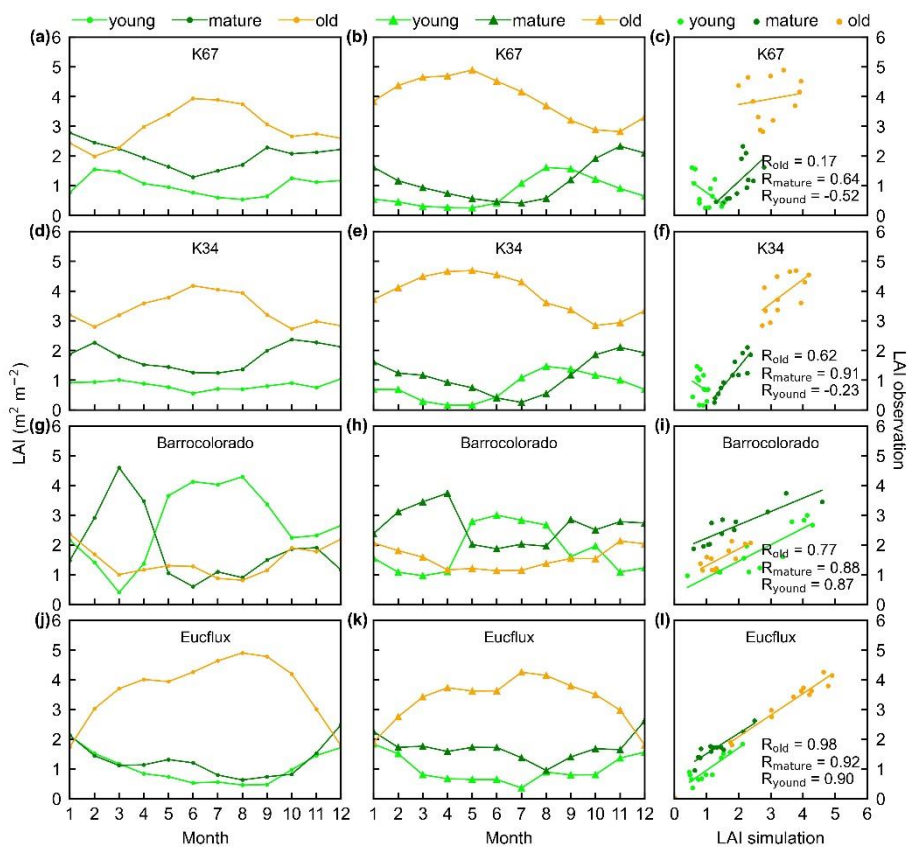

## 401 **4. Results**

### 402 **4.1 Comparison of LAI cohort seasonality with site observations**

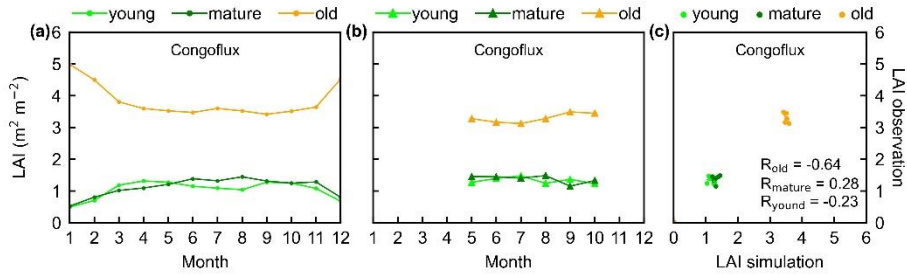

403 The simulated leaf age-dependent LAI seasonality product was validated against  
404 the camera-based measurements of LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub> at four sites in south  
405 America, one site in Congo and three sites in China. Overall, the LAI seasonality of  
406 mature and old classes from the new Lad-LAI products agrees well at these sites with  
407 very fine-scale collections of monthly LAI of mature (R=0.77, MSD=0.69) and old  
408 leaves (R=0.59, MSD=0.62). However, the seasonality of simulated LAI from young  
409 leaves performs a little poor (R=0.36, MSD=0.45). It is also interesting to note that the  
410 canopy leaf phenology of TEFs at these sites differ greatly. In south America, at K67,  
411 K34 and Eucflux sites, both *in situ* and simulated LAI<sub>young</sub> and LAI<sub>mature</sub> decrease at  
412 early dry season around February and convert to increase at early wet season around  
413 June (**Fig. 3 a, b, d, e, j, k**). At the Barrocolorado site, LAI<sub>young</sub> increases from the late  
414 dry to early wet season around Mar in response to the increasing incoming shortwave

415 radiation and in contrast,  $LAI_{mature}$  starts to increase at wet season around June (**Fig. 3**  
 416 **g, h**). However, in subtropical Asia,  $LAI_{young}$  and  $LAI_{mature}$  increase during the wet  
 417 season and peak with largest rainfall at June or July at Din, Gutian and Banna sites (**Fig.**  
 418 **5 a, b, d, e, g, h**). In Congo, we only found one site (Congoflux) with six months  
 419 observation period (from May to October). The seasonality of  $LAI_{young}$  and  $LAI_{mature}$   
 420 are similar as those in tropical Asia while having smaller variations in magnitude due  
 421 to the moderate seasonality of sunlight in the Equator region (**Fig. 4 a, b**). Overall, there  
 422 is a reverse pattern for  $LAI_{old}$  seasonality compared to  $LAI_{mature}$  for all the eight sites.  
 423

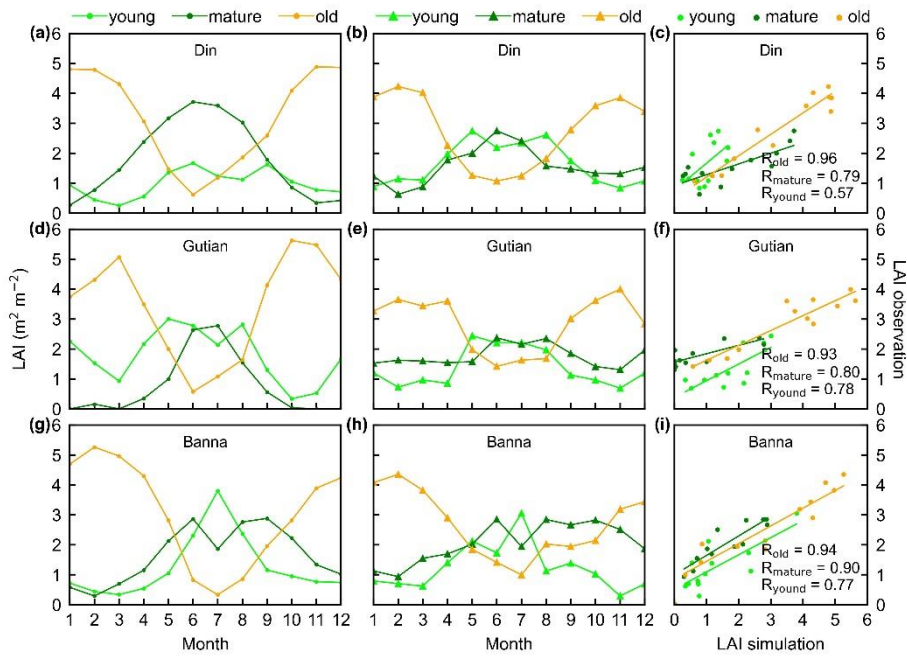

424  
 425 **Figure 3.** Seasonality of simulated  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  in comparison with  
 426 observed data at 4 sites in south America. (Panels a, d, g and j) simulated LAIs;  
 427 (panels b, e, h and k) observed LAIs; (panels c, f, i and l) scatterplots between  
 428 simulated and observed LAIs. Limegreen dots are  $LAI_{young}$ ; green dots are  $LAI_{mature}$ ;  
 429 orange dots are  $LAI_{old}$ .

430

431 **Figure 4.** Seasonality of simulated  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  in comparison with  
 432 observed data at one site in Congo. (a) Simulated LAIs; (b) observed LAIs; and (c)  
 433 scatterplots between simulated and observed LAIs. Limegreen dots are  $LAI_{young}$ ;  
 434 green dots are  $LAI_{mature}$ ; orange dots are  $LAI_{old}$ .

435

436 **Figure 5.** Seasonality of simulated  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  in comparison with  
 437 observed data at 3 sites in tropical Asia. (Panels a, d and g) simulated LAIs; (panels b,  
 438 e and h) observed LAIs; (panels c, f and i) scatterplots between simulated and observed  
 439 LAIs. Limegreen dots are  $LAI_{young}$ ; green dots are  $LAI_{mature}$ ; orange dots are  $LAI_{old}$ .

440

441 Additionally, only one ground site (Barrocolorado site in Panama) had observed  
 442 time-series camera-based phenological imageries, which were then used to evaluate the  
 443 capacity of Lad-LAI in representing the interannual dynamics of three LAI cohorts,  
 444 with R values being equal to 0.54, 0.64, 0.49 for  $LAI_{young}$ ,  $LAI_{mature}$ ,  $LAI_{old}$ , respectively

445 (Fig. 6). However, more *in situ* long-term observations are in need to test the robustness  
 446 of the time-series variations. The temporal variations of LAI<sub>young</sub>, LAI<sub>mature</sub>, LAI<sub>old</sub>  
 447 across 8 sub-regions classified by the *K*-means clustering analysis were shown in Fig.  
 448 S6. Results showed that, for example, the LAI<sub>mature</sub> increased significantly due to 2015  
 449 drought in Amazon basin (e.g., sub-region S2, Fig. S6) and southeast Asia (e.g., sub-  
 450 region S7, Fig. S6), indicating good capability of detecting the dynamics of LAI<sub>young</sub>,  
 451 LAI<sub>mature</sub>, LAI<sub>old</sub> in response to climate disturbances.

452  
 453 **Figure 6.** Timeseries of simulated LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub> in comparison with  
 454 observed data at Barro Colorado site in Panama. (a) Simulations LAIs; (b) observation  
 455 LAIs; and (c) scatterplots between simulated and observed LAIs.

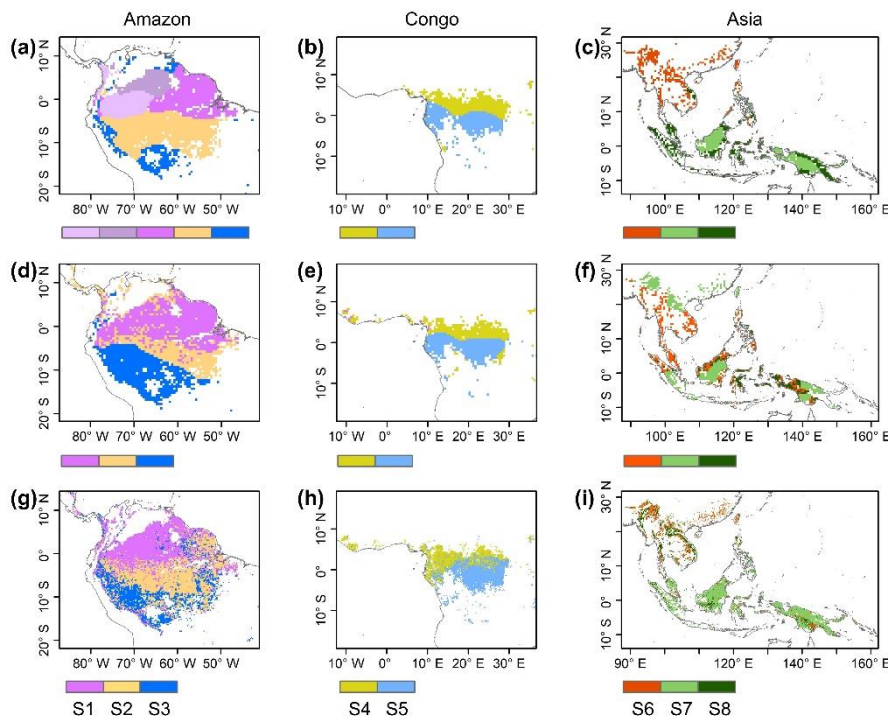

456

#### 457 4.2 Comparison of patterns of gridded LAI cohort seasonality with climatic and 458 phenological patterns

459 The *in situ* measurements of LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub> suggested diverse  
 460 patterns of Lad-LAI seasonality over the TEFs. Nevertheless, the sparse coverage of  
 461 these sites raised challenging for a comprehensive and direct evaluation of leaf age-  
 462 dependent LAI seasonality product. To evaluate the robustness of the gridded Lad-LAI  
 463 seasonality product at the regional scale, we further conducted spatial clustering  
 464 analyses of LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub> using the *K*-means analysis method.

465 Surprisingly, the spatial patterns of Lad-LAI product clustered from satellite-based  
 466 vegetative signals (Fig. 7 g-i) coincide well with those clustered from in-dependent  
 467 climatic variables (rainfall and radiation etc.) (Fig. 7 a-c). These patterns are also  
 468 similar as those of the climate-phenology rhythms mapped by Yang et al. (2021), which  
 469 suggested different correlations of litterfall seasonality with canopy phenology between

470 different climate-phenology rhythms (**Fig. 7 d-f**). In central (sub-region S2) and south  
 471 (sub-region S3) Amazon (**Fig. 7 g**), the seasonality of LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub>  
 472 (**Fig. 8 b, c**) are similar as those of BR-Sa1 and BR-Sa3 sites. And in subtropical Asia  
 473 (sub-region S6) (**Fig. 7 i**), the seasonality of three LAI cohorts (**Fig. 8 f**) are similar as  
 474 those of Din, Gutian and Banna sites. Notably, in the sub-region S8, located  
 475 geographically between sub-regions S6 and S7, LAI<sub>young</sub> shows a peak at July and  
 476 LAI<sub>mature</sub> shows a bimodal phenology (**Fig. 8 h**). The remaining 4 sub-regions (sub-  
 477 regions S1, S4, S5, S7) are all located nearby the Equator. The magnitudes of seasonal  
 478 changes in LAI cohorts are smaller than those in sub-regions S2, S3, S6 and S8 away  
 479 from the Equator. It is worth noting that for these sub-regions around the Equator there  
 480 is a bimodal seasonality pattern for LAI<sub>mature</sub>, with the first peak around March and the  
 481 second peak around August (**Fig. 8 a, d, e, g**). This is consistent with the findings of Li  
 482 et al. (2021) which found that tropical and subtropical TEFs changed from a unimodal  
 483 phenology at higher-latitudes to a bimodal phenology at lower-latitudes.

484  
 485 **Figure 7.** Comparison of sub-regions of Lad-LAI products (plots g-i) with those of  
 486 climatic factors classified by the K-means clustering analysis (plots a-c) (Chen et al.,  
 487 2021) and those of the three climate-phenology regimes (plots d-f) developed by Yang

489

490 **Figure 8.** Seasonality of simulated  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  in 8 sub-regions  
 491 classified by the K-means clustering analysis.

492

#### 493 **4.3 Sub-regional evaluations of gridded $LAI_{young+mature}$ seasonality using satellite-** 494 **based EVI products**

495 The gridded dataset of monthly  $LAI_{young+mature}$  was indirectly evaluated using the  
 496 satellite-based EVI products (Wang et al., 2017; de Moura et al., 2017; Xiao et al., 2005;  
 497 Wu et al., 2018), as EVI was consistent with  $LAI_{young+mature}$  in seasonality (**Figs. S7-S8**),  
 498 which agreed with previous findings that EVI can be considered as a proxy for leaf area  
 499 change of those leaves with high photosynthesis efficiency (Huete et al., 2006; Lopes  
 500 et al., 2016; Wu et al., 2018). It is because that EVI are very sensitive to changes in  
 501 near-infrared (NIR) reflectance (Galvão et al., 2011) while young and mature leaves  
 502 also reflect more NIR signals than the older leaves they replace (Toomey et al., 2009).  
 503 The linear correlation and MSD decompositions (see **Methods**) between simulated and  
 504 satellite-based EVI were displayed in **Fig. 9**. Overall, the seasonal  $LAI_{young+mature}$  is well  
 505 correlated with satellite-based EVI ( $R > 0.40$ ) in 78.26% of the TEFs and the average  
 506 correlation coefficient is equaling to 0.61(**Fig. 9 a-c**). The MSD is smaller than 0.1 in

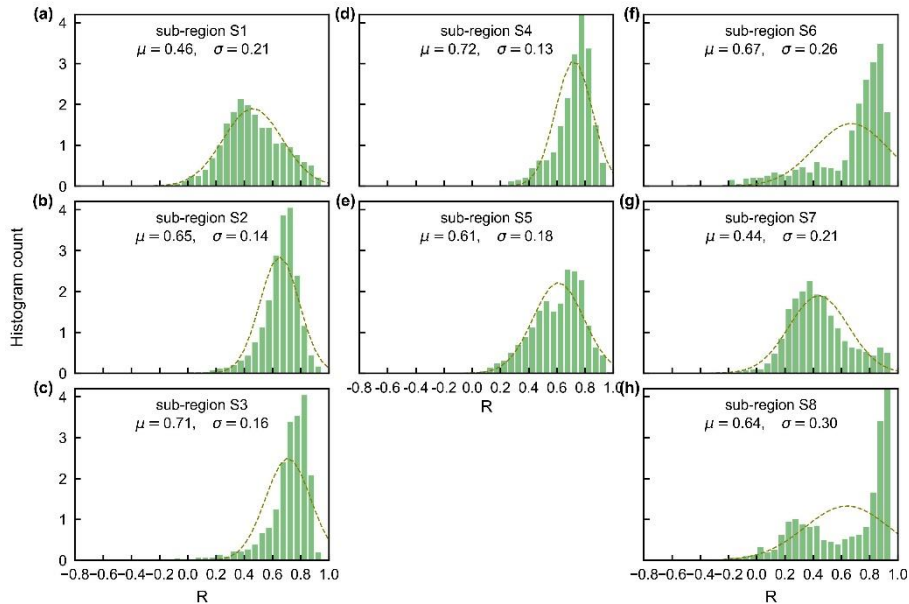

507 89.69% of the whole tropical and subtropical TEFs (**Fig. 9 d-f**). Statistics in the 8  
508 clustered sub-regions show that the seasonal  $LAI_{\text{young+ mature}}$  of Lad-LAI data mostly  
509 correlate better with seasonal EVI in high-latitude areas (sub-region S2:  $R=0.65$ , sub-  
510 region S3:  $R=0.71$ , sub-region S6:  $R=0.67$ ) than those in low latitudes (sub-region S1:  
511  $R=0.46$ , sub-region S5:  $R=0.61$ , sub-region S7:  $R=0.44$ , sub-region S8:  $R=0.64$ ) except  
512 for sub-region S4 ( $R=0.72$ ) (**Figs. 10, S9**). The MSD components also confirm a better  
513 performance of  $LAI_{\text{young+ mature}}$  seasonality in high-latitude areas (sub-region  
514 S2:  $d_{\text{bias}}=0.009$ ,  $d_{\text{var}}=0.001$ ,  $d_{\text{phase}}=0.030$ ; sub-region S3:  $d_{\text{bias}}=0.009$ ,  $d_{\text{var}}=0.002$ ,  
515  $d_{\text{phase}}=0.030$ ; sub-region S6:  $d_{\text{bias}}=0.016$ ,  $d_{\text{var}}=0.005$ ,  $d_{\text{phase}}=0.040$ ) than in low-latitude  
516 areas near the Equator (sub-region S1:  $d_{\text{bias}}=0.012$ ,  $d_{\text{var}}=0.001$ ,  $d_{\text{phase}}=0.041$ ; sub-region  
517 S4:  $d_{\text{bias}}=0.020$ ,  $d_{\text{var}}=0.001$ ,  $d_{\text{phase}}=0.031$ ; sub-region S5:  $d_{\text{bias}}=0.017$ ,  $d_{\text{var}}=0.001$ ,  
518  $d_{\text{phase}}=0.032$ ; sub-region S7:  $d_{\text{bias}}=0.018$ ,  $d_{\text{var}}=0.002$ ,  $d_{\text{phase}}=0.043$ ; sub-region S8:  
519  $d_{\text{bias}}=0.012$ ,  $d_{\text{var}}=0.005$ ,  $d_{\text{phase}}=0.035$ ) (**Figs. 11, S9**). This happens because that the  
520 accuracy of Lad-LAI in representing the seasonality of LAI cohorts depends highly on  
521 that of input SIF data, which is low sensitive to canopy phenology and shows  
522 marginally small seasonal changes nearby the Equator, for example in tropical Asia  
523 (Guan et al., 2015; 2016).

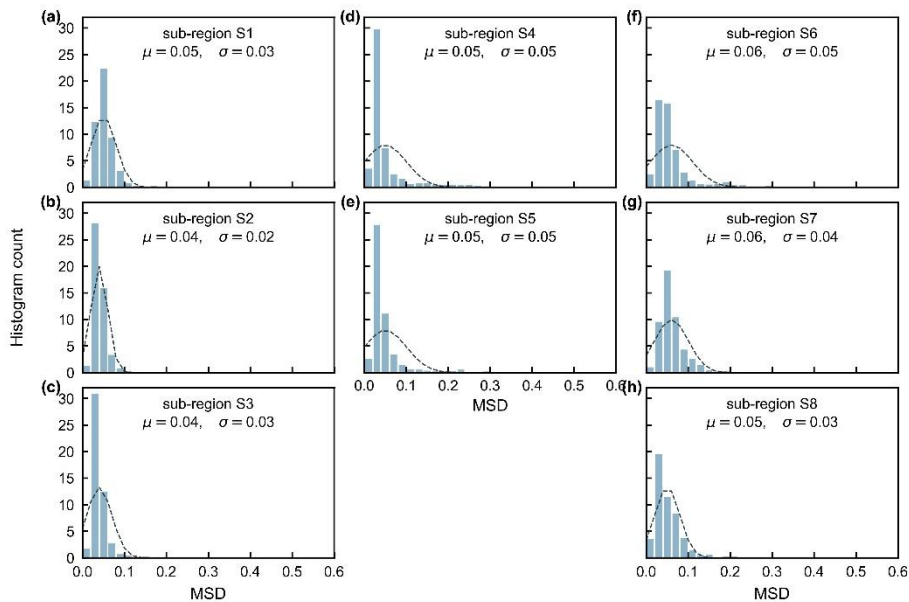

524

525 **Figure 9.** Pearson correlation coefficient (R) and mean squared deviation (MSD)

526 between seasonality of simulated LAI<sub>young+mature</sub> and MODIS Enhanced Vegetation  
 527 Index (EVI).  
 528

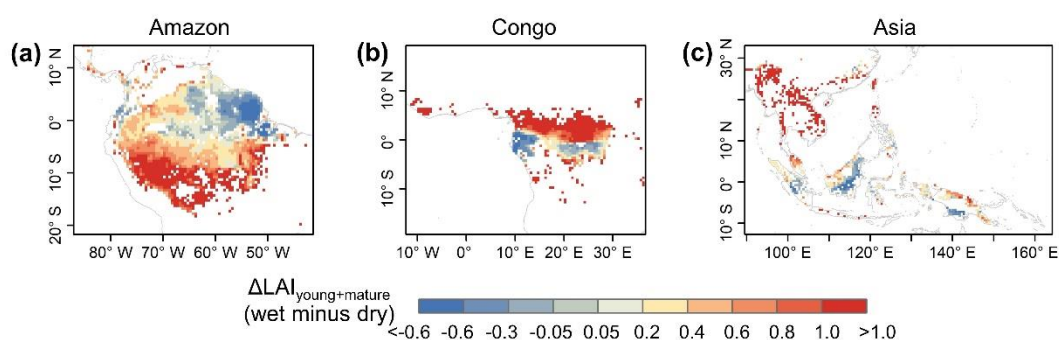

529  
 530 **Figure 10.** Statistics of the Pearson correlation coefficient (R) between seasonality of  
 531 simulated LAI<sub>young+mature</sub> and MODIS Enhanced Vegetation Index (EVI) in the 8  
 532 clustered sub-regions.

533  
 534 **Figure 11.** Statistics of the mean squared deviation (MSD) between seasonality of  
 535 simulated LAI<sub>young+mature</sub> and MODIS Enhanced Vegetation Index (EVI) in the 8  
 536 clustered sub-regions.

537

538 Additionally, previous studies indicated large-scale green-up area over tropical and  
 539 subtropical region during the dry seasons (i.e., Guan et al., 2015, Tang et al., 2017,  
 540 Myneni et al., 2007) where the average annual precipitation exceeds 2,000 mm yr<sup>-1</sup>.  
 541 Here, we calculated the differences ( $\Delta$ ) between wet- and dry-season LAI<sub>young+mature</sub> (i.e.,  
 542 LAI<sub>young</sub>+ LAI<sub>mature</sub>), to test whether the Lad-LAI can capture this green-up spatial  
 543 pattern. Spatial patterns of  $\Delta$ LAI<sub>young+mature</sub> (**Fig. 12**) are similar to those developed by  
 544 (Guan et al., 2015), with higher LAI<sub>young+mature</sub> during the dry season (blue area) in large  
 545 areas north of the Equator. This indicates an emergence of new leaf flush and increase  
 546 of mature leaves, resulting the canopy “green-up” phenomenon observed by previous  
 547 satellite-based signals. It is interesting to note that the total areas (blue regions in **Fig.**  
 548 **12**) of this dry-season green up shown by LAI<sub>young+mature</sub> is smaller than those shown by  
 549 SIF signals that almost everywhere north of the Equator. That is because that new and  
 550 mature leaves often have a higher photosynthetic capacity than old leaves. A slight or  
 551 moderate “green-up” in new and mature leaves (i.e., increase in LAI<sub>young+mature</sub>) would  
 552 boost strong increase in photosynthesis, inducing significant “green-up” shown by  
 553 photosynthesis-related signals, e.g., SIF data. Therefore, photosynthesis proxies likely  
 554 overestimate the areas with “green-up” of new leaves during the dry seasons in the real  
 555 world.

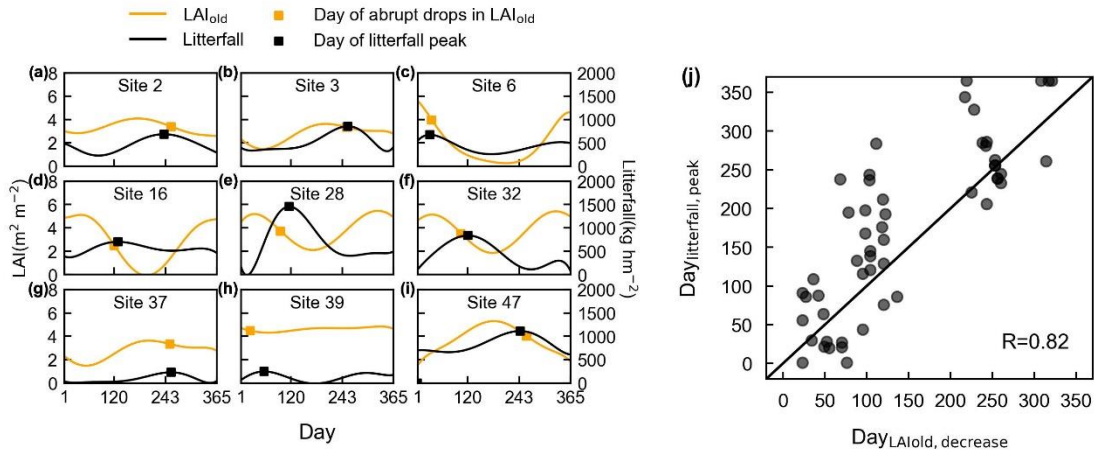

556  
 557 **Figure 12.** Spatial pattern of dry-season green-up using wet-season LAI<sub>young+mature</sub>  
 558 minus dry-season LAI<sub>young+mature</sub>.

559

560 **4.4 Sub-regional evaluations of gridded LAI<sub>old</sub> seasonality using site-based**  
 561 **litterfall observations**

562 The seasonal patterns of  $LAI_{old}$  were evaluated indirectly using ground-based  
 563 seasonal litterfall observations from 53 sites over the tropical and subtropical EBFs  
 564 (black circles in **Fig. 1**, **Figs. S10-S12**). Here, we selected 9 specific sites (**Fig. 13**) with  
 565 different patterns of litterfall seasonality and  $LAI_{old}$  seasonality, to illustrate the  
 566 analyses results. **Fig. 13 a-i** illustrate the days when there is an abrupt decrease in  
 567 monthly  $LAI_{old}$ , which are closely to monthly litterfall peak. The days when  $LAI_{old}$   
 568 decreases sharpest ( $Day_{LAI_{old}}$ ) agree well with the days when their monthly litterfall  
 569 peaks ( $Day_{litterfall}$ ) (**Fig. 13 j**), mostly distributed near the diagonal lines ( $R=0.82$ ). This  
 570 validation from seasonal litterfall data indirectly demonstrate the robustness of the  
 571  $LAI_{old}$  seasonality of the Lad-LAI product.

572  
 573 **Figure 13.** Evaluation of simulated  $LAI_{old}$  using ground-observed litterfall seasonality.  
 574 (a-i) Days of an abrupt decrease in  $LAI_{old}$  in comparison with days of corresponding  
 575 litterfall peak at 9 specific sites for examples. The orange curves represent simulated  
 576  $LAI_{old}$ . Dots on the orange curves represent the point with an abrupt decrease in  $LAI_{old}$ .  
 577 The black curves represent observed seasonal litterfall mass. The dots on the black  
 578 curves represent the point with litterfall peak. (j) Comparisons of the days when  $LAI_{old}$   
 579 has an abrupt decrease ( $Day_{LAI_{old}}$ ) against the days when monthly litterfall peaks  
 580 ( $Day_{litterfall}$ ).

581

#### 582 4.5 Testing potential uncertainties of the Lad-LAI products

583 To prove the robustness of the neighbor-based decomposition approach, we

584 compared the Lad-LAI products generated based on 2\*2 neighboring pixels with those  
 585 4\*4 based on neighboring pixels. Results show that the seasonality of  $LAI_{young}$ ,  
 586  $LAI_{mature}$  and  $LAI_{old}$  in the 0.5-degree Lad-LAI products based on 4\*4 neighboring  
 587 pixels are highly consistent with those of the 0.25-degree one based on 2\*2 neighboring  
 588 pixels across the whole tropical region (**Fig. 14**), with the correlation coefficients (R)  
 589 being equaling to 0.63, 0.68 and 0.95, respectively (**Fig. S13**).

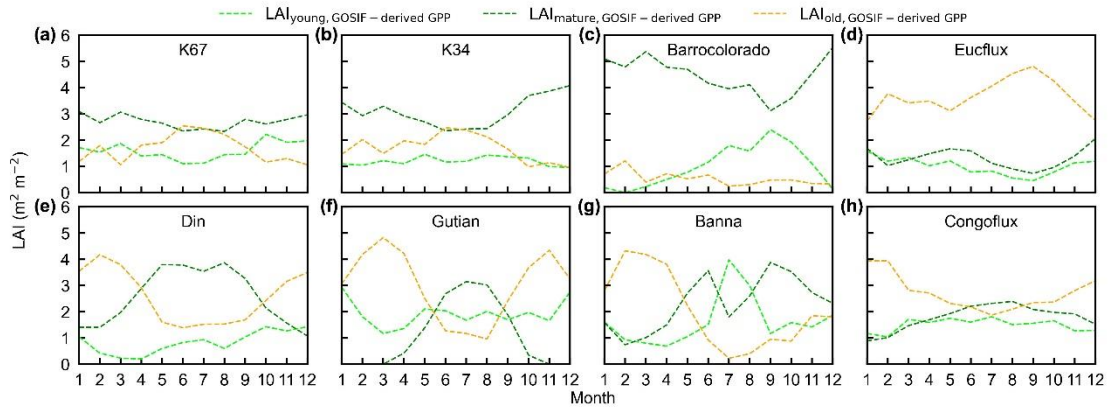

590  
 591 **Figure 14.** The seasonality of  $LAI_{young}$ ,  $LAI_{mature}$ ,  $LAI_{old}$  between 0.25-degree and 0.5-  
 592 degree Lad-LAI datasets in the 8 clustered regions. Limegreen color represents  $LAI_{young}$ ;  
 593 green color represents  $LAI_{mature}$ ; and orange color represents  $LAI_{old}$ . Solid lines  
 594 represent 0.25-degree dataset and the dashed lines represent 0.5-degree dataset.

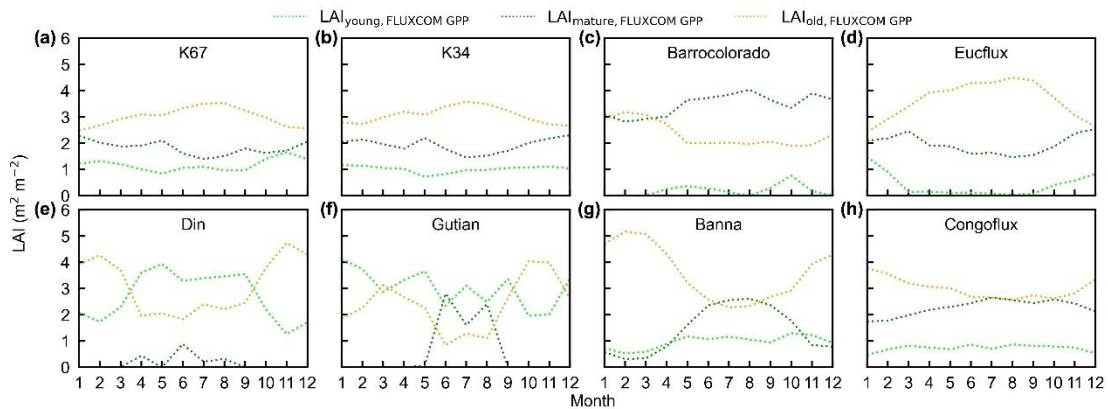

595

596 To test the uncertainties caused by the GPP estimation, we added two more GPP  
 597 products, i.e., GOSIF-derived GPP (Li and Xiao, 2019) and FLUXCOM GPP (Jung et  
 598 al., 2019), to produce another two versions of Lad-LAI products. The GPP seasonality  
 599 coincide well between these three data sources across all the 8 sub-regions (**Fig. S14**).  
 600 By comparing with the ground-based LAI cohorts at eight observation sites, results  
 601 show that the Lad-LAI generated from RTSIF-derived GPP show highest correlation  
 602 and minimal deviation with the *in situ* measurements, with R equaling to 0.36, 0.77 and

603 0.59 and MSD equaling to 0.45, 0.69 and 0.62 for  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$ ,  
 604 respectively (**Figs. 15-16, S15-S17**). Additionally, we also compared the seasonal  
 605 variability of  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  between three Lad-LAI versions in 8 sub-  
 606 regions classified by the K-means clustering analysis (**Fig. 17**). In general, three  
 607 versions of Lad-LAI products all performed well in 8 sub-regions with the consistent  
 608 seasonal variability (**Fig. 17**). On regional average, sub-regions S4, S5, S6, S7 and S8  
 609 show high consistent seasonality of  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  between these three  
 610 products; whereas the Lad-LAI generated from GOSIF-derived GPP performs a little  
 611 poor in capturing the seasonality of LAI cohorts in Amazon (sub-regions S1, S2 and  
 612 S3).

613  
 614 **Figure 15.** Seasonality of simulated  $LAI_{young}$ ,  $LAI_{mature}$ , and  $LAI_{old}$  from GOSIF-  
 615 derived GPP in comparison with observed data at 8 sites. (a) K67; (b) K34; (c)  
 616 Barrocolorado; (d) Eucflux; (e) Din; (f) Gutian; (g) Banna; (h) Congoflux.

623 products in 8 sub-regions classified by the K-means clustering analysis. Solid lines  
624 represent LAI generated from RTSIF-derived GPP; dashed lines represent LAI  
625 generated from GOSIF-derived GPP; and dotted lines represent LAI generated from  
626 FLUXCOM GPP. Limegreen represents  $LAI_{\text{young}}$ ; green represents  $LAI_{\text{mature}}$ ; and  
627 orange represents  $LAI_{\text{old}}$ .

628

## 629 5 Discussion

630 Leaf age-dependent LAI performs well in describing the seasonal replacements of  
631 canopy leaves in TEFs (Wu et al., 2016; Chen et al., 2020), showing to be a critical  
632 plant trait for representing the tropical and subtropical phenology (Doughty and  
633 Goulden, 2008; Saleska et al., 2007). However, to our knowledge, there are currently  
634 no continental-scale information of such leaf age-dependent LAI data over the whole  
635 TEFs, as it can neither be mapped from sparse site observations (Wu et al., 2016), nor  
636 can be modeled from ESMS which are triggered by unclear climatic drivers (Chen et  
637 al., 2020). These hinder global researches from accurately simulating large-scale  
638 photosynthesis (GPP) seasonality using remote sensing approaches and ESMS (Chen et

639 al., 2020).

640 The Lad-LAI product developed in this study is the first continental-scale gridded  
641 dataset of monthly LAI in different leaf age cohorts. Although still needing more *in situ*  
642 observations for an adequate validation, the seasonality of three LAI cohorts performs  
643 well at the eight sites (four in south America, three in subtropical Asia and one in Congo)  
644 with very fine-scale collections of monthly LAI<sub>young</sub>, LAI<sub>mature</sub>, and LAI<sub>old</sub>. To test the  
645 robustness of the gridded Lad-LAI products over the whole TEFs, the seasonality of  
646 LAI<sub>mature</sub> was also validated pixel by pixel using satellite-based EVI products, and the  
647 phase of LAI<sub>old</sub> seasonality were compared with those of seasonal litterfall data from  
648 53 site measurements, respectively. Moreover, the LAI<sub>young+mature</sub> from the new Lad-  
649 LAI products can also directly represent the large-scale dry-season green-up of canopy  
650 leaves north of the Equator. Overall, direct and indirect evaluations both demonstrated  
651 the robustness of the developed Lad-LAI products.

652 It should be noted that over the regions with a large magnitude of annual  
653 precipitation nearby the Equator, there are no obvious dry seasons, and thus tree canopy  
654 phenology changes are smaller than higher-latitude ones throughout the year (Yang et  
655 al., 2021). The LAI of young, mature and old leaf cohorts all show a bimodal phenology  
656 with marginally small seasonal changes nearby the Equator, which is captured by the  
657 developed Lad-LAI product. Secondly, we used a constant coefficient to transfer from  
658 SIF data to GPP and also assumed a constant value for the total LAI over the whole  
659 TEFs, which might bring additional uncertainties. This can be seen from the MSD  
660 evaluations, where the bias-related term dominates the total MSD, especially in regions  
661 nearby the Equator. However, this bring less impacts on the seasonality of Lad-LAI, as  
662 the phase-related term of MSD is much smaller.

663 Additionally, the maximum carboxylation rate ( $V_{c,max}$ ) of leaves changes  
664 significantly with leaf age (Xu et al., 2017). Currently, most Earth system models  
665 (ESMs) define  $V_{c,max}$  as a function of leaf age whereas their relationship is still less well  
666 understood in TEFs due to sparse in-situ measurements (Chen et al., 2020). This

667 consequentially leads to the poor representation of LAI and GPP seasonality in ESMs  
668 (De Weirdt et al., 2012). To overcome this challenge, here we simplified the tree canopy  
669 into three big leaves (i.e., young, mature and old) in TEFs, similar as the two-big leaves  
670 model developed for temperate and boreal forests (Best et al., 2011; Clark et al., 2011;  
671 Harper et al., 2016), which simplified tree canopy into sun and shade leaves. However,  
672 some uncertain remains on the assumption, as it neglects the spatial and temporal  
673 variations of  $V_{c,max}$ , which also changes with seasonal climate anomaly and also differs  
674 between nearby pixels in high heterogeneous forest ecosystems. This assumption may  
675 bring uncertainties for simulating seasonal  $A_n$  and therefore influence the seasonality  
676 of Lad-LAI.

677 In summary, we developed a new method to produce the first global gridded dataset  
678 of leaf age-dependent LAI product across the whole EBFs over the continental scale.  
679 Although some uncertainties might remain, the Lad-LAI products could provide  
680 seasonal age-dependent LAI data at the pixel-level to develop a common phenology  
681 model for the whole tropical and subtropical EBFs in ESMs that are currently run at a  
682 coarser resolution. With the development of remote sensing technology, finer temporal  
683 and spatial resolutions of SIF products will enable finer temporal and spatial resolutions  
684 maps of Lad-LAI products in the future.

685

## 686 **6. Data availability**

687 The 0.25-degree leaf age-dependent LAI seasonality (Lad-LAI) data from 2001-  
688 2018 are presented in this paper as the main one, and their time-series are as a  
689 supplementary dataset. The two datasets are available at  
690 <https://doi.org/10.6084/m9.figshare.21700955.v4> (Yang et al., 2022). Besides, we also  
691 provided another two versions of Lad-LAI generated from GOSIF-derived GPP and  
692 FLUXCOM GPP, respectively. These datasets are compressed in GeoTiff, with a spatial  
693 reference of WGS84. Each file in those dataset is named like “LAI\_{leaf age}\_{spatial  
694 resolution}\_{month/year-month}.tif”.

695

## 696 **7. Conclusion**

697 This study for the first-time developed a continental-scale gridded dataset of  
698 monthly LAI in three leaf age cohorts from 2001-2018 RTSIF data. The LAI seasonality  
699 of young, mature and old leaves was evaluated using *in situ* measurements of seasonal  
700 LAI data, satellite based EVI and *in situ* measurements of seasonal litterfall data. The  
701 evaluations from these datasets demonstrate the robustness of the seasonality of three  
702 leaf age cohorts. The new Lad-LAI products indicate diverse patterns over the whole  
703 tropical and subtropical regions. In central and south Amazon,  $LAI_{\text{young}}$  and  $LAI_{\text{mature}}$   
704 decrease at early dry season around February and start to increase at early wet season  
705 around June. On the contrary, in subtropical Asia,  $LAI_{\text{young}}$  and  $LAI_{\text{mature}}$  increase during  
706 the wet season and peak with largest rainfall at June or July. In regions nearby the  
707 Equator, the LAI cohorts show a bimodal phenology but with marginally small changes  
708 in the magnitude. The proposed method will enable to produce finer temporal and  
709 spatial resolutions maps of Lad-LAI products by using precise temporal and spatial  
710 resolutions data as the inputs. The Lad-LAI products will be helpful for diagnosing the  
711 adaption of tropical and subtropical forest to climate change; and will also help improve  
712 the development of phenology models in ESMs.
