29 **Abstract**

30 Quantification of large-scale leaf age-dependent leaf area index has been lacking in
31 tropical and subtropical evergreen broadleaved forests (TEFs) despite the recognized
32 importance of leaf age in influencing leaf photosynthetic capacity in this region. Here,
33 we simplified the canopy leaves of TEFs into three age cohorts, i.e., young, mature and
34 old one, with different photosynthesis capacity ($V_{c,max}$) and produced a first grid dataset
35 of leaf age-dependent LAI product (**referred to as Lad-LAI**) over the continental scale
36 from satellite observations of TROPOMI (the TROPospheric Monitoring Instrument)
37 sun-induced chlorophyll fluorescence (SIF) as a proxy of leaf photosynthesis. The
38 seasonality of three LAI cohorts from the new Lad-LAI products agree well at the three
39 sites (one in subtropical Asia and two in Amazon) with very fine collections of monthly
40 LAI of young, mature and old leaves. Continental-scale comparisons with independent
41 Moderate-resolution Imaging Spectroradiometer (MODIS) Enhanced Vegetation Index
42 (EVI) products and 53 samples of *in situ* measurements of seasonal litterfall data also
43 demonstrate the robustness of the LAI seasonality of the three leaf age cohorts. The
44 spatial patterns clustered from the three LAI cohorts coincides with those clustered
45 from climatic variables. And the young and mature LAI cohorts perform well in
46 capturing a dry-season green-up of canopy leaves across the wet Amazonia areas where
47 mean annual precipitation exceeds $2,000 \text{ mm yr}^{-1}$, consistent with previous satellite
48 data analysis. The new Lad-LAI products are primed to diagnose the adaption of
49 tropical and subtropical forest to climate change; and will also help improve the
50 development of phenology modules in Earth System Models. The proposed satellite-
51 based approaches can provide reference for mapping finer temporal and spatial
52 resolution LAI products with different leaf age cohorts. The Lad-LAI products are
53 available at <https://doi.org/10.6084/m9.figshare.21700955.v2> (Yang et al., 2022).

54

55

56 **1. Introduction**

57 Canopy phenology is the primary cause of photosynthetic seasonality (Chen et al.,
58 2020; Wu et al., 2016) and thus largely regulates the seasonal carbon sinks (Beer et al.,
59 2010; Aragao et al., 2014; Saatchi et al., 2011) in tropical and subtropical evergreen
60 broadleaved forests (EBFs). However, the ecological connotations of canopy
61 phenology in tropical and subtropical EBFs differ greatly from those in temperate and
62 boreal forests, that is, the latter one is closely related to a critical plant trait — total leaf
63 area index (LAI) that shows remarkable seasonal variations while the former one is
64 rarely linked to the total LAI which shows marginally small seasonal changes (Wu et
65 al., 2016; Chen et al., 2020). Due to the useless of total LAI as a proxy for tropical
66 phenology, it remains less clear what is the most effective plant trait to represent the
67 phenology seasonality in tropical and subtropical EBFs.

68 Recently, leaf age-dependent LAI is convergently shown by studies to well
69 representation of canopy phenology in tropical and subtropical EBFs (Chen et al., 2020).
70 Although there are less seasonal variations in the LAI of entire canopy, LAI of different
71 leaf age classes (i.e., cohorts) show considerable seasonality (Wu et al., 2016). *In situ*
72 measurements, even though spatially sparse, recorded an increase in LAI of young and
73 mature leaves and conversely a decrease in LAI of old leaves as solar radiation
74 enhances (Wu et al., 2016). The key point is that LAI of young and mature leaf cohorts
75 dominate regulating the seasonal cycles of carbon fluxes (Albert et al., 2018; Doughty
76 and Goulden, 2008a; Wu et al., 2016). It is because that the newly-flushed young leaves
77 and maturing leaves show higher photosynthetic capacity than the old leaves being
78 replaced (Xu et al., 2017), and thereby increase canopy photosynthesis by taking more
79 advantage of surface radiation (Anber et al., 2015; Wu et al., 2017), even during the dry
80 seasons (Manoli et al., 2018; Restrepo-Coupe et al., 2013; 2017; Saleska et al., 2003;
81 2016; Xu et al., 2015; Morton et al., 2014; Guan et al., 2015). This phenomenon has
82 been well documented from eddy covariance data (Wu et al., 2016), biometric
83 measurements of canopy foliage productivity (Doughty et al., 2015) and ESM model-
84 derived LAI and gross primary production data (De Weirdt et al., 2012; Chen et al.,

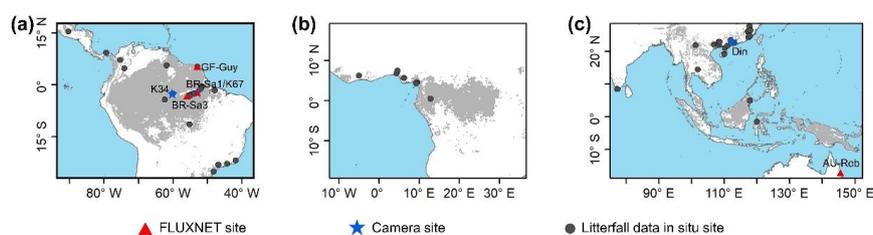

85 2020; Chen et al., 2021) in both humid- and dry-land tropical and subtropical EBFs.
86 However, seasonal patterns of leaf age-dependent LAI are still unclear and are rarely
87 studied at the continental scale. This vague notion \ imposes a challenge for accurately
88 modeling continental-scale canopy photosynthesis seasonality in most land surface
89 models (LSMs) due to their poor representation of the canopy phenology in tropical
90 and subtropical EBF biomes (Restrepo-Coupe et al., 2017; Chen et al., 2021).

91 In this study, we aim to fill this gap by firstly mapping the seasonal LAI of three
92 leaf age cohorts (i.e., young, mature and old leaves, denoted as LAI_{young} , LAI_{mature} , and
93 LAI_{old} , respectively) to interpret the phenological seasonality in tropical and subtropical
94 EBF biomes from 2001 to 2018. We simplified that canopy photosynthesis (i.e., gross
95 primary production (GPP)) is composed of three parts that are produced from young,
96 mature and old leaves, respectively. Based on this assumption, GPP is expressed as
97 functions of the sum of the product of each LAI cohort (LAI_{young} , LAI_{mature} , and LAI_{old})
98 and corresponding net CO_2 assimilation rate (A_{young} , A_{mature} , and A_{old}), which is
99 calculated by the widely used Farquhar-von Caemmerer-Berry (FvCB) leaf
100 photochemistry model (Farquhar et al., 1980). And the grid GPP maps are linearly
101 derived from an arguably better proxy — TROPOMI (the TROPOspheric Monitoring
102 Instrument) Solar-Induced Fluorescence (SIF) calibrated by eddy covariance GPP data.

103 To decompose the three LAI cohorts from **Equation 1**, we hypothesized that the
104 adjacent four cells in the grid map exhibit consistent magnitude and seasonality of GPP,
105 LAI_{young} , LAI_{mature} , and LAI_{old} . Then, we applied **Equation 1** to each of the four selected
106 cells and combined the four equations to derive the three LAI cohorts using a linear
107 least-squares with constrained method. *In situ* measurements of seasonal LAI_{young} ,
108 LAI_{mature} , and LAI_{old} in two Amazonian sites and subtropical Asian sites (blue
109 pentangles in **Fig. 1, Table S1**) are used to directly validate the simulating results. To
110 prove the robustness of the products over a large spatial coverage, the seasonal LAI
111 cohorts of young and mature leaves are evaluated against the enhanced vegetation index
112 (EVI) product, which is considered as a proxy for leaf area changes of photosynthetic

113 effective leaves (Saatchi, et al., 2015; Wu et al., 2016). Additionally, the LAI cohorts of
114 old leaves are compared with the phase of litterfall mass from 53 *in situ* sites (black
115 circles in **Fig. 1**) spanning tropical and subtropical EBF regions. This new dataset of
116 three LAI cohorts provides new insights into tropical and subtropical phenology with
117 more details of sub-canopy level of leaf seasonality in different leaf age cohorts and
118 will be helpful for developing accurate tropical phenology model in ESMs.

119
120 **Figure 1.** Study areas over tropical and sub-tropical for evergreen broadleaves forests.

122 sites of three LAI cohort seasonality. Black circles: observation sites of litterfall
123 seasonality.

124

125 2. Methodology

126 2.1 Decomposing LAI cohorts (young, mature and old) from SIF-derived GPP

127 **Figure 2** illustrates the overall framework used to generate leaf age-dependent LAI
128 seasonality product (Lad-LAI). The majority of the tropical and subtropical EBFs retain
129 leaves year-round and their total LAI shows marginally small seasonal changes (Wu et
130 al., 2016). Therefore, previous modelling studies have assumed a constant value for the
131 total LAI in tropical and subtropical EBFs (Cramer et al., 2001; Arora and Boer, 2005).
132 In this study, we follow above previous studies to assume a total constant value (total
133 LAI= 7) of total LAI in tropical and subtropical EBFs. We grouped the canopy leaves
134 of tropical and subtropical EBFs into three leaf age cohorts, i.e., young, mature and old
135 leaves, respectively. Then, the total GPP is the sum of those produced by the young,
136 mature and old leaves, respectively. According to the Farquhar-von Caemmerer-Berry

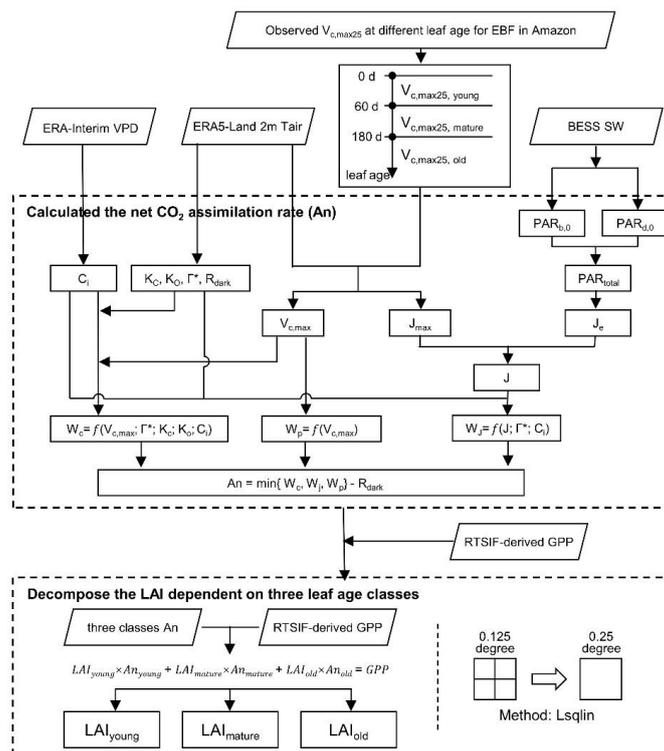

137 (FvCB) leaf photochemistry model (Farquhar et al., 1980), GPP can be expressed as
138 function of the sum of the products of each LAI cohort (LAI_{young} , LAI_{mature} , and LAI_{old})
139 and corresponding net CO₂ assimilation rate (An_{young} , An_{mature} , and An_{old}) (**Equation**
140 **1**).

$$141 \quad LAI_{young} \times An_{young} + LAI_{mature} \times An_{mature} + LAI_{old} \times An_{old} = GPP \quad (1)$$

142 where LAI_{young} , LAI_{mature} and LAI_{old} are the leaf area index cohorts; An_{young} , An_{mature}
143 and An_{old} are the net rate of CO₂ assimilation dependent on three leaf age classes; GPP
144 is canopy total gross primary production. The sum of LAI_{young} , LAI_{mature} and LAI_{old} is
145 set as a constant, equaling to 7 according to Chen et al. (2020).

146 The GPP is derived from SIF (denoted as RTSIF-derived GPP) using a linear
147 regression model (see sect. 2.2) based on the relationship between RTSIF and EC-
148 observed GPP from 4 sites (**Table S2**). The An_{young} , An_{mature} and An_{old} are calculated
149 according to the FvCB biochemical model (Farquhar et al., 1980; Bernacchi et al., 2003)
150 (see sect. 2.3). As there are still three unknown variables to be solved in equation 1
151 (LAI_{young} , LAI_{mature} and LAI_{old}), we hypothesized that the adjacent four pixels exhibit
152 homogenous EBFs and consistent leaf demography and canopy photosynthesis. Then,
153 we used the data from adjacent four pixels to solve the LAI_{young} , LAI_{mature} and LAI_{old}
154 from GPP based on **Equation 1** using a linear least-squares with constrained method.
155 The inputs grid datasets (i.e. SIF-derived GPP, T_{air} , VPD and SW, **Table S3**) in **Fig. 2**
156 are sampled at 0.125-degree spatial resolution; while the output maps of LAI_{young} ,
157 LAI_{mature} , and LAI_{old} are at 0.25-degree spatial resolution. Therefore, the output maps
158 of LAI_{young} , LAI_{mature} , and LAI_{old} are at a 0.25-degree spatial resolution. We used Python
159 version 3.7 (Python Software Foundation, <http://www.python.org>) and matlab R2019b
160 for all our analyses.

161

162 **Figure 2.** The workflow for mapping Lad-LAI using the LsqIn method. LsqIn is the
 163 abbreviation of Linear least-squares solver with bounds or linear constraints. All the
 164 abbreviations are described in supplementary **Tables S4**.

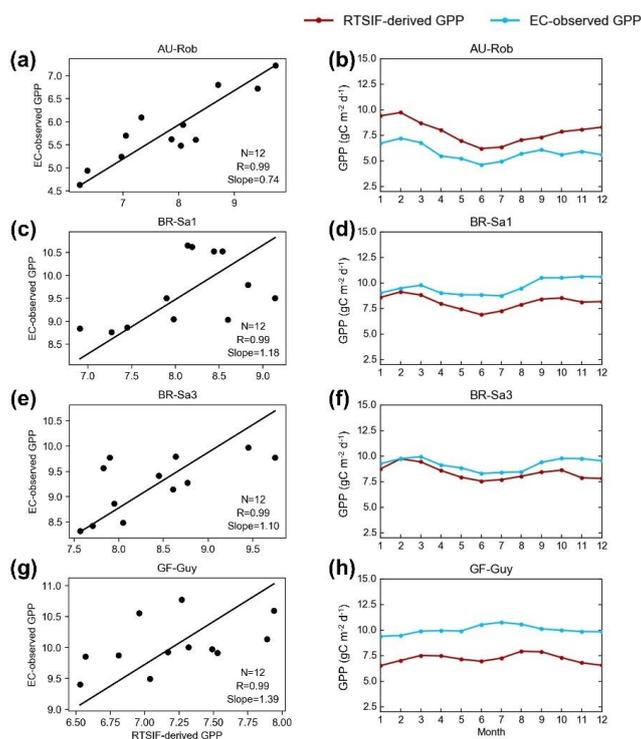

165

166 2.2 Calculating the GPP from TROPOMI SIF (RTSIF-derived GPP)

167 Satellite-retrieved solar-induced chlorophyll fluorescence (SIF) is a widely used
 168 proxy for canopy photosynthesis (Yang et al., 2015; Dechant et al., 2020). Here, we
 169 used a long-term reconstructed TROPOMI SIF dataset (RTSIF) (Chen et al., 2022) to
 170 estimate GPP seasonality. Previous analyses show that RTSIF is strongly linearly
 171 correlated to eddy covariance (EC) GPP and used 15.343 as a transformation coefficient
 172 to convert RTSIF to GPP (Fig. 8a in Chen et al., 2022). In this study, we collected GPP
 173 data at 4 EC sites from the FLUXNET 2015 Tier 1 dataset (**Table S2**; Pastorello et al.,

174 2020) and examined the relationship between RTSIF-derived GPP and EC GPP (**Fig.**
 175 **3**). Results confirmed the robustness of estimating the GPP seasonality using RTSIF-
 176 derived GPP ($R^2 > 0.90$). Despite potential overestimation (**Fig. 3 b**) or underestimation
 177 (**Fig. 3 h**) of the magnitudes, RTSIF-derived GPP mostly captures the seasonality of the
 178 EC GPP at all the 4 sites ($d_{\text{phase}} < 0.26$).

179
 180 **Figure 3.** Comparisons between monthly RTSIF-derived GPP (red) and EC-observed
 181 GPP (blue). (a-b) Au-Rob, (c-d) BR-Sa1, (e-f) BR-Sa3, and (g-h) GF-Guy. The
 182 regression is forced to pass the origin.

183

184 2.3 Calculating the net rate of CO₂ assimilation (A_n)

185 We calculated the net CO₂ assimilation (A_n) according to the FvCB biochemical
 186 model (Farquhar et al., 1980). In this model, the parameter A_n is calculated as the
 187 minimum of Rubisco (W_c), RuBP regeneration (W_j) and TPU (W_p), respectively, minus
 188 dark respiration (R_{dark}) (Bernacchi et al., 2013). The formulas for calculating A_n, W_c,

189 W_j , W_p , R_{dark} and corresponding intermediate variables are listed in **Tables S4**.

190 **Calculation of W_c .** W_c is expressed as a function of internal CO_2 concentration (c_i),
191 Michaelis-Menton constant for carboxylase (K_c), Michaelis-Menton constant for
192 oxygenase (K_o), CO_2 compensation point (Γ^*) and maximum carboxylation rate ($V_{c,\text{max}}$)
193 (**Table S4-part1**) (Lin et al., 2015; Bernacchi et al., 2013; Ryu et al., 2011; Medlyn et
194 al., 2011; June et al., 2004; Farquhar et al., 1980). The K_c , K_o , Γ^* and $V_{c,\text{max}}$ are
195 temperature-dependent variables. Thus, we used **Equation 2** to calculate their values at
196 T_k by converting from those at 25°C . Then, we used the Medlyn's stomatal conductance
197 model (Medlyn et al., 2011) to estimate internal CO_2 concentration (c_i) (**Equation 3**),
198 which is expressed as a function of vapor pressure deficit (VPD) rather than relative
199 humidity (Lin et al., 2015). The method of $V_{c,\text{max}}$ calculating for each LAI cohort is
200 introduced in sect. 2.4. The formulas for calculating corresponding intermediate
201 parameters are presented in **Table S4 -part2**.

$$202 \quad \text{Para} = \text{Para}_{25} \times \exp\left(\frac{(T_k - 298.15) \times \Delta H_{\text{para}}}{R \times T_k \times 298.15}\right) \quad (2)$$

203 where Para denotes a correction factor arising from the temperature dependence of
204 $V_{c,\text{max}}$; Para_{25} are values of the temperature-dependent parameters (K_c , K_o , Γ^* and $V_{c,\text{max}}$)
205 at the temperature 25°C ; T_k denotes temperature in Kelvin; ΔH_{para} is activation energy
206 for temperature dependence; R is universal gas constant.

$$207 \quad c_i = c_a \times \left(1 - \frac{1}{1.6 \times \left(1 + \frac{g_1}{\sqrt{\text{VPD}}}\right)}\right) \quad (3)$$

208 where c_a is atmospheric CO_2 concentration, 380 ppm; VPD is calculated from air
209 temperature and dew point temperature of the global ERA-Interim reanalysis dataset
210 (Dee et al., 2011) using the method of Yuan et al. (2019). The calculation formula of
211 VPD is described in supplementary files. In this study, we used the value of 3.77 for
212 the stomatal slope (g_1) in the stomatal conductance model according to Lin et al. (2015).

213 **Calculation of W_p .** W_p is calculated as the function of $V_{c,\text{max}}$, which are given
214 different values for different LAI cohorts based on multiple *in situ* observations (sect.
215 2.4).

216 **Calculation of W_j .** W_j is calculated from $V_{c,max}$, c_i and the rate of electrons through
217 the thylakoid membrane (J) (Bernacchi et al., 2013). The parameter J is calculated from
218 maximum electron transport rate (J_{max}) and the rate of whole electron transport provided
219 by light (J_e) (Bernacchi et al., 2013). J_{max} is expressed as a temperature dependence
220 function of maximum electron transport rate ($J_{max,25}$) at 25°C and temperature (T_{air}) and
221 J_e is expressed as a function of total PAR absorbed by canopy (PAR_{total}), which is the
222 sum of active radiation in beam ($PAR_{b,0}$) and diffuse ($PAR_{d,0}$) light firstly (Weiss et al.,
223 1985), which are calculated from downward short wave radiation (SW) (Zhang et al.,
224 2014). The formula for PAR_{total} is given in **Equation 4** and formulas for other
225 intermediate parameters 4 (i.e., $PAR_{b,0}$, $PAR_{d,0}$, ρ_{cb} , ρ_{cd} , k'_b , k'_d , and CI) are listed in
226 **Table S4-part3** and **Table S4-part4**.

$$227 \quad PAR_{total} = (1 - \rho_{cb}) \times PAR_{b,0} \times (1 - \exp(-k'_b \times CI \times LAI_{total})) + (1 - \rho_{cd}) \times \\ 228 \quad PAR_{d,0} \times (1 - \exp(-k'_d \times CI \times LAI_{total})) \quad (4)$$

229 where PAR_{total} is total PAR absorbed by canopy; $PAR_{b,0}$ is the active radiation; $PAR_{d,0}$
230 is diffuse radiation; LAI_{total} is a total LAI and here we used a constant value of 7
231 according to Chen et al. (2020).

232

233 **2.4 Classifying three LAI cohorts with different $V_{c,max}$**

234 In this study, we collected *in situ* samples of $V_{c,max25}$ data against different leaf age
235 across tropical and subtropical EBFs from previous publications (Keller et al., 2001;
236 Araújo, 2002). Mature leaves (leaf age: 70-160 days) show highest $V_{c,max25}$ than those
237 of new flushed leaves (leaf age: <60 days) and old leaves (leaf age: >200 days) as
238 Menezes et al. (2022). Therefore, in this study, we also classified the canopy leaves into
239 three cohorts: young (leaf age: <2 months), mature (leaf age: 3-5 months) and old
240 cohorts (leaf age: >6 months) as Wu et al. (2016). The $V_{c,max25}$ for young, mature and
241 old cohorts are set as 60, 40 and 20 $\mu\text{mol m}^{-2} \text{s}^{-1}$, respectively, according to previous
242 ground-based observations (Keller et al., 2001; Araújo, 2002).

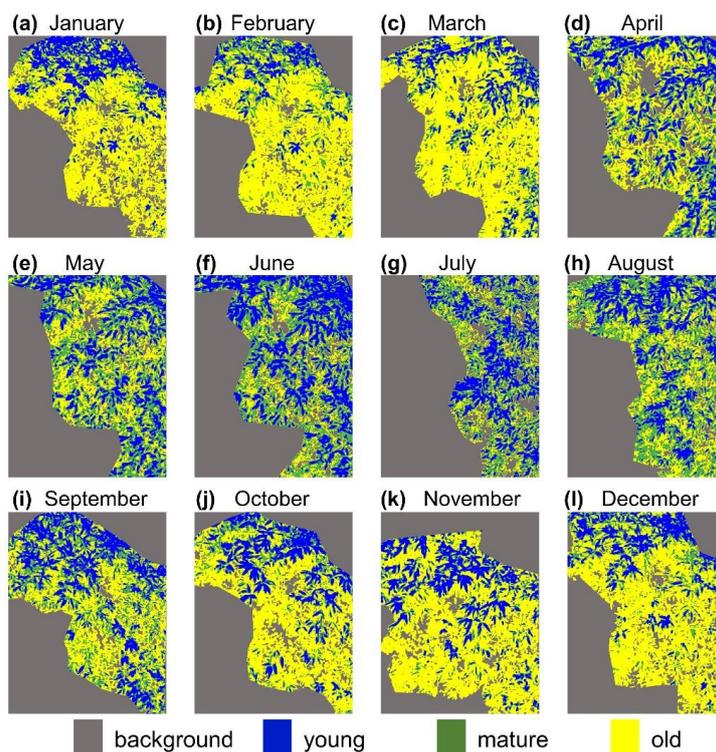

243

244 **2.5 Ground-based observations for LAI cohort validations**

245 At present, there are only several studies that have decomposed the total LAI into
246 different leaf age cohorts. Thus, only three sites with observation of LAI_{young}, LAI_{mature}
247 and LAI_{old} are used for validating the corresponding simulated LAI cohorts. Two sites
248 (K67 and K34) are at Amazon (Wu et al., 2016). The mean monthly LAI cohorts were
249 calculated from top-of-canopy images of a Tetracam Agricultural Digital Camera (Wu
250 et al., 2016). The camera-inferred LAIs were classified into three cohorts based on
251 different leaf ages: young (<2 months); mature (3–5months); old (>6 months). Detailed
252 information on camera data processing is given by Wu et al. (2016).

253 Another site is at Dinghushan station in subtropical China. The hourly top - of -
254 canopy images of trees are observed by an RGB camera. This study classified the
255 canopy leaves into young, mature and old age cohorts based on the green-color band,
256 as the brightness of different leaf age leaves in the same band differ greatly. Raster
257 density slicing is a useful classification method for detecting the attributes of various
258 ground objects (Kartikeyan et al., 1998). Therefore, we set three brightness thresholds
259 to divide young (blue), mature (green), old (yellow) leaves and background (gray) for
260 the same canopy extent in each month (**Fig. 4**). This analysis is conducted in ENVI5.3
261 software.

262

263 **Figure 4.** Classifications of canopy leaves into young, mature and old age cohorts in
264 Dinghushan station. The boundaries of the imageries are those of the tree canopies that
265 vary between months.

266

267 2.6 Evaluating the LAI of young and mature leaf age cohorts using satellite-based 268 EVI

269 To evaluate the LAI seasonality of photosynthesis-effective leaves, i.e. young and
270 mature leaves, this study used satellite-based MODIS Enhanced Vegetation Index (EVI)
271 from independent sensors (Huete et al., 2002; Lopes et al., 2016; Kobayashi, et al., 2018)
272 as a remotely sensed proxies alternatives of effective leaf area changes and new leaf
273 flush, i.e., $LAI_{\text{young+mature}}$ (Wu et al., 2016; Saatchi, et al., 2015). To compare the
274 seasonality of $LAI_{\text{young+mature}}$ with those of EVI, we calculate MSD and their three
275 components— d_{bias} , which denotes the differences about absolute value, d_{var} , which
276 denotes the differences of seasonal fluctuations, and d_{phase} , which denotes the

277 differences of peak phase to evaluate this consistence, comprehensively (see
278 Methodology 2.8 section).

279 Additionally, we compared the spatial patterns of the wet- minus dry-season
280 differences (Δ) between observed and simulated variables, following the work of Guan,
281 et al. (2015). To determine the wet and dry seasons in each grid cell, we defined a month
282 as dry one when its monthly average precipitation was smaller than the potential
283 evapotranspiration (PET) computed using the method of Maes et al. (2019); other
284 months are classified as wet ones. The wet- minus dry-season $LAI_{\text{young+mature}}$ (denoted
285 as $\Delta LAI_{\text{young+mature}}$) was calculated for each grid cell as the wet-season average
286 $LAI_{\text{young+mature}}$ value minus the dry-season average value of $LAI_{\text{young+mature}}$.

287

288 2.7 Evaluating the LAI of old leaf age cohorts using ground-based litterfall

289 Litterfall is closely related to the seasonal dynamics of old leaves, i.e. LAI_{old} (Chen
290 et al., 2020; Yang et al., 2021). Previous analyses indicated that, in general, a sharpening
291 decrease in LAI_{old} correspond to a peak in litterfall (Pastorello et al., 2020; Midoko
292 Iponga et al., 2019; Ndakara, 2011; Barlow et al., 2007; Dantas and Phillipson, 1989).
293 Based on this relationship between litterfall and LAI_{old} , we compare the time of
294 seasonal litterfall peak with the time of sharpest negative slopes of LAI_{old} , to indirectly
295 evaluate the LAI_{old} seasonality. To accurately detect the onset date of old leaves
296 shedding and the day of litterfall peak, we used a least-square regression analysis
297 method developed by Piao et al. (2006) to smoothen LAI_{old} and litterfall seasonal curves.
298 The sixth-degree polynomial function ($n=6$) is applicable to the regression (**Equation**
299 **5**).

$$300 LAI_{\text{old}} = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \quad (5)$$

301 where x is the day of a year.

302 Then, we identified the period of sharpest decrease in LAI_{old} as the beginning of
303 leaves shedding season. For this purpose, we firstly calculated the slope of LAI_{old} curve,
304 denoted as $LAI_{\text{old, ratio}}$ (**Equation 6**), from the series of consecutive 1-month periods

305 and detected the time t with the maximum $LAI_{old, ratio}$, and then used the corresponding
306 $LAI_{old(t)}$ as the LAI_{old} threshold for the onset date of old leaves shedding.

$$307 \quad LAI_{old, ratio(t)} = (LAI_{old(t+1)} - LAI_{old(t)}) / (LAI_{old(t)}) \quad (6)$$

308 Then, we determined the onset dates of old leaves shedding for each litterfall site,
309 using the polynomial regression results and the LAI_{old} thresholds calculated before, to
310 compare with the day of litterfall peak (see in sect. 3.4). In this study, we collected 53
311 samples of monthly litterfall data across tropical and subtropical EBFs from globally
312 published articles, and averaged multiyear data to the monthly mean data to compare
313 with the seasonality of LAI_{old} . The geographical positions of 53 field observations were
314 shown in **Fig. 1** (black circles). The seasonality of LAI (LAI_{young} , LAI_{mature} , LAI_{old}),
315 litterfall mass, photosynthesis proxies (EVI, RTSIF-derived GPP) and climate proxies
316 (T_{air} , VPD, SW) at these field are shown in **Fig. S1**. Litterfall datasets are listed in **Table**
317 **S5**.

318

319 2.8 Evaluation Metrics

320 Two metrics were chosen to evaluate the seasonality of Lad-LAI against the that
321 of other proxies: the Kobayashi decomposition of the Mean Square Difference between
322 model and observation (Kobayashi and Salam, 2000) and the Pearson correlation
323 coefficient (Pearson, 1896) for gridded fields.

324 **Mean square deviation (MSD).** The mean squared deviation (MSD) is given by
325 Kobayashi and Salam (2000):

$$326 \quad MSD = \frac{1}{n} \sum_{i=1}^n (x_i - y_i)^2 \quad (7)$$

$$327 \quad SB = (\bar{x} - \bar{y})^2 \quad (8)$$

$$328 \quad SD_s = \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \quad (9)$$

$$329 \quad SD_m = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \bar{y})^2} \quad (10)$$

$$330 \quad SDDS = (SD_s - SD_m)^2 \quad (11)$$

$$331 \quad LCS = 2SD_s SD_m (1 - r) \quad (12)$$

332 where mean squared deviation is the square of RMSD; i.e., $MSD = RMSD^2$. The lower
333 the value of MSD, the closer the simulation is to the measurement. MSD can be
334 decomposed into the sum of three components: the squared bias (d_{bias}), $d_{bias}=SB$; the
335 squared difference between standard deviations (variance-related difference, d_{var}),
336 $d_{var}=SDSD$; and the lack of correlation weighted by the standard deviations (phase-
337 related difference, d_{phase}), $d_{phase}=LCS$; r indicates the correlation coefficient between x
338 and y .

339 **Pearson correlation coefficient (R)**. The Pearson correlation coefficient is a
340 measure of linear correlation between two variables (Merkl and Waack, 2009). The
341 correlation coefficient between X and Y is as:

$$342 \rho_{X,Y} = \frac{cov(X,Y)}{\sigma_X \sigma_Y} = \frac{E((X-\mu_X)(Y-\mu_Y))}{\sigma_X \sigma_Y} \quad (13)$$

343

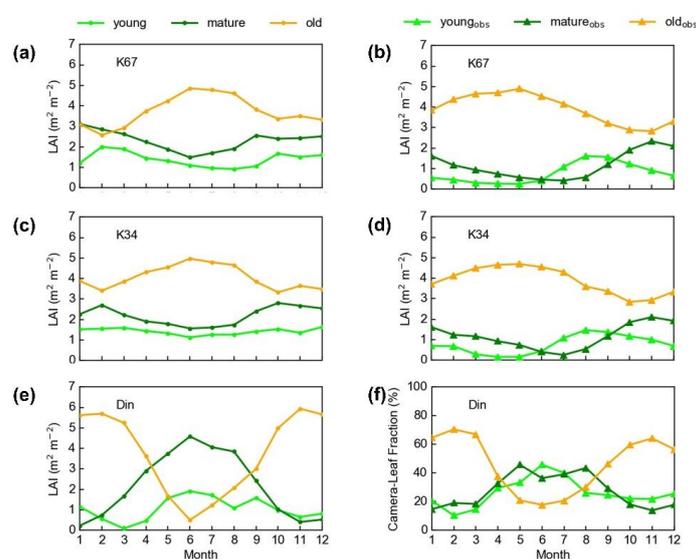

344 3. Results

345 3.1 Comparison of LAI cohort seasonality with sparse site observations

346 Despite very few site observations of LAI_{young} , LAI_{mature} , and LAI_{old} over TEFs, the
347 leaf age-dependent LAI seasonality product agrees well with these camera - based
348 measurements of LAI_{young} , LAI_{mature} , and LAI_{old} at K67, K34 sites in Amazon and
349 Dingshuan site in China. The LAI seasonality of mature and old classes from the new
350 Lad-LAI products agree well at these sites with very fine collections of monthly LAI
351 of mature ($R^2_{K67}=0.40$, $R^2_{K34}=0.81$, $R^2_{Din}=0.90$; $MSD_{K67}=1.55$, $MSD_{K34}=1.12$,
352 $MSD_{Din}=6.33$) and old leaves ($R^2_{K67}=0.02$, $R^2_{K34}=0.40$, $R^2_{Din}=0.92$; $MSD_{K67}=0.87$,
353 $MSD_{K34}=0.30$, $MSD_{Din}=15.57$). However, the seasonality of LAI from young leaves
354 performs a little poor in comparison with mature and old leaves ($R^2_{K67}=0.24$,
355 $R^2_{K34}=0.02$, $R^2_{Din}=0.48$; $MSD_{K67}=0.87$, $MSD_{K34}=0.65$, $MSD_{Din}=1.07$). It is because that
356 the trade-off between the phenology of mature and old leaves mainly control the
357 seasonality of canopy photosynthesis. It is interesting to note that the canopy leaf
358 phenology of TEFs at these sites differ greatly. At K67 and K34 sites, both *in situ* and
359 simulated LAI_{young} and LAI_{mature} decrease at early wet season around February and

360 convert to increase at early wet season around June (**Fig. 5 a-d**). On the contrary, at
361 Dinghushan sites, LAI_{young} and LAI_{mature} increase during the wet season and peak with
362 largest rainfall at June or July (**Fig. 5 e and f**). There is a reverse pattern for LAI_{old}
363 seasonality compared to LAI_{mature} for all the three sites.

364

365 **Figure 5.** Seasonality of simulated LAI_{young} , LAI_{mature} , and LAI_{old} in comparison with
366 observed data at Amazonian K67, K34 sites and Asian Dinghushan site.

367

368 **3.2 Comparison of patterns of grid LAI cohort seasonality with previous climatic** 369 **and phenological patterns**

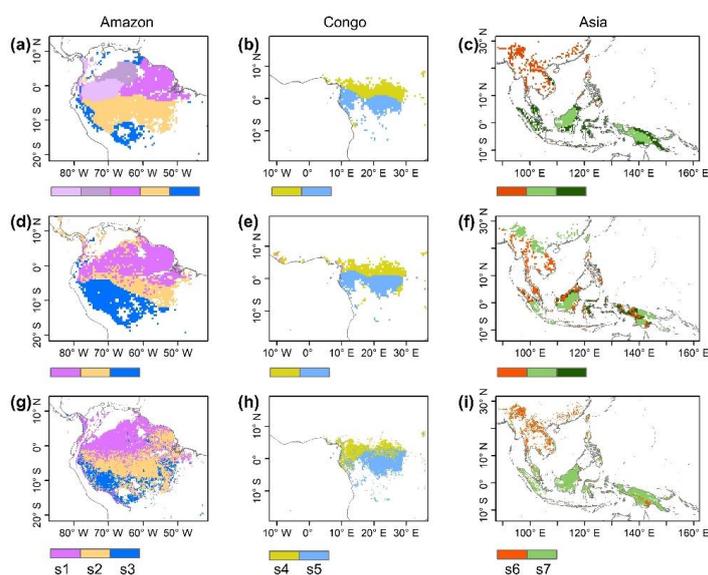

370 The *in situ* measurements of LAI_{young} , LAI_{mature} , and LAI_{old} suggest diverse patterns
371 of Lad-LAI seasonality over the TEFs; while the sparse coverage of these site
372 measurements limit a comprehensive and direct evaluation of leaf age-dependent LAI
373 seasonality product. To continue in-depth sub-regional evaluations of the grid Lad-LAI
374 seasonality product, we further conduct spatial clustering analyses of LAI_{young} , LAI_{mature} ,
375 and LAI_{old} using the *K*-means analysis method (see methods).

376 Surprisingly, the spatial clustering patterns of Lad-LAI product derived from
377 satellite-based vegetative signals (**Fig. 6 g-i**) coincide well with those clustered from

378 in-dependent climatic variables (rainfall and radiation etc.) (**Fig. 6 a-c**) (see methods).
379 These patterns are also similar as those of the climate-phenology rhythms mapped by
380 (Yang et al., 2021), which suggest different correlations of litterfall seasonality with
381 canopy phenology between different climate-phenology rhythms.

382 In central (sub-region s2) and south (sub-region s3) Amazon (**Fig. 6 g**), the
383 seasonality of LAI_{young} , LAI_{mature} , and LAI_{old} (**Fig. 7 b and c**) are similar as those of
384 BR-Sa1 and BR-Sa3 sites. And in subtropical Asia (sub-region s6) (**Fig. 6 i**), the
385 seasonality of three LAI cohorts (**Fig. 7 f**) are similar as those of Dinghushan sites. The
386 remaining 4 sub-regions (sub-regions s1, s4, s5, s7) are all located nearby the equator.
387 The magnitudes of seasonal changes in LAI cohorts are smaller than those in sub-
388 regions s2, s3 and s6 away from the equator. It is worth noting that for these sub-regions
389 around the equator there is a bimodal seasonality pattern for LAI_{mature} , with the first
390 peak in around March and the second peak in around August (**Fig. 7 a, d, e and g**). This
391 is consistent with the findings of Li et al. (2021) that showed tropical and subtropical
392 TEFs changed from a unimodal phenology at higher-latitudes to a bimodal phenology
393 at lower-latitudes.

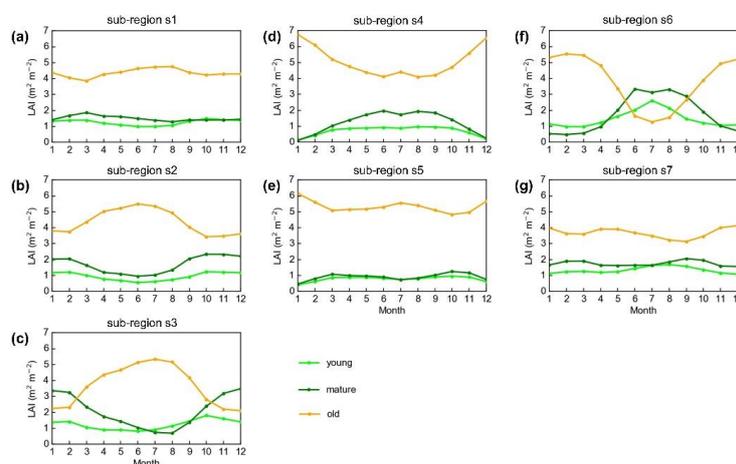

394

395 **Figure 6.** Comparison of sub-regions of Lad-LAI products (plots g-i) with those of

396 climatic factors classified by the *K*-means clustering analysis (plots a-c) (Chen et al.,
397 2019) and those of the three climate-phenology regimes (plots d-f) developed by Yang
398 et al. (2021).

399

402 classified by the *K*-means clustering analysis.

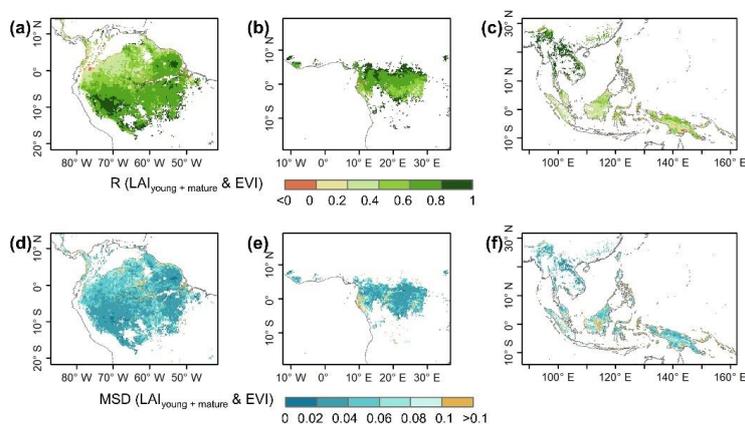

403

404 3.3 Sub-regional evaluations of grid $LAI_{young+mature}$ seasonality using satellite-based 405 EVI products

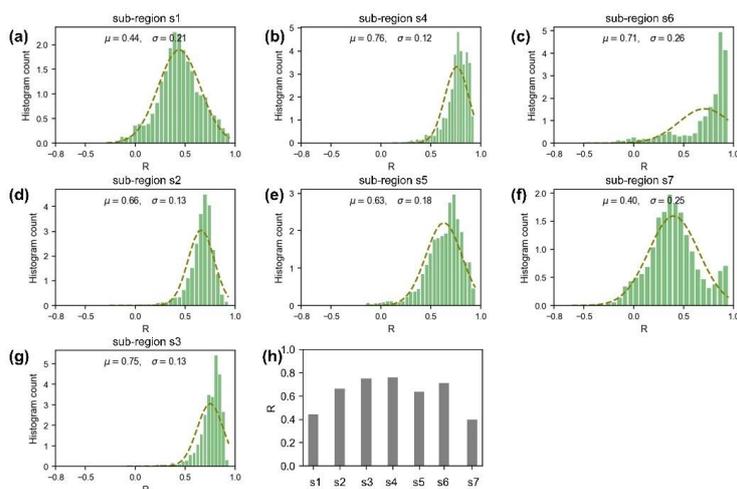

406 The grid dataset of $LAI_{young+mature}$ seasonality was indirectly evaluated using the
407 satellite-based EVI products (Wang et al., 2017; De Moura et al., 2017; Xiao et al.,
408 2005; Wu et al., 2018), as the Enhanced Vegetation Index (EVI) can be considered as a
409 proxy for leaf area change of those leaves with high photosynthesis efficiency (Huete
410 et al., 2006; Lopes et al., 2016; Wu et al., 2018). The linear correlation and MSD
411 decompositions (see methods) between simulated and satellite-based EVI are displayed
412 in **Fig. 8**. Overall, the seasonal $LAI_{young+mature}$ in 76.79% of the TEFs is well correlated
413 with satellite-based EVI ($R^2 > 0.40$) (**Fig. 8 a-c**). The MSD is smaller than 0.1 in 90.59%
414 of the TEFs over the whole tropical and subtropical region (**Fig. 8 d-f**). Statistics in the
415 7 clustered sub-regions show that the seasonal $LAI_{young+mature}$ of Lad-LAI data mostly

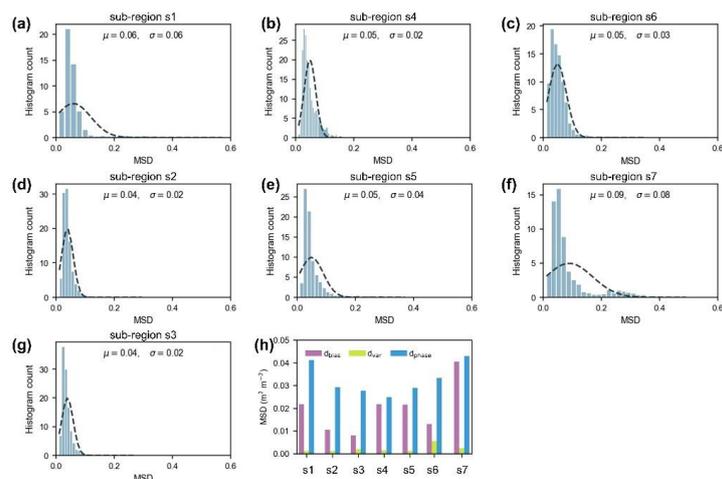

416 correlate better with seasonal EVI in high-latitude areas (sub-region s2: $R=0.66$, sub-
417 region s3: $R=0.75$, sub-region s6: $R=0.71$) than those in low latitudes (sub-region s1:
418 $R=0.44$, sub-region s5: $R=0.63$, sub-region s7: $R=0.40$) except for sub-region s4
419 ($R=0.76$) (**Fig. 9**). The MSD components also confirm the better performance of
420 $LAI_{\text{young+mature}}$ seasonality in high-latitude areas (sub-region s2: $d_{\text{bias}}=0.010$, $d_{\text{var}}=0.001$,
421 $d_{\text{phase}}=0.029$; sub-region s3: $d_{\text{bias}}=0.008$, $d_{\text{var}}=0.002$, $d_{\text{phase}}=0.028$; sub-region s6:
422 $d_{\text{bias}}=0.013$, $d_{\text{var}}=0.005$, $d_{\text{phase}}=0.033$) than in low-latitude areas near the Equator (sub-
423 region s1: $d_{\text{bias}}=0.022$, $d_{\text{var}}=0.002$, $d_{\text{phase}}=0.041$; sub-region s4: $d_{\text{bias}}=0.022$, $d_{\text{var}}=0.001$,
424 $d_{\text{phase}}=0.025$; sub-region s5: $d_{\text{bias}}=0.022$, $d_{\text{var}}=0.001$, $d_{\text{phase}}=0.029$; sub-region s7:
425 $d_{\text{bias}}=0.040$, $d_{\text{var}}=0.002$, $d_{\text{phase}}=0.043$) (**Fig. 10**).

 441 region.

442

443 Additionally, previous studies indicated large-scale dry-season green-up area over
444 tropical and subtropical region (i.e., Guan et al., 2015, Tang et al., 2017, Myneny et al.,
445 2007) where MAP exceeds 2,000 mm yr⁻¹. Here, we calculated the differences (Δ)
446 between wet- and dry-season $LAI_{\text{young+mature}}$ (i.e., $LAI_{\text{young}} + LAI_{\text{mature}}$), to test whether
447 the Lad-LAI can capture this green-up spatial pattern. Spatial patterns of
448 $\Delta LAI_{\text{young+mature}}$ (**Fig. 11**) were similar to those developed by (Guan et al., 2015), with
449 higher $LAI_{\text{young+mature}}$ during the dry season (blue area) in large areas north of the
450 Equator. This indicates an emergence of new leaf flush and increase of mature leaves,
451 resulting the canopy “green-up” phenomenon observed by previous satellite-based
452 signals. It is interesting to note that the total areas (blue regions in **Fig. 11**) of this dry-
453 season green up shown by $LAI_{\text{young+mature}}$ is smaller than those shown by SIF signals
454 that almost everywhere north of the Equator. That is because that new and mature leaves
455 show quite a higher photosynthetic capacity than old leaves. A slight or moderate
456 “green-up” in new and mature leaves (i.e., increase in $LAI_{\text{young+mature}}$) would boost
457 strong increase in photosynthesis, inducing significant “green-up” shown by
458 photosynthesis-related signals, e.g. SIF data. Therefore, using photosynthesis proxies
459 likely overestimate the areas with “green-up” of new leaves during the dry seasons in
460 the real world.

461

462

463 **Figure 11.** Spatial pattern of dry-season green-up using wet-season $LAI_{\text{young+mature}}$

464 minus dry-season $LAI_{\text{young+mature}}$.

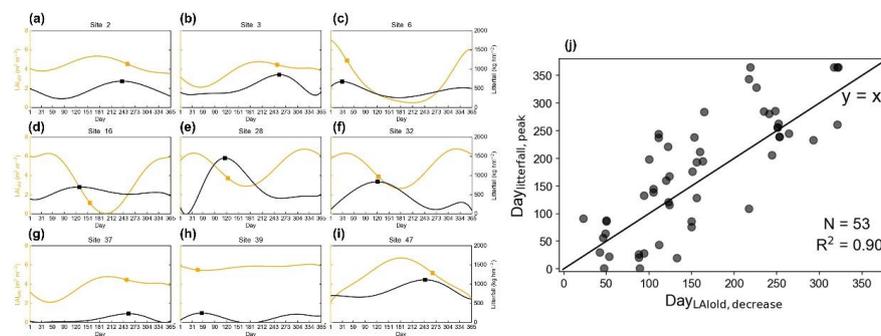

465

466 3.4 Sub-regional evaluations of grid LAI_{old} seasonality using site-based litterfall 467 observations

468 The seasonal patterns of LAI_{old} were evaluated indirectly using site-based seasonal
469 litterfall observations (black circles in **Fig. 1**). As there are 53 sites in total over the
470 tropical and subtropical EBFs, we selected 9 specific sites for examples with different
471 patterns of litterfall seasonality and LAI_{old} seasonality, to illustrate the analyses results.
472 **Fig. 12 a-i** illustrate the days when there is a sharpening decrease in monthly LAI_{old}, which
473 are closely to monthly litterfall peak. The days when LAI_{old} decreases sharpest
474 ($\text{Day}_{\text{LAIold}}$) agree well with the days when their monthly litterfall peaks ($\text{Day}_{\text{litterfall}}$) (**Fig.**
475 **12 j**), mostly distributed near the diagonal lines ($R^2=0.90$). This indirectly demonstrate
476 the robustness of the LAI_{old} seasonality of the Lad-LAI product.

477

478
479 **Figure 12.** Evaluation of simulated LAI_{old} using site-observed litterfall seasonality. (a-
480 i) Days of a sharpening decrease in LAI_{old} in comparison with days of corresponding
481 litterfall peak at 9 specific sites for examples. (j) Comparisons of the days when LAI_{old}
482 decreases sharpest ($\text{Day}_{\text{LAIold}}$) against the days when monthly litterfall peaks
483 ($\text{Day}_{\text{litterfall}}$).

484

485 4 Discussion

486 Leaf age-dependent LAI performs well in describing the seasonal replacements of
487 canopy leaves in TEFs (Wu et al., 2016; Chen et al., 2020), showing to be a critical
488 plant trait for representing the tropical and subtropical phenology (Doughty and

489 Goulden, 2008b; Saleska et al., 2007). However, to our knowledge, there are currently
490 no continental-scale information of such leaf age-dependent LAI data over the whole
491 TEFs, as it can neither be mapped from sparse site observations (Wu et al., 2016), nor
492 be modeled from ESMs which were triggered by unclear climatic drivers (Chen et al.,
493 2020). These hinder global researches on accurately simulations of large-scale
494 photosynthesis (GPP) seasonality using remote sensing approaches and ESMs (Chen et
495 al., 2020).

496 The Lad-LAI product developed in this study is a new continental-scale grid dataset
497 of monthly LAI in different leaf age cohorts. Although lacking of enough *in situ*
498 observations for adequate validations, the seasonality of three LAI cohorts performs
499 well at the three sites (K67, K34 and Din) with very fine collections of monthly LAI_{young},
500 LAI_{mature}, and LAI_{old}. To test the robustness of the grid Lad-LAI products over the whole
501 TEFs, the seasonality of LAI_{mature} seasonality was also validated pixel by pixel using
502 satellite-based EVI products and the phase of LAI_{old} seasonality were compared with
503 the those of seasonal litterfall data from 53 site measurements, respectively. Moreover,
504 the LAI_{young+mature} from the new Lad-LAI products can also directly represent the large-
505 scale dry-season green-up of canopy leaves north of the Equator. Therefore, direct and
506 indirect evaluations both demonstrated the robustness of the new grid Lad-LAI
507 products.

508 It should be noted that, over the regions with large magnitude of annual
509 precipitation nearby the Equator, there is no obvious dry seasons and thus tree canopy
510 phenology changes smaller than higher-latitude ones throughout the year (Yang et al.,
511 2021). Thus, the accuracy in the seasonality of LAI cohorts depend highly on that of
512 input SIF data, which shows marginally small seasonal changes nearby the equator. Our
513 analyses showed that the LAI_{young+mature} cohorts from Lad-LAI succeed to capture the
514 bimodal phenology of TEFs nearby the equator. It is also worth noting that we use a
515 constant to calculate to transfer from SIF data to GPP and also assume a constant value
516 for the total LAI over the whole TEFs, which tend to bring unexpected errors in the

517 magnitudes of simulated LAI cohorts. This can be seen from the MSD evaluations,
518 where the bias-related term dominated the total MSD, especially in regions nearby the
519 Equator. However, this bring less impacts on the seasonality of Lad-LAI, as the phase-
520 related term of MSD is much smaller.

521 Additionally, the maximum carboxylation rate ($V_{c,max}$) of leaves changes
522 significantly with leaf age (Xu et al., 2017). Currently, most Earth system models
523 (ESMs) define $V_{c,max}$ as a function of leaf age whereas their relationship is still less well
524 understood in TEFs due to sparse in-situ measurements (Chen et al., 2020). This may
525 consequentially lead to poorly representation of LAI and GPP seasonality in ESMs (De
526 Weirdt et al., 2012). To overcome this challenge, we simplified the tree canopy into
527 three big leaves (i.e., young, mature and old) in TEFs, similar as the two-big leaves
528 model developed for temperate and boreal forests (Best et al., 2011; Clark et al., 2011;
529 Harper et al., 2016), which simplified tree canopy into sun and shade leaves. However,
530 some uncertain remains on the assumption, as it neglected the spatial and temporal
531 variations of $V_{c,max}$, which also changes with seasonal climate anomaly and also differs
532 between nearby pixels in high heterogeneous forest ecosystems. These may bring
533 uncertainties for simulating seasonal An and therefore influence the seasonality of Lad-
534 LAI.

535 In summary, this study developed a new method to produce the first grid dataset of
536 leaf age-dependent LAI product over the continental scale. Although some uncertainties
537 remain associated with this assumption, it is important to improve the GPP simulation
538 accuracy in most ESMs that are currently run at a coarser resolution. And, the proposed
539 method could provide simulations of accurate age-dependent LAI seasonality by
540 dividing canopy leaves into more age cohorts. With the development of remote sensing
541 technology, finer temporal and spatial resolutions of SIF products will also enable finer
542 temporal and spatial resolutions maps of Lad-LAI products.

543

544 **5. Data availability**

545 The 0.25 degree leaf age-dependent LAI seasonality (Lad-LAI) datasets from
546 2001-2018 presented in this paper are available at
547 <https://doi.org/10.6084/m9.figshare.21700955.v2> (Yang et al., 2022). The format of this
548 dataset is GeoTiff, with a spatial reference of WGS84. Each file in this dataset is named
549 based on leaf age, start year, end year, and monthly. We divided the LAI into three
550 cohorts: LAI_{young}, LAI_{mature}, and LAI_{old}.

551

552 6. Conclusion

553 This study for the first-time mapped continental-scale grid dataset of monthly LAI
554 in three leaf age cohorts from 2001-2018 RTSIF data. The LAI seasonality of young,
555 mature and old leaves was evaluated using *in situ* measurements of seasonal LAI data,
556 satellite based EVI and *in situ* measurements of seasonal litterfall data. The evaluations
557 from these independent datasets all demonstrate the robustness of the seasonality of
558 three leaf age cohorts. The new Lad-LAI products indicate diverse patterns over the
559 whole tropical and subtropical regions. In central and south Amazon, LAI_{young} and
560 LAI_{mature} decrease at early wet season around February and convert to increase at early
561 wet season around June. On the contrary, in subtropical Asia, LAI_{young} and LAI_{mature}
562 increase during the wet season and peak with largest rainfall at June or July. In regions
563 nearby the Equator, the LAI cohorts show a bimodal phenology but with marginally
564 small changes in magnitudes. The proposed method will enable to produce finer
565 temporal and spatial resolutions maps of Lad-LAI products by using precise temporal
566 and spatial resolutions data as the inputs. The Lad-LAI products will be help for
567 diagnosing the adaption of tropical and subtropical forest to climate change; and will
568 also help improve the development of phenology models in ESMs.
