15 16 17 **Key Points**

- 18
19 • We present the release of 64 aerogeophysical datasets (including gravity, magnetic, bed-pick,
20 and radar data) obtained from 24 surveys flown by the British Antarctic Survey over West
21 Antarctica, East Antarctica, and the Antarctic Peninsula between 1994 and 2020.
- 22
23 • The published datasets have been standardised according to the FAIR (Findable, Accessible,
24 Interoperable and Re-Usable) data principles and integrated into a user-friendly data interface,
25 the Polar Airborne Geophysics Data Portal, to further enhance the interactivity of the datasets.
- 26
27 • We discuss how the data were acquired and processed and show the potential re-usability of
28 the newly released aerogeophysical data by investigating the englacial architecture of the ice
29 from airborne radars using an automatic layer-continuity method.
- 30

31 **Abstract**

32

33 Over the past 50 years, the British Antarctic Survey (BAS) has been one of the major acquirers of
34 aerogeophysical data over Antarctica, providing scientists with gravity, magnetic and radar datasets that
35 have been central to many studies of the past, present, and future evolution of the Antarctic Ice Sheet.
36 Until recently, many of these datasets were not openly available, restricting further usage of the data
37 for different glaciological and geophysical applications. Starting in 2020, scientists and data managers
38 at BAS have worked on standardising and releasing large swaths of aerogeophysical data acquired
39 during the period 1994-2020, including a total of 64 datasets from 24 different surveys, amounting to
40 ~450,000 line-km (or 5.3 million km²) of data across West Antarctica, East Antarctica, and the Antarctic
41 Peninsula. Amongst these are the extensive surveys over the fast-changing Pine Island (BBAS 2004-
42 05) and Thwaites (ITGC 2018-19 & 2019-20) glacier catchments, and the first ever surveys of the
43 Wilkes Subglacial Basin (WISE-ISODYN 2005-06) and Gamburtsev Subglacial Mountains (AGAP
44 2007-09). Considerable effort has been made to standardise these datasets to comply with the FAIR
45 (Findable, Accessible, Interoperable and Re-Usable) data principles, as well as to create the Polar
46 Airborne Geophysics Data Portal (<https://www.bas.ac.uk/project/nagdp/>), which serves as a user-
47 friendly interface to interact with and download the newly published data. This paper reviews how these
48 datasets were acquired and processed, presents the methods used to standardise them, and introduces
49 the new data portal and interactive tutorials that were created to improve the accessibility of the data.
50 Lastly, we exemplify future potential uses of the aerogeophysical datasets by extracting information on
51 the continuity of englacial layering from the fully published airborne radar data. We believe this newly
52 released data will be a valuable asset to future glaciological and geophysical studies over Antarctica
53 and will extend significantly the life cycle of the data. All datasets included in this data release are now
54 fully accessible at: <https://data.bas.ac.uk>.

60 1. Introduction

61 As one of the fastest changing environments on Earth, Antarctica has been at the epicentre of
62 scientific research since the early 1960s. Understanding the past, present, and future of the Antarctic
63 Ice Sheet is of special interest, particularly in the context of rapid climatic changes already affecting
64 large parts of the Antarctic Peninsula and threatening the stability of the West Antarctic Ice Sheet
65 (IPCC, 2021). One way to quantify how the ice sheet will respond to these changes is to conduct
66 studies of englacial and basal properties of the ice using geophysical techniques such as gravity,
67 magnetic, and radar. By studying the bedrock topography beneath an ice sheet, we can better estimate
68 where a retreating ice stream is more likely to stabilise or de-stabilise further (Holt et al., 2006;
69 Vaughan et al., 2006; Tinto and Bell, 2011; Ross et al., 2012; Morlighem et al., 2020) and how
70 landforms or subglacial water-routing systems can affect the flow-regime of ice streams (Bell et al.,
71 2011; Wright et al., 2012; Schroeder et al., 2013; Ashmore and Bingham, 2014; Siegert et al., 2014;
72 Young et al., 2016; Napoleoni et al., 2020). By studying the subglacial geology, we can better
73 understand magmatic, tectonic and sedimentary influences on ice flow over timescales of hundreds,
74 thousands or even millions of years (Bell et al., 1998; Blankenship et al., 2001; Studinger et al., 2001;
75 Bamber et al., 2006; Bell et al., 2006; Jordan et al., 2010; Bingham et al., 2012), and quantify the
76 influence of geothermal heat flux on ice dynamics (Schroeder et al., 2014; Jordan et al., 2018).
77 Finally, the use of gravity techniques enables us to better understand the bathymetry beneath fast-
78 changing ice shelves and ice-stream fronts and quantify areas of high sensitivity (Greenbaum et al.,
79 2015; Millan et al., 2017; Tinto et al., 2019; Jordan et al., 2020).

80 Since the mid-1960s, the British Antarctic Survey (BAS) has been involved in acquiring
81 aerogeophysical data with a particular focus on radar-data acquisition using a 35- and 60-MHz radio-
82 echo sounder developed at the Scott Polar Research Institute (Robin et al., 1970), and, in collaboration
83 with the Technical University of Denmark, using slightly improved versions of the same analogue
84 radar system until the early 1990s (Robin et al., 1977). The subsequent development of an in-house
85 digital radar system at BAS in 1993-94 (Corr and Popple, 1994), and accompanying gravity and
86 magnetic instruments, allowed for the first surveys over West Antarctica's Evans Ice Stream to be
87 conducted in 1994-95, marking the start of modern digital aerogeophysical surveying of the Antarctic
88 by BAS. Further improvements in survey techniques and instruments have allowed BAS to develop
89 its aerogeophysical capabilities further and become one of the leaders in aerogeophysics over the
90 Antarctic.

91 Since the mid-1990s, aerogeophysical datasets acquired by BAS have played a vital role in
92 understanding past and current ice-dynamical and lithospheric processes over the Antarctic Ice Sheet.
93 In total, BAS flew 24 survey campaigns between 1994 and 2020, representing a total of ~450,000
94 line-km of aerogeophysical data over the Antarctic Peninsula and the West and East Antarctic Ice
95 Sheets (hereafter abbreviated to WAIS and EAIS, respectively) (Fig. 1, Table 1). The total cumulative
96 survey coverage since 1994 is 5.3 million km², equivalent to > 30 % of the total area of the Antarctic
97 Ice Sheet (14.2 million km²). Many of these surveys were acquired as part of large international
98 collaborative projects such as the International Polar Year AGAP project, the European Space Agency
99 (ESA) PolarGAP project, and the US-UK International Thwaites Glacier Collaboration (ITGC),
100 amongst others. Importantly, much of the data acquired since then have been central to the output of
101 large international science groups, such as the SCAR-funded (Scientific Committee on Antarctic
102 Research) BEDMAP (I/II/III), ADMAP (I/II), AntArchitecture, and IBCSO projects (Lythe et al.,
103 2001; Arndt et al., 2013; Fretwell et al., 2013; Golynsky et al., 2018).

104

105 **Figure 1. Map showing all the published datasets included in this data release.** The colours are the
 106 same as those used on the data portal interface. Abbreviations are as follows: AC: AFI Coats Land (2001-02);
 107 AD: Andriill HRAM (2008-09); AG: AGAP (2007-09); AI: Adelaide Island (2010-11); BB: BBAS (2004-05);
 108 BC: Black Coast (1996-97); CI: Charcot Island (1996-97); DF: DUFEK (1998-99); EV: EVANS (1994-95);
 109 F15: FISS 2015 (2015-16); F16: FISS-EC-Halley 2016 (2015-16); GI: GRADES-IMAGE (2006-07); IG:
 110 ICEGRAV (2012-13); IM: IMAFI (2010-11); JRI: James Ross Island (1997-98); LA: Larsen Ice Shelf (1997-
 111 98); M: MAMOG (2001-02); PG: PolarGAP (2015-16); PI: Pine Island Glacier Ice Shelf (2010-11); SP:
 112 SPARC (2002-03); T18: ITGC Thwaites (2018-19); T19: ITGC Thwaites (2019-20); TO: TORUS (2001-02);
 113 WI: WISE-ISODYN (2005-06). The legend on the right-hand side of the figure shows the colour corresponding to
 114 each survey. The background image is from the Landsat Image Mosaic of Antarctica (LIMA; Bindshadler et
 115 al., 2008).

116 Despite the importance of these surveys for understanding the Antarctic cryosphere and
 117 tectonics, until now the underlying data have been relatively inaccessible to the wider scientific
 118 communities due to the scale of the data-management task required. This lack of accessibility has
 119 hampered the ability of the wider research community to extract further valuable information from
 120 these datasets. In 2020, a collaborative project between the UK Polar Data Centre (PDC,
 121 <https://www.bas.ac.uk/data/uk-pdc/>) and the BAS Airborne Geophysics science team was set up to
 122 improve the FAIR-ness (Findability, Accessibility, Interoperability and Re-Usability; Wilkinson et al.,
 123 2016) of these data. The main objectives of this collaboration were to comply with national and
 124 international policies on data sharing and accessibility, foster new collaborations, and allow the
 125 further re-use of these data beyond the lifespan of the science projects.

126 This paper presents the result of this successful collaboration between data managers and
 127 scientists to standardise and release most of BAS' aerogeophysical data acquired to date using modern

128 instruments from 1994 onwards. Data acquired prior to this, while particularly useful to long-term
129 monitoring of ice sheet conditions, are much more challenging and time-consuming to bring up to
130 modern standards (see Schroeder et al., 2019; Sect 5.3), and are thus not included in the data release
131 discussed here. Section 2 of this paper reviews the main scientific findings from each survey flown
132 between 1994 and 2020. Section 3 describes the various instruments and techniques used to acquire
133 and process the data. Section 4 outlines the format and data publishing strategy for our datasets
134 following the FAIR data principles, as well as the creation of a new data portal and interactive, open-
135 access tutorials. Finally, Section 5 provides a case study for the re-usability of the newly released
136 aerogeophysical data, as well as suggestions on future uses of the data portal and aspirations for future
137 data releases.

138

139 **2. Background**

140 The following section reviews the main scientific findings related to the acquisition of
141 aerogeophysical data from BAS for the period 1994-2020 and is divided into two sub-sections:
142 findings from surveys conducted pre-2004 using older aerogeophysical instruments and for which the
143 fully processed 2-D radar data is not published as part of this data release (see Table 1, Section 5.3),
144 and surveys conducted post-2004 using the PASIN-1 (2004-2015) and PASIN-2 (2015-2020) radar
145 systems and more modern data acquisition methods. Figures 2-3 present the wide-ranging datasets of
146 gravity and magnetic anomalies, bed elevation and ice thickness, and 2-D radar profiles ensuing from
147 the surveys discussed in sections 2.1. and 2.2.

148 **2.1. Aerogeophysical Surveys for the Period 1994-2004**

149 The first surveys conducted by BAS since the mid-1990s involved extensive gravity and
150 magnetic surveying of the western and eastern Antarctic Peninsula and Weddell Sea Embayment.
151 Surveys over Evans Ice Stream (1994-95), Black Coast (1996-97), Charcot Island (1996-97), and
152 James Ross Island (1997-98) (Fig. 1, Table 1) provided new insights into the history of crustal
153 boundaries between the eastern Antarctic Peninsula and the Filchner Block (Ferris et al., 2002),
154 evidence of crustal thinning below Evans Ice Stream (Jones et al., 2002), and new understanding of
155 the magmatic and tectonic processes around the Mount Haddington stratovolcano on James Ross
156 Island (Jordan et al., 2009). A further study covering the Larsen Ice Shelf (Antarctic Peninsula) was
157 conducted conjointly by BAS and Instituto Antártico Argentino in 1997-98. The radar data acquired
158 during this survey was used in ocean (Holland et al., 2009) and firn-density (Holland et al., 2011)
159 models to improve our understanding of ice-ocean interactions and ice-surface elevation change on
160 the ice shelf. In 1998-99, extensive aeromagnetic surveying of the Dufek Massif (West Antarctica /
161 East Antarctica) revealed the presence of a Jurassic dyke swarm that likely acted as a magma
162 transport and feeder system to the Ferrar Large Igneous Province (Ferris et al., 2003). In 2001-02, an
163 additional survey was flown as part of the TORUS (Targeting ice-stream Onset Regions and Under-
164 ice Systems) initiative to assess the factors controlling the dynamics of the Rutford Ice Stream using
165 gravity, magnetic and radar instruments over a high-resolution grid spacing of ~10 km (Vaughan et
166 al., 2008). Lastly for the WAIS, the SPARC (Superterranes of the Pacific Margin Arc) campaign of
167 2002-03 over Northern Palmer Land (Antarctic Peninsula) used gravity and magnetic instruments to
168 reveal subglacial imprints of crustal growth linked with the Gondwana margin (Ferraccioli et al.,
169 2006).

170 Over East Antarctica, two surveys conducted in 2001-02 acquired detailed gravity, magnetic
171 and radar measurements over Slessor Glacier (AFI; Antarctic Funding Initiative Coats Land survey)
172 and Jutulstraumen Ice Stream (MAMOG; Magmatism as a Monitor of Gondwana break-up). The AFI
173 Coats Land survey, a UK initiative between BAS and the University of Bristol, provided the first
174 accurate measurements of ice thickness and bed elevation in the area (Rippin et al., 2003a) (Fig. 2),

175 and led to the discovery of a ~3-km thick sedimentary basin associated with a weak till layer at the
 176 bed which enhances basal motion and affects the flow regime of this part of the EAIS (Rippin et al.,
 177 2003a ; Bamber et al., 2006; Shepherd et al., 2006). The MAMOG survey revealed the presence of a
 178 subglacial Jurassic continental rift in the area of western Dronning Maud Land, providing early
 179 evidence for the initial Gondwana break up (Ferraccioli et al., 2005a; 2005b).

180 2.2. Aerogeophysical Surveys for the Period 2004-2020

181 Building from the surveys prior to 2004 which were relatively small in areal extent, BAS
 182 began surveying larger areas from the mid-2000s onwards (Table 1), primarily due to enhanced
 183 international collaborations and improvements in data acquisition and instruments which led to data
 184 being acquired both at higher resolution and over larger spatial scales. The acquisition strategy was to
 185 collect data from multiple geophysical sensors mounted on BAS’ Twin Otter aircraft across every
 186 survey, giving a holistic view of vast and previously unsurveyed regions (Fig. 4-5). The core sensor
 187 suite included gravity and magnetic instruments used to understand the geological nature of the
 188 subglacial basins and mountains along with their tectonic structure, alongside the radar system used to
 189 map ice thickness and bed elevation. The development of a new radar system, the Polarimetric
 190 Airborne System Instrument (PASIN) (PASIN-1, 2004-2015) (see Section 3.1.3), and an improved
 191 version of the same system (PASIN-2, 2015-16 onwards), allowed for the efficient collection of high-
 192 quality digital radar data for BAS-led campaigns in the Antarctic.

193 We describe the findings from these surveys into two sub-sections (Section 2.2.1 for surveys
 194 between 2004-2015; Section 2.2.2 for surveys between 2015-20) to reflect the acquisition of data
 195 prior to and following the upgrade of the PASIN system (see Section 3.1.3).

196 2.2.1 2004-2015

197 The first mission to utilise the PASIN-1 radar system was the 2004-05 BBAS survey of Pine
 198 Island Glacier, which aimed to characterise the subglacial conditions of this sensitive glacier of West
 199 Antarctica (Vaughan et al., 2006). This survey provided two key findings: a) the discovery of a deep
 200 subglacial trough, 500 m at its deepest point and 250 km long, through which Pine Island Glacier
 201 flows; and b) the existence of well-constrained valley walls which would likely provide a buffer
 202 against a potential catastrophic collapse of the WAIS via Pine Island Glacier (Vaughan et al., 2006).
 203 Further studies utilising this dataset focused primarily on bed characteristics and the subglacial
 204 hydrology of the catchment (Rippin et al., 2011; Napoleoni et al., 2020; Chu et al., 2021), as well as
 205 tracking englacial layers and quantifying past-accumulation rates (Corr and Vaughan, 2008; Karlsson
 206 et al., 2009; 2014; Bodart et al., 2021). The survey was also conducted simultaneously with another
 207 covering the Thwaites Glacier catchment led by the University of Texas Institute for Geophysics and
 208 the National Science Foundation of the United States (Holt et al., 2006), enabling a comparison of the
 209 surveying capabilities where the surveys overlapped (e.g. Chu et al., 2021).

210 **Table 1. Information on the period, region, sub-region, type of data acquired, total line-coverage**
 211 **(km), total coverage area (km²), and key reference for each survey included in this data release.** For
 212 “Data”, the abbreviations are as follows: Gravity (G), Magnetic (M), Radar (R). For “Regions”, abbreviations
 213 are as follows: APIS (Antarctic Peninsula Ice Sheet), EAIS (East Antarctic Ice Sheet), WAIS (West Antarctic
 214 Ice Sheet). “DML” stands for Dronning Maud Land and “PIG” for Pine Island Glacier. The total area in km² is
 215 calculated as a cumulative total area of the spatial footprint of the survey’s minimum and maximum extent. *For
 216 AGAP, the data release only consists of the BAS-acquired data, which represents approximately half of the total
 217 (~120,000 km) survey coverage from the whole AGAP expedition (see Section 2.2.1).

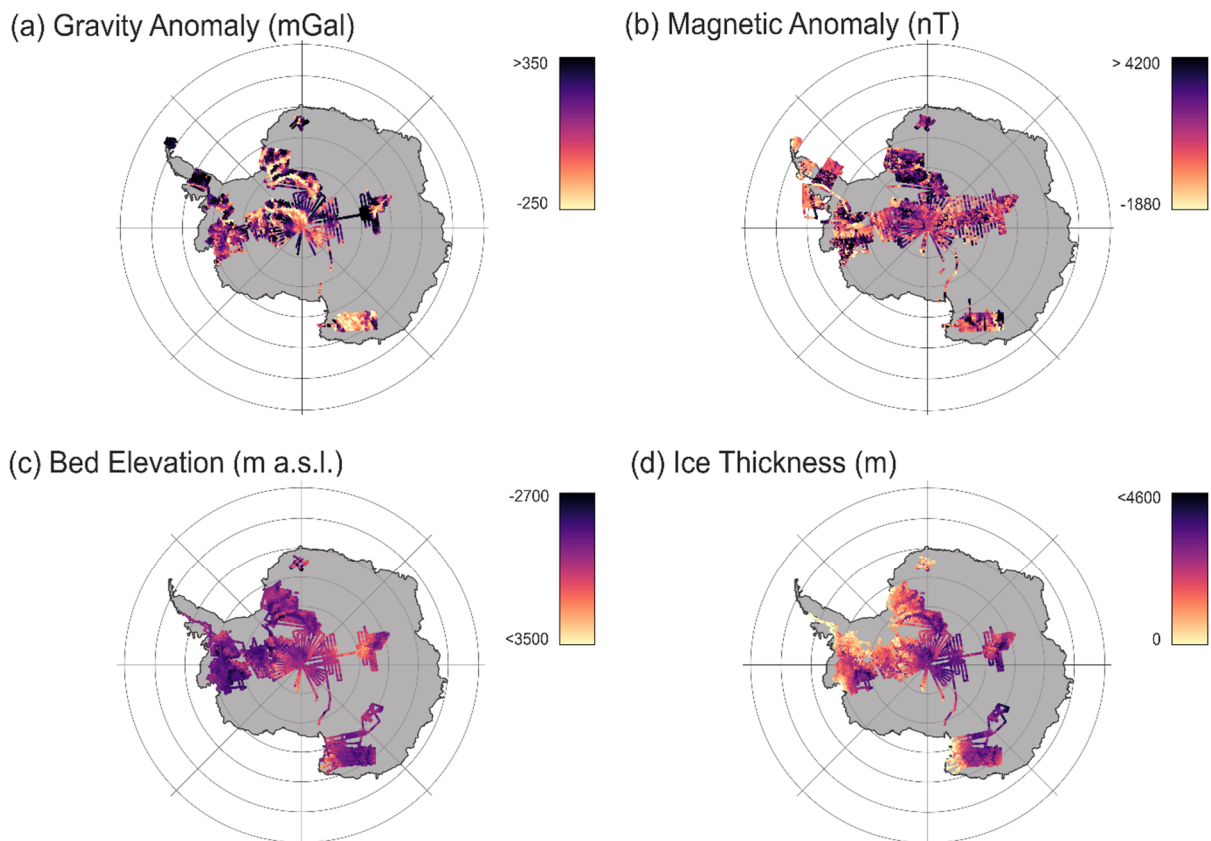

Survey	Year	Region	Sub-Region	Data	Total line coverage (km)	Total coverage area (km ²)	Reference

219 Following on from the BBAS survey, the suite of geophysical instruments on board the BAS
220 Twin Otter aircraft were used to survey the Wilkes Subglacial Basin, Dome C, and the Transantarctic
221 Mountains as part of the 2005-06 WISE-ISODYN survey between BAS and the Italian Programma
222 Nazionale di Ricerche in Antartide (Bozzo and Ferraccioli, 2007; Corr et al., 2007; Ferraccioli et al.,
223 2007; Jordan et al., 2007). This project revealed, for the first time, the crustal architecture of the
224 Wilkes Subglacial Basin (Ferraccioli et al., 2009; Jordan et al., 2013) and the distribution of a well-
225 preserved subglacial sedimentary basin underlying the Wilkes catchment (Frederick et al., 2016). The
226 following year, the 2006-07 GRADES-IMAGE (Glacial Retreat in Antarctica and Deglaciation of the
227 Earth System - Inverse Modelling of Antarctica and Global Eustasy) survey, comprising surveys over
228 the transitional area between the Antarctic Peninsula and the WAIS, provided detailed information on
229 subglacial properties of Evans Ice Stream (Ashmore et al., 2014), ice-thickness measurements along
230 the grounding line were used as key calibration for the Landsat-derived “ASAID” grounding-line
231 product (Bindshadler et al., 2011), and englacial layers through Bungenstock Ice Rise were used to
232 assess ice-divide stability and the wider ice-flow history and stability of the WAIS’s Weddell Sea
233 sector during the Holocene (Siegert et al., 2013).

234 Over two austral field seasons from 2007 to 2009, the AGAP (Antarctica’s Gamburtsev
235 Province Project) survey, coordinated as part of the fourth International Polar Year between the UK,
236 USA, Germany, Japan, Australia and China, comprised a comprehensive survey of the interior of the
237 EAIS, yielding important aerogeophysical data used to interrogate the origin and geophysical
238 characteristics of the Gamburtsev Subglacial Mountains. Significant scientific discoveries generated
239 by the AGAP survey included observations of widespread freeze-on at the bottom of the ice which
240 leads to thickening of the EAIS from the base (Bell et al., 2011), a thick crustal root formed during the
241 Proterozoic aeon (1 Gyr ago) surrounded by a more recent ~2,500-km-long rift system (Ferraccioli et
242 al., 2011), and the existence of ancient pre-glacial fluvial networks at the present ice bed which
243 confirmed the presence of the Gamburtsev Subglacial Mountains prior to the start of glaciation at the
244 Eocene–Oligocene climate boundary (ca. 34 Ma) (Rose et al., 2013; Creyts et al., 2014).

245 Between 2008 and 2011, three surveys utilised the magnetic and radar instruments on board
246 the BAS Twin Otter to conduct high-spatial resolution surveying of Coulman High on Ross Ice Shelf
247 as part of the ANDRILL HRAM (Antarctic Drilling - High Resolution Aeromagnetic) project,
248 Adelaide Island (Antarctic Peninsula), and Pine Island Glacier Ice Shelf (West Antarctica). The 2010-
249 11 Adelaide Island survey provided high-resolution aeromagnetic data to underpin a better
250 understanding of the complex magmatic structure of the Antarctic Peninsula Cenozoic arc/forearc
251 boundary (Jordan et al., 2014). The Pine Island Glacier Ice Shelf survey of the same year revealed a
252 network of sinuous subglacial channels, 500- to 3000-m wide and up to 200-m high, in the ice-shelf
253 base, which, combined with surface and basal crevasses formed as a result of the basal melting, could
254 lead to structural weakening of the shelf in the future (Vaughan et al., 2012).

Figure 2. Maps of gravity, magnetic, and radar (bed elevation and ice thickness) point measurements for all surveys published as part of this data release. (a) Gravity anomaly points (in milligal, or mGal), (b) Magnetic anomaly points (in nanotesla, or nT), (c) Bed elevation points from radar data (in metres above sea level, or m a.s.l.), (d) Ice thickness points from radar data (metres). In total, this data release consists of 3.62 million gravity, 7.41 million magnetics, and 14.5 million ice-thickness and bed-elevation data points. Note that no correction such as downward continuation has been applied to compile the gravity data shown in (a).

265
266
267

The early 2010s saw the deployment of the PASIN system used as part of two large collaborative projects, namely the 2010-11 Institute-Möller Antarctic Funding Initiative (IMAFI) survey over the Institute and Möller ice streams of West Antarctica, and the 2012-13 ICEGRAV survey over the Recovery and Slessor region of East Antarctica.

281

The 2010-11 IMAFI project was a UK initiative between BAS and the Universities of Edinburgh, York, Aberdeen and Exeter. The key aims were to investigate the potential stability of this sector of West Antarctica and test the ability of the subglacial sedimentary structure to control the flow of two large ice streams draining the WAIS into the Weddell Sea Embayment (Ross et al., 2012). Radar data revealed the presence of a reverse-bed slope with a 400-m decline over a 40-km distance away from the grounding line and that this region was relatively close to flotation, indicating the potential instability of this sector in the light of future grounding-line migration upstream of its current position (Ross et al., 2012). Additional analysis using gravity and magnetic data revealed the extent of the Weddell Sea Rift System, adding further evidence for the early-stages of Gondwana break-up and Jurassic extension in the region (Jordan et al., 2013). Further analysis of the radar data acquired during the IMAFI survey led to a new digital elevation model of the subglacial topography around the ice streams of the Weddell Sea Embayment at 1-km resolution, revealing deep subglacial troughs between the ice-sheet interior and the grounding line and well-preserved landforms associated with alpine glaciation (Ross et al., 2014; Jeofry et al., 2018), as well as evidence for a temperate

282 former WAIS via the discovery of extensive subglacial meltwater channels (Rose et al., 2014). The
283 data have also been used to assess the roughness of the subglacial bed (Rippin et al., 2014),
284 investigate englacial properties across the catchment as an indicator of past ice-flow dynamics
285 (Bingham et al., 2015; Winter et al., 2015; Ashmore et al., 2020; Ross et al., 2020), and to evidence
286 the presence of sub-ice shelf channels generated by water flowing from beneath the present ice-sheet
287 (Le Brocq et al., 2013).

288 The 2012-13 ICEGRAV survey, an international collaboration between BAS and the
289 Technical University of Denmark, National Science Foundation, Norwegian Polar Institute, and the
290 Instituto Antártico Argentino, carried out aerogeophysical surveys over the poorly explored Recovery
291 Glacier catchment and Recovery Subglacial Lakes (Forsberg et al., 2018), revealing a deep 800-km
292 trough underlying Recovery Glacier, with evidence for subglacial water controlling the fast flow in
293 the upstream portion of the ice stream (Diez et al., 2018).

294 **2.2.2 2015-2020**

295 The 2015-16 PolarGAP survey was a major international collaboration funded by the
296 European Space Agency (ESA) and led by BAS, Technical University of Denmark, Norwegian Polar
297 Institute and the National Science Foundation to fill a gap in global gravity surveying that the
298 European Space Agency GOCE (Gravity field and steady-state Ocean Circulation Explorer) satellite
299 network was unable to cover. Alongside the large swath of gravity surveying, opportunistic magnetic
300 and radar data were also acquired over the South Pole and parts of Support Force, Foundation, and
301 Recovery ice streams using for a further upgraded radar system, PASIN-2 (see Section 3.1.3).
302 Additional funding from the Norwegian Polar Institute also allowed for a number of dedicated flights
303 over the subglacial Recovery Lakes. The acquired data have led to major scientific findings,
304 including: (a) the presence of anomalously high geothermal heat flux near the South Pole (Jordan et
305 al., 2018), and (b) the delineation of two subglacial lakes (Recovery Lakes A and B) totalling ~4,320
306 km² in size and composed of saturated till, with evidence of bed lubrication and enhanced flow
307 downstream of their location as a result of water drainage (Diez et al., 2019). Additional evidence
308 showed that the Pensacola-Pole Basin is characterised by a topographic depression of ~0.5 km below
309 sea level and contains a thick sedimentary layer of 2-3 km in the southern part of the catchment
310 (Paxman et al., 2019). The radar data from the PolarGAP survey have also revealed large troughs at
311 the bottleneck between East and West Antarctica, suggesting that drawdown of the EAIS via the
312 WAIS is unlikely (Winter et al., 2018).

313 In the austral summers of 2015-16 and 2016-17, two surveys were flown as part of the
314 Filchner Ice Shelf System (FISS) project led by BAS and with support from the Alfred-Wenger
315 Institute in Germany and several other UK institutions (UK National Oceanography Centre, Met
316 Office Hadley Centre, and the universities of Exeter, Oxford, and University College London), with
317 the aim to investigate the potential contribution of the Filchner Ice Shelf system to sea-level rise. The
318 2015-16 survey acquired ~7,000 line-km of aerogeophysical data primarily over Foundation Ice
319 Stream and to a smaller extent over Bungenstock Ice Rise. In 2016-17, ~26,000 line-km of
320 aerogeophysical data were acquired over the Academy, Recovery, Slessor, and Support Force
321 glaciers), and parts of the Filchner, and Brunt Ice shelves. Data was also collected over outlet glaciers
322 of English Coast (western Palmer Land, Antarctic Peninsula). Early findings from the 2016-17
323 aerogeophysical survey revealed subglacial drainage channels beneath Support Force Glacier
324 (Hofstede et al., 2021), provided evidence for a large ~80 x 30 x 6 km mafic intrusion likely resulting
325 from mantle melting during Gondwana break-up (Jordan and Becker, 2018), and helped to delineate
326 the subglacial bathymetry beneath Brunt Ice Shelf (Hodgson et al., 2019).

327 During the 2018-19 and 2019-20 seasons, BAS was involved in aerogeophysical surveying of
328 Thwaites Glacier as part of the UK-US International Thwaites Glacier Collaboration (ITGC)
329 initiative. The 2018-19 survey acquired ~9,900 km of aerogeophysical data over lower Thwaites

330 Glacier and Thwaites Glacier Ice Shelf, and the 2019-20 survey acquired ~4,500 line-km over lower
 331 Thwaites Glacier, the WAIS Divide ice-core site, and Rutford Ice Stream. These surveys contributed
 332 to a new bathymetric map of Thwaites, Crosson and Dotson ice shelves from gravity measurements,
 333 revealing a deep (>800 m) marine channel extending beneath the ice shelf adjacent to the front of
 334 Thwaites Glacier (Jordan et al., 2020). These datasets have also contributed to a new bathymetry
 335 model of George VI Sound (Constantino et al., 2020) and were integrated with swath bathymetric data
 336 out-board from Thwaites Glacier (Hogan et al., 2020).

337

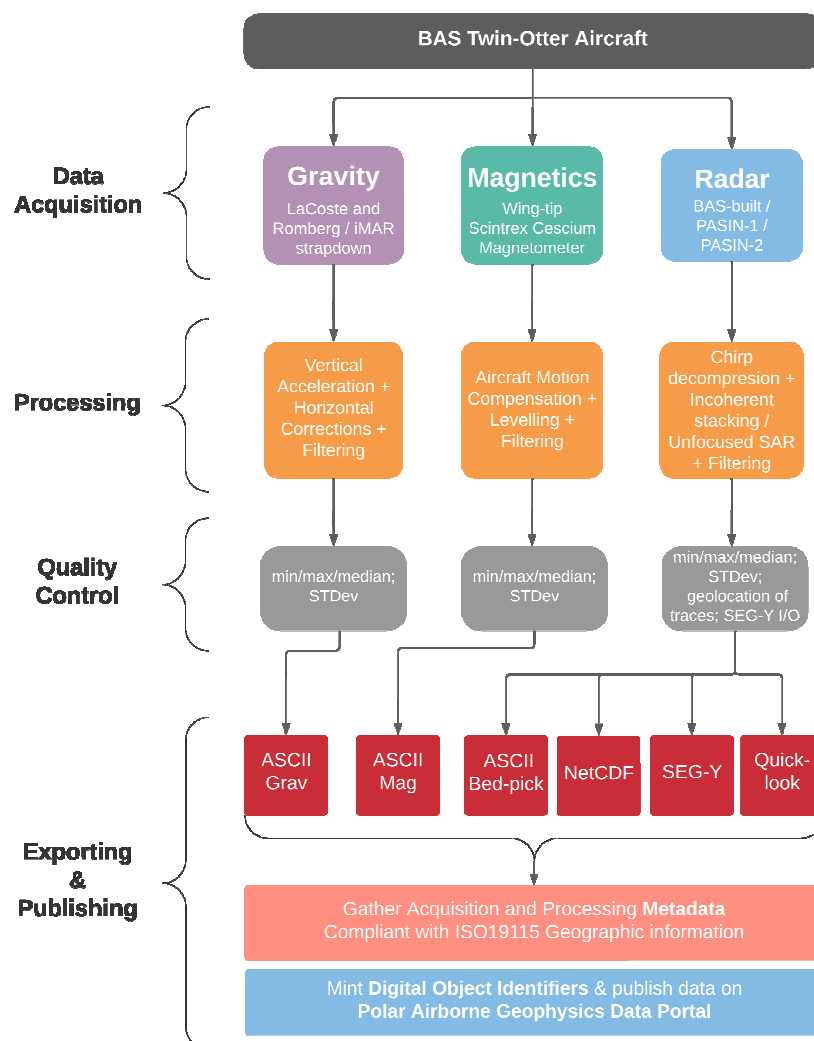

338 **Figure 3. Sample radargrams from the ten 2-D radar datasets released with this paper.** The
 339 colours for each survey on the map are the same as in Fig. 1 and the data portal. The location of each radargram
 340 (a-j) is marked on the map by black triangles. The red and blue dashed lines on the radargrams are the surface
 341 and bed picks, respectively. A description of each radargram is provided as follows: (a) Flightline G10
 342 (GRADES-IMAGE) showing well-defined subglacial valleys through which Evans Ice Stream flows (ice flow is
 343 approximately out of page), with stable layering at the onset and in the middle of the topographic low; (b)
 344 Flightline F03B (FISS 2015) showing undulating bed topography and disrupted layering at the onset of
 345 Foundation Ice Stream; (c) Flightline F27A (FISS 2016) showing variations in subglacial topography at the
 346 divide between the Antarctic Peninsula and West Antarctica, with potential evidence of basal freeze-on at the
 347 start of the segment; (d) Flightline C09A (IMAFI) showing evidence of preserved layering despite changes in
 348 local topography at the bottleneck between East and West Antarctica; (e) Flightline B01 (BBAS) over Ellsworth
 349 Subglacial Mountains showing a ~1.5 km trough in the ice sheet bed and one of the deepest points in the PIG
 350 basin with ~3km of ice underlying the surface; (f) Flightline W43B (WISE-ISODYN) showing internal layers
 351 draping over the highs and lows in the local Wilkes Subglacial Basin topography, with two particularly bright
 352 reflections in the middle and bottom of the ice column; (g) Flightline P33 (PolarGAP) showing the onset of a
 353 topographic high near the Transantarctic Mountain Range with internal layering visible down to the ice-bed
 354 interface; (h) Flightline A05A (AGAP) showing stable internal layering characteristic of the interior of the
 355 EAIS; (i) Flightline G09A (ICEGRAV) showing evidence of a bright reflection likely associated with a
 356 previously unidentified subglacial lake in the region; and (j) Flightline T10A (ITGC 2019) showing a section of
 357 inland-sloping bed from a profile in the main trunk of Thwaites Glacier, >200 km from the current grounding
 358 line position (ice flow is right to left). The horizontal and vertical white bars at the bottom of each radargram

359 represent ~3 km in the horizontal direction (i.e. distance) and ~1 km in the vertical direction (i.e. depth)
 360 respectively.

361

362 3. Data Acquisition and Processing

363 The typical acquisition and processing workflow for the aerogeophysical data is shown in
 364 Figure 4. Usually, the aircraft is set up systematically to acquire gravity, magnetic, and radar data
 365 together, except in situations where surveying objectives are not compatible with the acquisition of all
 366 three datasets at once (i.e. flying at constant terrain clearance for the radar data affects the quality of
 367 the gravity data which is better flown at constant altitude, and vice-versa); although novel gravity-
 368 acquisition methods are increasingly making this issue redundant (see Section 3.1.1). As shown in
 369 Table 1, the conventional gravity-magnetic-radar set-up was used in 15 out of 24 surveys, with the
 370 remaining seven campaigns using either a magnetic-radar- or gravity-magnetic-only set-up and only
 371 two using a magnetic-only set-up. The data acquisition steps for each type of data are described in
 372 Section 3.1, and the processing of the data is described in Section 3.2.

373

374 **Figure 4. Workflow describing the data acquisition, processing, and publishing for the BAS**
 375 **aerogeophysical data included in this data release.** “STDev” stands for standard deviation, whilst “I/O” refers
 376 to the output of the SEG-Y files and the import of the files into seismic-interpretation software for quality check.

377 3.1. Data Acquisition and Instrumentation

378 All BAS aerogeophysical data acquisition is conducted using Twin Otter aircraft due to their
 379 remote capabilities, long fuel range (up to 1,000 km), and operability. The aircraft's twin turbo-prop
 380 engines enable it to conduct rapid take-off and landing and operate in small and remote airfields
 381 commonly covered in snow and icy terrains using mounted skis. All data acquisition since the early
 382 1990s has been conducted using the BAS DeHavilland Twin Otter aircraft "VP-FBL" (Fig. 5). The
 383 aircraft typically flies at a nominal speed of ~60 m/s, which results in an along-track distance between
 384 each stacked radar trace of 0.2 m (prior to processing). The following sections describe the acquisition
 385 of the data for the gravity (3.1.1), magnetic (3.1.2), radar (3.1.3), and GPS and lidar (3.1.4)
 386 instruments on board the aircraft.

387
 388 **Figure 5. Photographs of the aerogeophysical set-up on the BAS Twin Otter aircraft "VP-FBL"**
 389 **for PASIN-2.** (a) The pre-PASIN-2 (used in 2015-16 PolarGAP only) configured to mimic the set-up of
 390 PASIN-1 data collection in polarimetric mode. The eight folded dipole transmitting and receiving antennas are
 391 fixed under the wings (two transmit and two receive antennas on each wing) with the port configured as V
 392 (vertical) and starboard as H (horizontal). The annotations show the location of the radar (R), magnetic (M), and
 393 gravity and lidar (G + L) instruments on board the aircraft. (b) The PASIN-2 set-up in standard/swath mode.
 394 The eight folded dipole transmitting and receiving antennas are fixed under the wings and inside the aircraft and
 395 are operated using a RF (Radio Frequency) switch, and an additional four receiving antennas are situated in the

396 belly enclosure. When in standard swath mode, all antennas are configured in H orientation with the starboard
397 and belly antennas also in H orientation. The PASIN-1 set-up in standard mode (not shown here) had a similar
398 configuration as shown in (b) but the belly antenna (i.e. only four transmit on port and four receive on starboard
399 in H orientation) (c) The PASIN-2 set-up in polarimetric mode. The eight folded dipole transmitting and
400 receiving antennas are fixed under the wings and inside the aircraft and are operated using an RF switch, and an
401 additional four receiving antennas are situated in the belly enclosure. When in polarimetric mode, the port
402 antennas are configured in V orientation and the starboard and belly antennas in H orientation. The PASIN-1
403 set-up in polarimetric mode (not shown here as rarely flown) had the two pairs of outboard antennas rotated to V
404 and the inboard in H configuration. Photo credit: Carl Robinson.

405 **3.1.1 Gravity**

406 Until 2012, BAS aerogravity measurements were acquired with a LaCoste and Romberg air-
407 sea gravimeter modified by Zero Length Spring Corporation (ZLS). The gravimeter was mounted in a
408 gyro-stabilised, shock-mounted platform at the centre of the aircraft to minimise the effect of
409 vibrations and rotational motions.

410 Starting with the 2015-16 PolarGAP survey, aerogravity data began to be acquired using a
411 novel strapdown method which, unlike traditional surveys using a stabilised gravity platform, allowed
412 for the collection of gravity data during draped or turbulent flights (Jordan and Becker, 2018). For this
413 survey, both the LaCoste and Romberg and the strapdown systems were operated together with results
414 from the two systems merged to provide an optimum data product with the long-term low and
415 predictable drift of the LaCoste and Romberg system and dynamic stability of the strapdown system.
416 Subsequent surveys used a strapdown sensor alone, removing the need to prioritise the quality of the
417 gravity data over the radar data and allowing for flights at a constant terrain clearance for optimal
418 radar-data collection. The optimum resolution of the system is approximately 100 s along-track
419 (Jordan and Becker, 2018).

420 The first strapdown sensor deployed by BAS was the iMAR RQH-1003 provided by
421 Technical University (TU) Darmstadt, and consisting of three Honeywell QA2000 accelerometers
422 (mounted in mutually perpendicular directions) and three Honeywell GG1230 ring laser gyroscopes.
423 The subsequent 2018-19 and 2019-20 ITGC surveys over Thwaites Glacier used the iMAR iCORUS
424 strapdown airborne gravimeter systems from Lamont-Doherty Earth Observatory and BAS
425 respectively, which have approximately equivalent internal components to the TU Darmstadt system.

426 **3.1.2 Magnetics**

427 The Twin Otter is configured for fixed wing magnetometer operation. The aircraft
428 modifications include inboard-positioned wingtip fuel pumps, pod-boom hard points and a
429 demagnetised airframe to maximise magnetic-data collection. Scintrex CS3 Cesium sensors are used
430 due to their high sensitivity, high cycling rates, excellent gradient tolerance, fast response and low
431 susceptibility to the electromagnetic interference. The resolution of the magnetometers has greatly
432 increased over time, with the current systems having a measurement accuracy of 0.2 pT compared
433 with the older systems used between 1991-2003 (10 pT; Sintrex H8 Cesium) and 1973-1990 (500 pT;
434 Geometrics G-803 Potassium).

435 **3.1.3 Radar**

436 Prior to 2004, BAS deployed a custom-built, 8-array element radar system, referred here as
437 “BAS-built” (Corr and Popple, 1994). This was a coherent radar system operating at a centre
438 frequency of 150 MHz and using a transmit power of 1,200 W (Rippin et al., 2003a). The radar
439 system was equipped with eight folded dipole transmitting and receiving antennas fixed under the
440 wings (four transmitting on port wing, four receiving on starboard wing). Similar to the current
441 systems, the “BAS-built” system transmitted both a conventional narrow-sounding pulse mode of
442 0.25 μ s and a deep-sounding 4 μ s, 10-MHz chirp (Table 2). As developments in digital acquisition

443 became commercially available, several technical upgrades were applied to the radar system. These
444 ranged from using a LeCroy scope to acquire logarithmic detected waveforms to accommodate complex
445 coherent acquisition, as well as the replacement of the LeCroy oscilloscope by a low sample-
446 frequency 12-bit dual ADC (analogue-to-digital converted) card in the later years of operation (see
447 Figure S1). During this time, the dynamic range of the system was extended by the interleaved
448 transmission of different waveform, which were conventional short wavetrain pulses at the centre
449 frequency.

450 After operating for ten successive field seasons, the “BAS-built” radar system was retired and
451 replaced by a more modern radar system, the Polarimetric Airborne Survey INstrument (PASIN)
452 (Corr et al., 2007). In contrast to the “BAS-built” system, PASIN was designed to sound ice much
453 deeper (up to 5 km compared with 3.3 km for the earlier system) thanks to improved digital
454 electronics and added power in the transmitting antennas (see Table 2). Additionally, modern methods
455 of digitisation enabled by the use of ADC cards, rather than a digitising scope, allowed phase and not
456 just power to be recorded in greater resolution on PASIN, which eventually allowed for the use of
457 more advanced processing techniques such as Synthetic-Aperture-Radar to be applied to the data (see
458 Section 3.2.3).

459 The older PASIN-1 (2004-2015) and the newer PASIN-2 (2015-Present) systems are bi-static
460 radars operating at a 150-MHz centre frequency and configured as follows: (a) PASIN-1: 10-MHz
461 bandwidth system with eight folded dipole transmitting and receiving antennas fixed under the wings
462 (four transmitting on port wing, four receiving on starboard wing) operating in H (horizontal)
463 orientation when in standard mode and more rarely with the port (transmit) and starboard (receive)
464 antennas positioned in both H and V (vertical) orientation when in polarimetric mode (see similar
465 PASIN-2 set-up in Figure 5a) (Corr et al., 2007); and (b) PASIN-2: 13-MHz bandwidth system with
466 eight folded dipole transmitting and receiving antennas fixed under the wings and inside the aircraft
467 with RF switches and an additional four receiving antennas in the belly enclosure (see Figure 5b-c;
468 Table 2). The main difference between the PASIN-1 and -2 systems is the ability for across-track
469 swath processing to be applied to the PASIN-2 data by allowing both transmit and receive on the
470 folded dipole antenna via the use of RF switches.

471 In further contrast with PASIN-1, the PASIN-2 radar has a very flexible configuration, with
472 the standard configuration being as a twelve channel swath radar (with eight transmit and twelve
473 receive). However, other configurations are also possible, including a polarimetric mode to give H
474 and V data where the port antennas are rotated 180 degrees (see Table S1). A final configuration is a
475 mixed antenna gain path for areas where ice is heavily disrupted and where the starboard signal can be
476 attenuated by several decibels. Since 2016, the PASIN-2 system has undergone minor modifications
477 to reduce noise and improve system operations, including (a) low-pass filters in the RF switches, (b)
478 the use of a 10-GHz waveform generator, and (c) new 1 kW solid-state power amplifiers which have
479 lowered transmit system noise and increased transmitter and receiver isolation.

480 Data for both versions of the PASIN system are received using sub-Nyquist digitisation and
481 stacking and stored on removable solid-state disks or tapes, and then copied to duplicate spinning
482 disks for data archiving. On average, a 4.5-hour flight will generate ~150-200 GB of data for PASIN-
483 1 and up to 3 TB of data for PASIN-2. The systems systematically acquire a shallow-sounding 0.1 μ s
484 pulse (PASIN-1) / 1 μ s short-attenuated chirp (PASIN-2), and a deep-sounding 4 μ s, 10-MHz
485 (PASIN-1) / 13-MHz (PASIN-2) linear chirp (Table 2). The shallow-sounding pulse/short-attenuated
486 chirp product is best used to assess internal layering in the upper ~1.5-2 km of the ice sheet, whereas
487 the deeper-sounding chirp is best suited to assess englacial layering and bed characteristics in deep-ice
488 conditions (Fig. 6 c-e). The radar is capable of sounding ice to depths of up to 5 km with a horizontal
489 resolution of 10 cm (before processing) and a depth resolution in the vertical direction of 8.4 m
490 (PASIN-1) and 6.5 m (PASIN-2).

491 **Table 2. Radar Parameters for the three radar systems deployed by BAS between 1994 and the**
492 **Present.** Note that PASIN-1/2 have a number of programmable settings for flight-specific objectives (e.g. 1 to 8
493 waveforms programmable for PASIN-2), and the numbers provided here are for the most commonly used
494 settings. For PASIN-2, a standard set-up consists of 5 waveforms as follows: 4 μ s H (0°), 4 μ s V (0°), 4 μ s H
495 (90°), 4 μ s V (90°), 1 μ s H (Table S1). Abbreviations in the table are as follows: ADC = Analogue to Digital
496 Converter; FPGA = Field Programmable Gate Array; SF = Sample Frequency; SI = Sample Interval; PRF =
497 Pulse-Repetition Frequency; PRI = Pulse Repetition Interval. *BAS-built and PASIN-1 systems used RF
498 combiners on the receiver to produce a single RF input-to-sample, with PASIN-1 splitting these into a high and
499 low gain channel for standard mode (2 ADC channels) and combining these for pairs of H and V in polarimetric
500 mode (4 ADC channels). **Radar Range Resolution is calculated using a radiowave velocity in ice of 168
501 m/microseconds and does not include the effect of the processing on the vertical resolution of the system which
502 is expected to be ~50% greater than the values provided in the table, thus these numbers should be interpreted as
503 the theoretical system performance. Diagrams showing the configurations of the three radar systems are
504 provided in the Supplementary Information (Fig. S1-3).

Radar Parameters	BAS-built (1994-2004)	PASIN-1 (2004-15)	PASIN-2 (2015-Present)
Antennas Configuration	8x folded dipole (4 Tx / 4 Rx)*	8x folded dipole (4 Tx / 4 Rx)*	8x folded dipole + 4x belly (8 Tx/Rx + 4 Rx only)
Centre Frequency	150 MHz	150 MHz	150 MHz
Transmitted Pulse Width	0.25 μ s (pulse) 4 μ s linear (chirp)	0.1 μ s (pulse) 4 μ s linear (chirp)	1 μ s (Tukey envelope chirp) 4 μ s linear (Tukey envelope chirp)
Chirp Bandwidth	4 MHz (pulse) 10 MHz (chirp)	10 MHz	13 MHz
Antenna Gain	11 dBi	11 dBi	11 dBi
PRF / PRI	20,000 Hz (PRI: 50 μ s)	15,635 Hz (PRI: 64 μ s)	15,635 Hz (PRI: 64 μ s)
Peak Transmit Power	300 W / antenna (1.2 kW total)	1 kW / antenna (4 kW total)	1 kW / antenna (8 kW total)
Receiver SF	25 MHz (scope max single shot)	88 MHz	120 MHz
Receiver FPGA decimation	-	4	-
Receiver Effective SF	25 MHz (SI: 40.0 ns)	22 MHz (SI: 45.5 ns)	120 MHz (SI: 8.3 ns)
Receiver Trace Stacking	64	25 (standard) 50 (polarimetric)	25
Effective PRF (post-stacking)	312.5 Hz	312.5 Hz (standard 2 waveforms)	125.1 Hz (5 waveforms) 208.5 Hz (3 waveforms)
ADC Resolution	12-bit	14-bit	16-bit
Equivalent Sustained Data Rate per ADCs (FPGA)	100 MB/s	176 MB/s (standard) 352 MB/s (polarimetric)	960 MB/s (system: 2.88 GB/s)
Average Data Storage Rate for Full PRI	~1 MB/s	11 MB/s (maximum)	173 MB/s (all arrays)
Radar Range Resolution**	21.0 m (pulse) 8.4 m (chirp)	8.4 m	6.5 m

505

506 The pulse repetition frequency of the PASIN (1/2) system is 15,635 Hz and hardware stacking
507 is typically set to 25 in standard mode, which results in an effective pulse-coded waveform acquisition

508 rate of 312.5 Hz for each transmit pulse (Table 2). Following stacking, the final sampling frequency
509 of PASIN-1 is 22 MHz and PASIN-2 is 120 MHz (Table 2).

510 **3.1.4 GPS and lidar**

511 Since 1978, navigation has transitioned from basic aircraft data, imagery, and dead reckoning
512 to more modern means, including the use of carrier-phase Global Positioning System (GPS) systems.

513 Between 1994 and 2004, the BAS Twin Otter aircraft was equipped with a Trimble GPS
514 system (1994-95 surveys: Trimble 4000SSE; 1996-2003 surveys: Trimble 4000SSI). Since 2004, the
515 aircraft is equipped with two, 10-Hz GPS receivers (Leica 500 and ASHTEC Z12 for 2004-18
516 surveys; Javad Delta and Novatel Span for post-2018 surveys) installed on board the aircraft. On the
517 ground, two Leica 500 GPS base stations (replaced by Javad TRIUMPH-2 for post-2018 surveys) are
518 positioned and equipped with choke-ring antennas set up specifically to obtain an unobstructed view
519 of the sky above. Aircraft turns are typically limited to 10-degree banking angles in order to avoid
520 losing lock with GNSS satellites orbiting close to the horizon. The estimated accuracy of the absolute
521 position of the aircraft is 10 cm or less, with the relative accuracy approximately one order of
522 magnitude better. Since 2010, the aircraft altitude and inertial information has been provided by an
523 iMAR FSAS inertial measurement unit (IMU), with the data logged on a Novatel Span receiver.
524 Additional attitude information from the strapdown gravity system is also available for post
525 processing of other datasets.

526 For all modern surveys, the aircraft was also equipped with a Riegl Q240i-80 laser altimeter
527 system (or lidar) in the floor camera hatch to accurately detect the ice surface. The lidar data used for
528 correction of the radar data are typically extracted from the nadir point value with no correction for
529 aircraft altitude. The system has a repetition frequency up to 2 kHz which results in an along-track
530 measurement every 3 cm with an accuracy of up to 5 cm. The lidar is used up to altitudes of 700 m
531 and is constrained by cloud/fog-free conditions. From 2010 onwards, the lidar onboard the Twin Otter
532 was capable of obtaining swath lidar data, although only the single-point data along the centre line is
533 provided as part of this data release.

534 **3.2. Data Processing**

535 **3.2.1 Gravity**

536 The raw aerogravity data are processed to obtain levelled free-air gravity anomalies.
537 Although additional survey-specific processing might have been applied to the data, general
538 processing steps for the LaCoste and Romberg system include the calculation of the observed gravity
539 and a range of corrections and filtering functions as described in Jordan et al. (2007; 2010) and
540 Valliant (1992). In particular, corrections for vertical acceleration, Eotvos horizontal motion (Harlan,
541 1968), latitude (Moritz, 1980), and free air (Hackney and Featherstone, 2003) were applied to obtain
542 the final free-air anomalies before subsequent 9-12 km low-pass filtering. As the free-air values refer
543 to the WGS84 ellipsoid, they are defined in geodesy as gravity disturbance (Hackney and
544 Featherstone, 2003).

545 The strapdown gravity method adopted from 2015-onwards directly combined observations
546 of acceleration in all three axes, with orientation and GPS observations combined in a Kalman filter to
547 solve simultaneously for aircraft position and variations in Earth's gravitational field (Becker et al.,
548 2015). For subsequent strapdown-acquisition surveys, some amount of levelling/correction for
549 thermal drift are required. Spectral analysis suggests that the strapdown system can resolve
550 wavelengths on the order of ~5 km (Jordan et al., 2020). Error estimates for the gravity data can be
551 found in the respective survey metadata (see Table 3), or in specific studies utilising the BAS
552 aerogravity data (e.g. Ferraccioli et al., 2006; Forsberg et al., 2018; Jordan and Becker, 2018).

553 Additional processing may include the use of masks to remove aircraft turns, start and end of
554 lines, and other regions of noisy data, or producing an upward continued free-air anomaly by upward
555 continuing each line segment from the collected flight altitude to the highest altitude in the survey.
556 The first level of free-air anomaly for all published BAS data is shown in Figure 2a, although it is
557 worth noting that no correction such as downward continuation has been applied to compile the data
558 shown in Figure 2a. It is considered that at the scale of the map, the vertical gradient of residual
559 gravity anomalies at flight altitude is inferior to 2 mGal. Additionally, as the gravity surveys are
560 acquired over the ice sheet, the distance to the bedrock is not only dependent on the flight altitude but
561 also on the ice thickness.

562 **3.2.2. Magnetism**

563 The raw aeromagnetic data have been processed using the SCAR ADMAP2 data-release
564 protocols (Golynsky et al., 2018). Data were collected at 10 Hz, allowing for modelling and removal
565 of aircraft dynamic movements using a so-called compensation correction (Ferraccioli, et al. 2007).
566 This correction typically requires a dedicated calibration flight in the direction of the survey lines and
567 tie-lines to have been flown. For some surveys with radial design, or where magnetic-data acquisition
568 was opportunistic, logistical constraints meant no calibration flight could be conducted. In these cases,
569 the generally large depth-to-source due to the thick ice allowed for a 10- to 15-second filter to be
570 applied to minimise noise generated by aircraft motion without compromising the geological signal.
571 Given the redundancy of collecting 10 Hz (~6 m spaced) observations over thick ice, most surveys
572 were down-sampled to 1 Hz (~60 m) prior to further processing.

573 After magnetic compensation, the magnetic data were corrected for the International
574 Geomagnetic Reference Field (IGRF), which is a standard mathematical description of the Earth's
575 main magnetic field. Data impacted by operation of aircraft systems such as pumps and heaters were
576 manually determined. Typically such data were discarded, but survey design and lack of alternative
577 data sources mean that sometimes important geophysical signatures may be present. In some cases the
578 contaminated data were therefore corrected using an offset correction, accepting that the data segment
579 may be more noisy.

580 Magnetic data were then corrected for diurnal variations in the magnetic field using
581 observations at a fixed base station, typically filtered with a 30-minute filter to remove short-
582 wavelength noise potentially not seen on the aircraft. Further statistical levelling of the data based on
583 internal intersections and crossovers with previous surveys was carried out at times to remove
584 systematic errors associated with flight direction (i.e. heading corrections) and additional long-
585 wavelength errors associated with incomplete removal of diurnal variations. In some cases,
586 continuation to a fixed altitude above the ice-sheet bed and a final grid-based micro-levelling
587 procedure was applied (Ferraccioli et al. 1998). The magnetic anomaly map shown in Figure 2b
588 shows the spatial coverage and magnitude of magnetic data available. Errors in the data are typically
589 presented as the standard deviation of the crossover errors and can be found in the respective survey
590 metadata (see Table 3).

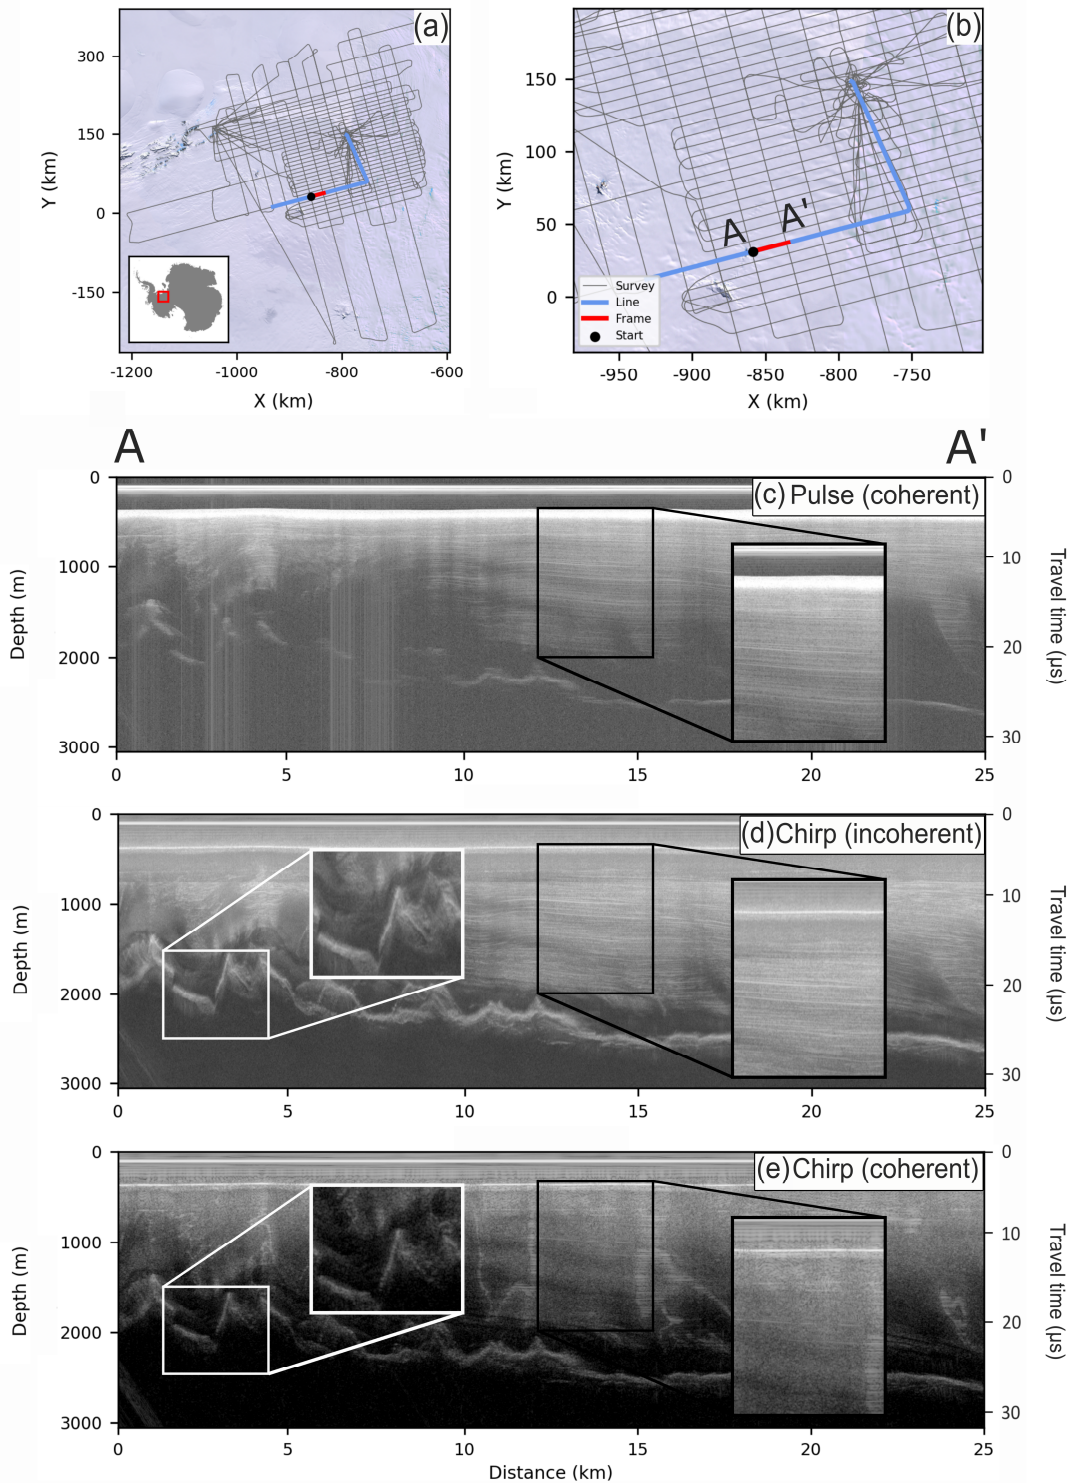

591 **3.2.3. Radar**

592 All data acquired with the earlier “BAS-built” radar system (1994-2004) were read using a C
593 code software to convert the LeCroy data to formats readable by Halliburton Landmark’s seismic-
594 processing software SeisSpace ProMAX, hereafter referred to as ProMAX. Basic processing was
595 applied to the data in the hardware analogue domain and later using ProMax, including power
596 normalisation and final SEG-Y export. Following the transition from the LeCroy oscilloscope to ADC
597 cards on the “BAS-built” system (see Section 3.1.3), MATLAB replaced the IDL language for data
598 processing.

599 As opposed to the “BAS-built” system which, by design, had some level of processing done
600 on the raw data internally, the PASIN system was designed to retain much of the sampled data in the
601 rawest form possible to allow for evolving processing techniques to be applied to the data in the
602 future. For all PASIN data (2004-onwards), the first high-level step was to extract the raw data from
603 the tape drives, convert the three-byte values to conventional four-byte integers, combine the
604 waveforms associated with each pulse transmit type, and then export the data into MATLAB-
605 formatted binary files. The second high-level step was to minimise sidelobe levels by applying a
606 chirp-decompression technique using a Blackman window from a custom-built MATLAB toolbox,
607 resulting in a processing gain of ~10 decibels (dB).

608 The next step was to apply processing techniques both to enhance along-track resolution and
609 improve the signal-to-noise ratio. For the 2004-05 BBAS survey, incoherent stacking of 10
610 consecutive traces was applied and a moving-average window filter used; however, no Synthetic
611 Aperture Radar (SAR) techniques were initially applied to these data. First tested on previously
612 acquired PASIN radar data (see Hélière et al., 2007), 2-D SAR processing based on the Omega-K
613 algorithm and subsequently improved versions using Doppler-beam sharpening were applied
614 systematically to all the deep-sounding chirp data from 2005-2006 onwards to increase spatial
615 resolution and remove backscattering hyperbolae in the along-track direction (Corr et al., 2007; Jeofry
616 et al., 2018). The benefit of using unfocused along-track SAR processing is that it resolves the bed in
617 much finer detail compared with non-SAR focused data (see Figure 6 d-e); however, SAR-processing
618 can also lead to distortions of the amplitude of the ice structure and bed reflection in unhomogenous
619 areas of the ice sheet (e.g. near grounding line; see Hélière et al., 2007) and thus might not always be
620 appropriate for assessing internal layering or absolute amplitudes such as required for bed-reflectivity
621 analysis (e.g. Peters et al., 2007; Castelletti et al., 2019). Additional moving-average filters of varying
622 lengths have also been applied to enhance englacial reflections and improve visualisation of the radar
623 data.

624 Figure 6 shows the three processed radar products provided for the 2010-11 IMAFI survey
625 over West Antarctica. Figure 6c shows the shallow-sounding pulse and Figures 6d-e the deep-
626 sounding chirp radar data using the unfocused SAR-processing technique from Hélière et al. (2007)
627 (Fig. 6d) and a version of the chirp product processed with coherent summations but with no SAR-
628 processing applied (Fig. 6e). Internal layering is more clearly visible in the upper part of the ice
629 column on the pulse data compared with the chirp data (see black-bordered insets in Fig. 6c and 6e).
630 In contrast, deeper internal layering is much more visible on the SAR-chirp than the non-SAR chirp
631 (Fig. 6d-e). Additionally, the peak amplitude of the bed is better resolved in the SAR-processed chirp
632 than the non SAR-processed chirp (see white-bordered inset in Fig. 6d-e).

633

634 **Figure 6. A 25-km segment for flightline 15d of the 2010-11 IMAFI survey showing the three**
 635 **radar products and processing attributes.** (a) shows an overview map of the entire survey with an inset over
 636 Antarctica and (b) shows a zoomed-in map over the specific flightline with the 25-km radar segment (defined as
 637 A-A') shown in red. The background satellite image in (a-b) is from the Landsat Image Mosaic of Antarctica
 638 (LIMA) (Bindschadler et al., 2008). (c-e) show a 25-km segment of the data for the three products provided for
 639 the 2010-11 IMAFI survey as follows: (c) the coherently processed, shallow-sounding pulse, (d) the unfocused
 640 2-D SAR-processed, deep-sounding chirp, and (e) the coherently processed, deep-sounding chirp. The black-
 641 bordered insets zoom to the internal layering in the upper portion of the ice column for (c-e) and the white-
 642 bordered insets show the difference in bed characteristics between (d-e).

643 Further processing of the PASIN data has also been applied by others using simple image-
644 processing techniques such as moving-average filters to enhance the internal layering of the ice and
645 reduce incoherent noise (Ashmore et al., 2020; Bodart et al., 2021), or by applying more complex
646 SAR processing techniques over previously incoherently processed radar data (Castelletti et al., 2019;
647 Chu et al., 2021). Additional techniques have also be employed in areas where side-echos from steep
648 valley walls lead to ambiguous bed reflections, as previously employed over Flask Glacier (Antarctic
649 Peninsula) using PASIN SAR-processed data and a combination of velocity and digital elevation
650 models to obtain more accurate ice thickness estimates (Farinotti et al., 2013).

651 Following radar data processing, bed and ice-surface reflections were determined by picking
652 the onset of the basal echo (i.e. where the echo amplitude is greater than the noise floor). We note that
653 this is not a universal method applied by all radar data providers, who, may pick the half-amplitude
654 delay or the peak value, leading in turn to measurement biases across data providers and products (e.g.
655 Peters et al., 2005; Chu et al., 2021).

656 The BAS approach to picking the bed was to use a semi-automatic first-break pick algorithm
657 on the chirp data below a top-mute window in ProMax (generally ~100 samples above the
658 approximate bed reflection) to locate the precise bed return, followed by manual checks and re-
659 picking to exclude any unrealistic spikes. In areas where multiple closely spaced reflections were
660 sounded at the bed, the shallowest reflection was assumed to be the bed as off-axis reflections would
661 likely appear lower down in this section. However, in some cases, reflections, which appeared deeper,
662 were chosen, with shallower weak reflections assumed to reflect entrained debris, accreted ice, or
663 uncompensated refraction hyperbolae close to the bed. We note, however, that this method has
664 evolved over the years, and that its success is inherently reliant on the radioglaciological experience
665 of the human picker to quality-check the results from the semi-automatic picker and manually re-pick
666 the data if necessary. The uncertainty associated with the picking procedure can be partially
667 approximated by calculating the Root-Mean-Square error (RMS) of the bed elevations at crossover
668 points across the survey area. Although these errors are site-specific and can depend on factors such
669 as varying bed topography and roughness, larger errors may reflect uncertainties in data processing or
670 analysis (i.e. picking in this case). Areas of more extreme topography typically show the highest
671 crossover errors, likely associated with off-axis reflections and entrained debris close to subglacial
672 cliffs, which make deciding on the correct bed pick challenging. In isolated cases, such errors can
673 exceed several hundred meters. In contrast, regions dominated by smooth and flat bed typically show
674 lower crossover errors, on the order of several meters only. Survey wide RMS errors are typically
675 reported in each survey's metadata (see Table 3) and average ~9 to 22 m depending on the survey (see
676 Rippin et al., 2003; Vaughan et al., 2006; Ross et al., 2012; Jeffery et al., 2018).

677 To estimate ice thickness and hence obtain the bed elevation, the location of the surface
678 reflection in the radar data must be known accurately. However, since the PASIN system does not
679 resolve the ice surface well due to errors in the phase centre of the pulse through the firn layer, the
680 surface reflection in the radargram was only rarely used on its own to calculate the ice surface.
681 Usually, range-to-surface from coincident on board-acquired lidar, or alternatively if lidar was not
682 available (i.e., due to clouds or ground clearance higher than 750 m), using the aircraft's radar
683 altimeter or surface elevation from an accurate Digital Elevation Model (DEM) (i.e. REMA 8-m
684 DEM for latest surveys; Howat et al., 2019), was used to calculate a "theoretical" surface pick, as
685 follows:

686 Firstly, the same semi-automatic picker used for picking the bed was used on a subset of the
687 shallow-sounding pulse radargrams with a bottom-mute window set at ~100 samples below the
688 surface reflection. Secondly, once aircraft-to-surface range was obtained from lidar, a linear trend
689 between the surface pick from the radargram and the surface range from the lidar was calculated, and
690 a resulting slope and offset was used to calculate the theoretical location of the surface. Where

691 possible, the range-to-ground value was derived from the lidar data or interpolated from the mean
 692 lidar elevation within ~700 m. In those rare cases where the surface reflection was picked directly
 693 from the radargram, a regression, local to the data gap, was used to fit the radar range to terrain
 694 clearance. If lidar was not available to calculate range-to-ground, the height of the aircraft above the
 695 surface was obtained by the aircraft’s radar altimeter which was then converted into a radar delay
 696 time. This conversion was done after a two-stage calibration process which involved recording the
 697 terrain clearance over a sea surface with the two instruments, and then correction for the penetration
 698 depth of the radar altimeter was obtained from the difference in the height above ellipsoid of a
 699 surveyed ‘flat’ snow surface and the aircraft. Where possible, the reference surface was chosen to be
 700 in the centre of the targeted area.

701 Once bed and surface were calculated, ice thickness was obtained by calculating the
 702 difference between the bed and surface pick in range samples (relative to the BAS system). The
 703 picked travel time was then converted to depth in metres using a radar wave speed of 168
 704 m/microseconds and a constant firn correction of 10 m. Bed and surface elevations were then
 705 integrated with a high-precision kinematic dual-frequency GPS position solution to provide the final
 706 point dataset of elevations relative to the WGS84 Ellipsoid. To ensure best accuracy of satellite-orbit
 707 definitions and atmospheric corrections, the interpolated survey locations and aircraft elevations were
 708 processed from 10-Hz coupled Precise Point Positioning (PPP) GNSS/INS solutions one month after
 709 data acquisition.

710 4. FAIR Data Publishing

711 In total, we have published 64 datasets from 24 surveys as part of this data release,
 712 representing ~566 GB of data and ~1800 files. This amounts to a total of 3.62 million gravity and 7.41
 713 million magnetic data points, as well as 14.5 million ice-thickness and bed-elevation measurements.
 714 The complete list of published datasets is provided in Table 3, including the short Digital Object
 715 Identifiers (DOI), which redirect to the metadata sheets and download folders for each respective
 716 dataset archived on the PDC Discovery Metadata System (DMS) data catalogue
 717 (<https://data.bas.ac.uk/>).

718 **Table 3. Short Digital Object Identifiers for the gravity, magnetic, bed-pick, and 2-D radar**
 719 **datasets for each survey flown by BAS and included in this data release.** Abbreviations used are the same as
 720 in Table 1. The links in this table can also be accessed by adding the short DOI preceded by ‘<https://doi.org/>’.⁽¹⁾
 721 For the AGAP radar data, the US-led survey lines can be found at: <https://doi.org/10.1594/IEDA/313685>.⁽²⁾ For
 722 the PolarGAP survey, data can be downloaded from both the ESA and BAS data catalogues, but the DOI for the
 723 gravity and magnetic data (<https://doi.org/10.5270/esa-8ff003e>) belongs to ESA. If using the PDC data
 724 catalogue, the PolarGAP gravity and magnetic data can be downloaded from [https://data.bas.ac.uk/full-](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01583)
 725 [record.php?id=GB/NERC/BAS/PDC/01583](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01583) and [https://data.bas.ac.uk/full-](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01584)
 726 [record.php?id=GB/NERC/BAS/PDC/01584](https://data.bas.ac.uk/full-record.php?id=GB/NERC/BAS/PDC/01584) respectively. “**” indicates that the data are not held at BAS, but
 727 instead are available on the CReSIS data portal (<https://data.cresis.ku.edu/>).

728

729 We note that individual profiles opportunistically acquired following larger aerogeophysical
730 surveys (i.e. flightlines over Flask Glacier; Farinotti et al., 2013) are not included in this data release
731 unless specifically mentioned in the metadata for each survey (see Table 3). Such small-scale datasets
732 will be added to the data portal in future releases.

733 Below, we discuss the release of the datasets centered around the four FAIR data principles
734 (i.e. Findable, Accessible, Interoperable and Re-Usable; Wilkinson et al., 2016), starting with the
735 formats and attributes used to store and describe the data (Interoperability; Sect. 4.1), the metadata
736 and Digital Object Identifiers assigned to each dataset (Findability; Sect. 4.2), the data-portal interface
737 and functionalities (Accessibility; Sect. 4.3), and finally the creation of a user guide and open-access
738 tutorials written in Python and MATLAB for reading the data programmatically (Re-usability; Sect.
739 4.4).

740 **4.1. Interoperability: Data Formats and Attributes**

741 In order to make our data as interoperable as possible, the choice of an open format for all our
742 datasets was a priority. We followed the best practices of the geophysics community and used
743 common data formats and naming conventions to describe the variable names. These are detailed
744 further here.

745 The gravity, magnetic, and bed-pick data are stored in open ASCII data formats, namely XYZ
746 and CSV files, to ensure long-term access and unrestricted use of the data in the future (Fig. 4).
747 Additionally, we followed the SCAR ADMAP2 data-release protocols (Golynsky et al., 2018) for the
748 naming convention of the channels for the magnetic data. For the radar data, we chose to release the
749 bed-pick data separately from the full radar data (Fig. 4), although the full radar product contains most
750 of the information stored in the ASCII bed-pick files. Publishing the bed-pick data separately from the
751 radar data was a deliberate choice: it alleviates the need for users to download the full radar datasets
752 to access light-weight tabular data, and improves the accessibility of the point data for large gridded
753 products such as SCAR's BEDMAP (Fretwell et al., 2013) and NASA's BedMachine (Morlighem et
754 al., 2020) projects. The bed-pick data are stored as ASCII-formatted files (namely XYZ and CSV),
755 whereas the full radar data are stored as SEG-Y and NetCDF files, reasons for which are described
756 below.

757 The SEG-Y format has been used extensively by radar scientists since the early 1980s to store
758 radar data. This is primarily due to the lack of a radar-specific format, SEG-Y having been developed
759 primarily to store seismic data. The advantage of using SEG-Y files is that data can be readily

760 imported into seismic-interpretation software for data interpretation and analysis. The drawbacks of
 761 using SEG-Y, however, are numerous, making this option unsuitable for long-term data storage.
 762 These include: (1) limited space for metadata, (2) the choice of byte-information to store the radar
 763 data is subjective due to the nature of the SEG-Y format, (3) until recently, the byte stream structure
 764 which includes the geolocation of each radar trace (i.e. the X and Y positions) was restricted to integer
 765 format leading to large inaccuracies in the actual trace position despite the use of high-resolution, sub-
 766 metre GPS data (see Section 3.1.4). Recognising, however, the need from the geophysical community
 767 to view and analyse the radar data in conventional data formats, we have decided to continue
 768 producing SEG-Y files for each flightline and acquisition mode (e.g. pulse and chirp). The SEG-Y
 769 files were produced using the Revision 1.0 SEG-Y format and georeferenced using the navigational
 770 position of each trace from the GPS on board the aircraft in Polar Stereographic (EPSG: 3031)
 771 projection. Each SEG-Y file contains the following byte-information: trace number (byte: 1-4 and 5-
 772 8), PRI-Number (byte: 9-12), Cartesian X-coordinate (byte: 73-76), Cartesian Y-coordinate (byte: 77-
 773 80), number of samples for each SEG-Y trace (byte: 115-116), and the sampling interval (byte: 117-
 774 118).

775 As a result of the issues mentioned above, we also exported and published the radar data in
 776 NetCDF-formatted files. We chose the NetCDF format due to its portability and array-oriented
 777 structure, the ability to store large amounts of metadata and variables into one portable file, its
 778 machine-readable capability, and to harmonise our data products with other fields such as climate
 779 science (e.g. ECMWF ERA5 reanalysis products; NCAR climate data), glaciology (e.g. Le Brocq et
 780 al., 2010; Morlighem et al., 2017; Lei et al., 2021) and, increasingly, radar geophysics itself (e.g.
 781 Paden et al., 2014; Blankenship et al., 2017), which already all make use of this data format
 782 effectively. The NetCDF files we produced contain extensive metadata relating to the acquisition and
 783 processing of the radar data, as well as a set of CF-compliant (Climate and Forecast;
 784 <https://cfconventions.org/>) variables that are tied to the radar data (Table 4). As a minimum, each
 785 NetCDF file contains a radar data variable (one for the pulse and/or one for the chirp if both exist) in
 786 2-D format, and a set of 1-D variables relating directly to the radar data, such as the trace number, PRI
 787 number, fast time, and the X and Y coordinates (Table 4). We also provided additional radar-related
 788 variables which were extracted from the radar data following processing, such as the surface and bed
 789 picks, the surface and bed elevation, the ice thickness, longitude and latitude, time of the trace, and
 790 the elevation of the aircraft (Table 4). Additional 1-D variables include the source of the surface pick
 791 (from lidar or radar) if this exists, the range between the aircraft and the ice surface, and in case the
 792 pulse- and chirp-radar variables do not have the same length, we provide two sets of variables for the
 793 trace number and PRI number.

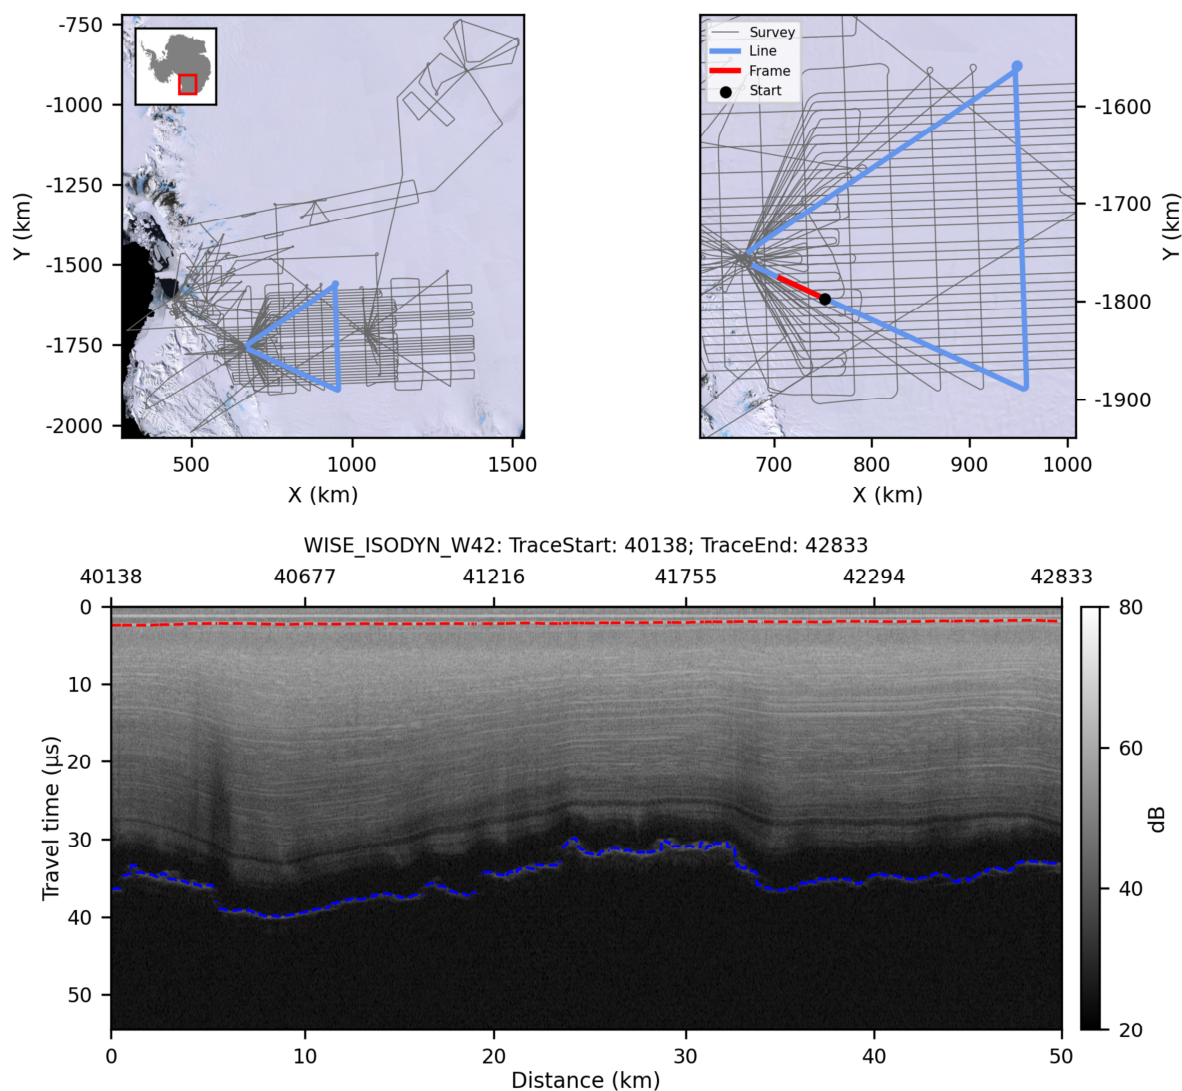

794 **Table 4. Attributes for each variable stored in the NetCDF files.** For each attribute name, we
 795 provide the long name, the dimension (1- or 2-D, x- or y-axis), the short or CF-compliant standard name, and
 796 the unit of the measurement. The standard name is only provided if it exists as part of the CF convention
 797 (<https://cfconventions.org/>), otherwise a short name is provided. “dBm” stands for decibel-milliwatts and “a.s.l.”
 798 stands for above sea level. Note that the surface and bed pick data are referenced to the sampling time of the
 799 BAS radar systems across the 64 microseconds pulse repetition interval window, and digitised according to the
 800 receiver sampling frequency (see Table 2).

NetCDF Attributes	Long Name	Dimension	Short / Standard Name	Unit
traces	Trace number for the radar data	1-D (x-axis)	traceNum	integer count (unitless)
fast_time	Two-way travel time	1-D (y-axis)	time	microseconds
x_coordinates	Cartesian x-coordinates for the radar data	1-D (x-axis)	projection_x_coordinate	meters (WGS84 EPSG: 3031)

y_coordinates	Cartesian y-coordinates for the radar data	1-D (x-axis)	projection_y_coordinate	meters (WGS84 EPSG: 3031)
chirp_data	Radar data for the processed chirp	2-D (x- and y-axis)	-	power (dBm)
pulse_data	Radar data for the processed pulse	2-D (x- and y-axis)	-	power (dBm)
longitude_layerData	Longitudinal position of the trace number	1-D (x-axis)	longitude	degree_east (WGS84 EPSG: 4326)
latitude_layerData	Latitudinal position of the trace number	1-D (x-axis)	latitude	degree_north (WGS84 EPSG: 4326)
UTC_time_layerData	Coordinated Universal Time (UTC) of trace number	1-D (x-axis)	resTime	seconds of the day
PriNumber_layerData	Incremental integer reference number related to initialisation of the radar system	1-D (x-axis)	PriNum	integer count (unitless)
terrainClearance_layerData	Terrain clearance distance from platform to air interface with ice, sea or ground	1-D (x-axis)	resHt	meters
aircraft_altitude_layerData	Aircraft altitude	1-D (x-axis)	Eht	meters a.s.l. (WGS84 ellipsoid)
surface_altitude_layerData	Ice surface elevation for the trace number	1-D (x-axis)	surface_altitude	meters a.s.l. (WGS84 ellipsoid)
surface_pick_layerData	Location down trace of surface pick (BAS system)	1-D (x-axis)	surfPickLoc	time sample (microseconds)
bed_altitude_layerData	Bedrock elevation for the trace number	1-D (x-axis)	bed_altitude	meters a.s.l. (WGS84 ellipsoid)
bed_pick_layerData	Location down trace of bed pick (BAS system)	1-D (x-axis)	bedPickLoc	time sample (microseconds)
land_ice_thickness_layerData	Ice thickness for the trace number	1-D (x-axis)	land_ice_thickness	meters

801

802 Lastly, to aid visualisation and improve efficiency in navigating the datasets, we created
803 lightweight quick-look PDF files of the radar data for each flightline of each survey (see example for
804 the WISE-ISODYN survey in Figure 7). The choice of ~25 or ~50-km length for the 2-D radargram
805 was chosen based on clarity of the image and varies from survey to survey. The quick-look PDF files
806 are stored alongside the SEG-Y and NetCDF files and are accessible using the links provided in Table
807 3.

808

809 **Figure 7. Example of a segmented quick-look image from the 2005-06 WISE-ISODYN survey.** (a)

810 Overview map of the survey flightlines (grey lines) with an inset over Antarctica and the specific flightline
 811 highlighted in blue. (b) Zoom-in version of (a) showing the specific flightline with the footprint of the 50-km
 812 segment (red line) and start point for the radargram (black dot) shown in (c). The background satellite image in
 813 (a-b) is from the Landsat Image Mosaic of Antarctica (LIMA) (Bindschadler et al., 2008). (c) 50-km segmented
 814 radar image of the chirp data with distance in kilometres shown in the bottom x-axis and the trace number
 815 shown in the top x-axis. The y-axis shows the travel time in microseconds. The format of the title in (c) is as
 816 follows: Survey Name and Flight ID, First Trace of Segment, Last Trace of Segment. The red and blue dashed
 817 lines on the radargram in (c) show the surface and bed pick respectively.

818 4.2. Findability: Metadata and Digital Object Identifiers

819 ISO 19115/19139 Geographic Information metadata are provided for each data type of each
 820 survey and is archived alongside the datasets onto the PDC DMS catalogue (<https://data.bas.ac.uk/>;
 821 see Table 3). Each metadata record provides detailed information about the dataset, including an
 822 abstract, list of personnel involved in the acquisition or analysis of the dataset, and detailed lineage
 823 information on the acquisition and processing steps used to produce the dataset amongst others. All
 824 our data are covered under the UK Open Government License
 825 (<http://www.nationalarchives.gov.uk/doc/open-government-licence/>), enabling the re-use of the data
 826 freely and with flexibility, whilst at the same time ensuring acknowledgment of those involved in the

827 collection and processing of the data. In addition, we use Earth Science-specific keywords and
828 vocabularies from the Global Change Master Directory (GCMD, 2021) to describe our data in a
829 consistent and comprehensive manner in accordance with ISO 19115 standards. Lastly, a Digital
830 Object Identifier is minted for each dataset so that it can be discoverable and adequately cited. The
831 end goal is to provide all the information necessary for effective, long-term data re-use.

832 The data are shared via the web-based RAMADDA (Repository for Archiving and MANaging
833 Diverse DAta; <https://geodesystems.com/>) data repository system which is an open-source content
834 and data management platform. The download of the data is done through a standard HTTP-protocol
835 where no login account is required. In the backend, the data are stored following a simple folder
836 structure on the PDC server that is mirrored onto RAMADDA. This simple structure allows us to
837 maintain a balance between the services we can provide and our ability to move away from specific
838 tools – RAMADDA in this case - and potentially adopt more performant systems in the future. The
839 goal is to stay as independent of the platform we use as possible while providing the most effective
840 service possible.

841 **4.3. Accessibility: Polar Airborne Geophysics Data Portal**

842 To increase the accessibility and discoverability of our data, we developed a new data portal,
843 the Polar Airborne Geophysics Data Portal (<https://www.bas.ac.uk/project/nagdpl/>). The portal
844 interactively showcases the wide coverage of aerogeophysical datasets collected by BAS and enables
845 users to easily discover and download the published datasets via a series of widgets and functionalities
846 aimed at enhancing the user experience.

847 The portal is divided into five layer-menus: “Aerogravity”, “Aeromagnetics”, “AeroRadar”,
848 “Boundaries & Features”, and “Basemaps”. The first three menus contain shapefile layers for the
849 gravity, magnetic, and radar datasets respectively. The “Boundaries & Features” menu contains a set
850 of specific boundary layers, such as the Antarctic Coastline and Ice Drainage boundaries amongst
851 others, and the “Basemaps” menu contains background gridded maps of ice thickness, surface and bed
852 elevations, magnetic anomaly and geothermal heat flow amongst others.

853 The track lines for each dataset correspond to individual polyline shapefiles (either segmented
854 in 25 or 50-km, or by flightline) which contain key statistics such as the minimum, maximum, and
855 median gravity and magnetic anomalies, and minimum, maximum, and median ice surface, bed
856 elevation, and ice thickness. The shapefiles also contain direct links to the survey’s metadata and to
857 direct links to download the data via the RAMADDA interface.

858 A powerful functionality of the portal is the ability to view the aerogeophysical data rapidly
859 via the creation of quick-look gravity, magnetic, and radar plots for each flightlines (see Section 5.2;
860 Figure 7c). For the magnetic and gravity data, graphs showing the magnetic or free-air anomaly along
861 straight lines were created in the direction Westernmost-Easternmost if the profile is mainly in the
862 direction of the longitude, or Northernmost-Southernmost if the profile is predominantly in the
863 direction of the latitude. For the radar data, the segmented images were produced in a similar format
864 to Figure 7c and split into ~25 and ~50 km segments depending on the survey.

865

866 **4.4. Re-Usability: User Guide and Tutorials**

867 To increase further the re-usability of our data, we provided a user guide for the data portal as
868 well as interactive, open-source Jupyter Notebook tutorials written in Python and MATLAB for
869 reading in the gravity, magnetic, and radar datasets and conducting first-order analyses on the data.
870 These are archived on the BAS GitHub repository and provided via an interactive web interface using
871 Jupyter Book (https://antarctica.github.io/PDC_GeophysicsBook). We believe these to be particularly
872 beneficial for ensuring accessibility and re-usability of our data to as wide of a range of users as
873 possible, primarily as a result of the complexity around reading in aerogeophysical data formats.

874 **5. Discussion**

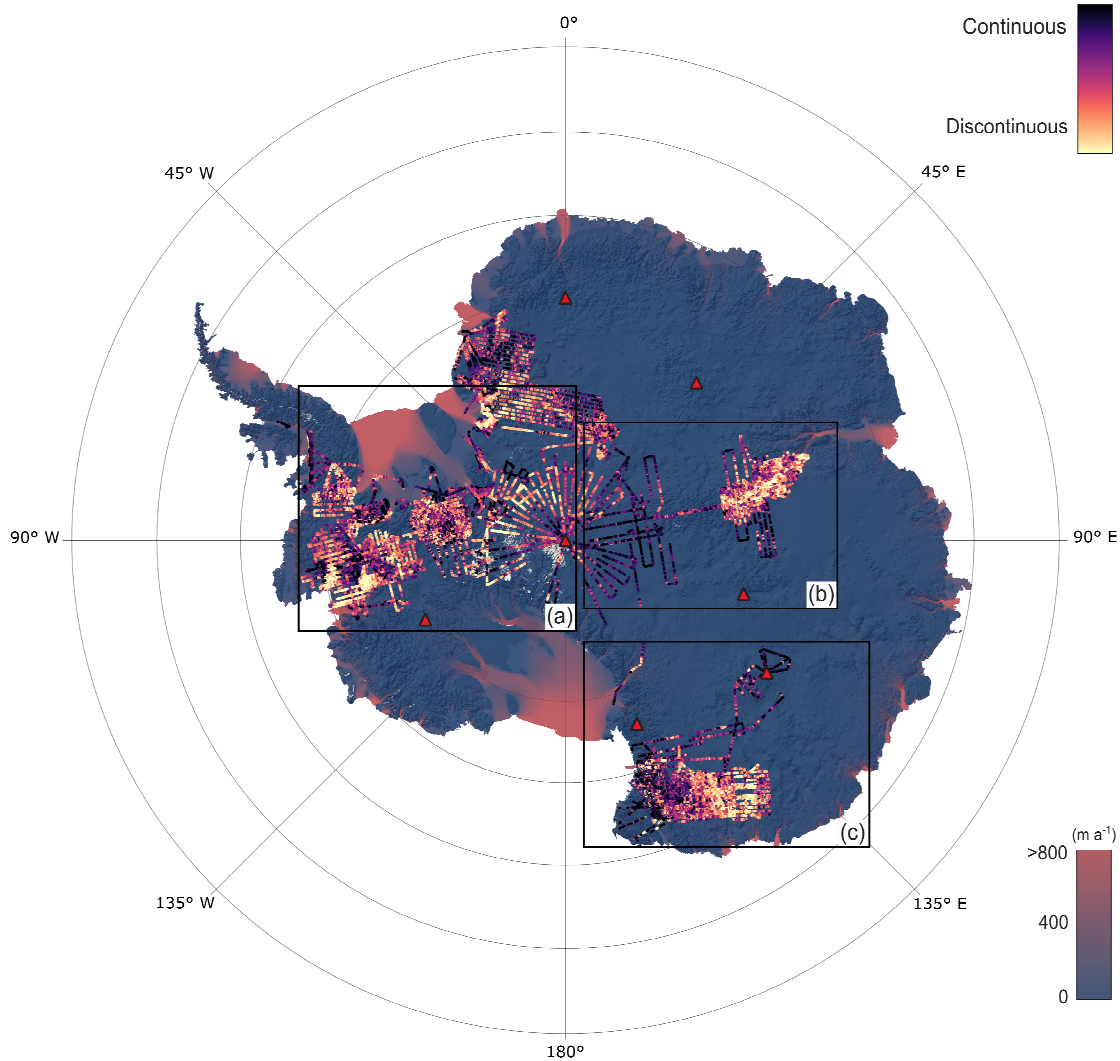

875 This final section exemplifies the potential re-usability of the newly released aerogeophysical
876 data via the interrogation of the englacial architecture of the ice as sounded by BAS ice-penetrating
877 radars. We also explore the future use of the new data portal and discuss opportunities in terms of data
878 release and further potential re-use of the BAS aerogeophysical data.

879 **5.1. Internal Layering Continuity Index**

880 Englacial layering, as imaged by ice-penetrating radars, is a powerful means of extracting
881 information on past ice-dynamical processes (Rippin et al., 2003b; Siegert et al., 2003; Bingham et al.,
882 2015) amongst others. For example, the presence of well-preserved and continuous englacial layering
883 may reflect stable ice conditions and suggest limited changes in past ice-flow conditions, ice divide
884 migration, or melting within or at the base of an ice sheet (Karlsson et al., 2012). In contrast, poor
885 continuity in englacial layering, primarily characterised by buckled or absent layering, may be
886 indicative of past ice-flow switching or increased englacial stress gradients (Siegert et al., 2003;
887 Bingham et al., 2015).

888 The Internal Layer Continuity Index (or ILCI; Karlsson et al., 2012) provides an automated
889 tool for quantitatively assessing the continuity of englacial layering based on A-scope radar profiles.
890 This method has the advantage of being much less laborious than manual methods (e.g. Rippin et al.,
891 2003a; Siegert et al., 2003; Bingham et al. 2007) and removes the potential subjectivity in assessing
892 layer continuity. By design, the ILCI is sensitive to the number and strength of internal reflections,
893 such that low values indicate discontinuity and high values indicate high continuity. Whilst the ILCI
894 has previously been calculated over individual surveys (Karlsson et al., 2012; Bingham et al., 2015;
895 Winter et al., 2015; Karlsson et al., 2018; Luo et al., 2020), until now, this approach had not been
896 tested at a regional scale over Antarctica and with the use of multiple radar datasets. Enabled by the
897 comprehensive release of large swaths of fully standardised and open-access aerogeophysical data
898 described in this paper, we aim to demonstrate that much more information can be extracted from
899 these data on a regional- to continental-scale, which would not have otherwise been possible before.

900 Here, we have calculated the ILCI on the ten PASIN radar datasets acquired between 2004-
901 2020 that have been published as part of this data release (see Table 3; Figure 8-9); and which amount
902 to ~300,00 line-km of data. Since we were primarily interested in regional changes in layer continuity,
903 the ILCI was smoothed using a horizontal window of 1,000 samples (representing ~25-45 km distance
904 depending on the dataset) to remove any small-scale anomalies in the data and only making use of the
905 deep-sounding chirp product due to its capability of imaging deeper internal layers. The upper and
906 lower 20% of the ice were also omitted in the calculations due to the inability of the PASIN system to
907 resolve continuous layers in the upper portion of the ice column, and because internal layering is
908 typically absent near the ice-bed interface (Drews et al., 2009; Karlsson et al., 2012).

909

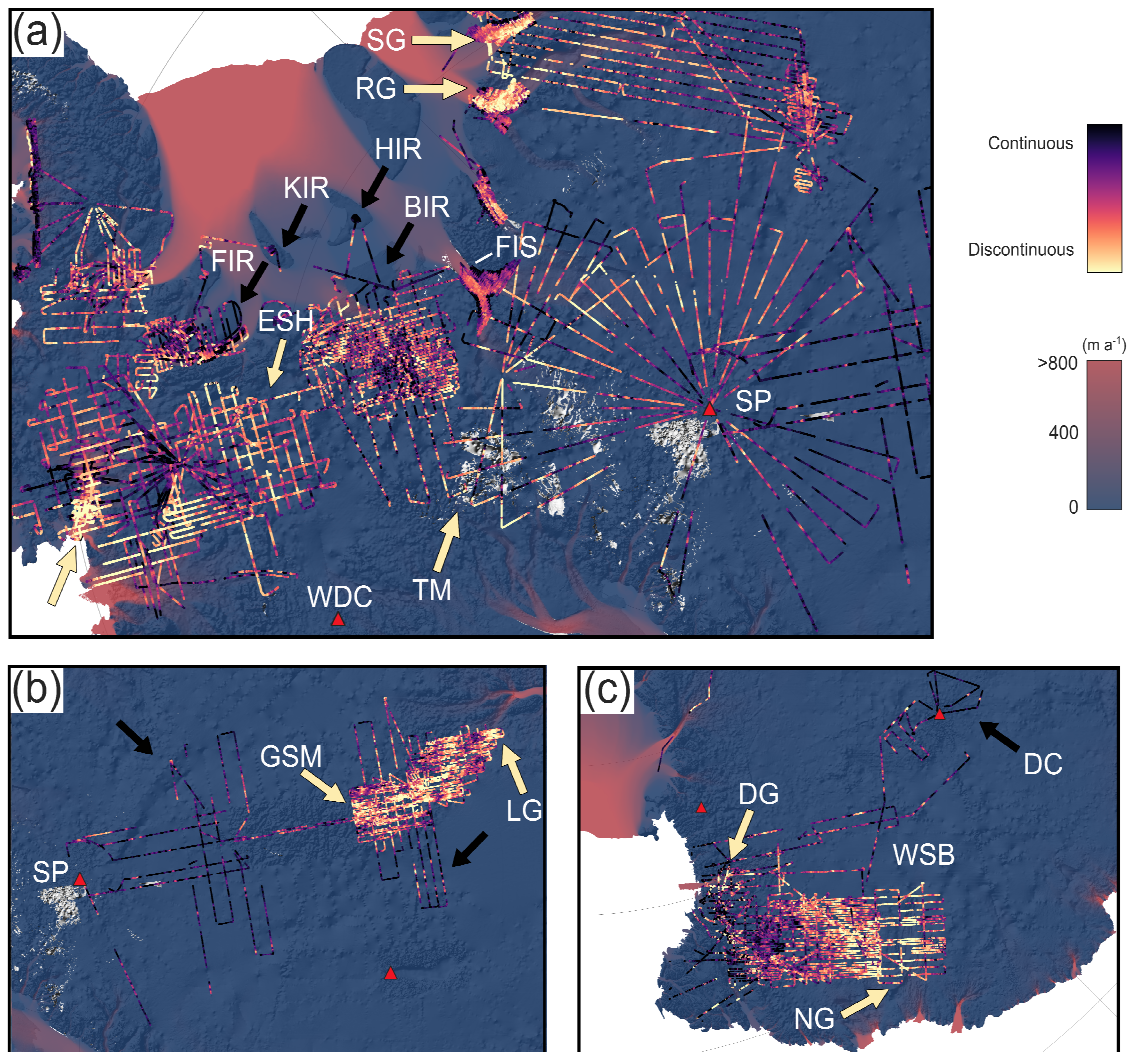

910 **Figure 8. Internal Layer Continuity Index for the ten PASIN datasets for which the fully**
 911 **processed 2-D radar data was released as part of this paper (see Table 3).** The background map shows ice-
 912 flow velocities from the In-SAR MEaSUREs dataset (Rignot et al., 2017) superimposed over a hill-shade from
 913 the BedMachine bed elevation V2 dataset (Morlighem, 2020). The red and blue colour bar shows ice-flow
 914 velocities in metres per annum, and the magma colour bar shows the continuity of internal layers throughout the
 915 radar dataset (low continuity = yellow; high continuity = dark purple). The black-bordered rectangles (a-c)
 916 correspond to the close-up plots in Figure 9a-c. The red triangles correspond to existing deep ice-cores located
 917 near the BAS radar surveys.

918 An important consideration in employing the ILCI over multiple datasets is that the results
 919 will vary based on data acquisition (i.e. radar frequency, system resolution) and processing applied
 920 (i.e. incoherent vs 2-D SAR), thus a pan-Antarctic comparison of internal layer continuity must be
 921 analysed in this context. This is especially the case here, where we have applied the ILCI to data
 922 acquired over a period of >15 years with two different systems (namely PASIN-1 and PASIN-2) and
 923 using different processing regimes. Therefore, care must be taken when interpreting the results from
 924 different surveys together, as for example, a low level of layer continuity in the main trunk of Pine
 925 Island Glacier on the BBAS survey may not reflect the same level of discontinuity on the low-
 926 continuity areas of the PolarGAP survey. This caution noted, the results presented here offer an
 927 opportunity to identify some regional patterns of potential value for future work, which we now
 928 discuss.

929 Figure 8 shows that there is a good correspondence between discontinuous layering where ice
930 flow is fast ($> 200 \text{ m a}^{-1}$) such as over Foundation Ice Stream (FISS) and the main trunk of Pine Island
931 Glacier (BBAS) and Slessor Glacier (ICEGRAV) (Fig. 8 and 9a). Whilst layer discontinuity is mainly
932 present over the WAIS due to the high concentration of fast-flowing ice streams in this region, several
933 sections covering the EAIS also show signs of layer discontinuity, particularly in the upstream
934 portions of the fast-flowing Lambert Glacier (AGAP) and David and Ninnis glaciers (WISE-
935 ISODYN) (yellow arrows in Fig. 9b-c).

936 Unsurprisingly, areas of high continuity are mainly observed over the interior of the EAIS,
937 particularly on flightlines extending deep into East Antarctica and South Pole (Fig. 8 and 9a-b), as
938 well as into the deeper parts of the Wilkes Subglacial Basin and Dome C (black arrow in Fig. 9c)
939 where deep ice-cores have been drilled (red triangles in Fig. 8-9). Areas of high layer continuity over
940 the WAIS include numerous ice-rises (i.e. Bungenstock, Fletcher, Henry, and Korff) as imaged on the
941 GRADES-IMAGE, IMAFI, and FISS surveys (black arrows in Fig. 9a), the deeper sections of the
942 southern Pine Island Glacier basin on the BBAS data, as well as on PolarGAP survey lines upstream
943 of the FISS grids covering Foundation Ice Stream and Recover and Slessor glaciers (Fig. 9a).

944 Also visible are the disruptive effects of local bed topography on the continuity of internal
945 layering, such as over the Ellsworth Subglacial Highlands (BBAS), the Transantarctic Mountains
946 (IMAFI and PolarGAP), and the Gamburtsev Subglacial Mountains (AGAP) (see yellow arrows in
947 Fig. 9a-b), whereas relatively flat bed topography in the deep interior of the EAIS allow layering to
948 remain relatively undisturbed there (Fig. 8 and black arrows in Fig. 9b).

Figure 9. Zoomed-in sections of the Internal Layer Continuity Index shown in the black-bordered rectangles on Figure 8. The basemap datasets and colour scales are the same as in Figure 8. (a) ILCI results over the WAIS (including Pine Island Glacier, Rutford Ice Stream, Institute-Möller Ice Stream, and Foundation Ice Stream) and bottleneck with the EAIS (including South Pole, Pensacola Mountains and Slessor Glacier), (b) ILCI results for the AGAP survey over East Antarctica's Dome A and South Pole, (c) ILCI results for the WISE-ISODYN survey over East Antarctica's Wilkes Subglacial Basin and Dome C. Arrows refer to locations mentioned in the text, with black arrows highlighting examples of high layer continuity and yellow arrows low layer continuity. As per Figure 8, the red triangles correspond to existing deep ice-cores located near the BAS radar surveys. Abbreviations correspond to locations mentioned in the text, as follows: BIR (Bungenstock Ice Rise); DC (Dome C); DG (David Glacier); ESH (Ellsworth Subglacial Highlands); FIR (Filchner Ice Rise); FIS (Foundation Ice Stream); GSM (Gamburtsev Subglacial Mountains); HIR (Henry Ice Rise); KIR (Korff Ice Rise); LG (Lambert Glacier); NG (Ninnis Glacier); RG (Recovery Glacier); SG (Slessor Glacier); SP (South Pole); TM (Transantarctic Mountains); WDC (WAIS Divide Core); WSB (Wilkes Subglacial Basin).

964

965

966

967

968

969

970

Altogether, the results presented in Figures 8 and 9 show considerable promise for those radar datasets to be exploited further in the future, particularly with regards to tracking or otherwise characterising the englacial architecture of the ice and as motivated by the SCAR AntArchitecture group. At present, only two BAS radar datasets (BBAS and IMAFI) have been comprehensively assessed for deep englacial layers (Karlsson et al., 2009; Ashmore et al., 2020; Ross et al., 2020; Bodart et al., 2021). Importantly, the close proximity of deep ice cores, such as the WAIS Divide (Buizert et al., 2015; Sigl et al., 2016), EPICA Dome C (EPICA Community Members, 2004), and

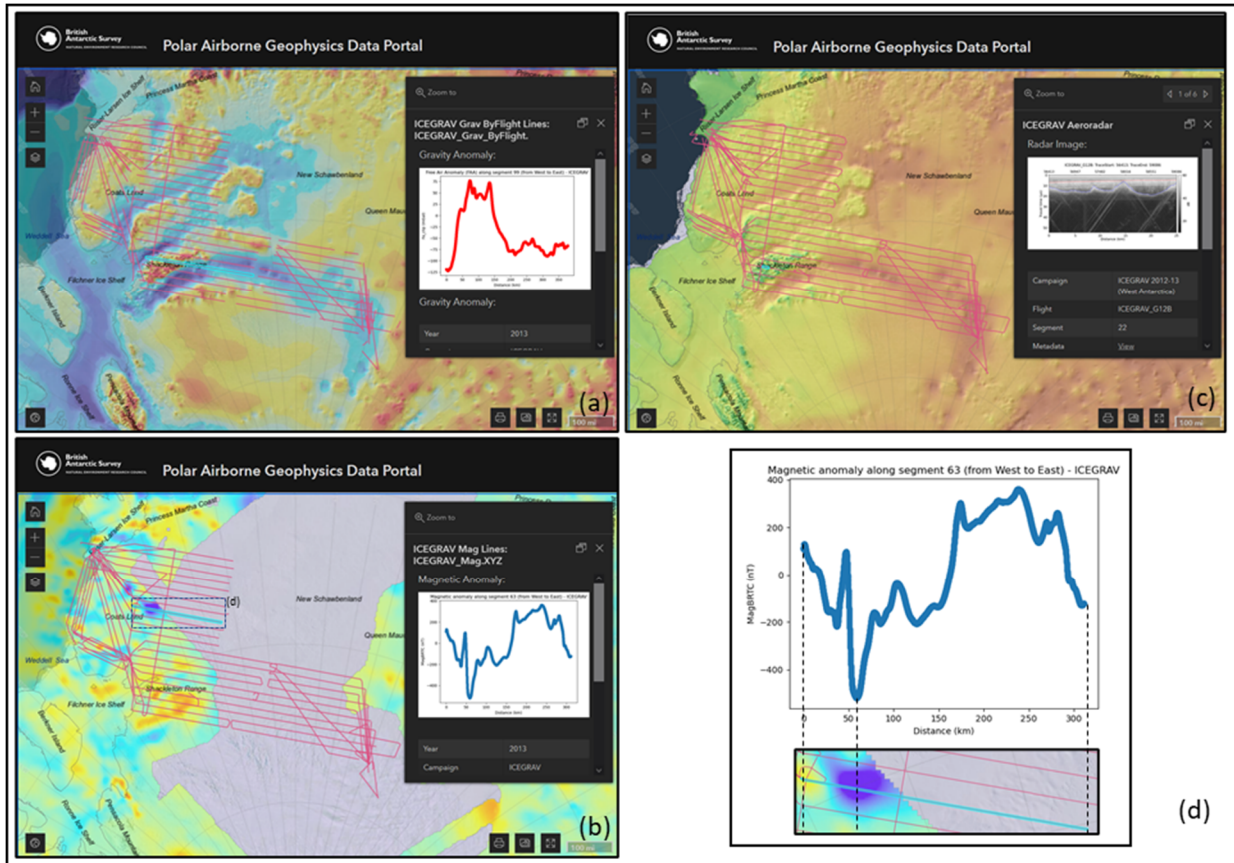

971 South Pole (Winski et al., 2019), to these newly released surveys (Fig. 8-9) provide ready
972 opportunities for these layers to be dated, increasing significantly their wider use for glaciological and
973 geophysical applications (i.e. Siegert and Payne, 2004; Parrenin and Hindmarsh, 2007; Cavitte et al.,
974 2018; Sutter et al., 2021).

975 **5.2. Polar Airborne Geophysics Data Portal**

976 One specificity of the platform is that it offers three types of geophysical datasets - namely
977 gravity, magnetic and radar - at the same time geospatially. Although some surveys were acquired
978 over 25 years ago, they may never have been exploited or analysed fully in a form that reached peer-
979 reviewed publications, nor combined with other geophysical data before, increasing in turn their re-
980 usability. By publishing this resource, we anticipate that the portal and datasets will foster new
981 research and discoveries related to our understanding of ice-sheet processes and crust and lithosphere
982 heterogeneity beneath the Antarctic Ice Sheet.

983 Additionally, the portal enables users to combine the published line datasets with gridded
984 products to compare the ability of the interpolated datasets to match the direct observations. For
985 instance, as shown in Figure 10 for the 2012-13 ICEGRAV survey, the portal allows users to readily
986 investigate the free-air gravity anomaly with the bed topography from BEDMAP2 or assess the
987 consistency between the measured ICEGRAV magnetic anomalies and the gridded aeromagnetic
988 product (Fig. 10). Alternatively, the quick-look radargrams can be compared with the ice-thickness
989 and bed-elevation grid cells from BEDMAP to assess sub-km variations in along- and across-flow on
990 the radar data which may have been smoothed out in the 1-km gridded product.

991 With its ~207,000 line-km of gravity, ~338,000 line-km of magnetic, and ~352,000 line-km
992 of radar data published, the Polar Airborne Geophysics Data Portal provides a robust platform for the
993 dissemination of the BAS aerogeophysical data. Further opportunities offered by the data portal are
994 the potential for the platform to be used to plan future field surveys or encourage future compilation
995 efforts based on gaps in the data coverage or quality of the data.

996

 1001 **thickness basemap from BEDMAP2. (d) Magnetic anomaly along the profile highlighted in (c) with a**
 1002 **comparison with the aeromagnetic anomaly map from Goodge and Finn (2010).**

1003
 1004 **5.3. Future Work**

1005 Although most of data published here have already been incorporated into previous data
 1006 compilations such as BEDMAP2 or ADMAP2, the more recent datasets presented here will provide
 1007 useful additions to future editions of such initiatives. Examples of this are the data acquired as part of
 1008 the 2012-13 ICEGRAV aeromagnetic campaign in Dronning Maud Land where the last compilation
 1009 effort of magnetic anomalies had shown a large gap (Goodge and Finn, 2010; Fig. 10), or the new ice-
 1010 thickness and bed-elevation data acquired over Thwaites Glacier (2018-20), South Pole (2015-16),
 1011 and Filchner Ice Shelf (2015-17) which are expected to be added to the new BEDMAP3 compilation.

1012 Even though most of the gravity, magnetic and bed-pick data acquired since the mid-1990s
 1013 are now fully published, radar data from older surveys (1994-2004) for which the bed-pick data are
 1014 published and already integrated into larger gridded products (e.g. BEDMAP; Fretwell et al., 2013)
 1015 are yet to be published in full as per the more modern surveys (2004-2020) released here (see Table
 1016 3). This is primarily due to poorer data management practices at times of acquisition and less well-
 1017 documented processing procedures which restrict the re-usability of these older radar dataset. Much
 1018 older analogue radar data acquired on films and video tapes prior to the deployment of digital radars
 1019 (i.e. pre-1994) also offer additional opportunities, although the necessity for manual digitisation
 1020 makes this task much more time consuming and challenging. It is worth noting, however, that many
 1021 of the regions broadly covered by these older surveys have recently been re-flown using more modern

1022 instruments, much as part of NASA's Operation IceBridge programme (MacGregor et al., 2021),
1023 although reprocessing and modernising older radar data can bring substantial benefits, as already
1024 demonstrated by Schroeder et al. (2019). Additional reprocessing of older radar data using modern 2-
1025 D SAR techniques would also be beneficial, as recently demonstrated on BAS data (see Castelletti et
1026 al., 2020; Chu et al., 2021).

1027 As a result of the very flexible configuration of the PASIN-2 system, much more data can
1028 also be extracted from the raw radar files already acquired, including fully polarised data used to
1029 image ice crystal-fabric orientation for estimating ice deformation processes (i.e. Young et al., 2021),
1030 or 3-D swath radar data used to reconstruct the sub-surface at finer resolution and without
1031 compromising on across-track resolution as for conventional 2-D data (Holschuh et al., 2020; Arenas-
1032 Pingarron et al., 2022).

1033 Combined, these will likely add further opportunities for future data releases, alongside our
1034 intention to publish newly acquired data regularly via the data portal and following the procedures
1035 detailed in this paper.

1036 **6. Conclusion**

1037 We have presented here the release of 64 aerogeophysical datasets from 24 surveys flown by
1038 BAS between 1994 and 2020 over the Antarctic Peninsula and East and West Antarctica. Altogether,
1039 the data release consists of ~450,000 line-km (or ~5.3.million km²) of aerogeophysical data on
1040 gravity, magnetic and radar measurements (including bed-pick from 1994-onwards and the fully
1041 processed 2-D radar data from 2004-onwards) which have all been standardised according to the
1042 FAIR (Findable, Accessible, Interoperable and Re-Usable) data principles. A new data portal, the
1043 Polar Airborne Geophysics Data Portal (<https://www.bas.ac.uk/project/nagdp/>), and interactive, open-
1044 access tutorials written in Python and MATLAB have also been created to improve the interactivity
1045 and user-accessibility of our datasets.

1046 Aside from discussing the data acquisition and processing steps, we have demonstrated that
1047 much more information can be extracted from the newly released aerogeophysical data by assessing
1048 the continuity of englacial layering along ~300,000 line-km of the ice-penetrating radar data. Using an
1049 automated layer continuity extraction method on all ten fully published 2-D radar datasets, we have
1050 shown that large volumes of radar lines contain well-preserved englacial layering from which further
1051 glaciological and geophysical information could be extracted. We note that the analysis shown in
1052 Section 5.1 is only possible because the data has been comprehensively standardised and made open-
1053 access. Whilst we acknowledge that this type of work may suffer from a lack of funding
1054 opportunities, the results presented here would suggests that re-modernising already acquired data
1055 may be as important as acquiring new data. It also enables their use in emerging fields such as
1056 artificial intelligence, which rely on large amounts of standardised data.

1057 Although all of the datasets released here have so far made a significant contribution to our
1058 understanding of past and current ice-dynamical and lithospheric influences, partly through their
1059 contributions to major international collaborative projects such as the SCAR BEDMAP and ADMAP
1060 programmes, they have until now largely remained unpublished in their full form, thus restricting the
1061 further usage of the data beyond the life cycle of the science projects. It is our hope that these newly
1062 released data will offer further research opportunities and enable the wider scientific community to
1063 benefit from the abundance of newly published aerogeophysical data over Antarctica, particularly
1064 within the context of recently established international projects such as the SCAR AntArchitecture
1065 and RINGS Action groups, the latter of which focuses primarily on fillings gaps in already-acquired
1066 observations at the boundaries of the Antarctic Ice Sheet.

1067 Reflecting on our collaboration between data managers and scientists, we believe that this
1068 project sets a positive example for further release of aerogeophysical data, particularly for future

1069 international initiatives that are aiming to harmonise the availability and findability of
1070 aerogeophysical data collected across Antarctica. A full list of all available datasets can be found in
1071 Table 3 of this paper, or via the BAS Discovery Metadata System (<https://data.bas.ac.uk>).

1072 **Data Availability Statement**

1073 All the data included in this manuscript are freely available via the BAS Discovery Metadata System
1074 (<https://data.bas.ac.uk>), with direct links to the datasets found in Table 3 of this paper. The user guide
1075 for the data portal and the Jupiter Notebook tutorials designed for reading in the gravity, magnetic,
1076 and radar data in Python and MATLAB are freely accessible on the Jupyter Book interface
1077 (https://antarctica.github.io/PDC_GeophysicsBook) or via the BAS GitHub repository
1078 (https://github.com/antarctica/PDC_GeophysicsBook). The code used to produce the Internal Layer
1079 Continuity Index over the whole BAS radar data (Fig. 8-9) is available on the GitHub page of J.A.B.
1080 (<https://github.com/julbod>).

1081 **Competing Interests**

1082 The authors declare that they have no conflict of interest.

1083 **Contribution Statement**

1084 A.C.F. and J.A.B. co-led this data release. A.C.F. initiated the collaboration between the Polar Data
1085 Centre and the BAS Airborne Geophysics science team, with input from H.J.P. A.C.F. quality-
1086 checked and published the gravity, magnetic and bed-pick datasets, with input from T.A.J., F.F. and
1087 J.A.B. J.A.B. re-processed, quality-checked, and published the fully processed radar datasets and
1088 accompanying files, with input from A.C.F., T.A.J. and C.R. The three BAS radar systems and
1089 accompanying radar processing software libraries were designed by H.F.J.C. The aerogeophysical
1090 data were primarily acquired and processed by H.F.J.C, C.R., F.F. and T.A.J. J.A.B. created the data
1091 portal, with input from A.C.F., T.A.J. and F.F. A.C.F. and J.A.B. populated the data portal with the
1092 gravity, magnetic, and radar track-lines. A.C.F. created the Jupyter Notebook tutorials, with input
1093 from J.A.B. for the radar tutorials and user guide. J.A.B. wrote the code and analysed the results for
1094 the layer continuity index. J.A.B. wrote the initial manuscript and created the figures, with input from
1095 A.C.F. All authors commented and contributed to the final edits of the manuscript prior to publication.

1096 **Acknowledgments**

1097 We would like to thank the many BAS personnel involved over the last three decades in developing
1098 and maintaining the aerogeophysical instruments and in acquiring and processing the data presented
1099 in this paper. In particular, we would like to credit and acknowledge Hugh Corr and Nick Frearson for
1100 designing the PASIN radar systems. We are also especially grateful to the many pilots that flew the
1101 BAS Twin Otter aircraft “VP-FBL” throughout the years, including Lee Proudfoot, Greg Harris, Pete
1102 Buckley, Doug Pearson, Mark Beasley, Doug Cochrane, Andy Vidamour, Oli Smith, and particularly
1103 David Leatherdale and Ian Potten who flew most of the survey km. We would also like to highlight
1104 the scientific contribution of the late Richard Hindmarsh, particularly with regards to the GRADES-
1105 IMAGE survey. Many campaigns that BAS conducted were also in partnership with national and
1106 international collaborators and institutes, which we would also like to acknowledge more widely. We
1107 would also like to acknowledge the help from the BAS PDC and MAGIC (Mapping and GIS) teams
1108 for their valuable input throughout this project. Lastly, the authors thank Neil Ross and an anonymous
1109 reviewer for their constructive suggestions, which improved this manuscript. J.A.B. was partly funded
1110 by the NERC Doctoral Training Partnership (grant reference number: NE/L002558/1) hosted in the
1111 Edinburgh E³ DTP program.
