Abstract

Accurate long-term temperature and precipitation estimates at high spatial and temporal resolutions are vital for a wide variety of climatological studies. We have produced a new, publicly available, daily, gridded maximum temperature, minimum temperature, and precipitation dataset for China with a high spatial resolution of 1 km and over a long-term period (1961 to 2019). It has been named the HRLT and the dataset is publicly available at <https://doi.org/10.1594/PANGAEA.941329> (Qin and Zhang, 2022). In this study, the daily gridded data were interpolated using comprehensive statistical analyses, which included machine learning **methods**, the generalized additive model, and thin plate splines. It ~~was~~ based on the $0.5^\circ \times 0.5^\circ$ **gridded** dataset from the China Meteorological Administration, together with covariates for elevation, aspect, slope, topographic wetness index, latitude, and longitude. The accuracy of the HRLT daily dataset was assessed using observation data from meteorological stations across China. The maximum and minimum temperature estimates were more accurate than the precipitation estimates. For maximum temperature, the mean absolute error (MAE), root mean square error (RMSE), Pearson's correlation coefficient (Cor), coefficient of determination after adjustment (R^2), and Nash-Sutcliffe modeling efficiency (NSE) were 1.07 °C, 1.62 °C, 0.99, 0.98, and 0.98, respectively. For minimum temperature, the MAE, RMSE, Cor, R^2 , and NSE were 1.08 °C, 1.53 °C, 0.99, 0.99, and 0.99, respectively. For precipitation, the MAE, RMSE, Cor, R^2 , and NSE were 1.30 mm, 4.78 mm, 0.84, 0.71, and 0.70, respectively. The accuracy of the HRLT was compared to those of the other three existing datasets and its accuracy was either greater than the others, especially for precipitation, or comparable in accuracy, but with higher spatial resolution or over a longer time period. In summary, the HRLT dataset, which has a high spatial resolution, covers a longer period of time and has reliable accuracy, ~~is suitable for future~~

45 environmental analyses, especially the effects of extreme weather.

46 **1 Introduction**

47 Climate change has led to an increase in the frequency and severity of extreme temperature
48 and precipitation events (Myhre et al., 2019), and these events have affected vegetation growth (Xu
49 et al., 2019), especially crop growth (Rao et al., 2015; Li et al., 2019b; Lu et al., 2018; Lobell et al.,
50 2011; Lesk et al., 2016). Thus, long-term and accurate daily maximum temperature, minimum
51 temperature, and precipitation data are important when attempting to reveal the mechanism
52 underlying the effects of extreme climate on plants, predicting disasters (such as drought, frost, and
53 floods), and for agricultural and forestry management. Although the meteorological observation
54 network makes better use of the data from meteorological stations (Merino et al., 2014; Yang et al.,
55 2014), there is a tradeoff between large spatial scale and the high density of stations in the
56 meteorological observation network. Moreover, the installation and maintenance of meteorological
57 stations are challenging in harsh areas (Hartl et al., 2020). Daily and gridded meteorological datasets
58 are also essential inputs for many models related to terrestrial, hydrological, and ecological systems
59 (Iizumi et al., 2017; Wang et al., 2018; Zhang et al., 2018; Lee et al., 2019). High-resolution, long-
60 term, and accurate gridded datasets can help improve the performance of these models.

61 Researchers have previously used interpolation methods, such as inverse distance weighting,
62 kriging, and regression analysis, to produce grided meteorological data (Brinckmann et al., 2016;
63 Herrera et al., 2019; Schamm et al., 2014). However, the accuracy of these interpolation results is
64 limited by the density of the meteorological stations. In recent years, artificial intelligence, machine
65 learning methods, such as random forest (Chen et al., 2021; Sekulić et al., 2021); artificial neural

66 networks (Sadeghi et al., 2021), and support vector machines (He et al., 2021) have been gradually
67 and widely applied to meteorological data estimation. Therefore, comprehensive statistical analyses
68 using machine learning and traditional interpolation, such as thin-plate-smoothing splines, are
69 feasible and reliable methods that can be used to estimate meteorological data.

70 At present, only a few research institutes in China are developing meteorological datasets for
71 temperature and precipitation with high spatial and temporal resolutions. Among them, Beijing
72 Normal University has produced meteorological datasets for 1958–2010 with a resolution of 1 km,
73 but the latest data is not available (Li et al., 2014). The China Meteorological Administration is also
74 developing the CMA Land Data Assimilation System product (Shi et al., 2011) and Tsinghua
75 University has published a driving dataset from 1979 to 2018 with a resolution of 0.1° over China
76 (He et al., 2020).

77 We present a new high-resolution daily gridded maximum temperature, minimum temperature,
78 and precipitation dataset for China (HRLT) with a spatial resolution of 1×1 km for the period 1961
79 to 2019. We created the HRLT dataset using comprehensive statistical analyses, which included
80 machine learning, the generalized additive model and thin plate splines. It uses the $0.5^\circ \times 0.5^\circ$ gridded
81 dataset from the China Meteorological Administration (CMA) as input data together with other
82 covariates, including elevation, aspect, slope, topographic wetness index (TWI), latitude, and
83 longitude. The dataset was created in three steps: (1) preparation of input data and covariates; (2)
84 the creation of the gridded dataset using comprehensive statistical analyses; and (3) an evaluation
85 of the accuracy of the gridded dataset and accuracy comparison with other three existing products
86 that use meteorological station data.

2 Data

2.1 The CMA dataset and meteorological stations data

The CMA dataset, which includes the daily surface temperature $0.5^\circ \times 0.5^\circ$ grided dataset (http://101.200.76.197/data/cdedetail/dataCode/SURF_CLI_CHN_TEM_DAY_GRID_0.5.html) and the daily precipitation $0.5^\circ \times 0.5^\circ$ grided dataset for China (V2.0) (http://101.200.76.197/data/cdedetail/dataCode/SURF_CLI_CHN_PRE_DAY_GRID_0.5.html <https://data.cma.cn/>, last access: 15 September, 2022), was obtained from the China Meteorological Data Service Centre and was used as the basic input data. The researchers also reported daily precipitation $0.5^\circ \times 0.5^\circ$ grided dataset during 1961-2010 from CAM dataset (Zhao and Zhu, 2015). The daily dataset of surface climatological data for China (V3.0) (http://101.200.76.197/data/cdedetail/dataCode/SURF_CLI_CHN_MUL_DAY_V3.0.html <https://data.cma.cn/>, last access: 15 September, 2022), which includes 699 meteorological stations, was also obtained from the China Meteorological Data Service Centre and was used to evaluate the new dataset (Fig. 1).

2.2 Topographic data

The basic topographic data, including elevation, flow direction, and flow accumulation with a 30 second (approximately 1 km) resolution, were obtained from the HydroSHEDS database. More detailed information can be found at these links: <http://www.worldwildlife.org/hydrosheds> (last access: 15 September, 2022) for general information and <http://hydrosheds.cr.usgs.gov> (last access: 15 September, 2022) for data download and technical information. The “Aspect” and “Slope” option of the Spatial Analyst Tools in ArcGIS10.6 were used to calculate aspect and slope.

108 The specific catchment area (SCA) was calculated based on flow direction and flow accumulation.

109 The TWI is formulated as **follow:** ~~$TWI = \ln(SCA / \tan(\text{Slope}))$~~ .

$$TWI = \ln\left(\frac{SCA}{\tan(\text{Slope})}\right) \quad (1)$$

110 **where TWI and SCA is topographic wetness index and specific catchment area,**

111 **respectively.**

112 **2.3 Other datasets**

113 **We used observed data from meteorological stations (Fig. 1) to evaluate our dataset and**
114 **the existing three daily datasets, then the accuracy of the existing three daily datasets was**
115 **compared to that of our dataset, respectively.** ~~Three temperature and precipitation products with~~

116 ~~daily resolutions were evaluated using observed meteorological stations data and the evaluation~~
117 ~~results were compared to the HRLT dataset in this study.~~ The China Meteorological

118 Administration Land Data Assimilation System (CLDAS) version 2 dataset was provided by the

119 China Meteorological Data Service Centre (<https://data.cma.cn/> , **last access: 15 September,**

120 **2022**) for 2017 to 2019 with a 0.0625° (approximately 7.5 km) spatial resolution and a 1 day

121 temporal resolution. The China Meteorological Forcing Dataset (CMFD) (He et al., 2020; Yang

122 and He, 2019) was obtained from the National Tibetan Plateau Third Pole Environment Data

123 Center (<https://data.tpdc.ac.cn/> , **last access: 15 September, 2022**) for 1979 to 2018 with a spatial

124 resolution of 0.1° (approximately 12 km) and a temporal resolution of 1 day. The historical dataset

125 relating to the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP3a) was obtained

126 from the web (<https://data.isimip.org/> , **last access: 15 September, 2022**) for 1961 to 2016 with a

127 spatial resolution of 0.5° (approximately 60 km) and a temporal resolution of 1 day. The daily

128 maximum temperature, minimum temperature, and precipitation data in the CLDAS and
129 ISIMIP3a were used for evaluation and comparison. The daily average temperature and
130 precipitation data from the CMFD was also used for evaluation and comparison.

131 **3 Methods**

132 **3.1 The input data and covariates**

133 In this study, the input data (dependent variable) was the daily $0.5^\circ \times 0.5^\circ$ CMA dataset, which
134 includes daily maximum temperature, minimum temperature and precipitation. Other covariates
135 (independent variables) included elevation, aspect, slope, TWI (with a spatial resolution of 1 km),
136 latitude, and longitude.

137 **3.2 The interpolation scheme**

138 As shown in Figure 2, the different combinations of six algorithms, which are the boosted
139 regression trees (BRT), random forests (RF), neural networks (NN), multivariate adaptive
140 regression splines (MAR), support vector machines (SVM) and the generalized additive model
141 (GAM), to predict the input data. Firstly, through k-fold cross validation ($k = 10$), the input data ~~was~~
142 was randomly divided into 10 sub-training datasets and sub-testing datasets. Each algorithm runs in
143 a loop through all the sub-training sets and calculates the residuals from the sub-testing sets. The
144 residuals obtained in each loop are retained. The residual of each algorithm is assigned a weight of
145 0-1 and summed up, and the ensemble of models that has the lowest residual sum is chosen. After
146 determining the best ensemble of models, surface results were interpolated using the best ensemble
147 of models, input data and covariates. The thin-plate-smoothing splines (TPS) is used to correct
148 residual error from the ensemble of models. Therefore, residuals of the ensemble are calculated from

149 the input data and these values are interpolated using TPS. Surface results from the ensemble add
150 residuals from the thin-plate-smoothing splines to get the surface result of final model. Compare R^2
151 of surface result from the ensemble and final model, and retain the surface result with higher R^2 .

152 **3.3 The interpolation methods**

153 The introduction of individual algorithm (method) and the implementations for model training
154 (R packages and functions) of that is as follows. After the model training, the function ‘predict’ in
155 R package ‘raster’ used to **implemented** spatial interpolation for BRT, RF, NN, MAR, SVM and
156 GAM model, and the function ‘interpolate’ in R package ‘raster’ used to spatial interpolation for
157 TPS. More details on R packages and functions could refer the web
158 (<https://www.rdocumentation.org/>, **last access: 15 September, 2022**).

159 **3.3.1 The BRT model**

160 As a powerful tool for exploratory regression analysis, BRT is a combination of two techniques:
161 decision trees and boosting method (Elith et al., 2008). The BRT can automatically detect the best
162 fit and is robust to missing values and outliers, therefore, BRT now widely used in ~~Remote~~-**remote**
163 sensing, species distribution and meteorological interpolation (Pouteau et al., 2011; Appelhans et
164 al., 2015; Froeschke and Froeschke, 2011). There are two important parameters in BRT, (1) the tree
165 complexity (TC): this controls the number of splits in each tree. (2) learning rate (LR): this
166 determines the contribution of each tree to the growth model. The smaller value of LR, the more
167 trees will be built. These two parameters together determine the number of trees required for the
168 best prediction in order to find the combination of parameters that leads to the least prediction error.
169 The function ‘gbm.step’ in R package ‘dismo’ for the BRT implementation. The ~~the~~-tree complexity
170 was set at 5, the learning rate was set at 0.001. In addition, the ‘bag.fraction’, which specifies the

171 proportion of data to be selected at each step, was set at 0.5 and other parameters are default values
172 in 'gbm.step'.

173 **3.3.2 The RF model**

174 Like BRT, the main technology of RF also includes decision trees, however, the way in which
175 the data to build the trees is selected is different (boosting method for BRT, bagging method for RF).
176 For regression analysis, the bagging method, which take a random subset of all data for each new
177 tree that is built, makes the final output based on average of multiple trees (Breiman, 2001). As one
178 of the most accurate algorithms, RF has been used widely for predicting spatio-temporal variables,
179 such as temperature and precipitation (He et al., 2016; Mital et al., 2020; Webb et al., 2016). The
180 function 'randomForest' in R package 'randomForest' for the RF implementation. The importance
181 was set TRUE, and other parameters are default values in 'randomForest'.

182 **3.3.3 The NN model**

183 As a powerful set of tools for solving problems in pattern recognition, data processing, and
184 non-linear control (Bishop, 1994), the NN consists of a large number of nodes and connections and
185 it includes input layer, hidden layer and output layer (Lek and Guégan, 1999). Information from
186 each node in the input layer is fed to the hidden layer. Connections between input layer nodes and
187 hidden layer nodes can all be given specific weights according to their importance. The connection
188 between the hidden layer and the output layer is also weighted, so the output is the result of the
189 weighted sum of the hidden nodes. Information transfer between hidden layer and output layer
190 through transfer function. Since the 1980s, the NN has been used in a number of fields, such as
191 prediction for meteorological variables (Snell et al., 2000; Lek and Guégan, 1999; Tang et al., 2020).
192 The function 'nnet' in R package 'nnet' for the NN implementation. The number of units in the

193 hidden layer (size) was set 10, the transfer function is linear for the output layer (linout was set
194 TRUE), the maximum number of iterations (maxit) was set 10000, and other parameters are default
195 values in 'nnet'.

196 **3.3.4 The MAR model**

197 The MAR is an extension of linear model, which can build multiple linear regression models
198 within the range of predictive variable values by partitioning data (Friedman, 1991; Friedman and
199 Roosen, 1995). The MAR consists of two steps: firstly, it creates a set of so-called basis functions.
200 In this process, the range of predictive variable values is divided into several groups. For each group,
201 separate linear regression was modeled. Secondly, MAR estimates a least square model with its
202 basis function as the independent variable. Overfitting is avoided by iterating to remove the basis
203 functions that contribute least to the model fitting. The MAR works well with a large number of
204 predictor variables, automatically detects interactions between variables and is robust to outliers,
205 therefore, studies has done on downscaling or predicting meteorological data using MAR (Panda et
206 al., 2022; Li et al., 2019a; Zawadzka et al., 2020). The function 'earth' in R package 'earth' for the
207 MAR implementation. Use linear model to estimate standard deviation as a function of the predicted
208 response (varmod.method = 'lm'). The nfold was set 10, the ncross was set 30, and other parameters
209 are default values in 'earth'.

210 **3.3.5 The SVM model**

211 The SVM is also one of the machine learning supervised algorithms and mainly deals with the
212 ideas of classification and regression (Vapnik, 1999; Vapnik, 1991; Brereton and Lloyd, 2010). The
213 SVM is well supported by mathematical theory and can use kernel tricks to efficiently process non-
214 linear data. With the development of SVM, it also has been widely used in the regression and

215 prediction of meteorological variables (Belaid and Mellit, 2016; Chen et al., 2010; Tripathi et al.,
216 2006). In this study, the function ‘ksvm’ in R package ‘kernlab’ for the SVM implementation and
217 all parameters are default values in ‘ksvm’.

218 **3.3.6 The GAM model**

219 The GAM is an extension of the generalized linear model (GLM). Like GLM, GAM consists
220 of three important components: the probability distribution of the dependent variable, the linear
221 predictor and the link function, however, in GAM, the coefficient of the independent variable in the
222 linear is replaced by a sum of smooth functions (Hastie and Tibshirani, 2017; Liu, 2008). Because
223 the GAM can deal with nonlinear and non-monotone relationships between dependent and
224 independent variables, it has been used to predict and interpolate meteorological data (Hjort et al.,
225 2016; Burnett and Anderson, 2019; Aalto et al., 2013). The function ‘gam’ in R package ‘mgcv’ for
226 the GAM implementation and all parameters are default values in ‘gam’.

227 **3.3.7 The TPS method**

228 As a traditional interpolation method, the TPS has been widely used to spatially interpolate
229 surface climate data (Gong et al., 2022; Hancock and Hutchinson, 2006; Risk and James, 2022). In
230 this study, it used to correct residual error from the ensemble of models. The function ‘Tps’ in R
231 package ‘fields’ for the TPS implementation. The matrix of independent variables consists latitude
232 and longitude, the vector of dependent variables is residual error in the combinations of above
233 algorithms, and other parameters are default values in ‘Tps’.

234 **3.4 The interpolation implementation**

235 A complete operation was constructed per day per variable, so there were 64647 operations
236 (21549 days \times 3 variables) from January 1, 1961 to December 31, 2019 for maximum temperature,

237 minimum temperature and precipitation. A complete operation for a day per variable requires a
 238 Central Processing Unit core, 18 G of operating memory, and 2 hours of time. In order to shorten
 239 the running time, we carried out parallel computing on a supercomputer platform. Spatial
 240 interpolation work was executed by R version 4.0.2 (R Core Team, 2018) and the R package
 241 "machisplin" (Brown, 2019) was referenced to achieve it.

242 3.5 Evaluation metrics

243 The mean absolute error (MAE), root mean square error (RMSE), Pearson's correlation
 244 coefficient (Cor), coefficient of determination after adjustment (R^2), and Nash-Sutcliffe modeling
 245 efficiency (NSE) were used to evaluate the interpolation results. Pearson's correlation coefficient
 246 was used to evaluate the correlation between the simulated and observed values and the other
 247 metrics are defined separately as follows:

$$MAE = \frac{1}{n} \sum_{i=1}^n |S_i - O_i| \quad (42)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (S_i - O_i)^2} \quad (43)$$

$$R^2 = 1 - \left(1 - \frac{\sum_{i=1}^n (S_i - \bar{O})^2}{\sum_{i=1}^n (O_i - \bar{O})^2}\right) \frac{(n-1)}{(n-k-1)} \quad (44)$$

$$NSE = 1 - \frac{\sum_{i=1}^n (S_i - O_i)^2}{\sum_{i=1}^n (O_i - \bar{O})^2} \quad (45)$$

248 where S_i and O_i are the model predicted and the experimentally observed values, respectively;
 249 \bar{O} is the mean of the observed values; n is the number of observations; and k is the value of the
 250 independent variable. High Cor, R^2 , and NSE values, and small RMSE and MAE values indicate
 251 the strength of agreement between the predicted and observed values.

4 Results and discussion

4.1 Validation of temperature and precipitation

The spatial interpolation results, including daily maximum temperature, minimum temperature, and precipitation, were validated using meteorological station data. The results of the validation showed that the daily maximum and minimum temperatures were highly accurate (Fig. 3 and Table 1). The fitting slopes between the simulated and observed values were both close to 1 and the coefficients of determination after adjustment were 0.98 and 0.99, respectively, for daily maximum and minimum temperature (Figs. 3a, b). As shown in Table 1, the MAE was 1.07 °C and 1.08 °C, and the RMSE was 1.62 °C and 1.53 °C for daily maximum and minimum temperatures, respectively. In addition, the Cor and NSE values were close to 1 for both the daily maximum and minimum temperatures. Daily precipitation was less accurate than temperature with an R^2 of 0.71 (Fig. 3c), which was mainly caused by underestimating high daily precipitation. However, most of the points were concentrated in the low daily precipitation section. Furthermore, the MAE and RMSE for daily precipitation were 1.30 mm and 4.78 mm, respectively; the Cor between the simulated and observed daily precipitation was 0.84, and the NSE was 0.70 (Table 1).

The interpolation accuracy shows spatial differences (Fig. 4). The R^2 values of the daily maximum and minimum temperatures in southwest China were less than 0.94 and lower than those for other regions (Figs. 4a, c). The mean absolute errors for the daily maximum and minimum temperature ranges at most meteorological stations were less than 1 °C. However, there were some meteorological stations with mean absolute errors of more than 2 °C and these were evenly distributed across China (Figs. 4b, d). The R^2 value for daily precipitation at most meteorological

273 stations was greater than 0.7 and the MAE decreased from south to north across China (Figs. 4e, f).
274 **For precipitation where the R^2 map (Fig. 4e) shows a west-east gradient in the scores that is**
275 **different from the north-south gradient in the MAE map (Fig. 4f). There are fewer**
276 **meteorological observation stations in the western region than in the eastern region, which**
277 **may lead to the subtle east-west gradient of the R^2 value for daily precipitation. The obvious**
278 **north-south gradient for MAE of daily precipitation could be caused by the rainfall frequency**
279 **(Fig. 4f, Fig. 5), the MAE of monthly precipitation in China from other study showed a similar**
280 **pattern (Peng et al., 2019). Rainfall frequency above light rainfall, which is defined as a daily**
281 **rainfall from 0 to 4 mm (Alpert et al., 2002), is strongly correlated with the MAE of daily**
282 **precipitation (illustration in Fig. 5), so that the MAE of daily precipitation in the southern**
283 **region with higher rainfall frequency is larger than that in the northern region with lower**
284 **rainfall frequency.**

285 The meteorological stations were divided into the middle and lower reaches of the Yangtze
286 River (MLYR), North China (NC), Northeast China (NEC), Northwest China (NWC), South China
287 (SC), and Southwest China (SWC) (Fig. 1) according to their diverse geographic and climatic
288 conditions and administrative areas (Qin, et al., 2022). The **cumulative distribution**
289 **functions**~~density distribution~~ **curve trend of difference between the estimated and observed**
290 **values**~~for the simulated value and the observed value~~ was always similar for daily maximum
291 temperature, minimum temperature, and precipitation in the six regions, **as well as in whole China.**
292 The daily maximum and minimum temperatures were all underestimated in the MLYR, NEC, NWC,
293 SC, and SWC(**Fig. 6a**). ~~The, and the~~ daily minimum temperatures were all underestimated in the

294 MLYR, **NC**, NWC, SC, and SWC (Fig. **56b**). For both daily maximum and minimum temperatures,
295 the lowest **average** difference between the simulated and observed ~~average~~ values occurred in **NC**
296 **and** NEC, while the greatest difference occurred in SWC (**Figs. 6a,b**~~Fig. 5~~). Except in the NWC
297 region, the **average difference between simulated and observed values**~~simulated average~~ for
298 daily precipitation was **less than 0 mm**~~lower than the observed average~~ in the other regions (**Fig.**
299 **6c**). The largest **averages** difference between simulated and observed ~~averages~~ for daily
300 precipitation occurred in the SC region, with a value of ~~0.5~~**49** mm (Fig. **56c**). **Across whole China,**
301 **the average difference between simulated and observed values for daily maximum**
302 **temperature, minimum temperature, and precipitation was 0.36 °C, 0.30 °C and 0.12 mm,**
303 **respectively.**

304 Figure 6 shows that the average diurnal variation values for daily temperature and precipitation
305 ~~based on the meteorological station data were almost the same as our estimations. Compared to the~~
306 ~~observations from the meteorological stations, the average values for daily maximum temperature~~
307 ~~decreased from 17.79 °C to 17.44 °C (1.9%) and the average values for daily minimum temperature~~
308 ~~decreased from 7.24 °C to 6.94 °C (4.1%) after interpolation, between 1961 and 2019 (Figs. 6a, b).~~
309 ~~The maximum values for daily maximum and minimum temperature measured by the~~
310 ~~meteorological stations were 33.35 °C and 22.24 °C, and the minimum values for those were -4.710 °C~~
311 ~~and -14.54 °C, respectively. After interpolation, these corresponding values became 33.23 °C and~~
312 ~~22.45 °C, -5.06 °C and -15.01 °C, respectively. Compared to the observations from meteorological~~
313 ~~stations, the average values for daily precipitation decreased from 2.43 mm to 2.31 mm (4.9 %) after~~
314 ~~interpolation, between 1961 and 2019 (Fig. 6c).~~

315 **4.2 Temporal and spatial distributions of temperature and precipitation**

316 The results showed that detailed spatial changes in temperature and precipitation over time
317 could be obtained (Fig. 7). For example, the increase in annual average values (both maximum
318 temperature and minimum temperature) were obvious over the Tibetan Plateau from 1965 to 2010
319 (Figs. 7a–h, the d1 and h1 subregions). In addition, compared with other years, the annual average
320 daily minimum temperature clearly increased in some areas of NWC (Figs. 7e–h, the h2 and h3
321 subregions) and MLYR (Figs. 7e–h, the h4 subregion) in 2010. The most significant annual
322 precipitation changes occurred in NEC (Figs. 7i–l, the l1 subregion) between 1965 and 2010.

323 The distributions of annual average daily maximum and minimum temperatures and annual
324 precipitation across the six regions of China in 1965, 1980, 1995, and 2010 were analyzed (Fig. 8).
325 Compared with other years, the areas with smaller values for annual average daily maximum
326 temperature (less than 0) and annual average daily minimum temperature (less than –10) in SWC
327 and NWC decreased in 2010 (Figs. 8a1, 8a2, 8b1, 8b2). These areas are mainly distributed on the
328 Qinghai-Tibet Plateau, which has seen a large increase in temperature over the past few decades.
329 The density distribution peak for the annual average daily maximum and minimum temperatures in
330 NEC moved to the right from 1965 to 1995, but moved to the left in 2010 (Figs. 8a3, 8b3). The
331 mean annual average daily minimum temperature in 2010 was higher in the MLYR, NC, and SC
332 than in the other three years (Figs. 8b4–6). There was an increase in mean annual precipitation in
333 the northern part of China over the period 1965–2010 (Figs. 8c2–4). It increased from 335 mm to
334 415 mm across NWC (Fig. 8c2), from 487 mm to 593 mm across NEC (Fig. 8c3), and from 531
335 mm to 654 mm across NC (Fig. 8c4). In the MLYR, there were more areas with annual precipitation

336 of less than 1000 mm, and areas with an annual precipitation of more than 2000 mm increased in
337 1995 and 2010 compared 1965 and 1980 (Fig. 8c5). Similarly, compared with other years, there
338 were more areas with annual precipitation of less than 1000 mm and more than 2000 mm in SC in
339 2010 (Fig. 8c6).

340 **4.3 Accuracy comparison with other products**

341 The performances of the CMFD, CLDAS and ISIMIP3a generated daily temperatures and
342 precipitations were evaluated against observations from all the meteorological stations and
343 compared their performance with that of our dataset (Figs. 9–11; Tables 2–4). The fitting slopes
344 between the simulated and observed daily temperature values were always close to 1 for all datasets
345 (Figs. 9a–c; Figs. 10a–d; Figs. 11a–d). The R^2 for the CMFD daily average temperature was
346 slightly smaller than that for daily minimum temperature in our dataset (Figs. 9b, c), but was equal
347 to our data set for daily maximum temperature (Figs. 9a, c). The Cor and NSE for the CMFD daily
348 average temperature were also similar to our estimated daily maximum and minimum temperatures
349 (Table 2). By contrast, the MAE and RMSE for the CMFD daily average temperature were 1.12 °C
350 and 1.64 °C, respectively, which were greater than for our estimated daily maximum and minimum
351 temperatures (Table 2). The MAEs of daily maximum and minimum temperature for our dataset
352 were 1.07 °C and 1.08 °C respectively; and the RMSEs of daily maximum and minimum
353 temperature for our dataset were 1.63 °C and 1.54 °C, respectively, between 1979 and 2018 (Table
354 2). The R^2 , Cor, NSE, MAE, and RMSE for the CLDAS daily maximum temperatures were 0.91,
355 0.95, 0.90, 2.54 °C, and 3.63 °C, respectively. Accuracy clearly improved for our daily maximum
356 temperature, and the corresponding metrics were 0.98, 0.99, 0.98, 1.10 °C, and 1.73 °C (Figs. 10a,

357 b; Table 3). The MAE and RMSE for the CLDAS daily minimum temperature were clearly higher
358 than our estimates for daily minimum temperature, and the R^2 , Cor, and NSE for daily minimum
359 temperature in our dataset were higher than those for the CLDAS daily minimum temperature (Figs.
360 10c, d; Table 3), thus indicating that the accuracy of our daily minimum temperature estimates was
361 superior to that of the CLDAS daily minimum temperature product. Compared with the ISIMIP3a,
362 the R^2 , Cor, and NSE of daily maximum and minimum temperature in our dataset are always higher
363 and the MAE and RMSE of these are always smaller (Figs. 11 a–d; Table 4).

364 The R^2 value for our estimated daily precipitation clearly improved compared to the other
365 three datasets, especially the ISIMIP3a and CLDAS dataset (Figs. 9d, e; Figs. 10e, f; Figs. 11e, f).
366 The Cor and NSE for the CMFD daily precipitation were obviously smaller than those for our
367 dataset, and the RMSE for CMFD daily precipitation were greater than those for our dataset (Table
368 2). During 2017–2019, the Cor, NSE, MAE, and RMSE for our estimated daily precipitation were
369 0.84, 0.70, 1.42 mm, and 4.93 mm, respectively, and the corresponding values for the CLDAS daily
370 precipitation changed to 0.58, 0.28, 2.36 mm, and 7.67 mm, respectively (Table 3). During 1961–
371 2016, the Cor, NSE, MAE, and RMSE for our estimated daily precipitation were 0.84, 0.70, 1.30
372 mm, and 4.78 mm, respectively, and the corresponding values for the ISIMIP3a daily precipitation
373 changed to 0.48, 0.14, 2.75 mm, and 8.10 mm, respectively (Table 4). Thus, the daily precipitation
374 accuracy of our dataset was generally higher than that of CMFD, CLDAS and ISIMIP3a.

375 **5 Data availability**

376 The HRLT dataset includes daily maximum temperature, minimum temperature, and
377 precipitation at a 1 km spatial resolution across China from January 1961 to December 2019. The

378 datasets are publicly available in NetCDF format at <https://doi.org/10.1594/PANGAEA.941329>
379 (Qin and Zhang, 2022).

380 **6 Conclusions**

381 The result of this study is a high-resolution (1 km) daily gridded maximum temperature,
382 minimum temperature and precipitation dataset across China for the long-term (1961–2019)
383 (HRLT). The HRLT dataset shows an overall high correlation with the observations from
384 meteorological stations for daily maximum and minimum temperatures (R^2 was 0.98 and 0.99,
385 respectively; Cor were both 0.99; NSE was 0.98 and 0.99, respectively) and the errors were smaller
386 (MAE was 1.07 °C and 1.08 °C, respectively; RMSE was 1.62 °C and 1.53 °C, respectively).
387 Although the HRLT dataset showed that the daily precipitation accuracy was lower than the daily
388 temperature accuracy (R^2 , Cor, NSE, MAE, and RMSE were 0.71, 0.84, 0.70, 1.30 mm, and 4.78
389 mm, respectively), the daily precipitation data in the HRLT dataset were more accurate and had a
390 finer spatial resolution compared to the other three existing datasets (CMFD, CLDAS and
391 ISIMIP3a). Furthermore, the accuracies for daily maximum and minimum temperatures and
392 precipitation were lower in the southwestern part of China, probably because of the complex
393 topography in that area compared to other areas. Calculation and interpolation by subregions may
394 solve this problem in future studies. The use of satellite data as an input covariate in future studies
395 will further improve the accuracy of the HRLT dataset, especially for precipitation. The HRLT
396 dataset will help identify future extreme climatic events and can be also used to improve process-
397 based models for prediction, adaptation, and mitigation strategies.

398 **Author contributions**

399 Rongzhu Qin and Feng Zhang calculated the dataset, analyzed the results, and wrote the
400 manuscript; all other authors reviewed and revised the manuscript.

401 **Competing interests**

402 The authors declare that they have no conflict of interest.

403 **Acknowledgements**

404 This study was supported by the Second Tibetan Plateau Scientific Expedition and Research
405 (Grant No. 2019QZKK0305), National Natural Science Foundation of China (Grant No. 32071550),
406 and the “111” Programme (BP0719040). We thank the Supercomputing Center of Lanzhou
407 University for providing the computing requirements for this study. We are also grateful to the China
408 Meteorological Data Service Centre, National Tibetan Plateau Third Pole Environment Data Center,
409 Potsdam Institute for Climate Impact Research and the International Institute for Applied Systems
410 Analysis for contributing datasets to the study. We are also thanking Dr. Marianne Rehage from
411 PANGAEA for processing and publishing the dataset.

Table 1 Summary of the accuracies for the HRLT datasets using data from the meteorological stations

Variable	MAE	RMSE	Cor	NSE	N	Period
Maximum temperature (°C)	1.07	1.62	0.99	0.98	14731830	1961–2019
Minimum temperature (°C)	1.08	1.53	0.99	0.99	14730410	1961–2019
Precipitation (mm)	1.30	4.78	0.84	0.70	14730380	1961–2019

MAE, RMSE, Cor, and NSE are the mean absolute error, root mean square error, Pearson's correlation coefficient, and Nash-Sutcliffe modeling efficiency, respectively. N is the number of observations and Period is the beginning to end years of the data.

Table 2 Comparison of accuracies for the HRLT and CMFD datasets using data from the meteorological stations

Variable	Dataset	MAE	RMSE	Cor	NSE	N	Period
Maximum temperature (°C)	HRLT	1.07	1.63	0.99	0.98	9969602	1979–2018
Minimum temperature (°C)	HRLT	1.08	1.54	0.99	0.99	9969602	1979–2018
Average temperature (°C)	CMFD	1.12	1.64	0.99	0.98	9969602	1979–2018
Precipitation (mm)	HRLT	1.30	4.73	0.84	0.71	9968784	1979–2018
	CMFD	1.30	5.85	0.75	0.55	9968784	1979–2018

MAE, RMSE, Cor, and NSE are the mean absolute error, root mean square error, Pearson’s correlation coefficient, and Nash-Sutcliffe modeling efficiency, respectively. N is the number of observations and Period is the beginning to end years of the data.

Table 3 Comparison of accuracies for the HRLT and the CLDAS datasets using data from the meteorological stations

Variable	Dataset	MAE	RMSE	Cor	NSE	N	Period
Maximum temperature (°C)	HRLT	1.10	1.73	0.99	0.98	686653	2017–2019
	CLDAS	2.54	3.63	0.95	0.90	686653	2017–2019
Minimum temperature (°C)	HRLT	1.14	1.65	0.99	0.98	686653	2017–2019
	CLDAS	1.58	2.63	0.98	0.95	686653	2017–2019
Precipitation (mm)	HRLT	1.42	4.93	0.84	0.70	685936	2017–2019
	CLDAS	2.36	7.67	0.58	0.28	685936	2017–2019

MAE, RMSE, Cor, and NSE are the mean absolute error, root mean square error, Pearson's correlation coefficient, and Nash-Sutcliffe modeling efficiency, respectively. N is the number of observations and Period is the beginning to end years of the data.

Table 4 Comparison of accuracies for the HRLT and the ISIMP3a datasets using data from the meteorological stations

Variable	Dataset	MAE	RMSE	Cor	NSE	N	Period
Maximum temperature (°C)	HRLT	1.06	1.61	0.99	0.98	13973110	1961–2016
	ISIMP3a	2.47	3.47	0.96	0.91	13973110	1961–2016
Minimum temperature (°C)	HRLT	1.07	1.52	0.99	0.99	13971690	1961–2016
	ISIMP3a	2.63	3.60	0.96	0.92	13971690	1961–2016
Precipitation (mm)	HRLT	1.30	4.78	0.84	0.70	13971680	1961–2016
	ISIMP3a	2.75	8.10	0.48	0.14	13971680	1961–2016

MAE, RMSE, Cor, and NSE are the mean absolute error, root mean square error, Pearson’s correlation coefficient, and Nash-Sutcliffe modeling efficiency, respectively. N is the number of observations and Period is the beginning to end years of the data.

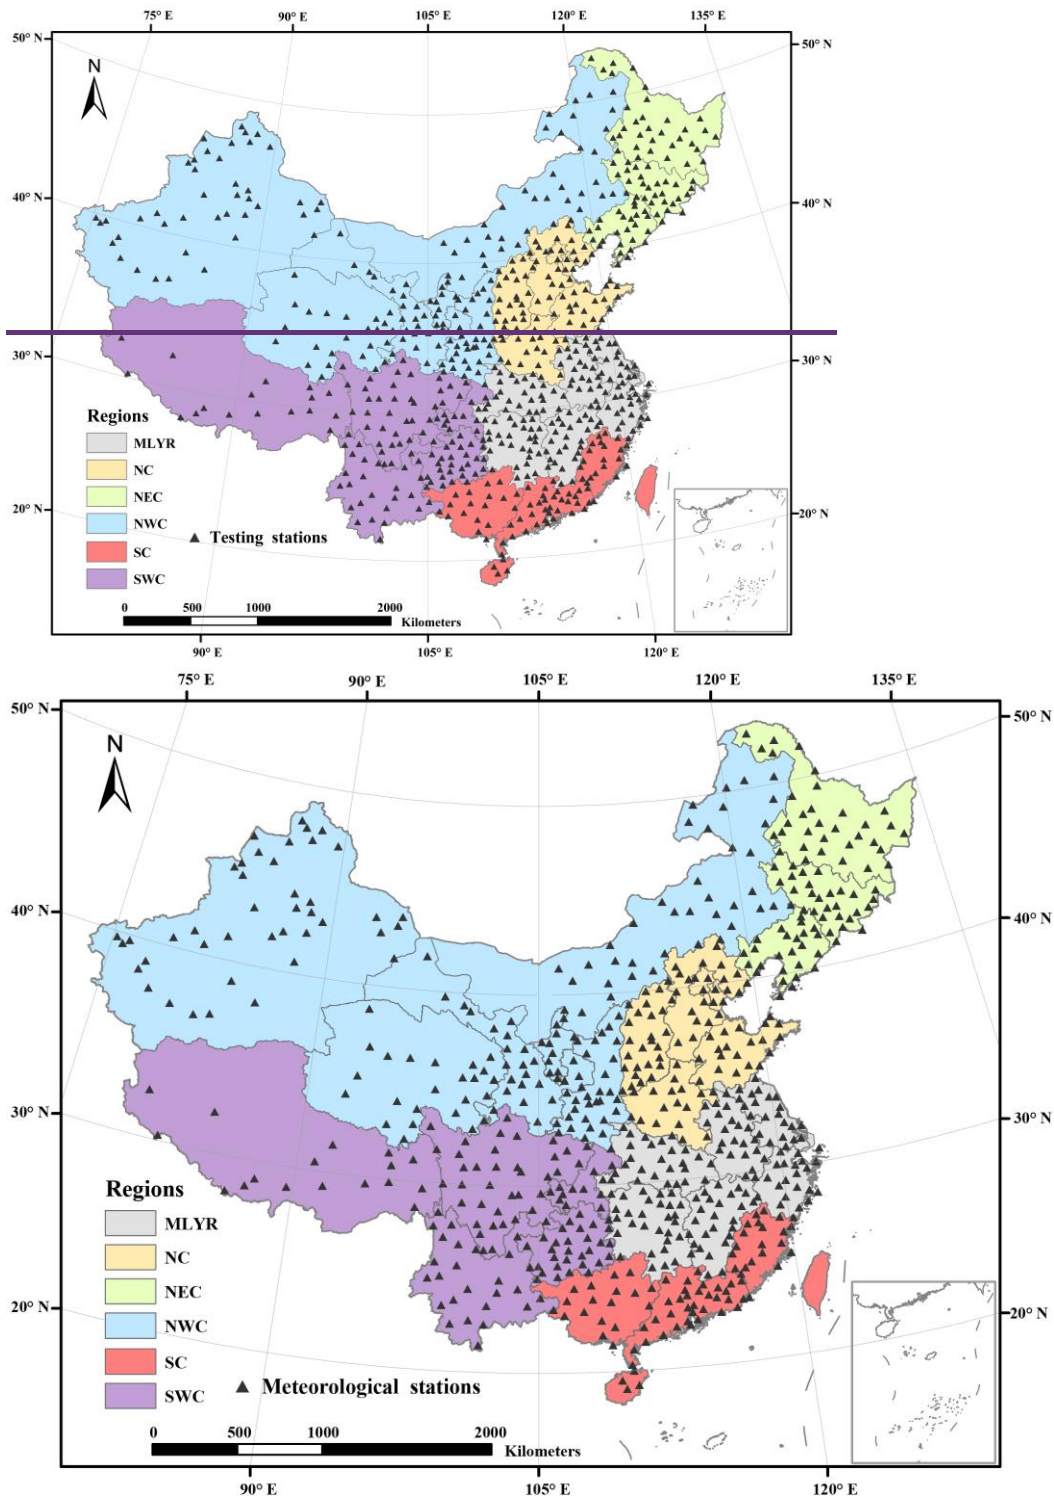

Figure 1. Regions and spatial distribution of the meteorological stations in China. MLYR, NC, NEC, NWC, SC, and SWC are the Middle and Lower reaches of the Yangtze River, North China, Northeast China, Northwest China, South China, and Southwest China, respectively. Note: meteorological stations data were missing for Taiwan Province.

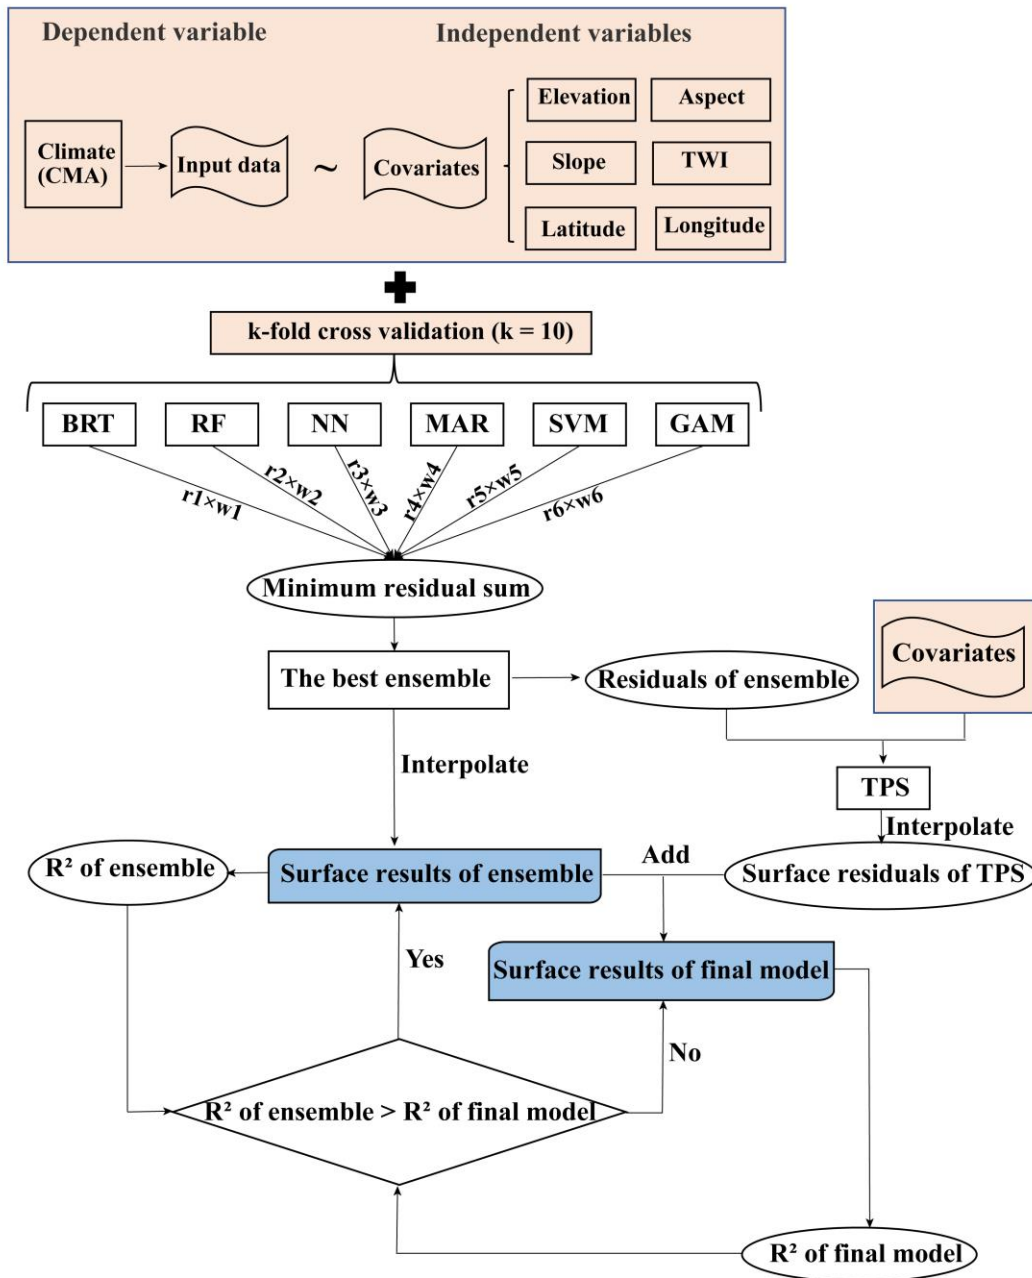

Figure 2. The process of spatial interpolation. The r_1 to r_6 are the residual error from each algorithm, respectively. The w_1 to w_6 are the weights of each algorithm, respectively. BRT, RF, NN, MAR, SVR, GAM and TPS are the boosted regression trees, random forests, neural networks, multivariate adaptive regression splines, support vector machines, the generalized additive model and thin-plate-smoothing splines, respectively. R^2 is the coefficient of determination between the estimated and observed values. **The TWI is topographic wetness index.**

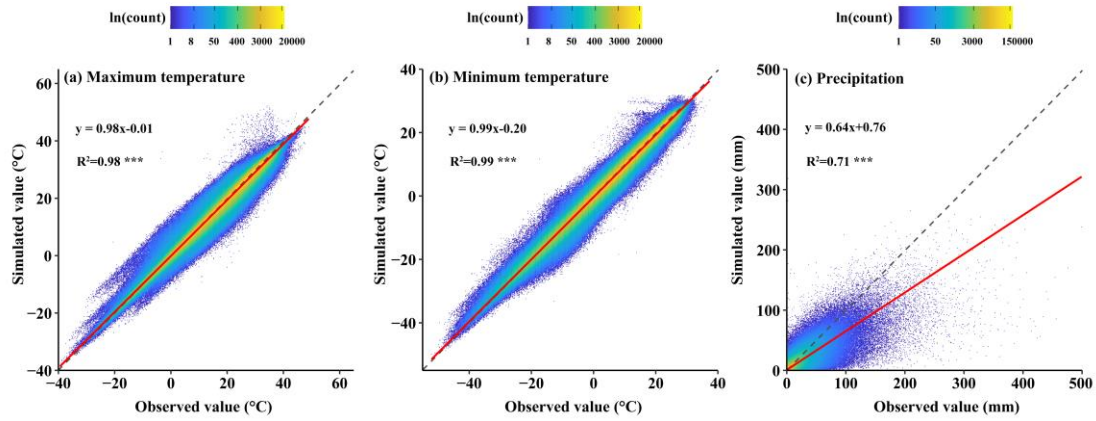

Figure 3. Scatter density plots of daily maximum and minimum temperatures and precipitation between estimated and observed values at meteorological stations were used to test the HRLT dataset. Dashed line is a line with slope 1 and the red line is a fitting between estimated and observed values. R^2 is the coefficient of determination between the estimated and observed values. *** asterisks indicate that the significance of the regression equation between the estimated and observed values was $p < 0.001$.

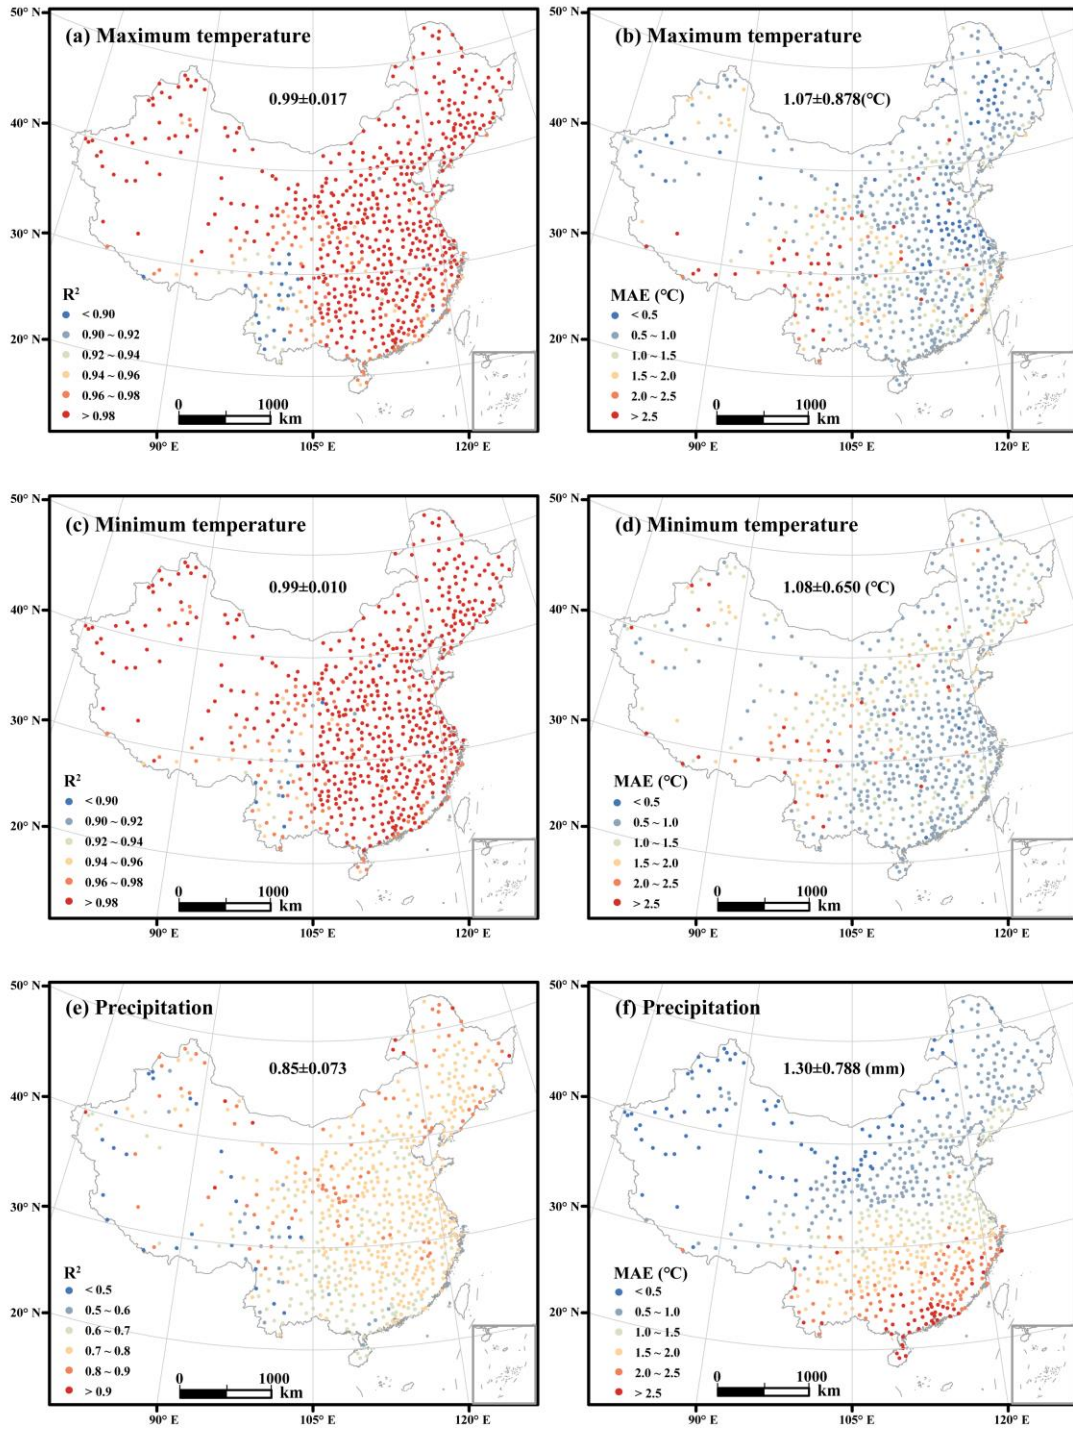

Figure 4. Spatial distribution of R^2 and MAE for daily maximum temperature, minimum temperature, and precipitation between 1961 and 2019. The value before the \pm is the R^2 or MAE mean value and the value after the \pm is the R^2 or MAE standard deviation for all meteorological stations.

Figure 5. Comparisons of the density distribution between the estimated value in our dataset and the observed values from meteorological stations for daily maximum temperature, minimum temperature, and precipitation in the different regions from 1961 to 2019.

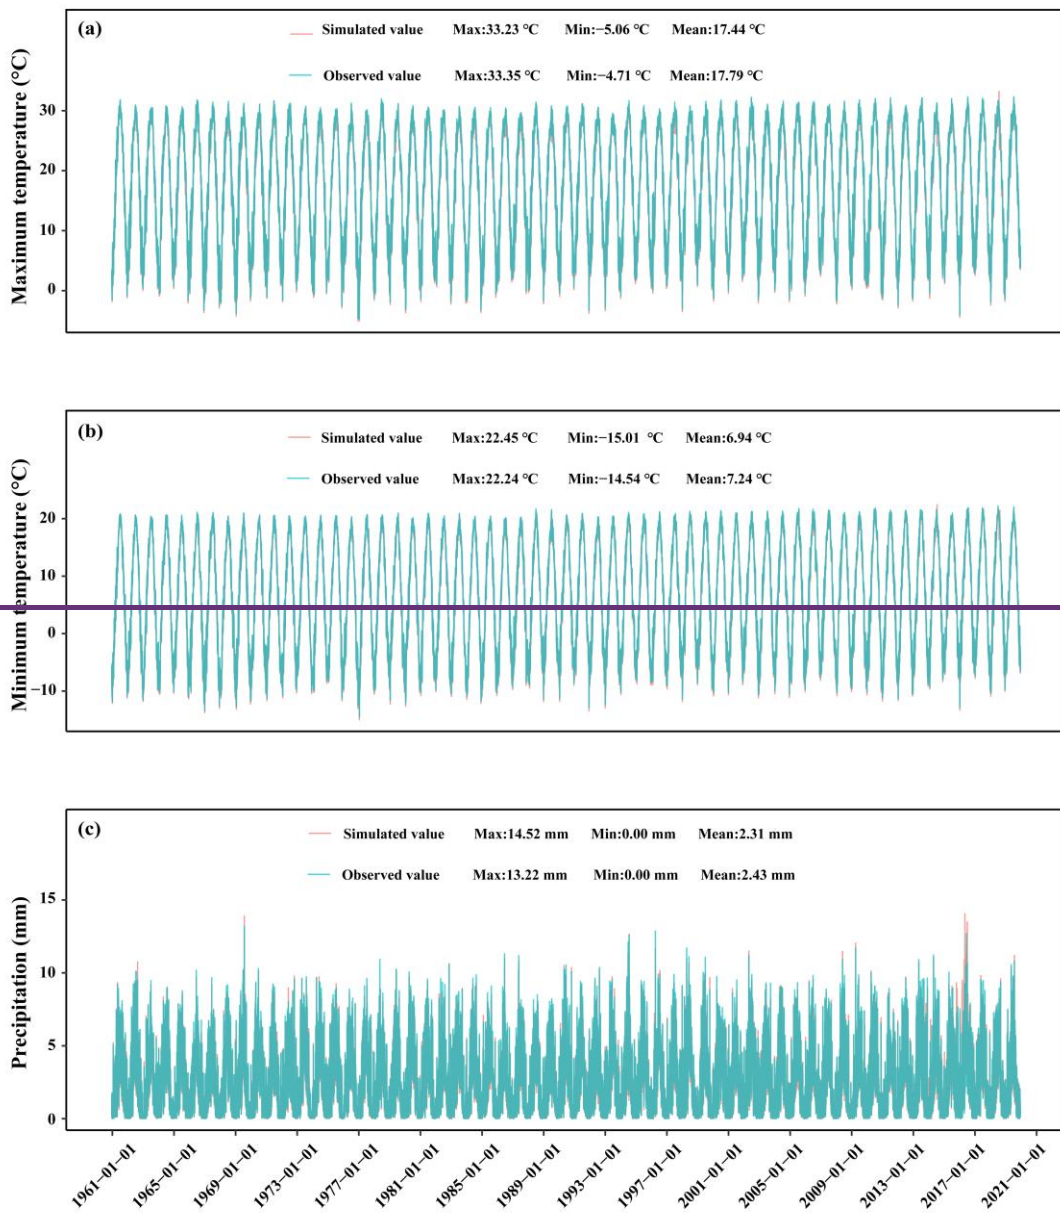

Figure 6. Comparisons of the daily changes between the estimated and observed values for daily maximum temperature, minimum temperature, and precipitation from January 1, 1961 to December 31, 2019 over all meteorological stations.

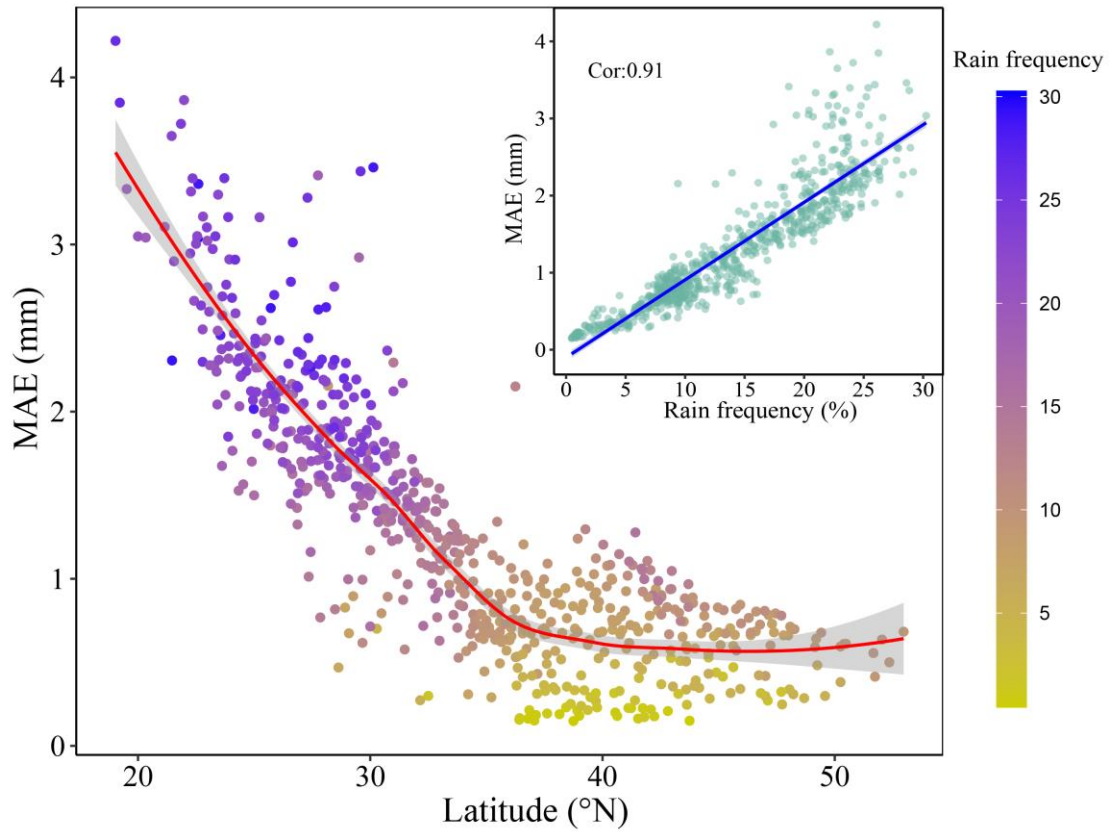

Figure 5. The relationship between latitude and MAE of daily precipitation. Illustration indicates the relationship between rainfall frequency above light rainfall and MAE of daily precipitation. MAE is the mean absolute error, Cor is Pearson's correlation coefficient, Rain frequency is rainfall frequency above light rainfall, which is defined as a daily rainfall from 0 to 4 mm (Alpert et al., 2002)

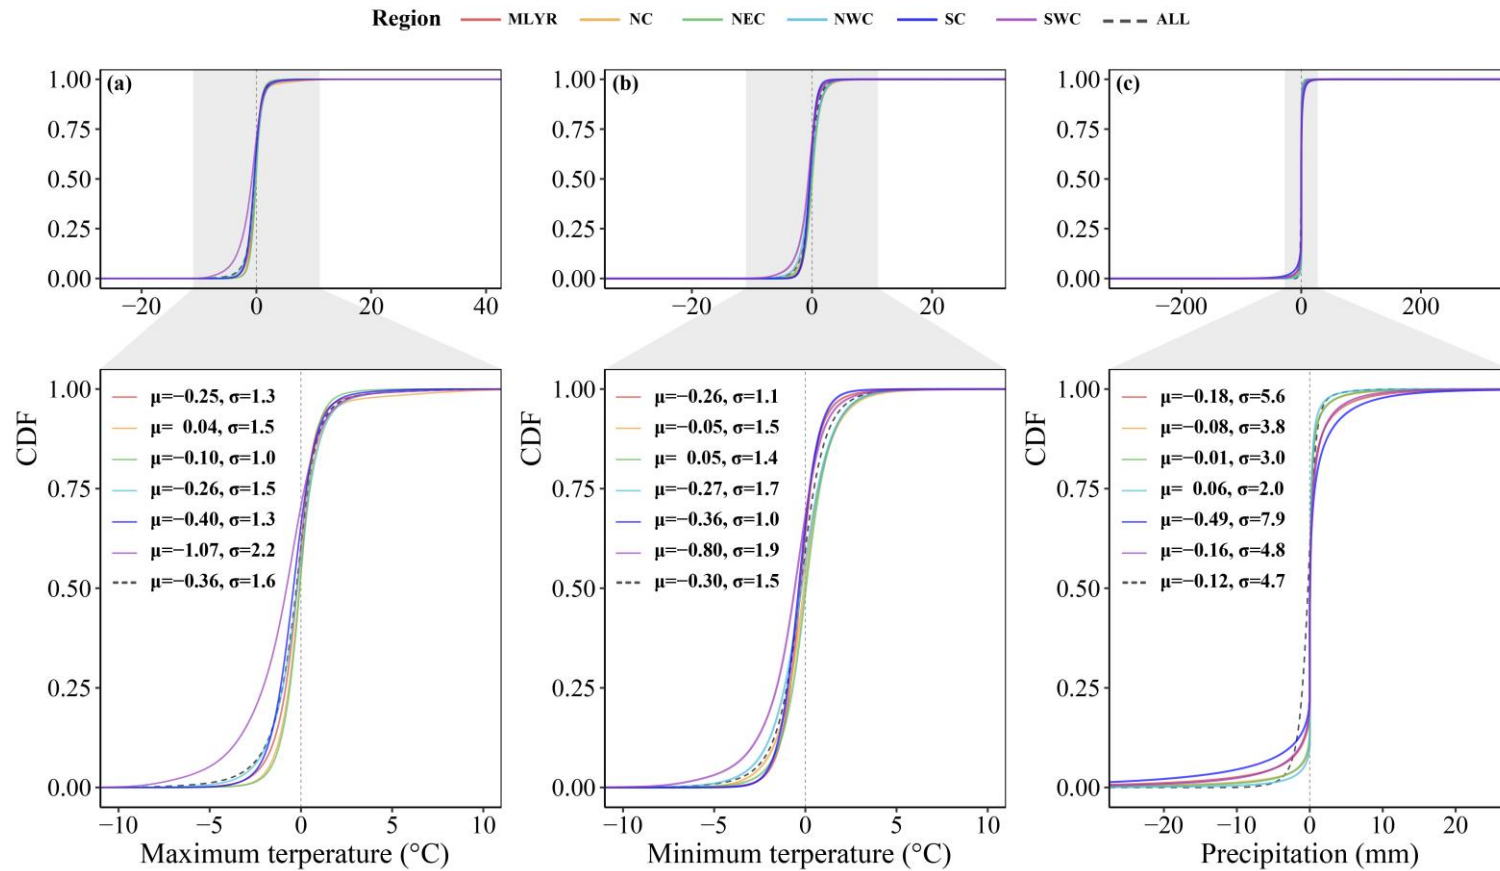

Figure 6. Cumulative distribution functions (CDF) of difference between the estimated and observed values for three variables in all meteorological stations from 1961 to 2020. μ is the mean and σ is the standard deviation. MLYR, NC, NEC, NWC, SC, and SWC are the Middle and Lower reaches of the Yangtze River, North China, Northeast China, Northwest China, South China, and Southwest China, respectively.

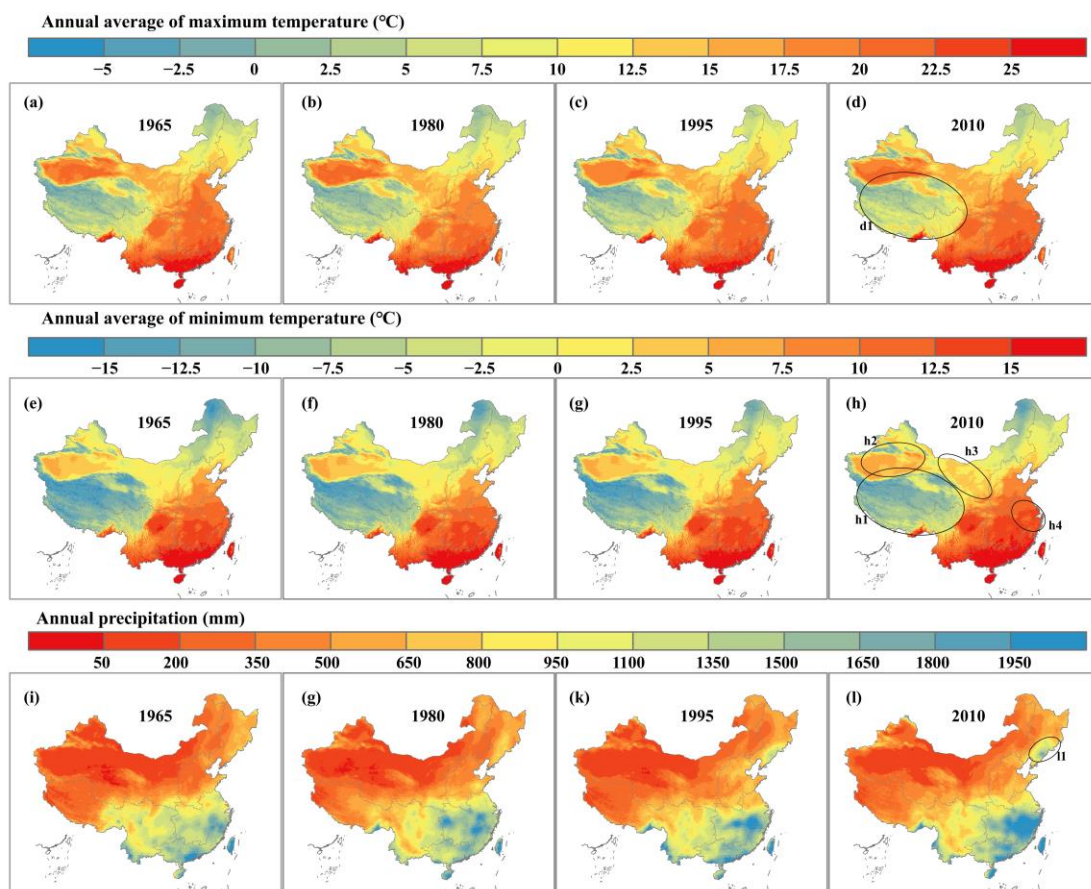

Figure 7. Spatial distributions of annual average values for daily maximum and minimum temperatures, and the spatial distribution of annual precipitation in 1965, 1980, 1990, and 2010. The ellipse regions are where the change is most visible.

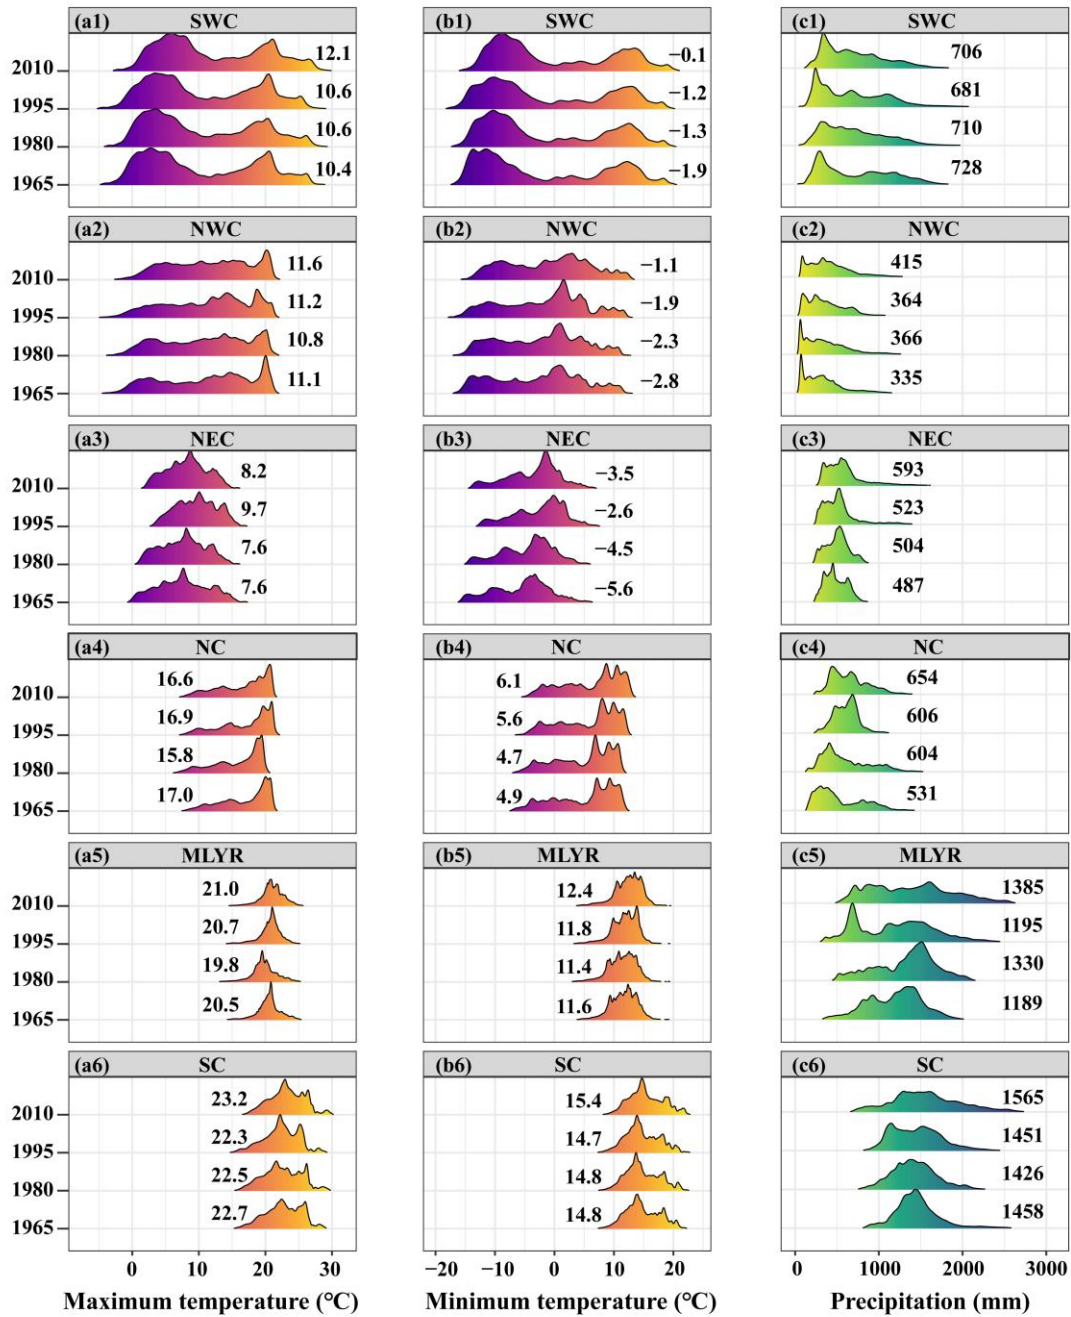

Figure 8. Density distributions of annual average values for daily maximum and minimum temperatures, and annual precipitation across the different regions in 1965, 1980, 1990, and 2010. The value in the illustrations is the mean value.

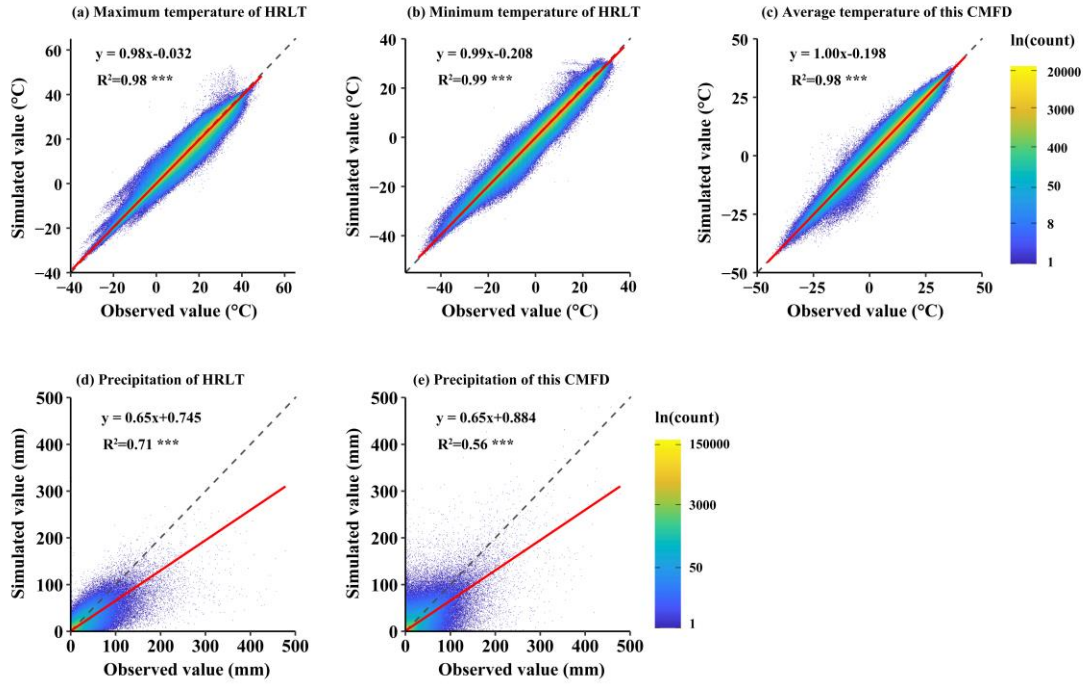

Figure 9. Scatter density plots of daily temperature and precipitation between the estimated and observed values at all meteorological stations (both training sets and testing sets) for the HRLT dataset and the CMFD dataset between 1979 and 2018. The dashed line is a line with slope 1 and the red line is a fitting between the estimated and observed values. R^2 is the coefficient of determination between the estimated and observed values. *** asterisks indicate that the significance of the regression equation between the estimated and observed values was $p < 0.001$.

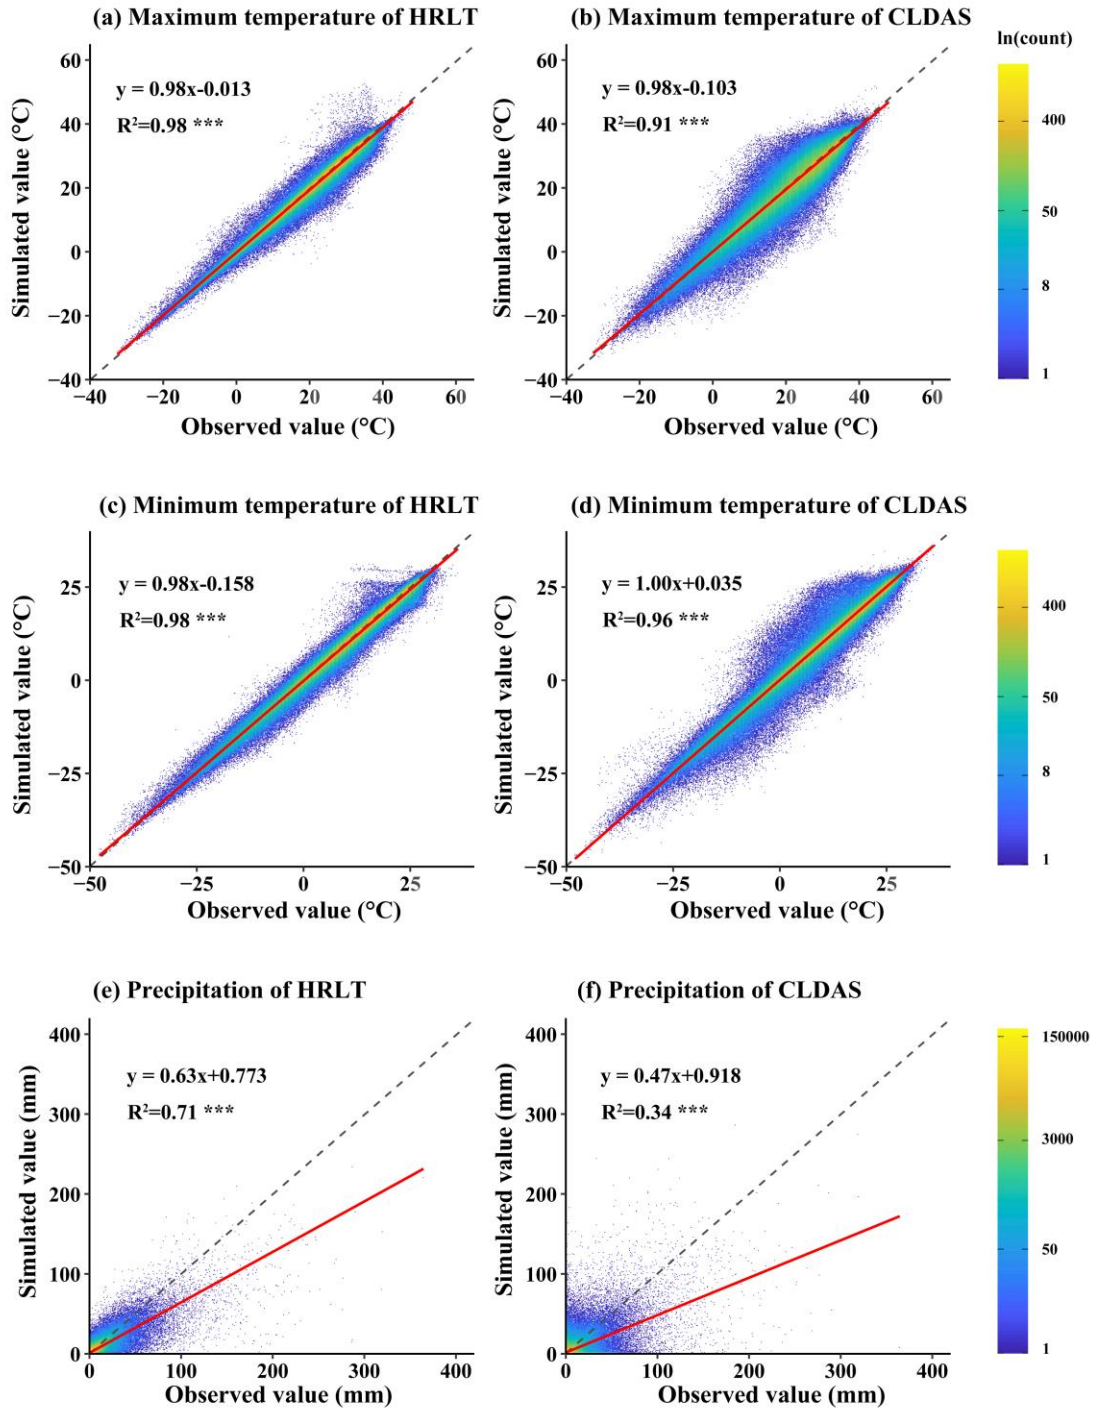

Figure 10. Scatter density plots of daily temperature and precipitation between the estimated and observed values from all meteorological stations (both training sets and testing sets) for our HRLT dataset and the CLDAS dataset between 2017 and 2019. Dashed line is a line with slope 1 and the red line is the fitting between the estimated and observed values. R^2 is the coefficient of determination between the estimated and observed values. *** asterisks indicate that the significance of the regression equation between the estimated and observed values was $p < 0.001$.

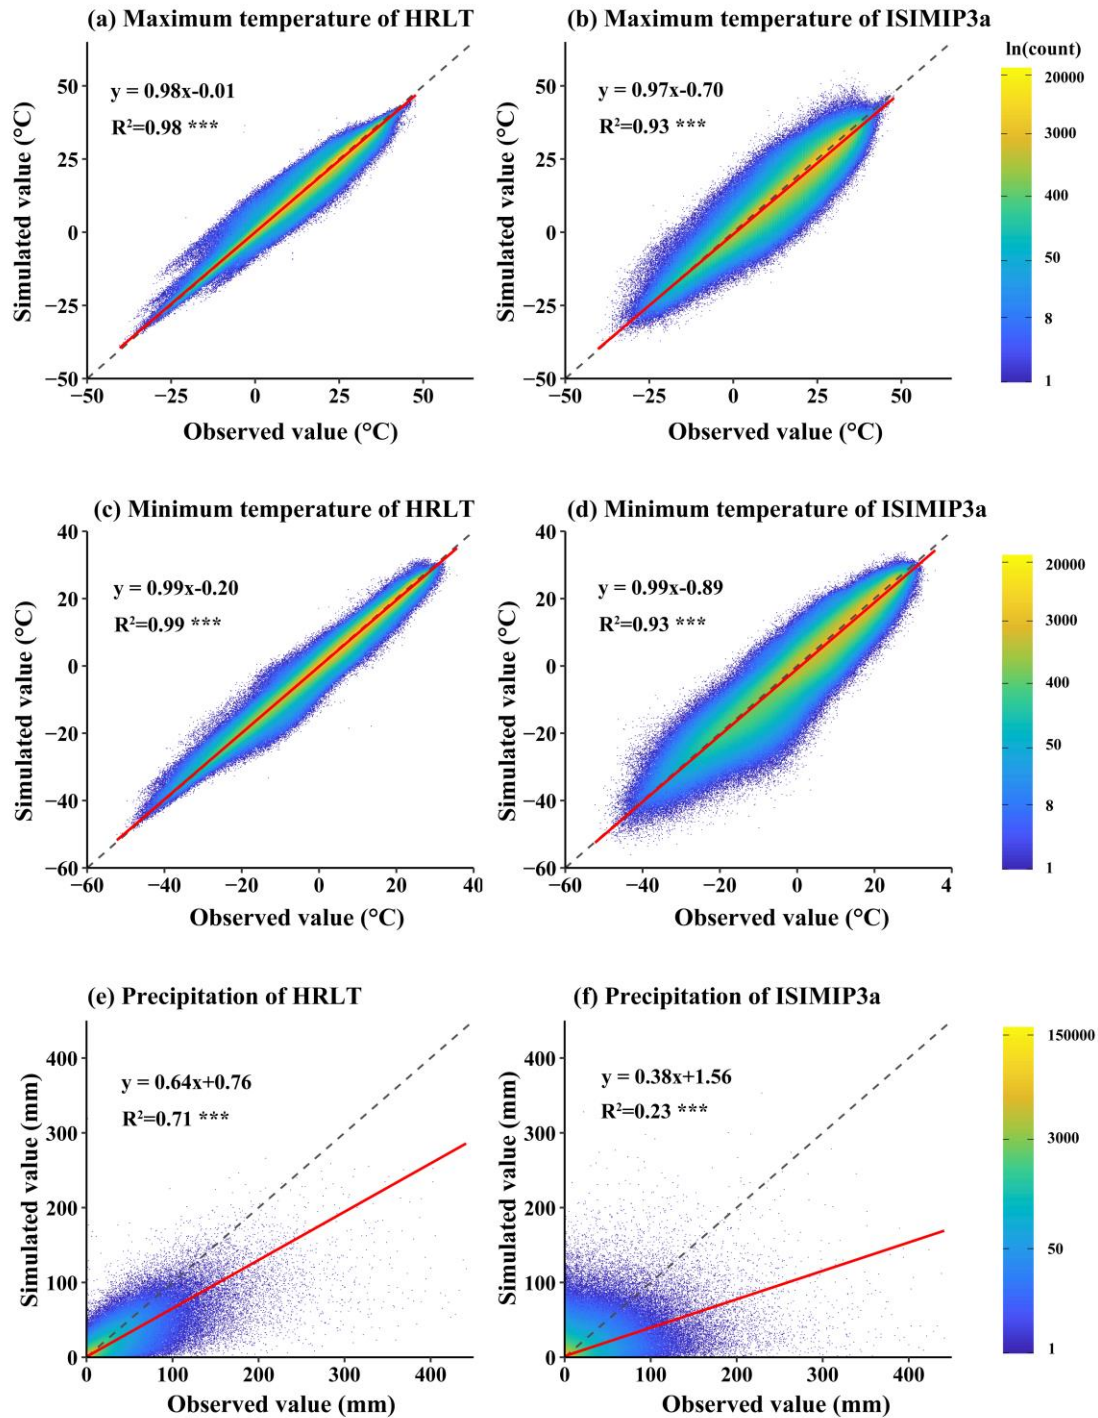

Figure 11. Scatter density plots of daily temperature and precipitation between the estimated and observed values from all meteorological stations (both training sets and testing sets) for our HRLT dataset and the ISIMIP3a dataset between 1961 and 2016. Dashed line is a line with slope 1 and the red line is the fitting between the estimated and observed values. R^2 is the coefficient of determination between the estimated and observed values. *** asterisks indicate that the significance of the regression equation between the estimated and observed values was $p < 0.001$.
