22 **Abstract**

23 Soils in the northern high latitudes are a key component in the global carbon cycle; the northern permafrost region  
24 covers 22% of the Northern Hemisphere [land surface area](#) and holds almost twice as much carbon as the atmosphere.  
25 Permafrost soil organic matter stocks represent an enormous long-term carbon sink which is in risk of switching to a  
26 net source in the future. Detailed knowledge about the quantity and the mechanisms controlling organic carbon storage  
27 is of utmost importance for our understanding of potential impacts of and feedbacks on climate change. Here we  
28 present a geospatial dataset of physical and chemical soil properties calculated from 651 soil pedons encompassing  
29 more than 6500 samples from 16 different study areas across the northern permafrost region. The aim of our dataset  
30 is to provide a basis to describe spatial patterns in soil properties, including quantifying carbon and nitrogen stocks;  
31 [turnover times, and soil texture](#). There is a particular need for spatially distributed datasets of soil properties, including  
32 vertical and horizontal distribution patterns, for modelling at local, regional or global scales. This paper presents this  
33 dataset, describes in detail soil sampling, laboratory analysis and derived soil geochemical parameters, calculations  
34 and data clustering. Moreover, we use this dataset to estimate soil organic carbon and total nitrogen storage estimates  
35 in soils in the northern circumpolar permafrost region ( $17.9 \times 10^6 \text{ km}^2$ ) using the ESA's Climate Change Initiative  
36 (CCI) Global Land Cover dataset at 300 m pixel resolution. We estimate organic carbon and total nitrogen stocks on  
37 a circumpolar scale (excluding Tibet) for the 0-100 cm and 0-300 cm soil depth to be 380 Pg and 813 Pg for carbon  
38 and 21 Pg and 55 Pg for nitrogen, respectively. Our organic carbon estimates agree with previous studies, with most  
39 recent estimates of 1000 Pg (- 170 to +186 Pg) to 300 cm depth. Two separate datasets are freely available on the  
40 Bolin Centre Database repository. Dataset references and DOIs are presented in the "Data access" section in the end.

41 **1. Introduction**

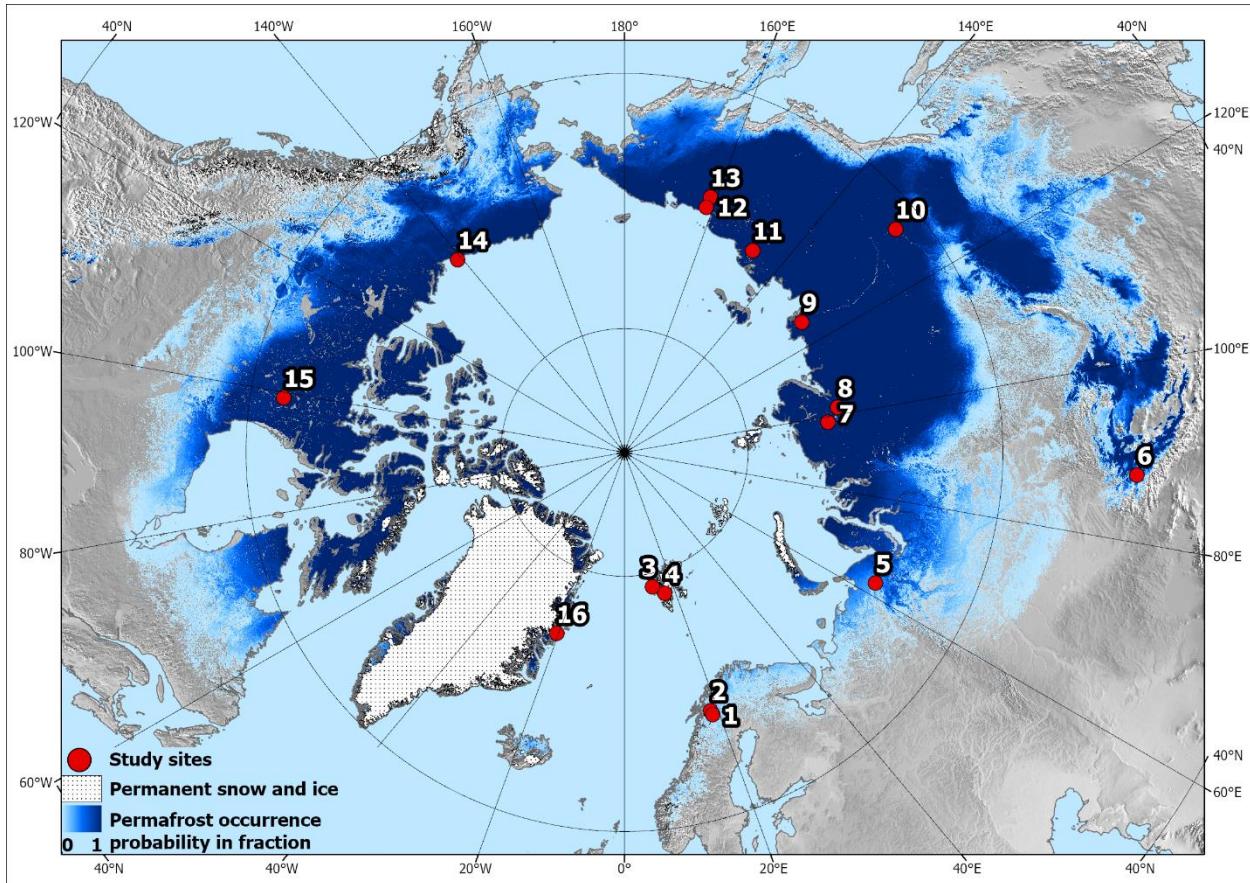

42 Permafrost soils represent a large part of the terrestrial carbon reservoir and form a significant and climate-sensitive  
43 component of the global carbon cycle (Hugelius et al., 2014). High-latitude ecosystems are experiencing rapid climate  
44 change causing warming of the soil, thawing of permafrost, and fluvial and coastal erosion (Biskaborn et al., 2019;  
45 Fritz et al., 2017). Warming enhances the decomposition of organic matter (OM) by microorganisms, which [in turn](#)  
46 produces carbon dioxide, methane, and nitrous oxide. The release of these greenhouse gases to the atmosphere would  
47 in turn generate further climate change, resulting in a positive feedback on global warming (Turetsky et al., 2020). To  
48 better predict the magnitude and effect of environmental changes in the permafrost region, improved data on the  
49 properties and quantities of carbon and nitrogen stored in these climate vulnerable soils are needed.

50 In many cases, a lack of observational data for parameterization or evaluation can limit model development or accurate  
51 model projections (Flato, 2011). Soil properties such as OM content, soil texture and soil moisture or their derivatives  
52 are commonly used to parametrize, train or validate models (e.g. Oleson et al., 2010). Yet, the representation of  
53 northern soil profiles in global datasets remains limited (Köchy et al., 2015; Batjes, 2016), the northern circumpolar  
54 permafrost region ( $20.6 \times 10^6 \text{ km}^2$ ) in which permafrost can occur accounts for 22% of the Northern Hemisphere  
55 exposed land area (Obu et al, 2019).

56 Many previous studies have shown a robust relationship between land cover and soil organic carbon (SOC)  
57 distribution, making land cover datasets useful for upscaling estimates from soil profiles to full landscape coverage  
58 (e.g. Kuhry et al., 2002; Hugelius, 2012; Palmtag et al., 2015; Siewert et al., 2015; Wojcik et al., 2019). Here we  
59 describe the compilation of a harmonized soil dataset for permafrost-affected landscapes derived from 15 different  
60 high latitude sites and one high alpine study site in Canada, Greenland, Svalbard, Sweden, and Russia (Fig. 1; Table  
61 1). In total, 651 soil pedons contain information from up to 6529 samples on carbon and nitrogen content, carbon to  
62 nitrogen (C/N) ratio, isotopic composition, texture (sand, silt + clay) and coarse fraction content, land cover type, wet  
63 and dry bulk density, calculated volumetric contents for ice/water, and volumetric content of organic soil material,  
64 mineral soil material and air. ~~In addition, soil pedon descriptions include metadata on actual sampling site, coordinates~~  
65 ~~and elevation, slope and aspect, drainage, percentage of stones and boulders, landform, and maximum sampling depth.~~  
66 Site data were upscaled to the northern circumpolar permafrost region using the European Space Agency (ESA)  
67 Climate Change Initiative (CCI) Global Land Cover dataset at 300 m pixel resolution, which is the very first long-  
68 term global land cover time series product.

69 This study has two main aims. Firstly, the ~~core-primary objective aim~~ of this dataset is to provide a harmonized, high  
70 resolution, quality controlled, and contextualized soil pedon dataset with a focus on SOC, nitrogen and other  
71 parameters essential to determine the role of northern permafrost region soils in the climate system. ~~Particularly, the~~  
72 ~~extensive metadata on soil properties included for many samples when available (texture, volumetric densities, active~~  
73 ~~layer depth, ice content, isotopic composition, etc.) are of great importance and can be used to identify and model the~~  
74 ~~processes responsible for the current and future carbon balance.~~ Secondly, ~~to we used this soil~~ dataset and an existing  
75 spatial product for upscaling to provide a new and independent estimate of the ~~soil organic carbon~~SOC and total  
76 nitrogen (TN) storage estimates within the northern circumpolar permafrost region. ~~Particularly, the extensive~~  
77 ~~metadata on soil properties included for many samples when available (texture, volumetric densities, active layer~~  
78 ~~depth, ice content, isotopic composition, etc.) are of great importance and can be used to identify and model the~~  
79 ~~processes responsible for the current and future carbon balance.~~

80

81

82 Figure 1: Overview map with location of the 16 sampling sites (see Table 1). Blue shading indicates permafrost  
 83 probability (dark hues showing higher permafrost occurrence probability), based on an equilibrium state model for  
 84 the temperature at the top of the permafrost (TTOP) for the 2000–2016 period (Obu et al., 2019). North Pole Lambert  
 85 azimuthal equal area projection (datum: WGS 84). Base map: Made with Natural Earth.

86

87 **2. Methods**

88 **2.1 Dataset structure**

89 The dataset contains 6529 analyzed samples from 651 soil pedons in 16 different sampling locations across the  
 90 northern permafrost region (Fig 1; Table 1) (Palmtag et al., 2022a, b). Each sampled pedon was described and  
 91 classified according to land cover type. Land cover is defined as the biophysical cover of the Earth's terrestrial surface  
 92 such as different vegetation types, water, and bare ground.

93

94 Table 1: Summary of all study sites

Nr.	Study area	Country	Long	Lat	n=pedons	Reference

95

96 Land cover products are commonly satellite derived and sometimes globally available. We opted for a two-tier  
 97 approach, where more classes can be used in products with higher thematic or spatial resolution (Table 2). First, we  
 98 differentiated land cover into 5 primary tier classes (Tier I) which represent the major land cover types: forest, tundra,  
 99 wetland, barren, and Yedoma. Although Yedoma is a sedimentary deposit and not a typical land cover class, it was  
 100 added due to its large areal extent, special soil organic matter (SOM) and ground ice properties, as well as soil  
 101 characteristics (Strauss et al., 2017; Weiss et al., 2016). Subsequently, Tier I classes were subdivided into 10 Tier II  
 102 subclasses (Table 2).

103

104 Table 2: Hierarchical structure of the two-tier land cover class system applied to the pedons based on field  
 105 observations.

TIER I		TIER II	
1	Forest	1.1	Deciduous broadleaf forest
		1.2	Evergreen needleleaf forest
		1.3	Deciduous needleleaf forest
2	Tundra	2.1	Shrub tundra
		2.2	Graminoid / forb tundra
3	Wetland	3.1	Permafrost wetlands
		3.2	Non-permafrost wetlands
4	Barren	4.1	Barren
5	Yedoma	5.1	Yedoma tundra
		5.2	Yedoma forest

106 **2.1.1 Class definitions of soil pedons to land cover types**

107 All sampling sites were classified with Tier I descriptions using field descriptions and, where possible, assigned a  
 108 more detailed (Tier II) description. The forest class was used for sparse to dense forests, further separated into three  
 109 different Tier II classes: deciduous broadleaf, evergreen needleleaf and deciduous needleleaf forest. Tundra is  
 110 separated in Tier II to shrub tundra (dominated by erect shrubs > 50 cm height) and graminoid / forb tundra (with low  
 111 growth heath vegetation or graminoid dominated). Wetland includes terrain that is saturated with water for sufficient  
 112 time of the year to promote aquatic soil processes with low oxygen conditions and occurrence of vegetation fully  
 113 adapted to these conditions, as well as all types of peatlands. Areas that met the National Wetlands Working Group  
 114 (1997) definition of a wetland were classified as such. We applied a classification that is adapted from the Canadian  
 115 system (National Wetlands Working Group, 1997) describing the wetlands in the field and following types of wetlands  
 116 were included to the Tier I wetland class: organic, mineral, seasonal, permanent, ombrotrophic and minerotrophic  
 117 wetlands. The permafrost status within the top 2 m of a site was used to distinguish in Tier II the permafrost wetlands  
 118 and the non-permafrost wetlands. Although a substantial part of the northern circumpolar permafrost region is  
 119 classified as water ( $0.98 \times 10^6 \text{ km}^2$ ) or permanent snow/ice ( $0.06 \times 10^6 \text{ km}^2$ ), no soil sample or pedon data from these  
 120 classes are included in the database. The Tibetan permafrost region was also excluded from our estimates as none of  
 121 the sampling sites originated from that area. The class barren includes land cover types such as exposed bedrock,  
 122 boulder fields, talus slopes, debris cones, rock glaciers, where soil is either almost completely absent, or occurs only  
 123 in minor patches (<10 % area) or in between boulders. The land cover class Yedoma is defined as areas in Siberia,  
 124 Alaska, and Yukon underlain by late Pleistocene ice-rich syngenetic permafrost deposits. We used the spatial extent

125 for the Yedoma domain from Strauss et al. (2017) which occupied an area of 570,000 km<sup>2</sup> from ~~here-the used~~ ESA  
126 CCI land cover product. Tier II divides the Yedoma domain into Yedoma tundra and Yedoma forest.

127 **2.2 Soil sampling**

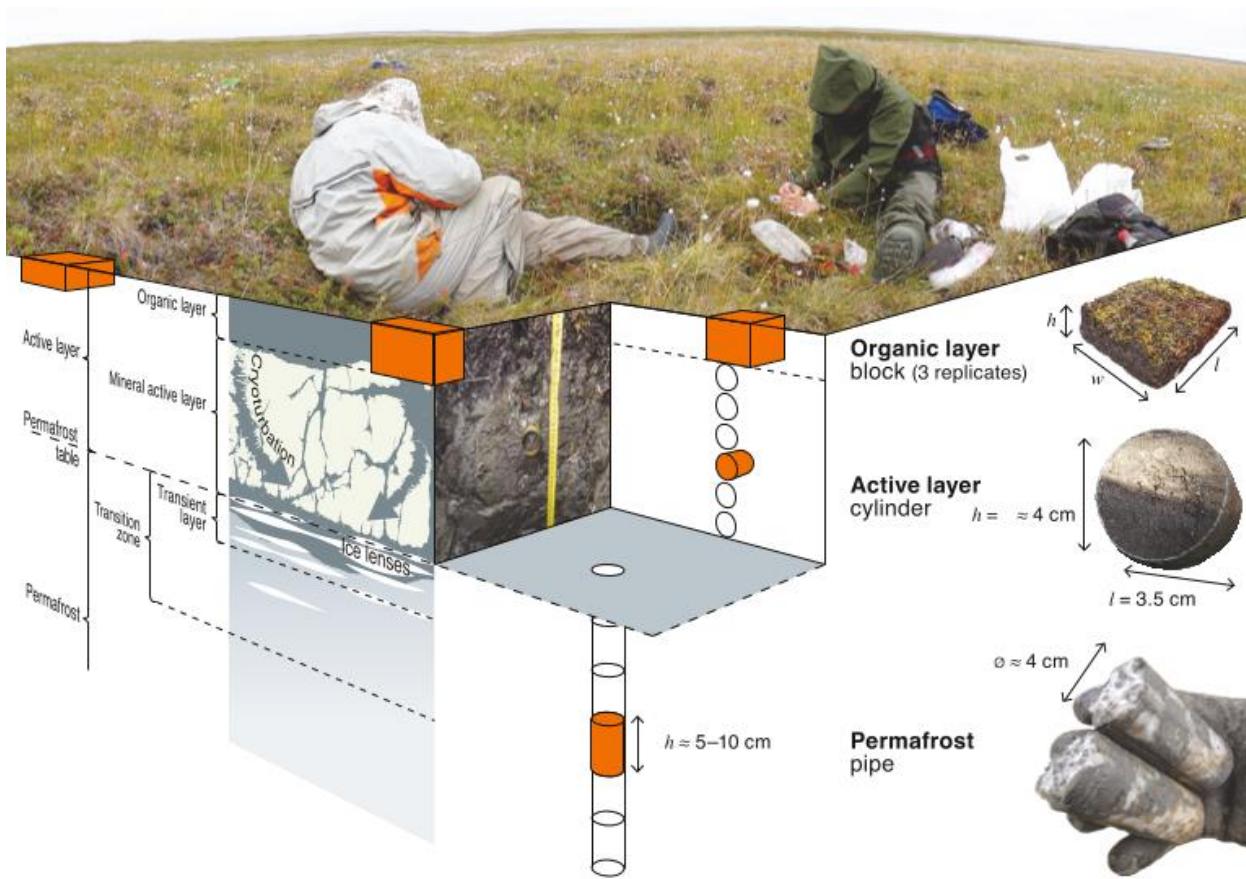

128 Field soil sampling took place in summer months (late June to early September) between 2006 and 2019, most  
129 frequently in August or September in order to capture the maximum seasonal thaw (active layer) depth at each site.  
130 Active layer thickness was measured at each location using a graduated steel probe or measuring tape in excavated  
131 soil pits. A stratified sampling scheme ~~(582 out of 651)~~ consisting of linear transects with predefined equidistant  
132 intervals of typically 100 to 200 m across all major landscape elements was used to retrieve soil pedons (n = 582),  
133 with on average 37 sampling sites per study area. To ensure that this sampling scheme covered all representative  
134 landscape units and types, maps (including vegetation, surficial geology) and remote sensing products (including air  
135 photos, satellite imagery, and elevation models) were assessed prior to fieldwork. Detailed field reconnaissance  
136 involving visual observation of the manageable study area were conducted before establishing transects. Sampling  
137 sites were located and marked at the exact position based on distance to the first sampling point and compass bearing  
138 using a hand-held GPS device. This ensured an unbiased location of individual sampling sites. When sufficient time  
139 was available in the field, additional sampling (n = 69) using a random or stratified random distribution of sampling  
140 points was used. Following the field sampling protocol (Figure S1), a site description, soil and in several cases  
141 phytomass sampling were conducted at each sampling point.

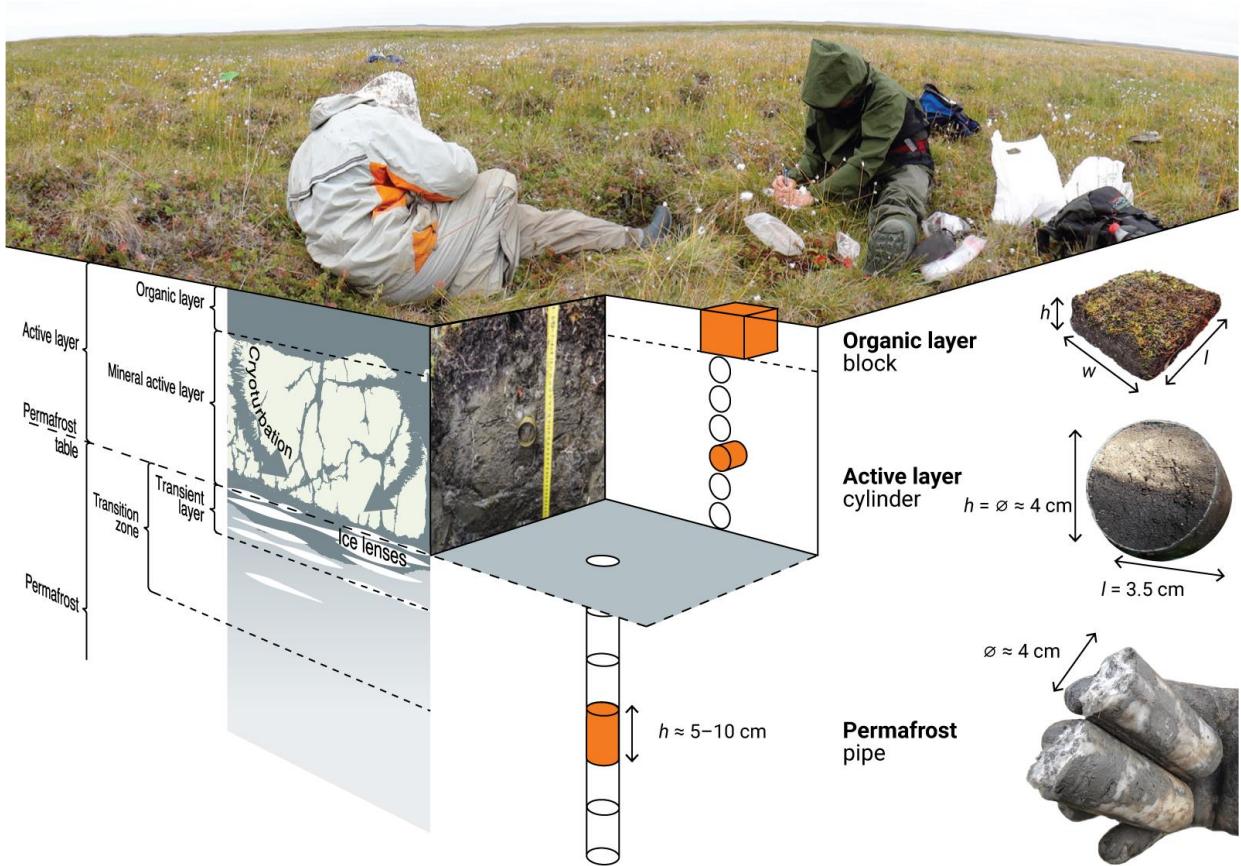

142 For each pedon, the organic layer ~~(OL)~~ and the active layer was sampled from an open soil pit excavated to the bottom  
143 of the active layer, to the bedrock or when this was not possible, to a depth of at least 50 cm to at least reach a depth  
144 ~~beyond ± 50 cm~~ (Fig. 2). Deeper unfrozen soil layers were sampled using a steel pipe (see permafrost sampling below).  
145 The organic layer sample was cut out as a block using a pair of scissors or a knife (removing living vegetation), and  
146 the block volume was measured in the field. The active layer samples were collected using 100 cm<sup>3</sup> soil sampling  
147 rings inserted horizontally into the soil profile. Sampling of the active layer was performed in fixed depth intervals  
148 (5–10 cm) or along soil horizon boundaries. For non-permafrost wetland sites, a Russian peat corer with a 50 cm long  
149 chamber was used. After extraction, the core was ~~described and~~ subdivided into smaller increments (generally 5 cm)  
150 which. ~~This~~ resulted typically in about 5–15 samples per sampling site depending on the reached depth.

151 The permafrost section of the soil profile and very deep unfrozen soil layers were sampled using a steel pipe that was  
152 hammered into the ground in short (5 to 10 cm) depth increments. The pipe was pulled out after each sampled  
153 increment using large pipe wrenches, and the sample was pushed out of the pipe using a steel rod. At several locations  
154 (n = 18) permafrost samples were also collected from exposures along lake shores or river valleys where the steel pipe  
155 was hammered in horizontally. These steel pipes are industry standardized with an outer diameter of 42.2 mm (1.25  
156 inches), affordable and widely available even in remote locations. At several locations (n = 5), soil cores were collected  
157 using a handheld motorized rotational Earth Auger (Stihl BT 121) with a 50 cm core barrel and 52 mm outside  
158 diameter. Samples were split lengthwise into two halves: one half was analyzed to determine sediment characteristics,

159 volumetric ice content, and gravimetric water content. Disturbance material was removed from the core surface by  
160 repeated scraping with a razor blade. ~~All half cores were then photographed and described in detail.~~ The other half of  
161 each core was kept as a frozen archive to be used in the event of laboratory error. Since the accurate determination of  
162 soil bulk density (BD) is crucial when ~~calculating SOC converting sample weight to volume or area and is essential to~~  
163 ~~calculate SOC stocks. Therefore~~, special attention was paid to accurate soil volume estimation during field sampling.  
164 The target depth for soil cores was 100 cm, or until bedrock or massive ground ice (e.g. ice-wedges) was reached.  
165 Pedons were often extended beyond 100 cm depth (n = 313), in particular to assess full peat depth and organic/mineral  
166 transition in organic soils.

167 ~~All samples were described in the field and packed into sampling bags.~~ Wet or frozen samples were described and  
168 placed in double bags to assure no soil water was lost in transport. For each sampled soil profile, pictures and notes  
169 were taken to describe land cover type, landform, elevation, slope and aspect, surface moisture, and surface features.  
170 Specific observations regarding the collected sample depths, such as excess ground ice (visual estimate, %),  
171 occurrence of large stones (visual estimate, %), colour (general description or using a Munsell scale), soil structure,  
172 including signs of cryoturbation, roots and rooting depth were noted. Samples with cryoturbated soil material were  
173 marked or rated on a scale from 1 to 3 according to the relative amount of cryoturbated soil material. Soil texture,  
174 which refers to particle size and relative content of mineral components (sand, silt + clay) is of importance as it affects  
175 the physical and chemical properties of a soil, including cryoturbation (Palmtag and Kuhry, 2018). Soil texture was  
176 estimated for most samples using manipulation tests and assessment by hand in the field under varying weather  
177 conditions. To avoid misinterpretation, we decided to combine silt and clay and refer to them as one fine-grained soil  
178 texture class. In case of permafrost samples, subsamples were thawed, analyzed and returned back to the sample bag.  
179 To avoid misinterpretation, we decided to combine silt and clay and refer to them as one fine grained soil texture  
180 class. The land cover and vegetation community were described at all sites. For many sites, vegetation cover was  
181 described in terms of relative plant functional type coverage per square meter. Beyond assigning the profiles to land  
182 cover, vegetation data is not included in this database and not further discussed.

184

185 Figure 2: A three-dimensional field sampling protocol with typical soil layers in permafrost ground (reprinted from  
 186 Weiss 2017, p.12). The orange shapes represent the different sampling techniques for organic surface layer (block),  
 187 active layer sample from an excavated pit (fixed volume cylinder) and permafrost sampling (steel pipe).

188 **2.3 Laboratory analysis**

189 In the laboratory, soil samples ( $n = 5315$ ) were weighed before and after oven-drying at  $60-70^\circ\text{C}$  for at least 24 h (or  
 190 until no further weight change was observed) to determine field-moist mass ( $m_{ws}$ ) and the oven-dried mass ( $m_d$ ), thus  
 191 permitting the calculation of wet bulk density ( $\text{BD}_w$ ) and dry bulk density ( $\text{BD}$ ,  $\text{g cm}^{-3}$ ) using the known sample  
 192 volume. To ensure that there was no remaining water in the organic rich and/or fine grained samples ( $n=3684$ ),  
 193 subsamples of  $\sim 10$  g were dried again at  $105^\circ\text{C}$  to verify the oven dried weights. From organic rich and fine grained  
 194 samples ( $n = 3684$ ), subsamples of around 10 g were dried again at  $105^\circ\text{C}$  to verify dry weight and correct in case  
 195 not all water was lost at the lower temperature. Remaining samples which were not dried again, were sand or coarse  
 196 grain samples and showed in tests no noteworthy differences. The reason for the main sample being dried at lower  
 197 temperature is to ensure that samples can be dried in the original plastic sample bags (without loss of sampled  
 198 materials) and subsequently used for additional analyses that may be sensitive to the higher drying temperature (results  
 199 from such additional analyses are not included here). After drying, samples were homogenized and sieved to determine

200 the concentration of coarse mineral fragments (CF, >2 mm, %). For a subset of samples, particle size analysis was  
201 performed using a Malvern Mastersizer 3000 laser particle size analyzer (Malvern Instruments Ltd, Malvern, UK),  
202 which can analyze particles in the range of 0.01–3500  $\mu\text{m}$  in diameter. It measures the intensity of light scattered as a  
203 laser beam passes through a dispersed particulate sample. A detailed description of these samples is given in Palmtag  
204 et al. (2018). Out of 5331 samples where OC % data is available, subsamples from 4471 samples were burned-heated  
205 to 550° C for 5h at 550° C to obtain organic matter content through loss on ignition (LOI; Heiri et al., 2001), and about  
206 half of the samples (n = 2960), were burned at heated to 950° C for 2 h to determine carbonate content (for details, see  
207 Palmtag et al., 2015; 2016). To determine the elemental content of carbon and nitrogen (TOC and TN) and their  
208 isotopic composition, 2674 samples were analysed using an Elemental Analyser (EA). If LOI950 following Heiri et  
209 al. (2001) indicated presence of inorganic carbon with > 1%, samples were acid treated (Abisko, Sweden; Ny Ålesund,  
210 Norway; Aktru, Altai mountains, Russia) with hydrochloric acid prior to determination of TOC. To estimate the  
211 organic carbon % (OC %) for samples where only LOI was available (44 %), a polynomial regression model ( $R^2 =$   
212 95%) was performed between LOI550 and OC % from EA on samples for which both analyses were available at study  
213 area level.

214 ~~Carbon to nitrogen ratios are often used as an indicator for SOM decomposition. As during the metabolic activity by~~  
215 ~~microorganisms more carbon than nitrogen is released, the C/N ratio decreases with a higher degree of humification.~~  
216 ~~This is why C/N ratios usually decrease with depth, as deeper layers are typically older and more decomposed (Kuhry~~  
217 ~~and Vitt, 1996). The C/N ratios together with stable carbon isotopes ( $\delta^{13}\text{C}$ ) can be used to gain insight into the~~  
218 ~~biochemical processes of SOM, botanical origin with depth and the degradation state (Kracht and Gleixner, 2000).~~

## 219 2.4 SOC/TN stock calculations and upscaling

220 Dry and wet bulk density ( $\text{g cm}^{-3}$ ), sample volume ( $\text{cm}^3$ ) and % carbon was used to calculate the volumetric contents  
221 of water, organic soil material, mineral soil material and air for each sample. The soil organic carbon content ( $\text{kg C}$   
222  $\text{m}^{-2}$ ) was calculated for each sample separately based on dry bulk density (BD,  $\text{g cm}^{-3}$ ), percentage organic C in the  
223 sample (OC %), sample thickness T (cm), and coarse fraction correction (CF) (Equation 1). Equation 1 was also used  
224 to calculate the TN content, in which OC % was replaced with N %.

$$225 \text{SOC}(\text{g C cm}^{-2}) = \text{BD} * \text{OC \%} * (1 - \text{CF}) * T$$

1

226 SOC content for each pedon was calculated by summing up individual samples on 1 cm resolution until the maximum  
227 sampling depth was reached. The pedons were assigned to a specific land cover class and the SOC content averaged  
228 for different depth intervals (0–30 cm, 30–50 cm, 50–100 cm, 100–200 cm, 200–300 cm, and summed to 0–100 cm  
229 and 0–300 cm). In areas with large stones in the soil column (e.g. alpine areas) or areas with massive ice bodies (e.g.  
230 Yedoma deposits), it is also important to deduct the volume of stones or massive ice from the calculations. These  
231 additional variables are not included in equation 1, but were accounted for in the SOC calculations at the pedon level.  
232 If bedrock was encountered at any point, a SOC content of 0  $\text{kg C m}^{-2}$  was assigned for the remaining part down to  
233 300 cm depth at that specific sampling site. In pedons where some increments were missing or the full sampling depth

234 was not reached, the nearest samples from the same pedon for BD and OC % were interpolated or extrapolated. To  
235 avoid overestimation of the SOC storage, such extrapolations were only used where field notes showed that the  
236 deposits were homogeneous and bedrock was not reached.

237 Masses of soil components (water ( $m_w$ , g), organic matter ( $m_{OM}$ , g) and mineral component ( $m_{min}$ , g)) were calculated  
238 based on the laboratory analysis for all the individual samples. The mass of water was calculated as a difference  
239 between field-moist mass and oven-dried mass. Organic matter mass was calculated from the OC % and dry sample  
240 weight and multiplied by 2, which is a standard conversion factor between SOC and SOM (Pribyl, 2010). The mass  
241 of the mineral fraction was calculated as a difference between dry sample mass and organic matter mass.

242 Volumetric fractions of soil components were calculated by dividing the volume of the component with the total  
243 sample volume (V). We calculated component volumes from mass by assuming the following densities: 1 g cm<sup>-3</sup> for  
244 water, 0.91 g cm<sup>-3</sup> for ice, 1.3 g cm<sup>-3</sup> for organic matter (Farouki, 1981) and 2.65 g cm<sup>-3</sup> mineral component. The  
245 volumetric fraction of air was calculated as one minus the sum of the other fractions.

246 All profiles were assigned to land cover class based on field descriptions. Dry bulk density, SOC density, TN density  
247 and the volumetric contents of mineral and organic matter and water and air were averaged according to land cover  
248 classes for depths until 3 m using Python scripting language and pandas library (McKinney, 2011). Soil parameters  
249 were assigned to pedon sample depth ranges and these were grouped according to land cover classes yielding means  
250 and standard deviations for each centimetre of depth. Fractions of soil texture classes (sand and silt + clay) were  
251 created using the same procedure by counting occurrences of texture classes within pedons. Typical soil stratigraphies  
252 were generated for each class which can be used as input for permafrost modelling and mapping (e.g. Westermann et  
253 al., 2013; 2017; Czekirda et al., 2019).

254 For the upscaling, we used the land cover map from the Global ESA Land cover Climate Change Initiative (CCI)  
255 project at 300 m spatial resolution (<http://maps.elie.ucl.ac.be/CCI/viewer/index.php>). The overall classification  
256 accuracy, based on 3167 random sampling cases, is stated as 73 % (Defourny et al., 2008). The land cover class dataset  
257 for upscaling was generated from ESA CCI land cover yearly products from period 2006 to 2015 (corresponding to  
258 the sampling period) by identifying prevailing land cover classes within this period. The extent of the Yedoma land  
259 cover classes was defined from shapefiles of the Yedoma database by Strauss et al., (2017), where all the layers were  
260 used except for QG2500k, which is showing the lowest probability of Yedoma occurrence.

261 Since the ESA land cover product uses a different nomenclature for land cover types with different sub-categories,  
262 similar classes were amalgamated to fit our tiered land cover system (Table 2). Several minor classes consisting of  
263 single pixels spread over the map were generalized and merged with the class surrounding the pixel. We defined **Tier**  
264 II Yedoma classes (Yedoma tundra and Yedoma forest) according to the ESA CCI Land cover classes coinciding with  
265 Yedoma deposits (Table 3).

266 The spatial land cover extent was constrained to the Northern Hemisphere permafrost region indicating probability of  
267 permafrost occurrence but not the actual area underlain by permafrost (Obu, 2021). This dataset stretches over

268  $17.9 \times 10^6 \text{ km}^2$  of the Northern Hemisphere, and is based on equilibrium state model for the temperature at the top of  
 269 the permafrost (TTOP) for the 2000–2016 period (Obu et al., 2019).

270 Table 3: Amalgamation of ESA's CCI land cover classes with the Tier class system above the Yedoma deposits.

CCI class	ESA CCI landcover	TIER I class	TIER II class
40	Mosaic natural vegetation (tree, shrub, herbaceous cover) (>50 %)	1	1.1 & 5.2
50	Tree cover, broadleaved, evergreen, closed to open (>15 %)	1	1.1 & 5.2
60	Tree cover, broadleaved, deciduous, closed to open (>15 %)	1	1.1 & 5.2
61	Tree cover, broadleaved, deciduous, closed (>40 %)	1	1.1 & 5.2
70	Tree cover, needleleaved, evergreen, closed to open (>15 %)	1	1.2 & 5.2
71	Tree cover, needleleaved, evergreen, closed (>40 %)	1	1.2 & 5.2
72	Tree cover, needleleaved, evergreen, open (15-40 %)	1	1.2 & 5.2
80	Tree cover, needleleaved, deciduous, closed to open (>15 %)	1	1.3 & 5.2
90	Tree cover, mixed leaf type (broadleaved and needleleaved)	1	1.1 & 5.2
100	Mosaic tree and shrub (>50 %) / herbaceous cover (<50 %)	1	1.1 & 5.2
110	Mosaic herbaceous cover (>50 %) / tree and shrub (<50 %)	1	1.3 & 5.2
120	Shrubland	2	2.1 & 5.1
121	Evergreen shrubland	2	2.1 & 5.1
122	Deciduous shrubland	2	2.1 & 5.1
130	Grassland	2	2.2 & 5.1
140	Lichens and mosses	2	2.2 & 5.1
150	Sparse vegetation (tree, shrub, herbaceous cover) (<15 %)	2	2.1 & 5.1
152	Sparse shrub (<15 %)	2	2.1 & 5.1
160	Tree cover, flooded, fresh or brackish water	3	3.1
180	Shrub or herbaceous cover, flooded, fresh/saline/brackish water	3	3.1
200	Bare areas	5	4.1
201	Consolidated bare areas	5	4.1
202	Unconsolidated bare areas	5	4.1

271  
 272 The upscaling to estimate the total carbon storage in the northern circumpolar permafrost region was performed in  
 273 ArcGIS Pro (ESRI, Redlands, CA, USA) by multiplying the mean SOC storage for each tier Tier I and tier Tier II  
 274 class with the spatial extent of the corresponding CCI land cover class. To determine reasonable error estimates for  
 275 carbon stocks within the permafrost region, we used a spatially weighed 95 % confidence interval (CI) as described  
 276 by Thompson (1992) assuming that our residuals are normally distributed (Hugelius, 2012).

$$277 CI = t * \sqrt{\sum((a_i^2 * SD_i^2)/n_i)} \quad 2$$

278 The CI accounts for the relative spatial extent, carbon stock variations in pedons and number of replicates in each  
 279 upscaling class. Replicates were only considered for pedons reaching the full sampling depth, resulting in fewer

280 replicates [available](#) with increasing sampling depth. In equation 2:  $t$  is the upper  $\alpha/2$  of a normal distribution ( $t \approx 1.96$ ),  
281  $a$  the % of the area;  $SD$  is the standard deviation,  $n$  is to the number of replicates and  $i$  refers the specific Tier class.

282 **3. Results**

283 **3.1 SOC estimates**

284 Using our pedon based dataset, we obtain SOC stock estimates within the northern circumpolar permafrost region of  
285 379.7 and 812.6 Pg for 0–100 cm and 0–300 cm depth, respectively. Table 4 shows mean SOC storage ( $\text{kg C m}^{-2}$ ) and  
286 total SOC stock for all depth increments, including 95 % confidence intervals. The upscaling using this new pedon  
287 data shows that almost half of SOC in the northern circumpolar permafrost region is stored in the top meter. The three  
288 most abundant classes together (deciduous needleleaf forest, shrub tundra and graminoid / forb tundra) occupy 67 %  
289 of the permafrost region (Table 5) and store most of terrestrial SOC in the northern circumpolar region (74 %). The  
290 permafrost wetland class has the largest SOC content to 300 cm with  $112.2 \text{ kg C m}^{-2}$ , but has only a small areal  
291 coverage in the ESA LCC product (1.4 %) which results in a total SOC storage contribution of 3.5 % within the  
292 permafrost region. Figure 3 illustrates the spatial distribution of total SOC storage ( $\text{kg C m}^{-2}$ ) to a depth of 0–100 cm  
293 and 0–300 cm for the circumpolar permafrost region. Spatially, the SOC distribution [in Figure 3](#) is following [the](#) same  
294 pattern and [is highlighting the largest SOC content predominantly in mostly](#) permafrost peatlands in Western Siberia,  
295 Russia and the Nunavut territory in Canada. Despite that, more than 77% of the area has a SOC storage to a depth of  
296 300 cm higher than  $50 \text{ kg m}^{-2}$ .

297 Table 4: Landscape mean and total SOC storage with 95 % CI for the different depth increments for the northern  
298 circumpolar permafrost region, excluding water bodies and permanent snow and ice.

Depth increment	n:	Landscape mean-Mean SOC storage ( $\text{kg C m}^{-2}$ )	95 % CI <sup>a</sup>	Total SOC in Pg	95 % CI <sup>a</sup>
0–30 cm	452	9.0	± 1.4	160.0	± 25
30–50 cm	402	3.9	± 0.5	69.2	± 8
50–100 cm	328	8.4	± 1.4	150.5	± 25
100–200 cm	257	12.4	± 1.9	222.0	± 35
200–300 cm	253	11.8	± 1.7	211.0	± 31
0–100 cm	328	21.3	± 3.2	379.7	± 58
0–300 cm	253	45.5	± 7.6	812.6	± 136

 309      permafrost region. North Pole Lambert azimuthal equal area projection (datum: WGS 84). Base map: Made with  
 310      Natural Earth.

311 **3.2 TN estimates**

312 Our estimates show that the TN stocks down to 100 cm and 300 cm depth in the northern circumpolar permafrost  
313 region are 21.1 Pg and 55.0 Pg, respectively. Table 6 presents the mean and total TN storage for different depth  
314 increments with their 95% confidence interval. As with SOC storage, the most abundant land cover classes (deciduous  
315 needleleaf forest, shrub tundra and graminoid / forb tundra) store most (68 %) of the total TN in the permafrost region.  
316 The land cover classes permafrost and non-permafrost wetlands have the largest TN storage with a mean of up to 7  
317 kg N m<sup>-2</sup> for the 0–300 cm soil depth (Table 7). Figure 4 illustrates the spatial distribution of total TN storage (kg N  
318 m<sup>-2</sup>) for the circumpolar permafrost region for two depth intervals, 0–100 cm and 0–300 cm. The spatial distribution  
319 of TN has a similar pattern to SOC and is highlighting the permafrost peatlands in Western Siberia, Russia and the  
320 Nunavut territory in Canada.

321 Table 6: Mean and total TN storage with 95 % CI for the different depth increments for the northern circumpolar  
322 permafrost region, excluding water bodies and permanent snow and ice.

Depth increment	Landscape mean	Mean TN storage (kg N m <sup>-2</sup> )	95 % CI <sup>a</sup>	Total TN in Pg	95 % CI <sup>a</sup>
0–30 cm	271	0.5	± 0.1	8.1	± 1.5
30–50 cm	250	0.2	± 0.0	4.2	± 0.5

332

333 Figure 4. Estimated total Nitrogen storage ( $\text{kg N m}^{-2}$ ) to a depth of 0–100 cm and 0–300 cm in northern circumpolar  
 334 permafrost region. North Pole Lambert azimuthal equal area projection (datum: WGS 84). Base map: Made with  
 335 Natural Earth.

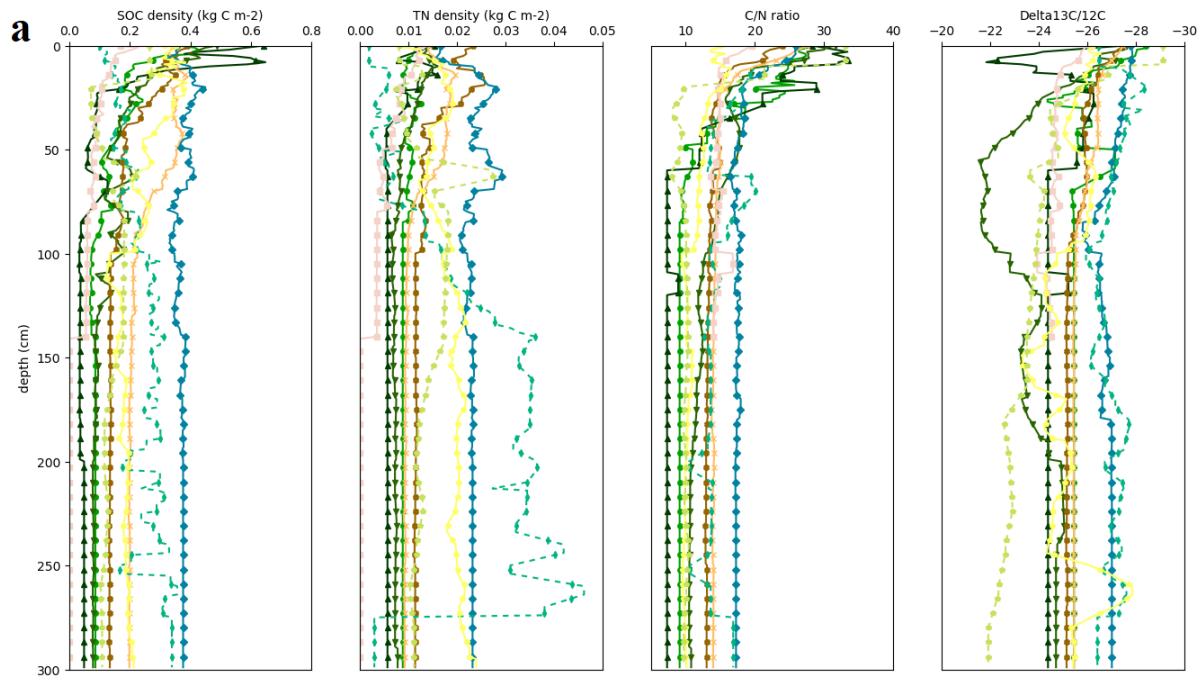

336 **3.3 C/N ratio and  $\delta^{13}\text{C}$**

337 Carbon to nitrogen ratios are often used as an indicator for SOM decomposition. As during the metabolic activity by  
338 microorganisms more carbon than nitrogen is released, the C/N ratio decreases with a higher degree of humification.  
339 This is why C/N ratios usually decrease with depth, as deeper layers are typically older and more decomposed (Kuhry  
340 and Vitt, 1996). Our data confirms this pattern of fast decreasing C/N ratio with depth in all land cover classes to about  
341 50 cm of depth followed by weak decline throughout the full pedon depth (Figure 5 a). The C/N values of SOC rich  
342 top soil organic and peat samples are significantly higher than from the mineral samples ( $p < 0.05$ ). The C/N ratios  
343 together with stable carbon isotopes ( $\delta^{13}\text{C}$ ) can be used to gain insight into the biochemical processes of SOM,  
344 botanical origin with depth and the degradation state (Kracht and Gleixner, 2000). The lowest  $\delta^{13}\text{C}$  values,  
345 predominantly in the upper 50 cm, indicates that this SOM is more easily available for microbial utilization with  
346 lowest values in peatlands connected to differences in hydrology.

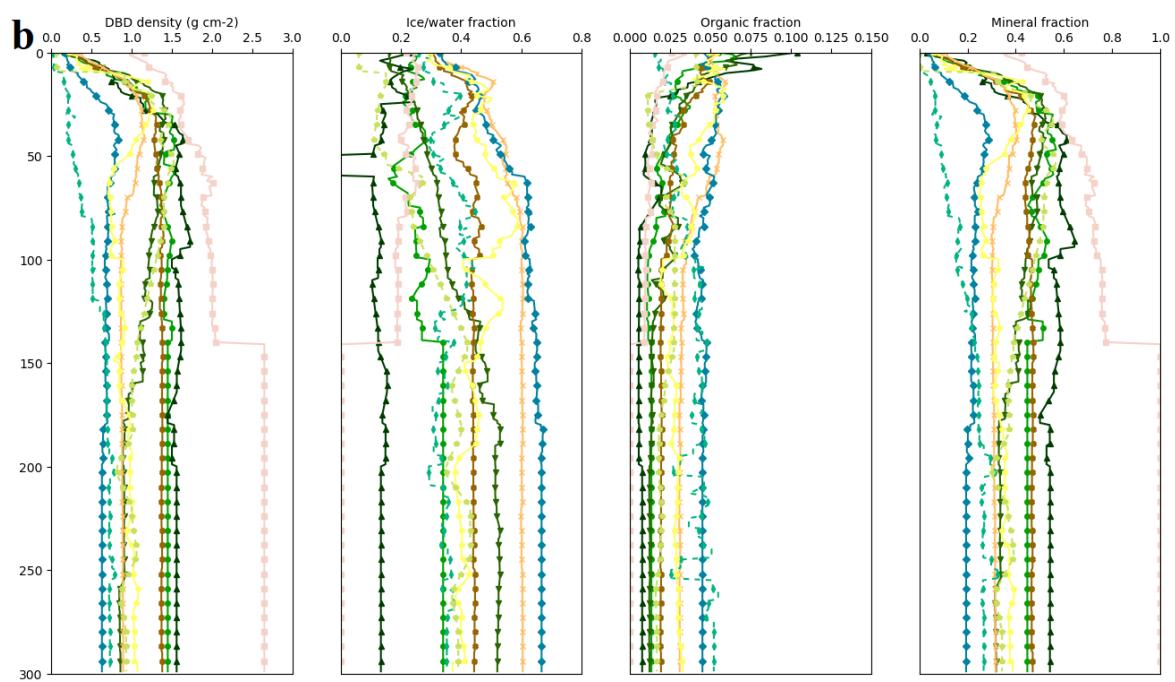

347

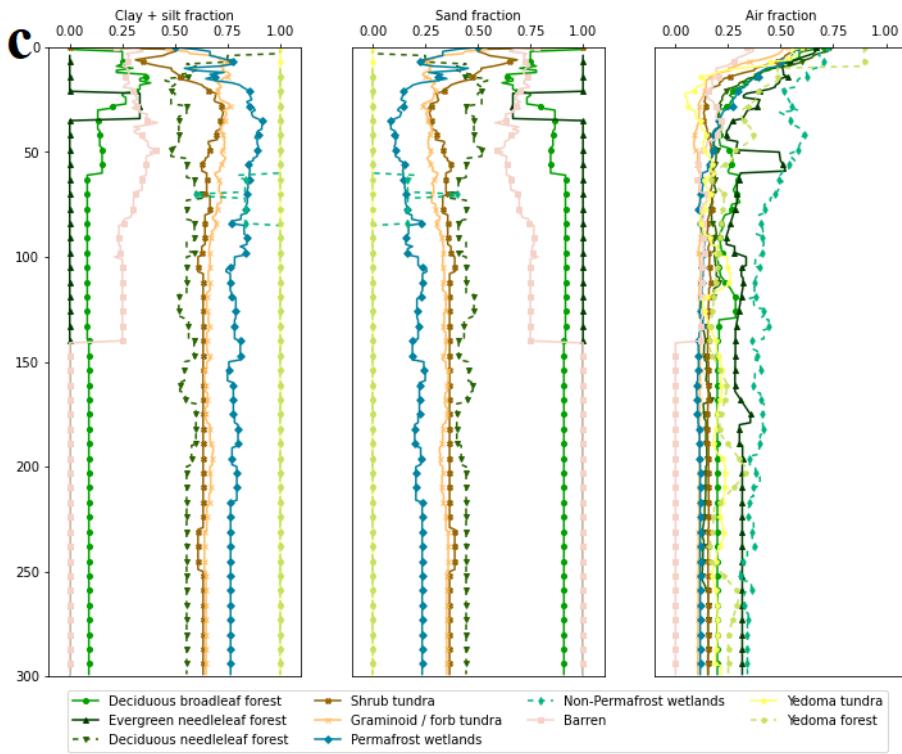

348 **3.3.4 Soil stratigraphies**

349 Figure 5 illustrates averaged vertical soil stratigraphies for SOC and TN density, C/N ratio with  $\delta^{13}\text{C}$ , dry bulk density,  
350 volumetric fractions for water/ice, organic, mineral, air and texture (sand, silt + clay fraction) separated by land cover  
351 class to 300 cm depth. The data shows clear differences occurring in the more variable top meter in comparison to the  
352 rather stable second and third meter with the. With an exception in NonnonPermafrostpermafrost wetlands where  
353 the TN and SOC density is more variable below 100 cm depth, which results from only 2 stratigraphy different  
354 available pedons where TN data is available (Table 7). Instead, tThe Permafrostpermafrost wetland class shows the  
355 highest and rather stableconsistent stratigraphy for SOC and TN density, which is due to the high organic fraction of  
356 these soilsalso supported by the high organic fraction with low DBD and low mineral fraction. In comparison, the  
357 barrenhas the lowest SOC and TN, as these soils are dominated by the coarse mineral fraction Which is the opposite  
358 for the Barren class with low SOC and TN surrounded by mainly coarse mineral fraction and from ca. 140 cm depth  
359 where also even our deepest barren samples reached bedrock. While the stratigraphy for the Yedoma classes proves  
360 the Yedoma typical ice-rich silt sediments visible in the high silt + clay and high water/ice fraction. These important  
361 trends are more evident, e.g. high variability in water fraction between classes or high silt + clay fraction, in Yedoma  
362 tundra. Stratigraphy for DBD shows a strong dependence with the mineral fraction and almost identical soil  
363 stratigraphy.

365

367

368 Figure 5. Typical vertical soil stratigraphies for all the land cover classes to 300 cm depth separated for SOC density,  
 369 TN density, C/N ratio and Delta 13C/12C (a); DBD density, Ice/water fraction, Organic fraction and Mineral fraction  
 370 (b); Clay + silt fraction, Sand fraction and Air fraction (c).

371 **4. Discussion**

372 The goal of the field studies to collect this dataset has mainly been to improve the knowledge base for studies of  
 373 climate feedbacks resulting from permafrost thaw. This new open access database provides georeferenced and quality  
 374 assessed soil profile data to serve different scientific communities. While there are multiple databases available  
 375 containing data on soil carbon storage (Hugelius et al., 2013, Michaelson et al., 2013, Mishra et al., 2021), there is  
 376 still a lack of soil field data covering a wider range of properties within the hard-accessible northern circumpolar  
 377 permafrost region.

378 To test and exemplify usage of the soil profile database, we used our field-based metadata to classify soil profiles  
 379 according to a coherent land cover scheme and combined it with ESA's land cover product to provide a new estimate  
 380 of soil organic carbon storage in the northern circumpolar permafrost region. Our estimate for SOC is  $380 \text{ Pg} \pm 58 \text{ Pg}$   
 381 to 100 cm soil depth and  $813 \text{ Pg} \pm 136 \text{ Pg}$  to 300 cm soil depth for the permafrost region occupying an area of  
 382  $17.9 \times 10^6 \text{ km}^2$  (excluding area of Tibetan permafrost region, permanent snow and ice and water bodies). In  
 383 comparison, Hugelius et al., (2014) estimated SOC stocks in the northern circumpolar permafrost region ( $17.8 \times 10^6$   
 384  $\text{km}^2$  excluding exposed bedrock, glaciers and ice-sheets and water bodies) to be  $472 \pm 27 \text{ Pg}$  and  $1035 \pm 150 \text{ Pg}$  to  
 385 100 cm and 300 cm for soils, respectively. A recent publication by Mishra et al., (2021) based on > 2700 soil profiles

386 with environmental variables in a geostatistical mapping framework, estimated a total SOC stock of 510 Pg (− 78 to  
387 +79 Pg) and 1000 (− 170 to +186 Pg) to 100 cm and 300 cm, respectively. Although our values are a bit lower than  
388 their estimates, they are within each other ~~errorsranges~~. Usage of a different landcover based upscaling approach could  
389 be the cause of some of these differences.

390 Despite the importance of nitrogen for microbial decomposition and plant productivity processes, few large-scale  
391 datasets are available on TN storage. Our TN estimate for the northern circumpolar permafrost region is  $21 \text{ Pg} \pm 5 \text{ Pg}$   
392 to 100 cm soil depth and  $55 \text{ Pg} \pm 15 \text{ Pg}$  to 300 cm soil depth. This is in line with the only other circumpolar estimate  
393 of  $66 \text{ Pg} (\pm 35 \text{ Pg})$  by Harden et al. (2012).

394 According to Kuhry and Vitt (1996), C/N ratios of peat deposits decrease over time due to cumulative anaerobic  
395 degradation while in aerobic environment decomposition and release of CO<sub>2</sub> is lowering the C/N ratios in organic and  
396 mineral soil horizons (Ping et al., 1998). Our data show that the C/N ratios in organic soil horizons and peat layers  
397 were significantly higher than from mineral subsoil horizons. Based on this, we can use the C/N ratio data to assess  
398 the relative degree of SOM decomposition on circumpolar scale. However, C/N ratios and stable carbon isotopes are  
399 affected by the original plant type and climate.

400 A key element to this upscaling exercise is the accuracy of the land cover dataset. Despite the relatively high spatial  
401 resolution of 300 m, many Arctic landscape features cannot be represented at this scale. Although, ESA's land cover  
402 map has a good overall accuracy of 73 %; however, this means that 27 % of the land cover is possibly mismatched  
403 and in need of improvement. Moreover, the accuracy for natural and semi-natural aquatic vegetation, which  
404 corresponds to our wetland class, is unfortunately as low as 19 % which corresponds to our class (wetland). According  
405 to Hugelius et al. (2020), the areal extent of peatlands for the northern permafrost region ( $3.7 \times 10^6 \text{ km}^2$ ) is almost  
406 four times the ESA's land cover product estimated areal extent ( $1.0 \times 10^6 \text{ km}^2$ ). Therefore, wrongly classified areas  
407 would partly explain our lower estimate for SOC and TN on a circumpolar scale since the wetland classes have the  
408 largest SOC and TN contents, particularly at greater depths (100–300 cm). Which is also visible on This is evident ~~e~~ on  
409 maps (Figure 3 and Figure 4) where areas classified as peatlands are clearly standing out with their high SOC and TN  
410 contents. If we exchange the ESA wetland areal coverage for the values from Hugelius et al. (2020) to  $3.7 \times 10^6 \text{ km}^2$   
411 ( $2.0 \times 10^6 \text{ km}^2$  in permafrost-free peatlands and  $1.7 \times 10^6 \text{ km}^2$  permafrost-affected peatlands) and deduct this in  
412 proportion from the other classes, our updated SOC and TN stock to 300 cm soil depth increases from  $813 \text{ Pg} \pm 136$   
413 Pg to  $954 \text{ Pg} \pm 162 \text{ Pg}$  and from  $55 \text{ Pg} \pm 15 \text{ Pg}$  to  $66 \text{ Pg} \pm 22 \text{ Pg}$ , respectively.

414 Even though the current estimates are based on 651 soil pedons from 16 different study areas, there are uncertainties  
415 and data gaps for several regions and ecosystems. With e.g. only one high alpine site and one Yedoma forest site,  
416 several areas are highly underrepresented. Also, the study areas are concentrated in European and Russian locations  
417 which additionally increases the uncertainties in current estimates. Therefore, combining this data with other datasets  
418 especially from North America, Tibet, Yedoma sites and a different wetland extent would substantially reduce  
419 potential error sources and create a more complete picture of SOC and TN storage estimates from land cover based  
420 upscaling. To our knowledge, this is the first product which presents a more complete dataset in regard to variables  
421 on a circumpolar scale that are commonly used to parameterize earth system models. With this database we aim to

422 provide georeferenced point data that can easily be implemented and used for geospatial analysis at a circumpolar  
423 scale. This upscaling approach was chosen because this database can be easily extended with additional sampling  
424 sites, higher-resolution land cover maps that will further increase the resolution on a circumpolar scale. This data can  
425 also be used for upscaling in a particular area of interest. This will assist to quantify and model ongoing pedological  
426 and ecological processes relevant to climate change. Furthermore, this may help identifying regions that are more  
427 vulnerable to permafrost degradation and greenhouse gas release due to knowledge on texture, water/ice content or  
428 SOC storage.

429 **5. Conclusion**

430 This dataset represents a substantial contribution of high-quality soil pedon data and metadata across the northern  
431 permafrost region. Our land cover based estimates of total SOC to 100 cm and 300 cm soil depth are  $380 \text{ Pg} \pm 58 \text{ Pg}$   
432 and  $813 \text{ Pg} \pm 136 \text{ Pg}$ , respectively. In addition, we contribute with novel TN estimates for the different land cover  
433 classes and depth increments. Our TN estimate to 100 cm and 300 cm soil depth are  $21.1 \pm 4.7 \text{ Pg}$  and  $55 \text{ Pg} \pm 15 \text{ Pg}$   
434 which is in line with the only other product available on that scale for TN. Despite a different methodology, are similar  
435 but on the lower edge to other recent numbers. We provide data for a wide range of environments and geographical  
436 regions across the permafrost region including georeferencing and metadata. This serves as a base that can be easily  
437 combined and extended with data from other sources, as several regions are underrepresented (Alaska, Canada, Tibet).  
438 This dataset offers high scientific value as it also contains data on chemical and physical soil properties across the  
439 northern circumpolar permafrost region. This additional data can be used to develop or parametrize broad scale models  
440 and to help better understand different aspects of the permafrost-carbon climate feedback.

441 **6. Data access**

442 Two separated datasets are freely available on the Bolin Centre data set repository (<https://bolin.su.se/data/>). The  
443 dataset (Detailed pedon data on soil carbon and nitrogen for the northern permafrost region,  
444 <https://doi.org/10.17043/palmtag-2022-pedon-1>) (Palmtag et al., 2022a) is a geospatial dataset of physical and  
445 chemical soil properties from 651 soil pedons and the second dataset (A high spatial resolution soil carbon and nitrogen  
446 dataset for the northern permafrost region, <https://doi.org/10.17043/palmtag-2022-spatial-1>) (Palmtag et al., 2022b)  
447 contains GIS grids of the northern circumpolar permafrost region for SOC, TN and C/N ratios for the different depth  
448 increments.

449

450 **Funding**

451 This study was funded through the European Space Agency CCI + Permafrost project (4000123681/18/I-NB), the  
452 European Union Horizon 2020 research and innovation project Nunataryuk (773421), the Changing Arctic Ocean  
453 (CAO) program project CACOON (NE/R012806/1) and the Swedish Research Council (2018-04516).

454

455 **Author contribution**

456 GH, PK, SW and JP designed the concept of the study. JO wrote the script in Python. JP wrote the initial draft of the  
457 manuscript. All authors contributed to the writing and editing of the manuscript.

458 **Competing Interests**

459 The authors declare that they have no conflict of interest.

460 **Acknowledgements**

461 We thank the ESA CCI Land Cover project for providing the data, which was used for upscaling our product to  
462 circumpolar scale.
