29 **Abstract**

30 Excessive anthropogenic nitrogen (N) inputs to the biosphere have disrupted the global nitrogen
31 cycle. To better quantify the spatial and temporal patterns of anthropogenic N enrichments, assess
32 their impacts on the biogeochemical cycles of the planet and other living organisms, and improve
33 nitrogen use efficiency (NUE) for sustainable development, we have developed a comprehensive
34 and synthetic dataset for reconstructing the History of anthropogenic N inputs (HaNi) to the
35 terrestrial biosphere. The HaNi dataset takes advantage of different data sources in a
36 spatiotemporally consistent way to generate a set of high-resolution gridded N input products from
37 the preindustrial to present (1860-2019). The HaNi dataset includes annual rates of synthetic N
38 fertilizer, manure application/deposition, and atmospheric N deposition in cropland, pasture, and
39 rangeland at a spatial resolution of 5-arcmin. Specifically, the N inputs are categorized, according
40 to the N forms and land uses, as ten types: 1) NH_4^+ -N fertilizer applied to cropland, 2) NO_3 -N
41 fertilizer applied to cropland, 3) NH_4^+ -N fertilizer applied to pasture, 4) NO_3 -N fertilizer applied
42 to pasture, 5) manure N application on cropland, 6) manure N application on pasture, 7) manure
43 N deposition on pasture, 8) manure N deposition on rangeland, 9) NH_x -N deposition, and 10) NO_y -
44 N deposition. The total anthropogenic N (TN) inputs to global terrestrial ecosystems increased
45 from 29.05 Tg N yr⁻¹ in the 1860s to 267.23 Tg N yr⁻¹ in the 2010s, with the dominant N source
46 changing from atmospheric N deposition (before the 1900s) to manure N (the 1910s-2000s), and
47 to synthetic fertilizer in the 2010s. The proportion of synthetic NH_4^+ -N fertilizer increased from
48 64% in the 1960s to 90% in the 2010s, while synthetic NO_3 -N fertilizer decreased from 36% in
49 the 1960s to 10% in the 2010s. Hotspots of TN inputs shifted from Europe and North America to
50 East and South Asia during the 1960s-2010s. Such spatial and temporal dynamics captured by the
51 HaNi dataset are expected to facilitate a comprehensive assessment of the coupled human-earth
52 system and address a variety of social welfare issues, such as climate-biosphere feedback, air
53 pollution, water quality, and biodiversity. **Datasets are available at**
54 <https://doi.org/10.1594/PANGAEA.942069> (Tian et al., 2022).

55

56

57

58 1. Introduction

59 Nitrogen (N) is an essential element for the survival of all living organisms, required by various
60 biological molecules, for instance, nucleic acids, proteins, and chlorophyll (Galloway et al., 2021;
61 Schlesinger and Bernhardt, 2020). Most N on the Earth is not readily available for organisms, since
62 it either exists in the form of inert N₂ gas or is stored in crust and sediments (Ward, 2012). Driven
63 by the human demand for food and energy, a spectrum of approaches **has** been developed to
64 produce biologically available N (Sutton et al., 2013; Lassaletta et al. 2016), ranging from traditional
65 methods, such as legume crops cultivation and manure application, to modern techniques, such as
66 industrial compost and the Haber-Bosch process that produce organic fertilizer mixture and
67 chemical fertilizer, **respectively**. Increasing anthropogenic N inputs have significantly boosted
68 crop yield and improved food security (Stewart and Roberts, 2012), but also resulted in over
69 twofold increase in terrestrial reactive N (Galloway and Cowling 2002; Fowler et al. 2013; Melillo,
70 2021; Scheer et al., 2020) and are expected to continually increase in the coming decades due to
71 human demand for food (Kanter et al. 2020; Sutton et al. 2021).

72 The large amount of excessive reactive N in terrestrial ecosystems has led to multiple
73 environmental issues like water quality deterioration, air pollution, global warming, and
74 biodiversity loss (Bouwman et al., 2005; Gruber and Galloway, 2008; Howarth, 2008; Pan et al.,
75 2021; Tian et al., 2020a; Vitousek et al., 1997). The river export of various forms of nitrogen
76 (ammonium, nitrate, dissolved organic N) has largely increased (Schlesinger et al., 2006; Tian et
77 al., 2020b), frequently causing large-scale hypoxia along coastal oceans for example, in the
78 northern Gulf of Mexico (Bargu et al., 2019; Dodds, 2006; Rabalais and Turner, 2019). The global
79 emission of ammonia (NH₃), **a major precursor of aerosols contributing to air pollution**, had rapidly
80 increased from 1.0 Tg N yr⁻¹ in 1961 to 9.9 Tg yr⁻¹ in 2010, mainly due to the wide use of N
81 fertilizer (Xu et al., 2019a). The emissions of nitrous oxide (N₂O), the third most important
82 greenhouse gas, had increased by 30% over the past four decades, which was mainly attributed to
83 N addition to croplands (Cui et al., 2021; Tian et al., 2020a; **Wang et al., 2020**). Moreover,
84 excessive usage of N over other nutrients (e.g. phosphorus) brings nutrient imbalance that may
85 induce significant alterations in the structure and functions of ecosystems and finally result in
86 losses of biodiversity (Galloway et al., 2003; Lun et al., 2018; Peñuelas and Sardans, 2022;
87 Houlton et al., 2019).

88 In light of the critical impacts of N excess on the human-earth system, numerous efforts have been
89 conducted to generate distribution maps of N inputs for different sectors with varied temporal
90 coverage and spatial resolution (Potter et al., 2010; Nishina et al., 2017; Bian et al., 2021; Liu et
91 al., 2010). Country-level N fertilizer data from the Food and Agriculture Organization of the
92 United Nations (FAO) and the International Fertilizer Association (IFA) have been widely used to
93 assess global and national nitrogen budgets for crop production (Xiong et al., 2008; Zhang et al.,
94 2021b; Eickhout et al., 2006). However, spatial variations of N inputs within countries have been
95 overlooked in country-level data, while detailed geospatial distributions of N inputs are required
96 for many process-based modeling studies (Tian et al., 2019, 2018). Potter et al. (2010) and Mueller
97 et al. (2012) both generated crop-specific spatially-explicit N fertilizer data which, however,
98 represented the average fertilizer application patterns around 2000. Liu et al. (2010) developed a
99 N balance model, and made the first attempt to quantify six N inputs (e.g. mineral fertilizer, manure,
100 atmospheric deposition, biological fixation, input from sedimentation, and input from recycled
101 crop residual) and five N outputs (e.g. output to harvested crops, crop residues, leaching, gaseous
102 losses, and soil erosion) in cropland for the year 2000 with a spatial resolution of 5-arcmin. Lu and
103 Tian (2017) created an annual dataset of global N fertilizer application in cropland at a spatial
104 resolution of $0.5^\circ \times 0.5^\circ$ during 1961-2013, and Nishina et al. (2017) further split synthetic N
105 fertilizer application into NH_4^+ and NO_3^- forms. Meanwhile, Zhang et al. (2017) reconstructed
106 global manure N production and application rates in cropland which covered the period 1860-2014
107 and had a resolution of 5-arcmin; using a similar methodology, Xu et al., (2019b) further developed
108 three gridded datasets, i.e., rangeland manure deposition, pasture manure deposition, and pasture
109 manure application, all of which had a resolution of $0.5^\circ \times 0.5^\circ$ and spanned from 1860-2016.
110 Although these datasets are valuable in addressing their respective objective issues, there is a
111 barrier in taking advantage of them simultaneously, due to the inconsistent temporal coverage,
112 spatial resolution, data sources (e.g., N inputs statistics and land use), and spatial allocation
113 algorithms. Therefore, the reconstruction for the History of Anthropogenic N Inputs (HaNi) to the
114 terrestrial biosphere with rich spatial details and long-term coverage is essentially needed.

115 To address this issue, using sophisticated methodologies, we employed multiple statistical data,
116 empirical estimates, atmospheric chemistry model outputs (Eyring et al., 2013), and high-
117 resolution land-use products to generate the HaNi dataset. This comprehensive dataset consists of
118 N fertilizer/manure application to cropland, manure application/deposition to pasture, manure

119 deposition to rangeland, and atmospheric N deposition on all agricultural land at a resolution of 5-
120 arcmin from 1860 to 2019. Additionally, we tried to investigate the impacts of social-economic
121 forcing on N use across different regions. These efforts are anticipated to benefit understanding
122 the spatial and temporal patterns of human-induced N enrichment, assessing impacts of excessive
123 N on global and regional biogeochemical cycles, and providing data support for resource
124 management. The HaNi dataset has also been expected to serve as input data for Earth system
125 models, biogeochemical models, and hydrological models for improving our understanding and
126 assessment of global consequences of anthropogenic nitrogen enrichment for climate change, air
127 and water quality, ecosystems, and biodiversity (e.g. Tian et al., 2018).

128 **2. Methods**

129 **2.1. Data sources of fertilizer/manure use**

130 Multiple anthropogenic N input databases were integrated to generate the HaNi dataset (Table 1).
131 For the period of 1961-2019, annual country-level statistics data was obtained from the FAOSTAT
132 “Land, Inputs and Sustainability” domain (FAO, 2021). “N fertilizer applied to soil” was from the
133 “Fertilizers by Nutrient” subsection. “Manure applied to soil” and “Manure left on pasture” data
134 were from the “Livestock Manure” subsection. Before 1961, the time series of fertilizer and
135 manure use from Holland et al. (2005) was adopted and corrected to be consistent with FAO
136 statistics. For countries (e.g., the former Soviet Union, the Socialist Federal Republic of
137 Yugoslavia, Eritrea, Ethiopia, and the Czechoslovak Republic) that experienced political
138 disintegration, we partitioned their pre-disintegration N fertilizer/manure use into each individual
139 new-formed country using the ratios derived from the N uses of the new-formed countries in the
140 first year after disintegration.

141 The FAOSTAT agricultural use of N fertilizer and manure referred to the N use for crops, livestock,
142 forestry, fisheries, and aquaculture, excluding N use for animal feed. Since the use of N fertilizers
143 and manure for forestry, fisheries, and aquaculture was minor compared to that for crops and
144 livestock, this part was taken as negligible. The partitioning ratio of N fertilizer application to
145 cropland and pasture was adopted from Lassaletta et al. (2014). Since Lassaletta’s ratio values only
146 covered the period of 1961-2009, values in 2009 were used to calculate the N application
147 partitioning after 2009. By FAO’s definition, manure applied to soil was equal to the difference
148 between all treated manure and N loss during stored and treated processes. Therefore, we assumed

149 that the total quantity of manure applied to soil was equal to the total quantity of manure applied
 150 to cropland and pasture. The fraction values for cropland were from Zhang et al. (2015), who
 151 assumed the fraction value ranged between 0.5 and 0.87 for European countries, Canada, and the
 152 U.S., while it was 0.9 for other countries.

153 **Table 1. Summary of main data sources**

Data Source	Dataset	Reference
FAOSTAT	Annual country-level fertilizer and manure inputs to land from 1961 to 2019	FAO (2021)
EARTHSTAT	Fertilizer and manure application rates for major crops	(Mueller et al., 2012) (West et al., 2014)
EARTHSTAT	Harvested area and yield for major crops	(Monfreda et al., 2008)
Hyde3.2/LUHv2	Cropland, Pasture, and rangeland area from 1860 to 2019	(Klein Goldewijk et al., 2017) (Hurt et al., 2020)
Holland et al., 2005	Global fertilizer and manure N from 1860 to 1960	(Holland et al., 2005)
Nishina et al., 2017	Annual NH ₄ and NO ₃ fraction in total fertilizer from 1961 to 2014	(Nishina et al., 2017)
GLW3	Livestock distribution maps	(Gilbert et al., 2018)
Eyring et al. 2013	Monthly atmospheric N depositions (NH _x -N and NO _y -N) during 1850–2014	(Eyring et al., 2013)

154

155

156 **2.2 Land use data**

157 The HYDE3.2 dataset (Klein Goldewijk et al., 2017) provides historical spatial distributions of
 158 cropland, pasture, and rangeland at a 5-arcmin resolution and at an annual time-step after 2000 but
 159 a decadal time-step before the 1990s. In contrast, the LUHv2 dataset (Hurt et al., 2020), derived
 160 mainly from HYDE3.2, has an annual time-step across 1860-2019 but at a relatively low spatial
 161 resolution of $0.25^\circ \times 0.25^\circ$. To reconcile these two datasets, we first conducted a linear
 162 interpolation to HYDE3.2 before 1999 using the data of every two neighbor decades. Then the
 163 fraction of crop/pasture/rangeland of a LUHv2 grid was partitioned into all grid cells of HYDE3.2
 164 that fell in the LUHv2 grid, according to their shares in HYDE3.2. Through this routine, we
 165 obtained a land-use dataset that both kept spatial information of HYDE3.2 and was consistent with
 166 LUHv2 on the total area for each land use type.

167 2.3 Spatializing N fertilizer and manure application in cropland

168 The workflow of spatializing the country-level N fertilizer and manure use amount to gridded maps
169 is shown in Fig 1. First, the grid-level crop-specific N fertilizer and manure use rates per cropland
170 area of 17 dominant crop types (wheat, maize, rice, barley, millet, sorghum, soybean, sunflower,
171 potato, cassava, sugarcane, sugar beet, oil palm, rapeseed, groundnut, cotton, and rye), which were
172 developed by Mueller et al. (2012) and West et al. (2014), were combined with the crop-specific
173 harvested area (Monfreda et al. 2008) to generate baseline distribution maps circa 2000 of fertilizer
174 and manure application in cropland. The crop-area-based average N fertilizer and manure rates in
175 each grid cell (at a resolution of 5-arcmin) were calculated as:

$$176 \quad \overline{C_{fer/man}} = \frac{\sum_i (C_{fer/man,i} \times AH_i)}{\sum_i AH_i} \quad (1)$$

177 where $\overline{C_{fer/man}}$ is the area-weighted average of N fertilizer or manure application rates (i.e.,
178 gridded baseline fertilizer or manure application rate, in the unit of g N m⁻² cropland yr⁻¹).
179 $C_{fer/man,i}$ and AH_i are crop-specific N fertilizer or manure application rate (g N m⁻²) and
180 harvested area (m²), respectively, for crop type i .

181 Second, we used annual country-level N fertilizer and manure application amounts from FAO
182 (1961-2019) and the annual cropland area to scale the baseline year 2000 maps of N fertilizer and
183 manure application rates across time using the following equation:

$$184 \quad R_{fer/man,y,j} = \frac{FAO_{fer/man,y,j}}{\sum_{g=1}^{g=n \text{ in country } j} (\overline{C_{fer/man}} \times AC_{y,g})} \quad (2)$$

185 where $R_{fer/man,y,j}$ is the regulation ratio (unitless) in the year y and country j . $FAO_{fer/man,y,j}$ is
186 country-level total N fertilizer or manure use amount (g N yr⁻¹) on cropland derived from
187 FAOSTAT. $AC_{y,g}$ is the area of cropland (m²) derived from the historical land use data in the year
188 y and grid g . The actual N fertilizer and manure application rates were then calculated using the
189 following equation:

$$190 \quad N_{fer/man} = \overline{C_{fer/man}} \times R_{fer/man,y} \quad (3)$$

191 where $N_{fer/man}$ is the “real” gridded N fertilizer or manure use rates (g N m⁻² cropland yr⁻¹) in
192 the year y .

193 Then, we extended the fertilizer data back to 1925 and manure data back to 1860 using the global
 194 N flux change rates (Holland et al. 2005). Since industrial production of synthetic fertilizer was
 195 developed in the early 1910s, we further extend fertilizer data back by assuming the fertilizer
 196 production linearly increased from 1910 to 1925. Finally, N fertilizer application in cropland was
 197 further divided into the NH_4^+ form the NO_3^- form based on the annual country-level NH_4^+
 198 application ratio in total N fertilizer provided by Nishina et al. (2017). This data was estimated
 199 based on FAOSTAT's consumption data by chemical fertilizer type, which takes into account the
 200 NH_4^+ and NO_3^- content in each fertilizer type individually.

201

202

203 **Figure 1.** The workflow for developing the dataset of global annual N fertilizer and manure
 204 application rates during 1961-2019.

205

206 2.4. Spatializing the total fertilizer and manure N in pasture and rangeland

207 2.4.1. N fertilizer use in pasture

208 Due to the lack of grid-level spatial information of N fertilizer use in pasture, we assumed that
 209 pasture within each country has an even annual N fertilizer use rate. The fertilizer use in pasture
 210 per country was divided by the total pasture area of that country. Then this N fertilizer use rate per
 211 country was assigned to all the pasture grid cells in that country (Fig 2). The detailed method was
 212 introduced in Xu et al. (2019b).

213

214 **Figure 2.** The workflow for developing the global pasture fertilizer application rate data during
 215 1961-2019.

216 **2.4.2. Spatializing manure application in pasture**

217 To generate spatial patterns of manure application in pasture, we first calculated the spatial
 218 distribution of annual manure N production. The Global Livestock of World 3 database (GLW3;
 219 Gilbert et al., 2018) was used as a reference map of livestock distribution, which provided spatial
 220 information for buffaloes, cattle, chickens, ducks, horses, goats, pigs, and sheep at a spatial
 221 resolution of 0.083° in 2010. For the period 1961-2019, the FAO statistics of livestock population
 222 in a country in one year was compared with the sum of GLW3 grid values within that country and
 223 the ratio of the two values was used to scale all the GLW3 grid values of the country to generate
 224 the spatial distribution of livestock in that year (Fig. 3). This routine can be represented as:

225
$$D_{l,c,y}^{FAO} = D_{l,c}^{GLW3} \times \frac{T_{l,c,y}^{FAO}}{T_{l,c}^{GLW3}} \quad (4)$$

226 where $T_{l,c,y}^{FAO}$ indicates the FAO statistics of the population of the l th type of livestock of country c
 227 in year y , $T_{l,c}^{GLW3}$ indicates the national population of the l th type of livestock of country c
 228 summarized from GLW3, $D_{l,c}^{GLW3}$ is the spatial distribution corresponding to $T_{l,c}^{GLW3}$, and $D_{l,c,y}^{FAO}$ is

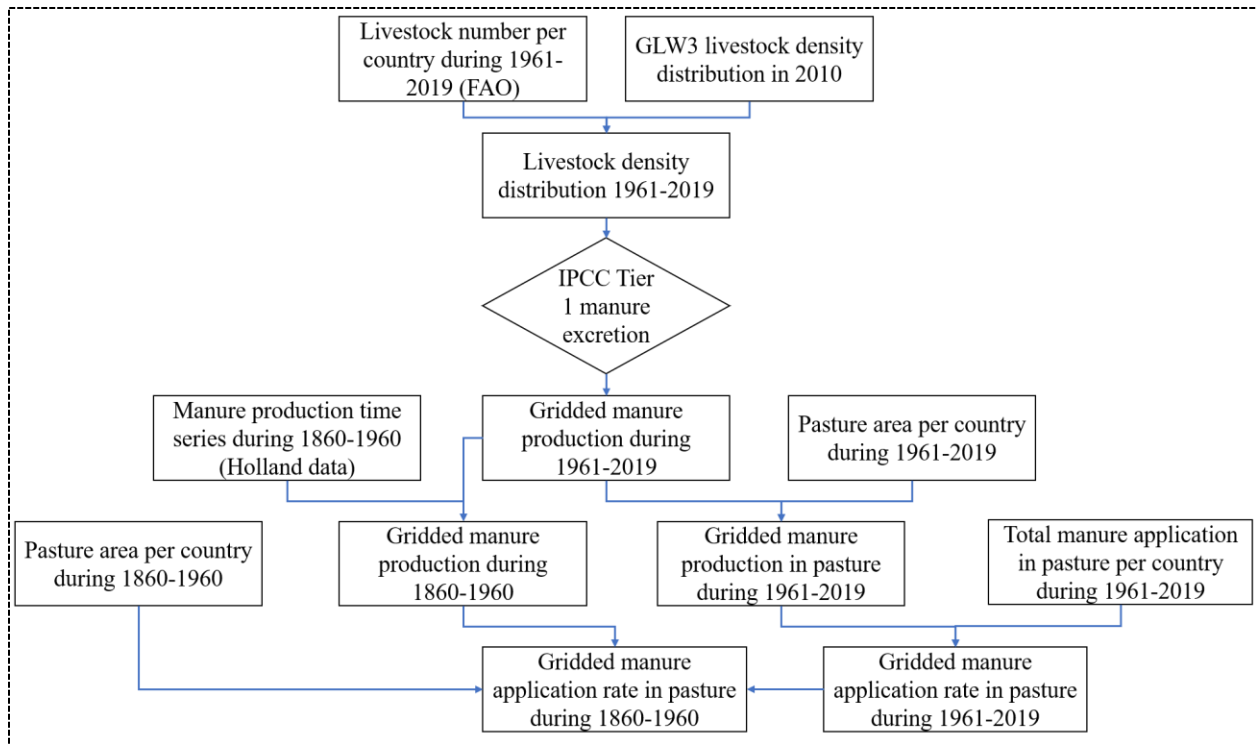

229 the corresponding spatial distribution to $T_{l,c,y}^{FAO}$. Applying the IPCC Tier 1 methodology for N
 230 excretion (Dong et al., 2006) to these derived spatial distribution maps of livestock, we can have
 231 the spatial maps of annual manure production during 1961-2019. Specifically, the average daily N
 232 excretion rate was different for each livestock and for each group of countries, which were
 233 classified by socioeconomic and geographic conditions. All manure production data were
 234 resampled to 5-arcmin to be consistent with the pasture land use data.

235 Manure application to pasture during 1961-2019 is then estimated using manure production and
 236 pasture area (Fig. 3) as:

$$237 \quad R_{c,y}^{Napp/Nprod} = \frac{Napp_{c,y}^{FAO}}{\text{sum}(GNprod_{c,y}^{FAO} \times GParea_{c,y}^{LU})} \quad (5)$$

$$238 \quad GNapp_{c,y}^{FAO} = \text{mask}(R_{c,y}^{Napp/Nprod} \times GNprod_{c,y}^{FAO}, GParea_{c,y}^{LU}) \quad (6)$$

239 where $R_{c,y}^{Napp/Nprod}$ is the ratio of FAO statistics of manure application to pasture in country c in
 240 year y ($Napp_{c,y}^{FAO}$) over the estimated manure production in the same country and the same year,
 241 $GNprod_{c,y}^{FAO}$ is the gridded manure production in country c in year y estimated based on FAO
 242 statistics of livestock data, $GParea_{c,y}^{LU}$ is the gridded pasture area in country c in year y from our
 243 land use data, and $GNapp_{c,y}^{FAO}$ is the corresponding gridded manure application to pasture in
 244 country c in year y through masking the product raster of $R_{c,y}^{Napp/Nprod}$ and $GNprod_{c,y}^{FAO}$ by the
 245 $GParea_{c,y}^{LU}$ raster. The manure application to pasture in year y during 1860-1960 was estimated as
 246 the product of $GNprod_{c,y}^{Holland}$ and $R_{c,1961}^{Napp/Nprod}$ (Fig 3). As for the period 1860-1960, the time
 247 series of manure application data were also generated according to the manure N change rates
 248 derived from Holland et al. (2005).

249

250 **Figure 3.** The workflow for developing the global pasture manure application rate data during
 251 1860-2019.

252

253 2.4.3. Spatializing manure deposition in pasture and rangeland

254 The routine for spatializing FAO statistics of manure deposition on pasture and rangeland was
 255 similar to the method for manure deposition to pasture in Xu et al. (2019b). The only difference is
 256 that the manure deposition intensity on pasture was assumed to be twice that on rangeland within
 257 a grid cell, according to previous research (Campbell and Stafford Smith, 2000). To avoid
 258 inconsistencies between total manure use and total manure production within a grid cell and
 259 unrealistic transport distances, the sum of manure application to cropland and pasture and manure
 260 deposition to pasture and rangeland was constrained to be less than or equal to manure production
 261 within a grid cell. In fact, the case that the total manure use surpassed the total manure production
 262 in a grid cell was rare. If there was, the four components, namely the manure application to
 263 cropland and pasture and manure deposition to pasture or rangeland, were scaled by multiplying
 264 the ratio of their sum over the total manure production within a grid cell.

265 **2.5 Atmospheric nitrogen deposition**

266 Monthly atmospheric N depositions ($\text{NH}_x\text{-N}$ and $\text{NO}_y\text{-N}$) during 1850–2014 were from N
267 deposition fields of model simulations in the International Global Atmospheric Chemistry
268 (IGAC)/Stratospheric Processes and Their Role in Climate (SPARC) Chemistry–Climate Model
269 Initiative (CCMI) (Morgenstern et al., 2017). For the period 2015–2020, N deposition under
270 SSP585 (the highest emission scenario in shared socio-economic pathways) was used, consistent
271 with Dynamic Global Vegetation Model simulations (TRENDY) for the global carbon budget
272 (Friedlingstein et al., 2020). The CCMI models considered N emissions from multiple sources,
273 including anthropogenic and biofuel sources, natural biogenic sources, biomass burning and
274 lightning, and the transport of N gases and wet/dry N deposition (Eyring et al., 2013). The CCMI
275 N deposition data was developed in support of the Coupled Model Intercomparison Project Phase
276 6 (CMIP6) and used as the official products for CMIP6 models that lack interactive chemistry
277 components. The nearest interpolation method was used to resample N deposition data to a spatial
278 resolution of 5-arcmin.

279 **2.6 Regional Analysis**

280 In order to compare anthropogenic N inputs across different regions, we divided the global land
281 area into 18 regions according to national or continental boundaries (Tian et al. 2019). The 18
282 regions are USA, Canada (CAN), Central America (CAM), Northern South America (NSA),
283 Brazil (BRA), Southwest South America (SSA), Europe (EU), Northern Africa (NAF), Equatorial
284 Africa (EQAF), Southern Africa (SAF), Russia (RUS), Central Asia (CAS), Middle East (MIDE),
285 China (CHN), Korea and Japan (KAJ), South Asia (SAS), Southeast Asia (SEAS), and Oceania
286 (OCE).

287 **3. Results**

288 **3.1. Temporal and spatial changes in total anthropogenic N inputs**

289 The total anthropogenic N (TN) inputs to global terrestrial ecosystems increased from 29.05 Tg N
290 yr^{-1} in the 1860s to 267.23 Tg N yr^{-1} in the 2010s (Fig 4 and Table 2). The most rapid increase of
291 total N inputs was 3.53 Tg N yr^{-2} occurred during 1945–1990 driven by both elevated fertilizer
292 application rates and cropland expansion. The TN inputs leveled off within the 1990s, but
293 increased again after 2001 with a lower increasing rate though. The TN inputs were dominated by
294 atmospheric N deposition before the 1900s. Manure N kept an increasing trend, accounting for

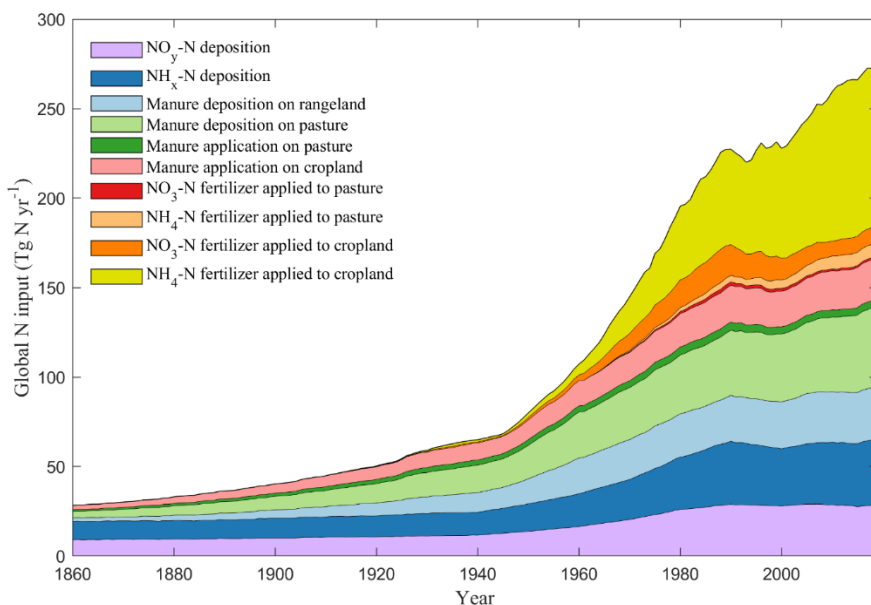

295 more than half of the TN inputs from the 1910s to the 1960s. Thereafter, the proportion of N
 296 fertilizer in TN inputs substantially increased from 15% in the 1960s to 39 % in the 2010s,
 297 meanwhile, the proportions of manure N and atmospheric N deposition decreased from 54% and
 298 31% to 37% and 24%, respectively.

299 Table 2. Decadal average of N inputs into the terrestrial ecosystem (Tg N yr⁻¹)

Decade	Nfer NH ₄ Crop	Nfer NO ₃ Crop	Nfer NH ₄ Pas	Nfer NO ₃ Pas	Nman App Crop	Nman App Pas	Nman Dep Pas	Nman Dep Ran	Ndep NH _x	Ndep NO _y	Total

303
 304 **Figure 4.** Long-term trends of anthropogenic nitrogen inputs to terrestrial ecosystems during 1860-
 305 2019. N input to global terrestrial ecosystems from three major categories: N fertilizer, manure N,
 306 and N deposition, which are further divided into ten specific types, including NH₄-N fertilizer
 307 applied to cropland, NO₃-N fertilizer applied to cropland, NH₄-N fertilizer applied to pasture, NO₃-
 308 N fertilizer applied to pasture, manure N application on cropland, manure N application on pasture,

309 manure N deposition on pasture, manure N deposition on rangeland, $\text{NH}_x\text{-N}$ deposition, and $\text{NO}_y\text{-}$
310 N deposition.

311

312 The TN inputs exhibited high spatial heterogeneity across the globe, associated with the
313 imbalances in regional economic development and population growth (Fig. 5). From the 1860s to
314 the 1910s, the TN inputs mainly increased in the eastern U.S., Europe, and India, driven by the
315 increase in manure N application and deposition. In the 1960s, several hotspots of the TN inputs
316 emerged in Europe (Fig. 5c) where synthetic fertilizer was first widely used. Meanwhile, the TN
317 inputs were also intensified in many regions of the developing countries, such as eastern China,
318 southern Brazil, India, and countries in central Africa, mainly due to the increasing use of manure
319 N (Fig. 5c). As the access to the synthetic N fertilizer became easier, the TN inputs significantly
320 increased across the globe from the 1960s to the 2010s, and the inter-regional imbalance of N
321 inputs had also been amplified, with regions of high N inputs concentrated in eastern and central
322 China, India, Europe, midwestern U.S., and southern Brazil (Fig. 5d).

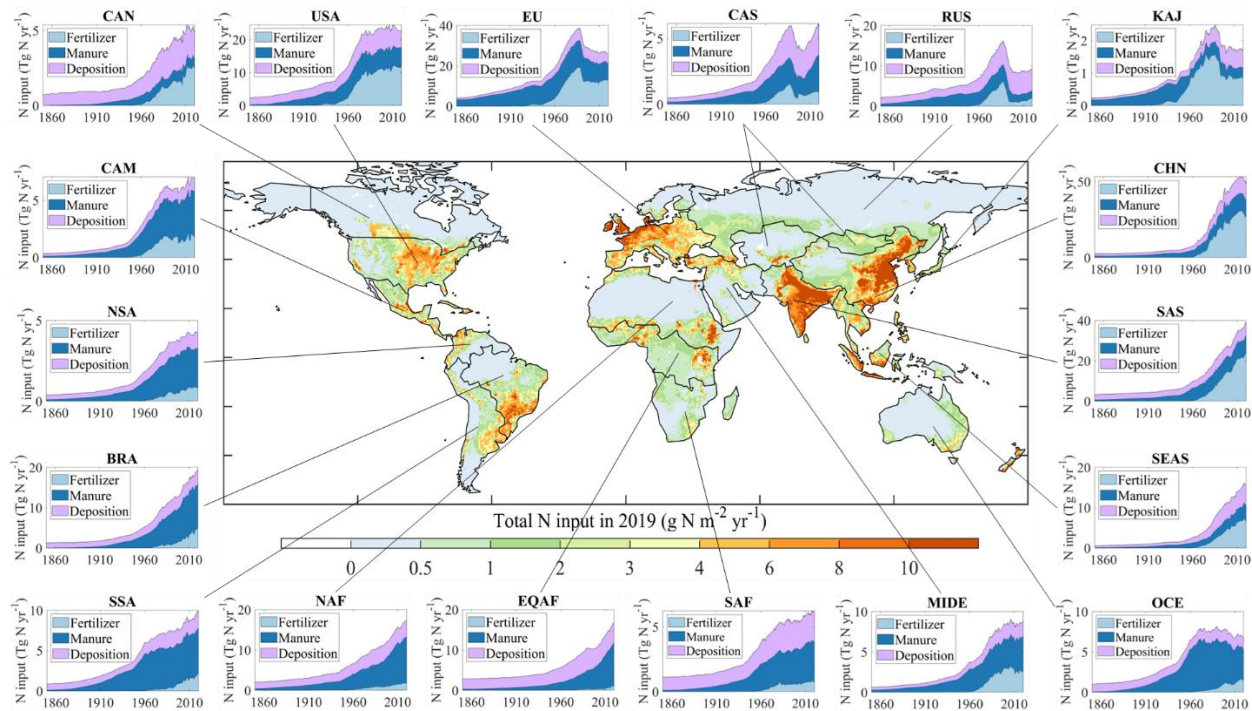

323

324 **Figure 5.** Spatial patterns of total N input in the (a) 1860s, (b) 1910s, (c) 1960s, and (d) 2010s.
325 For the pie chart in the spatial map, the numbers 1-10 represent the percentage of each component,
326 respectively (1. 'NH₄-N fertilizer applied to cropland', 2. 'NO₃-N fertilizer applied to cropland',
327 3. 'NH₄-N fertilizer applied to pasture', 4. 'NO₃-N fertilizer applied to pasture', 5. 'Manure

328 application on cropland’, 6. ‘Manure application on pasture’, 7. ‘Manure deposition on pasture’,
329 8. ‘Manure deposition on rangeland’, 9. ‘NH_x-N deposition’, 10. ‘NO_y-N deposition’).

330

331 Among the 18 regions (Fig 6), the top three regions with the highest TN inputs in 1960 were
332 Europe (19.0 Tg N yr⁻¹), USA (11.8 Tg N yr⁻¹), and South Asia (9.9 Tg N yr⁻¹). From 1960 to 2019,
333 the largest increases in TN inputs were found in China, South Asia, and Brazil, which accounted
334 for 26%, 18%, and 9% of the increase of the global N inputs, respectively. The increasing TN
335 inputs in China and South Asia were mainly driven by the wide use of synthetic fertilizer, while
336 those in Brazil were driven by the use of both livestock manure and synthetic fertilizer. The TN
337 inputs in USA became relatively stable since 1980, whereas the TN inputs in Europe decreased by
338 32% from 1988 to 2019, primarily due to the increase in crop N use efficiency and the reduction
339 in synthetic fertilizer application (Zhang et al., 2021a; Lassaletta et al., 2014). Although the TN
340 inputs in China experienced a rapid increase in recent decades, it started to show a decreasing trend
341 after 2014. However, the TN inputs in South Asia and Brazil continued maintaining a strong
342 growth trend. In 2019, China (49.1 Tg N yr⁻¹) contributed the largest share (18%) to global TN
343 inputs, followed by South Asia (38.9 Tg N yr⁻¹, 14%) and Europe (26.2 Tg N yr⁻¹, 10%). The TN
344 inputs in North America (USA and CAN), Europe (EU), East and South Asia (CHN, KAJ, SAS,
345 and SFAS) were dominated by synthetic fertilizer, while those in Central and South America (BRA,
346 SSA, NSA, and CAM), Africa (NAF, EQAF, and SAF), Central and West Asia (CAS and MIDE),
347 and Oceania (OCE) were dominated by manure. RUS was the only region where atmospheric N
348 deposition was the major anthropogenic N source in 2019.

349
 350 **Figure 6.** Long-term trends and variations of regional N inputs (synthetic fertilizer, livestock
 351 manure, and atmospheric deposition) to terrestrial ecosystems during 1860-2019. The 18 regions
 352 are USA, Canada (CAN), Central America (CAM), Northern South America (NSA), Brazil (BRA),
 353 Southwest South America (SSA), Europe (EU), Northern Africa (NAF), Equatorial Africa (EQAF),
 354 Southern Africa (SAF), Russia (RUS), Central Asia (CAS), Middle East (MIDE), China (CHN),
 355 Korea and Japan (KAJ), South Asia (SAS), Southeast Asia (SEAS), and Oceania (OCE).

356
 357 **3.2. N fertilizer inputs on cropland and pasture**

358 From the 1960s to the 2010s, the N fertilizer inputs on cropland and pasture increased from 18.1
 359 Tg N yr⁻¹ to 105.0 Tg N yr⁻¹. Specifically, N fertilizer inputs on cropland increased from 17.8 Tg
 360 N yr⁻¹ to 96.6 Tg N yr⁻¹, and N fertilizer inputs on pasture increased from 0.3 Tg N yr⁻¹ to 8.5 Tg
 361 N yr⁻¹ (Fig. 4 and Table 2). The proportion of NH₄⁺ fertilizer in N fertilizer increased from 64%
 362 in the 1960s to 90% in the 2010s, contrarily NO₃⁻-N fertilizer decreased from 36% in the 1960s
 363 to 10% in the 2010s. At the regional level, Europe and USA were the top two N fertilizer-
 364 consuming regions in the 1960s, accounting for 38% and 25% of global N fertilizer application,
 365 while China (28%) and South Asia (21%) were the top two in the 2010s (Fig. 6). Fertilizer

366 application rates in China and South Asia increased at a rate of $0.59 \text{ Tg N yr}^{-2}$ and $0.43 \text{ Tg N yr}^{-2}$
367 ($p < 0.05$) during 1960-2019, respectively.

368
369 **Figure 7.** Spatial patterns of N fertilizer application on cropland in the 1960s, 1980s, 2000s, and
370 2010s.

371
372 Fertilizer application rates on cropland in Europe reached the maximum in the 1980s, but fertilizer
373 application rates in India, eastern Asia, and southern Brazil kept increasing continuously (Fig 7).
374 In the 2010s, extremely high N fertilizer inputs ($> 20.0 \text{ g N m}^{-2} \text{ yr}^{-1}$) mainly occurred in eastern
375 and southeastern China. Croplands in northern India and western Europe also had high N fertilizer
376 rates ($> 10.0 \text{ g N m}^{-2} \text{ yr}^{-1}$). N fertilizer application changed slowly in Africa, with most croplands
377 receiving N fertilizer less than $2.0 \text{ g N m}^{-2} \text{ yr}^{-1}$. For pasture, Europe was the main region with N
378 fertilizer application over $6.0 \text{ g N m}^{-2} \text{ yr}^{-1}$ before the 1980s (Fig. S1). N fertilizer application on
379 pasture in southern Canada and India increased significantly with rates over $8.0 \text{ g N m}^{-2} \text{ yr}^{-1}$ in the
380 2010s. Most other regions (e.g., China, U.S., Brazil, Africa) received N fertilizer application of
381 less than $3.0 \text{ g N m}^{-2} \text{ yr}^{-1}$.

382

383

384 3.3. Manure N inputs on cropland, pasture, and rangeland

385 The total manure N inputs to land increased from 9.48 Tg N yr⁻¹ in the 1860s to 98.31 Tg N yr⁻¹ in
386 the 2010s, with an increasing rate of 0.6 Tg N yr⁻² (Fig 4 and Table 2). The manure N application
387 on cropland, manure application on pasture, manure deposition on pasture, and manure deposition
388 on rangeland changed from 14.86 Tg N yr⁻¹ (22% of total manure input), 3.60 Tg N yr⁻¹ (5%),
389 26.99 Tg N yr⁻¹ (41%), and 20.77 Tg N yr⁻¹ (31%) in the 1960s to 22.29 Tg N yr⁻¹ (23%), 4.09 Tg
390 N yr⁻¹ (4%), 43.25 Tg N yr⁻¹ (44%), and 28.68 Tg N yr⁻¹ (29%) in the 2010s, respectively. Europe
391 was the largest contributor (39%) to global manure N inputs in the 1860s, but its share decreased
392 in the last century and became 9% in the 2010s (Fig. 6). The manure N inputs in Brazil grew
393 rapidly from 0.55 Tg N yr⁻¹ (2% of global manure N inputs) in the 1910s to 10.77 Tg N yr⁻¹ (11%)
394 in the 2010s. Similarly, manure N inputs in Equatorial Africa and Northern Africa were only 2.22
395 Tg N yr⁻¹ (3%) and 4.20 Tg N yr⁻¹ (6%) in the 1960s and increased dramatically to 9.40 Tg N yr⁻¹
396 (10%) and 10.60 Tg N yr⁻¹ (11%) in the 2010s, respectively. China was the largest contributor
397 (12%) of global total manure N inputs in the 2010s, while it contributed 8% in the 1960s and 12%
398 in the 1860s.

399
400 **Figure 8.** Spatial patterns of manure N application on cropland in the 1860s, 1910s, 1960s, and
401 2010s.

402

403 Manure application rates on cropland gradually intensified across the globe since the 1860s except
 404 in Australia and part of Africa (Fig. 8). Hotspots of manure application on cropland ($> 6.0 \text{ g N m}^{-2}$
 405 yr^{-1}) first appeared in western Europe in the 1910s, then intensified manure application was
 406 observed in eastern Asia and northern South America in the 2010s. Manure application and
 407 deposition on pasture had higher spatial variability than that on cropland (Fig. 9). Pasture in Europe
 408 and South Asia received higher manure N than that in other regions. Eastern South America,
 409 central Africa, and eastern Asia also experienced a significant increase in manure N inputs on
 410 pasture since the 1910s. For manure deposition on rangeland, South Asia stood out over the study
 411 period, with several other hotspots emerging in central Africa, northern China, Europe, and eastern
 412 South America since the 1910s (Fig 10).

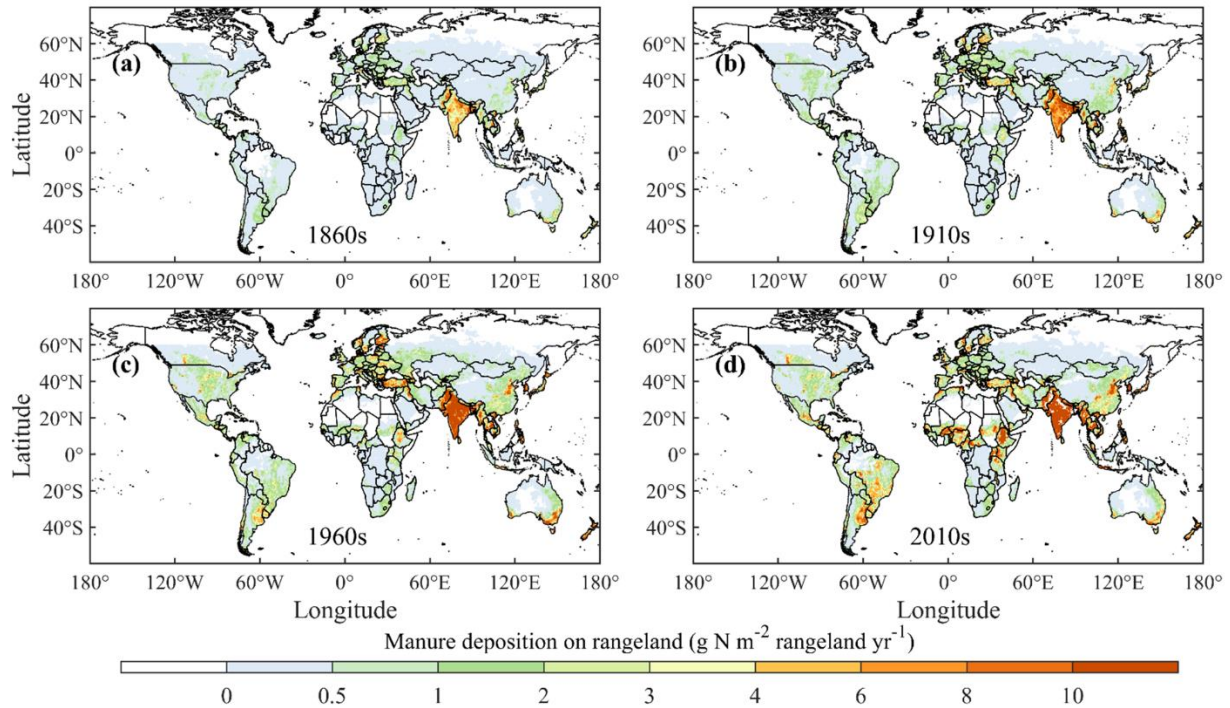

413

414

415 **Figure 9.** Spatial patterns of manure N application and deposition on pasture in the 1860s,
 416 1910s, 1960s, and 2010s.

417

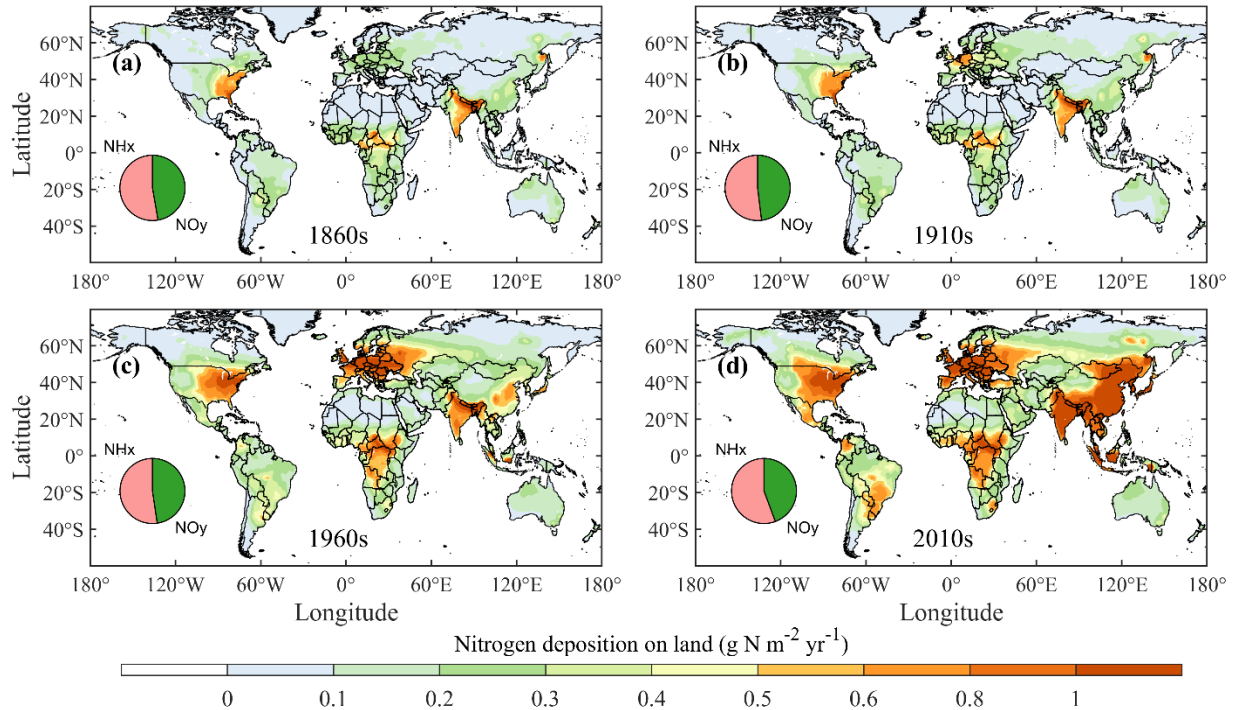

418

419 **Figure 10.** Spatial patterns of manure N deposition on rangeland in the 1860s, 1910s, 1960s, and
 420 2010s.

421 **3.4. Atmospheric N deposition on land**

422 Atmospheric N deposition has a threefold increase from 19.06 Tg N yr⁻¹ to 60.87 Tg N yr⁻¹ during
 423 the 1850s - the 2010s, with NH_x deposition increasing from 10.02 Tg N yr⁻¹ to 35.58 Tg N yr⁻¹ and
 424 NO_y deposition increasing from 9.04 Tg N yr⁻¹ to 28.30 Tg N yr⁻¹ (Fig 4 and Table 2). The share
 425 of NH_x in atmospheric N deposition started to increase after the 1970s, changing from 52% to 56%
 426 in the 2010s. At the regional scale, South Asia, Equatorial Africa, and USA were the largest
 427 contributors in the 1860s, accounting for 13%, 13%, and 12% of global atmospheric N deposition,
 428 respectively (Fig 6). In the 2010s, China was the region with the largest atmospheric N deposition
 429 (10.66 Tg N yr⁻¹, 17% of global atmospheric N deposition), followed by South Asia (5.90 Tg N
 430 yr⁻¹, 9%) and USA (5.69 Tg N yr⁻¹, 9%). Atmospheric N deposition peaked in the 1980s in Europe
 431 and Equatorial Africa, the 1990s in USA, and the 2010s in South Asia and China. Spatially,
 432 atmospheric N deposition intensified and increased dramatically across the globe since the 1910s
 433 (Fig. 11), and regions with high N deposition rates (>1.0 g N m⁻² yr⁻¹) were mainly in Europe,
 434 central Africa, southern Asia, U.S. (since the 1960s), and eastern Asia (in the 2010s).

435
 436 **Figure 11.** Spatial patterns of atmospheric N deposition on land in the 1860s, 1910s, 1960s, and
 437 2010s.

438

439 4. Discussion

440 4.1 Socioeconomic forcing of N use

441 The total anthropogenic nitrogen inputs (excluding N deposition) showed a close relationship with
 442 GDP per capita in all the three agricultural sectors of cropland, pasture, and rangeland (Fig. 12).
 443 These relationships could be generally categorized into three groups: a hump-shaped curve, a rapid
 444 increase curve, and an asymptote curve. The first was typically seen in regions like China and
 445 Europe. China, as the top N consumer, has successfully reduced its nitrogen use for crop
 446 production from the peak of 33.6 Tg yr^{-1} in 2014 to 30.0 Tg yr^{-1} in 2020. Crop production in China
 447 increased in the same period due to the improvements in crop varieties, fertilizer management, and
 448 land use policies (Cui et al., 2018; Wu et al., 2018). The mandatory policies and directives for N
 449 use in Europe since the late 1980s have effectively curbed its N use to a stable level (Van Grinsven
 450 et al., 2014). The second could be seen in South Asia, Southeast Asia, North Africa, etc. These
 451 regions are still in the developing stage and need to tackle the food demand of rapidly growing
 452 population, which, together with low nitrogen use efficiency, results in a surge of nitrogen

453 pollution (Chang et al., 2021). The third could be well represented by USA and Canada. For the
454 USA, although its crop nitrogen use efficiency has considerably improved since the 1990s driven
455 by technological and management improvements (Zhang et al., 2015), its cropland area has kept
456 expanding recently with the new cropland usually producing yields below the national average
457 (Lark et al., 2020), which undermines its efforts for reducing N excess induced environmental
458 pollution. For the same curve type, there also existed obvious differences. For example, the turning
459 points for crop N inputs in Europe and China emerged at varied socioeconomic development levels.
460 Meanwhile, it was difficult to predict when China's crop N inputs would decrease to its lowest as
461 Europe's case had shown. For different sectors of one country or region, their N inputs could also
462 show asynchrony with GDP per capita increases. Take the USA as an instance, its N inputs on
463 cropland and pasture kept growing while its N inputs on rangeland had kept stable. The N input
464 rate-GDP per capita relationships also generally fell into the three groups (Fig. 12). But a notable
465 phenomenon is that N input rate in Korea and Japan was much higher than other regions in almost
466 all the three agricultural sectors (Fig. 12). This is also reported by Lim et al. (2021) and they
467 attributed it to decrease of arable land area, high fertilizer input and especially large manure inputs,
468 although fertilizer input in Korea had been considerably reduced. Despite such a diversity of the
469 N use changes in varied socioeconomic circumstances, the N use/N input rate-GDP per capita
470 relationships and the related spatial patterns will be a valuable reference for any future projection
471 of global anthropogenic N inputs.

472

473

474 **Figure 12.** Relationships between total N inputs (excluding N deposition; the top row) or N input
 475 rate (the bottom row) and GDP per capita in cropland, pasture and rangeland, respectively, within
 476 each of 18 regions during 1961-2019. The lines were fitted using the generalized additive models.
 477 For displaying clarity, not all region names are shown in each panel. The 18 regions are USA,
 478 Canada (CAN), Central America (CAM), Northern South America (NSA), Brazil (BRA),
 479 Southwest South America (SSA), Europe (EU), Northern Africa (NAF), Equatorial Africa (EQAF),
 480 Southern Africa (SAF), Russia (RUS), Central Asia (CAS), Middle East (MIDE), China (CHN),
 481 Korea and Japan (KAJ), South Asia (SAS), Southeast Asia (SEAS), and Oceania (OCE).

482

483 4.2 Implications for nitrogen use management

484 Excessive N use has induced a variety of environmental issues, due to the magnitude, trend and
 485 the constitute forms. In regions or countries like Europe and the US, though the N inputs have been
 486 stable (Fig. 12), the large magnitude of annual N inputs results in a considerable fraction of reactive
 487 N that is stored in soils. This N pool can cause strong legacy effects, of which the influence on

488 water quality would last for decades (Meter et al., 2018). Therefore, maintaining the current levels
489 of N inputs is far from reducing N related environmental issues in these regions or countries (Liu
490 et al. 2016). Instead, agricultural nitrogen inputs are required to be eliminated drastically, which,
491 however, seems rather difficult at the current technological level even the social-economic
492 conditions are improving (Fig. 12). But for regions or countries like South Asia and Southeast Asia,
493 where N inputs have been increasing rapidly, the management options or activities that are
494 successful in Europe or USA can be promoted to inhibit the further increase of anthropogenic N
495 inputs and local N induced pollution. This requires wide international collaboration and efficient
496 coordination between developing countries and developed countries. As for the changes in N input
497 forms, a signal worth noting is the increasing fraction NH_4^+ -N in the global total N inputs (Figs. 7,
498 11, and S1). High NH_4^+ -N fraction has contributed significantly to N induced air pollution (Li et
499 al., 2016), and the change of the ratio of NH_4^+ -N over NO_3^- -N may affect biodiversity (van den
500 Berg et al., 2016) and plant growth (Zhu et al., 2020; Yan et al., 2019). Improved use of NH_4^+ -N
501 will benefit both human society and ecosystems.

502 **4.3 Limitations in data development and knowledge gaps**

503 The uncertainties and limitations of this global N input dataset are mainly derived from the
504 following aspects: (1) Fixed manure excretion rate. The IPCC Tier 1 method adopts a fixed manure
505 excretion rate for each animal and each country, which can bias the manure production estimate.
506 Although the IPCC Tier 2 method is more realistic in reflecting the dynamic energy intake of
507 livestock (Zhang et al., 2022), its parametrization is more difficult. Meanwhile, to be consistent
508 with manure production estimates by Holland et al. (2005), the IPCC Tier 1 method was adopted
509 in this study. (2) Land use maps. Cropland, pasture, and rangeland distribution maps are critical
510 for the spatialization of N fertilizer and manure application. In the data development process, we
511 constrain N input amount of this dataset with the country-level fertilizer/manure consumption from
512 FAO to ensure the total input consistent, but fertilizer use rate per unit cropland area could be
513 significantly biased if the global data differs a lot from the country-specific data. For example, in
514 the US, the higher cropland acreage in HYDE/LUH2 database, compared with the USDA census,
515 is likely to make fertilizer input rate diluted, which could affect the impact assessment of N inputs
516 (Yu and Lu, 2018). (3) Spatial patterns of fertilizer and manure application and deposition rate.
517 The baseline of crop-specific fertilizer and manure use rates is fixed and has been used to determine
518 the spatial patterns of fertilizer and manure inputs over the study period. This conflicts with the

519 reality of inter-and intra-annual dynamics of crop rotation, annual changes in crop harvested area
520 as well as changes in crop-specific fertilizer use rate over time. An ideal spatially explicit fertilizer
521 input data, in the future, ought to consider the dynamics of crop rotation, individual crop area
522 changes, and crop-specific fertilizer use rate over space and time. In addition, the spatial
523 distribution of livestock has greatly changed with industrialization, which would probably lead to
524 changing spatial distributions of total manure over time, given that manure is not usually
525 transported at large distances. (4) Country-level survey data. The country-level fertilizer and
526 manure data from FAO don't separate N application to cropland and pasture. In this study, we
527 separated fertilizer and manure application to cropland and pasture simply based on constant ratios
528 generated by Lassaletta et al. (2014) and Zhang et al. (2015), which ignored either the temporal or
529 the spatial changes of allocation of fertilizer and manure application to cropland and pasture. (5)
530 Pre-1961 N inputs. Since the country-level fertilizer and manure data are only available after 1961,
531 we assumed the change rates of global manure and fertilizer inputs before 1961 followed the
532 change rates of annual global data reported by Holland et al. (2005). (6) Other N sources to
533 terrestrial ecosystems. In this study, the "anthropogenic N inputs" actually do not exclude the
534 natural source of atmospheric N deposition and do not include legume crop biological N fixation
535 (BNF). Leguminous BNF was the most common nitrogen-containing soil fertility maintenance
536 cropping practice before the widespread use of synthetic fertilizer, and is also used in current
537 organic farming practices (Cherr et al., 2006). According to Herridge et al. (2008), the global
538 legume crop BNF was around 21.5 Tg N yr⁻¹ in 2005. Since the HaNi dataset here was developed
539 to serve as inputs for terrestrial biosphere models, N components like BNF, which are simulated
540 using different mechanisms by models, were not included. Nevertheless, a related agricultural BNF
541 database will be much meaningful for deepening our understanding of global N cycling and
542 serving as a benchmark for ecosystem models. To accomplish this, in the future more efforts are
543 required in developing long-term spatial and temporal distribution maps of various crops such as
544 cover crops and legume crops, which are not available at the global scale for now to our knowledge.

545 For future data improvements, we call for advanced N management survey/reporting mechanism
546 to develop fine-scale N consumption or use rate data. For example, the commonly used survey
547 data for the global fertilizer database is country-level consumption amount or crop-specific
548 fertilizer input from IFA and FAO, which smoothed large variations in fertilizer application rate
549 at farm level and sub-national scales. A continuous survey of crop-specific fertilizer and manure

550 use at sub-national scale, development of dynamic global land use data, and crop rotation maps
551 with more precise regional patterns are important for improving the resolution and accuracy of
552 geospatial fertilizer and manure data. Additionally, considering fertilizer and manure application
553 timing in the data is also important for agricultural nutrient management, which relies on the efforts
554 and investigations regarding the fertilizer and manure application behavior at multiple spatial
555 scales.

556 **Data availability**

557 The History of Anthropogenic N Inputs (HaNi) dataset is available at
558 <https://doi.org/10.1594/PANGAEA.942069> (Tian et al., 2022).

559 **Summary**

560 In this work, we developed a global annual anthropogenic N input dataset at 5-arcmin resolution
561 during 1860-2019 by integrating multiple available databases into a uniform framework. This
562 dataset for characterizing the History of anthropogenic N inputs (HaNi) includes major pathways
563 and species of anthropogenic N input to the terrestrial biosphere, such as synthetic fertilizer N use
564 in cropland and pasture, manure N application in cropland and pasture, manure N deposition in
565 pasture and rangeland, and atmospheric N deposition. The TN input to global terrestrial
566 ecosystems raised rapidly since the 1940s due to the widespread usage of synthetic N fertilizer,
567 and the increase started to slow down after 2010. The hotpots of TN inputs shifted from Europe
568 and North America to eastern and southern Asia. The TN inputs in North America, Europe, and
569 East and South Asia were dominated by synthetic fertilizer, while those in Central and South
570 America, Africa, Central, and West Asia, and Oceania were dominated by livestock manure. The
571 N usage varied significantly in different socioeconomic circumstances, but the N use-GDP
572 relationships still could provide a valuable reference for future projection of global anthropogenic
573 N inputs. The HaNi dataset can serve as input data for a wide variety of modeling studies in earth
574 system and its components (land, water, atmosphere and ocean), providing detailed information
575 for the assessment of anthropogenic N enrichment impacts on global N cycling and cascading
576 effects on climate, ecosystem, air and water quality. This data will keep updated in the future.

577

578

579 **Author contributions**

580 H.T. designed this work. Z.B., H.S. and X.Q. performed the study and developed the datasets. N.P.
581 plotted all figures. F.N.T. and G.C. provided the FAO dataset. N.M. provided the crop-specific
582 fertilizer and manure datasets. K.N. provided the fertilizer type dataset. S.P., C.L., and R.X.
583 proposed the methods in the study. All authors contributed to the writing of the manuscript.

584

585 **Competing interests**

586 The authors declare that they have no conflict of interest.

587

588 **Acknowledgments**

589 This study has been partly supported by National Science Foundation (Grant numbers: 1903722;
590 1922687), Andrew Carnegie fellowship Program (Grant No. G-F-19-56910). J.L. acknowledge
591 National Natural Science Foundation of China (Grant no. 41625001), H.S. and X.Q. acknowledge
592 National Key R & D Program of China (grant nos. 2017YFA0604702) and National Natural
593 Science Foundation of China (Grant no. 41961124006). F.N.T. acknowledges funding from FAO
594 regular programme. The views expressed in this publication are those of the author(s) and do not
595 necessarily reflect the views or policies of FAO. K.N. is supported by a project, JPNP18016,
596 commissioned by the New Energy and Industrial Technology Development Organization (NEDO)
597 and a JSPS KAKENHI Grant Number JP18K11672. J.C. is supported by the Fundamental
598 Research Funds for the Central Universities (2021QNA6005). We also thank James Gerber for
599 providing us with the data on crop-specific nitrogen manure application. We especially appreciate
600 the constructive comments and suggestions from Dr. Eduardo Aguilera and Dr. Feng Zhou.
