## Abstract

Surface solar radiation (SSR) is an essential factor in the flow of surface energy, enabling accurate capturing of long-term climate change and understanding the energy balance of Earth's atmosphere system. However, the long-term trend estimation of SSR is subjected to significant uncertainties due to the temporal inhomogeneity and the uneven spatial distribution of the *in-situ* observations. This paper develops an observational integrated and homogenized global-terrestrial (except for Antarctica) stational SSR dataset (SSRIH<sub>station</sub>) by integrating all available SSR observations, including the existing homogenized SSR results. The series ~~are~~ is then interpolated in order to obtain a  $5^{\circ} \times 5^{\circ}$  resolution gridded dataset (SSRIH<sub>grid</sub>). On this basis, we further reconstruct a long-term (1955-2018) global land (except for Antarctica) SSR anomalies dataset with a  $5^{\circ} \times 2.5^{\circ}$  resolution (SSRIH<sub>20CR</sub>) by training improved partial convolutional neural network deep learning methods based on the reanalysis 20CRv3. Based on this, we analysed the global land (except for Antarctica) /regional scale SSR trends and spatiotemporal variations: the reconstruction results reflect the distribution of SSR anomalies and have high reliability in filling and reconstructing the missing values. At the global land (except for Antarctica) scale, the decreasing trend ~~of the of the~~ SSRIH<sub>20CR</sub> ( $-1.276 \pm 0.205$  W/m<sup>2</sup> per decade) is slightly smaller than the trend of the SSRIH<sub>grid</sub> ( $-1.776 \pm 0.230$  W/m<sup>2</sup> per decade) from 1955 to 1991. The trend of SSRIH<sub>20CR</sub> ( $0.697 \pm 0.359$  W/m<sup>2</sup> per decade) from 1991 to 2018 is also marginally lower than that of the SSRIH<sub>grid</sub> ( $0.851 \pm 0.410$  W/m<sup>2</sup> per decade). At the regional scale, the difference between the SSRIH<sub>20CR</sub> and SSRIH<sub>grid</sub> is more significant in years and areas with insufficient coverage. Asia, Africa, Europe and North America cause the global dimming of the SSRIH<sub>20CR</sub>, while Europe and North America drive the global brightening of the SSRIH<sub>20CR</sub>. Spatial sampling inadequacies have largely contributed to a bias in the long-term variation of global /regional SSR. This paper's homogenized gridded dataset and the Artificial Intelligence reconstruction gridded dataset (Jiao and Li, 2023) are all available at <https://doi.org/10.6084/m9.figshare.21625079.v1>.

## 42 **1 Introduction**

43 Energy flows at the Earth's surface play an essential role in climate change and human activity and link  
44 to physical processes such as global warming, glacier retreating, hydrological cycle, and carbon budget  
45 (Hoskins and Valdes, 1990; Peixoto et al., 1992; Trenberth and Fasullo, 2013; Wild, 2012). As a critical  
46 factor characterizing surface energy flows, Surface Solar Radiation (SSR) largely determines the climatic  
47 conditions and ecological environment in which we live. Therefore, a more accurate and comprehensive  
48 analysis of the SSR fluxes will help better understand the Earth's atmospheric system. *In-situ*  
49 observations provide the most accurate baseline data for measuring SSR. They allowed for the first time  
50 the detection of decadal changes in SSR known as “dimming and brightening” (Wild et al., 2005),  
51 especially considering that they cover a longer period concerning another type of data like for example  
52 satellite data (Pfeifroth et al., 2018). ~~even~~ Even if observational data often have uneven distribution and  
53 missing data with respect to the satellite data, especially in areas with complex orography (Manara et al.,  
54 2020).

55 The sources of *in-situ* SSR observations are mainly collected from the Global Energy Balance Archive  
56 (GEBA) (Wild et al., 2017) and the World Radiation Data Centre (WRDC) (Tsvetkov et al., 1995).  
57 Furthermore, other SSR station series are obtained from the high quality Baseline Surface Radiation  
58 Network (BSRN) (Driemel et al., 2018) and the data centres of individual national hydrometeorological  
59 services. However, two issues still need to be addressed: 1) the inhomogeneity of station data resulting  
60 from station relocations and instrumentation changes severely impacts the climate change assessment.  
61 For the regions with a relatively high density of stations, like Europe (Manara et al., 2019; Manara et al.,  
62 2016; Sanchez-Lorenzo et al., 2013a; Sanchez-Lorenzo et al., 2015; Sanchez-Lorenzo et al., 2013b),  
63 Japan (Ma et al., 2022) and China (Ju et al., 2006; Wang, 2014; Wang et al., 2015; Wang and Wild, 2016;  
64 Yang et al., 2018b; You et al., 2013), much previous work has redefined the degree and timing of  
65 “dimming and brightening” by addressing the inhomogeneity of the SSR data series. For example, in  
66 Spain, the average annual homogenized SSR series has a significant increasing trend (+ 3.9 W/m<sup>2</sup> per  
67 decade) during the 1985–2010 period (Sanchez-Lorenzo et al., 2013a). The period of dimming observed  
68 in Italy’s homogenized SSR series is not apparent in the 1960s and early 1970s when the raw series  
69 (inhomogenized) are taken into account (Manara et al., 2016). The direct measurements of SSR show a  
70 level trend from 1961 to 2014 over Japan, while their homogenization series display a decreasing trend

71 (0.8-1.6 W/m<sup>2</sup> per decade) (Ma et al., 2022). In China, homogenization largely eliminated the dramatic  
72 non-climatic rise of the early 1990s and also reduced the increasing trend from 1990 to 2016 (Yang et  
73 al., 2018b). However, most of the research was still limited to regional scales. 2) The issue of limited  
74 spatial sampling of long observational stations and their uneven distribution especially over areas with  
75 complex orography. Considerable efforts have been devoted to filling in /interpolating the missing values  
76 in climate datasets ("spatial analysis") (Collins, 1996; Erxleben et al., 2002; Scudiero et al., 2016). The  
77 traditional spatial interpolation methods commonly used include Inverse Distance Weighted (Fisher et  
78 al., 1993; Shepard, 1968), Kriging (Krige, 1951), Thin-Plate Splines (Bookstein, 1989) et cetera. Since  
79 the 1980s, physical parametric interpolation (Feng and Wang, 2021; Tang et al., 2019) and Bayesian  
80 fusion schemes (Aguilar et al., 2015) based on multi-source observational data were widely used, when  
81 the emergence of highly accurate and relatively precise satellite data. However, the resulting fusion  
82 datasets cover a too short period to investigate their decadal and multi-decadal variations and to study  
83 the underlying causes. The spatial, temporal, and spectral coverage of a single satellite is limited, and  
84 multiple satellite data are therefore often used in tandem with each other; however, such a  
85 discontinuity in time and space can introduce inhomogeneity into a dataset (Evan et al., 2007; Feng  
86 and Wang, 2021; Shao et al., 2022). Reanalysis products are an important complement containing  
87 long-term SSR data, therefore have been widely used in climate studies (Huang et al., 2018; Jiao et  
88 al., 2022; Urraca et al., 2018; Zhou et al., 2018a; Zhou et al., 2017) due to the dynamically consistent  
89 and spatiotemporally complete atmospheric fields with high resolution and open access to data.  
90 However, existing studies have shown that reanalysis products generally overestimate multi-year  
91 mean SSR values compared to observations over land (He et al., 2021). With the continuous  
92 development of climate system simulations, model data from the Coupled Model International  
93 Program (CMIP) have become an important resource for conducting climate change research (Gates  
94 et al., 1999; Zhou et al., 2019). Previous studies have shown that the models used in CMIP6  
95 overestimate the global mean SSR (He et al., 2023; Jiao et al., 2022; Wild, 2020). The rise of deep  
96 learning and big data techniques has brought about an explosion of artificial intelligence (AI). Machine  
97 learning is increasingly being used in spatial interpolation, such as the spatial reconstruction of surface  
98 temperature datasets (Huang et al., 2022; Kadow et al., 2020; Cao et al., 2022), the spatial and temporal  
99 reconstruction of turbulence resolution (Fukami et al., 2021), etc. Furthermore, it shows high accuracy  
100 and low uncertainty in reproducing and predicting SSR (Leirvik and Yuan, 2021; Tang et al., 2016; Yang

101 et al., 2018a; Yuan et al., 2021). However, long-term homogenized SSR datasets with global terrestrial  
102 coverage have yet to be developed, resulting in significant uncertainties in assessing global SSR variation  
103 (Jiao et al., 2022).

104 Therefore, developing a more homogeneous and comprehensive global long-term SSR climatic dataset  
105 that provides a better benchmark for observational constraints on the global surface energy balance  
106 /budget remains a valuable and challenging task. This paper first homogenizes and grids the most  
107 extensive collection of available global SSR station observations. Then, the missing grid boxes /years  
108 are spatially interpolated using a convolutional neural network (CNN) approach to obtain a globally  
109 covered land surface SSR anomalies dataset. Finally, the reconstructed datasets are initially analysed and  
110 evaluated. Thus, the paper is divided into seven main sections. The data resources are introduced in  
111 Section 2. Section 3 presents the data homogenization, and the CNN model reconstruction methods. The  
112 data homogenization and verification are shown in Section 4. Section 5 gives the AI reconstruction results.  
113 Section 6 is the availability of the datasets. Conclusions are provided at the end of the paper.

## 114 **2 Data**

115 Nine SSR datasets are collected to derive the global SSR variable. In particular, six datasets contain data  
116 from observational stations (Section 2.1): two global ground-based measurement datasets (GEBA,  
117 WRDC) and four homogenized products at regional and country levels (Europe, China, Japan and Italy).

118 Three of the adopted datasets are reanalysis data (Section 2.2.1): [Fifth generation European Centre for](#)  
119 [Medium-Range Weather Forecasts \(ECMWF\) reanalysis \(ERA5\)](#), 20th Century Reanalysis version 3  
120 (20CRv3) reanalysis data and the Coupled Model Intercomparison Project Phase 6 (CMIP6) historical  
121 simulation output (125). Specifically, the ERA5 data are used to fill the data over oceans and Antarctica  
122 (Section 3.2.1), 20CRv3 data and CMIP6 simulations are used for the AI model training (Section 5.1)  
123 and reconstruction. All have been listed in Table 1.

### 124 **2.1 In situ observational Data**

#### 125 **2.1.1 Global datasets**

126 There are two main sources of raw SSR data (see Table 1): the ETH Zurich GEBA with monthly data  
127 from 2,445 globally distributed stations, starting from 1922 until 2020, and the WRDC dataset with

128 monthly globally distributed data from 1136 stations since 1964. The first one is available for download  
129 at <https://geba.ethz.ch> (Last access: 2022.7. 2). The second one published the first SSR radiation balance  
130 data in 1965 and then its publication has been issued four times a year since 1993 and is available for  
131 download at <http://wrdc.mgo.rssi.ru/> (Last access: July 2021).

### 132 **2.1.2 National (regional) homogenized station datasets**

#### 133 1) Chinese homogenized SSR dataset

134 The China Meteorological Radiation Fundamental Elements Monthly Value Data Set has been  
135 downloaded at <http://www.nmic.cn>. The homogenized SSR dataset in China is released by the National  
136 Meteorological Information Centre (NMIC), China Meteorological Administration (CMA) (Yang, 2016).  
137 The data are available for the period between Jan 1950 to Dec 2014, and the follow-up data are extended  
138 with raw observations from NMIC. They used the sunshine duration (SSD) data from nearby stations to  
139 construct an arguably better reference to identify inhomogeneities in the SSR data. Then, a combined  
140 metadata and the maximum penalty t-test (PMT) method was used to detect the change points. Finally,  
141 they were adjusted by a quantile matching (QM) algorithm (Wang and Feng, 2013). The final  
142 homogenized SSR station dataset was converted to gridded data using the first difference method (FDM  
143 (Peterson et al., 1998)) and is available for download at <http://www.nmic.cn>. Last Access: September  
144 2022.

#### 145 2) Japanese homogenized SSR dataset

146 Ma et al. (Ma et al., 2022) released a Japanese SSR homogenized dataset in 2022 spanning the period  
147 between 1870 and 2015. First, they homogenized SSD based on PMF (penalized maximal F test) and  
148 QM algorithms. They then used the homogenized SSD from the previous step as a reference series,  
149 combined with metadata and PMT, to detect change points. Finally, they adjusted the change points by  
150 the QM algorithm. For more details on data descriptions, the adopted methodology and downloading  
151 data refer to <https://data.tpsc.ac.cn/en/data/45d73756-3f5a-4d27-82a4-952e268c20e8/>, Last Access:  
152 March 2022.

#### 153 3) European homogenized SSR data

154 A homogenized dataset of European SSR stations was developed by Sanchez-Lorenzo et al. (Sanchez-  
155 Lorenzo et al., 2015) and is currently available as a full public download at  
156 <https://agupubs.onlinelibrary.wiley.com/doi/full/10.1002/2015JD023321>. They selected the 56 longest

157 Central European SSR series available in GEBA dataset with data for the period comprised between  
158 1922 and 2012. They adjusted them to ensure temporal homogeneity homogenizing the data with the  
159 Standard Normal Homogeneity Test (Alexandersson, 1986) and the Craddock test (Craddock, 1979).

160 4) Italian homogenized SSR dataset

161 The Italian homogenized SSR datasets are those published by (Manara et al., 2019; Manara et al.,  
162 2016). As candidate stations to use as reference series, they selected the ten series located in the same  
163 area of the series to be tested and that series correlate well with the test one. In particular, they tested the  
164 change points with the Craddock test (Manara. et al., 2017) and when a break is identified by more than  
165 one reference series the preceding portion of the series is corrected, leaving the most recent portion  
166 unchanged. In this way, the SSR stations were homogenized, and then the missing values were  
167 interpolated.

## 168 **2.2 Other datasets**

### 169 **2.2.1 Reanalysis**

170 ERA5 can be used to fill in SSR data from the oceans and Antarctica and carry out the global  
171 reconstruction, taking into account its high spatial resolution and reliable performance of SSR (Jiao et  
172 al., 2022; Liang et al., 2022). After the reconstruction, we removed the data for the ocean reanalysis and  
173 maintain the data only in the land area (except for Antarctica). In addition, two SSR data products  
174 (20CRv3, CMIP6) are used to train AI models. These are:

175 1) ERA5 (space-filling data): ERA5 is the fifth generation of the European Centre for Medium-Range  
176 Forecasting reanalysis product, which currently publishes data from 1950 to the present (Hersbach et al.,  
177 2020). In addition, ERA5 has an hourly output and an uncertainty estimate from the ensemble. The data  
178 is based on the Integrated Forecasting Model Cy41r2 run in 2016, which contains a 4D-Var assimilation  
179 scheme. In ERA5, SSR is obtained from a Rapid Radiation Transfer Model (RRTM) (Mlawer et al.,  
180 1997). The present study utilizes monthly SSR data for the period 1955-2018 from ERA5 with a  
181 resolution of  $0.25^\circ \times 0.25^\circ$  (last accessed in July 2022). It can be downloaded at  
182 <https://cds.climate.copernicus.eu>

183 2) 20CRv3 (data for AI model training): The 20CR Project is an effort led by NOAA's Physical  
184 Sciences Laboratory and CIRES at the University of Colorado, supported by the Department of Energy,  
185 to produce reanalysis datasets spanning the entire 20th century and much of the 19th century (Slivinski

186 et al., 2019). 20CR provides a comprehensive global atmospheric circulation data set from 1850 to 2015.  
187 Its chief motivation is to provide an observational validation dataset, with quantified uncertainties, for  
188 assessing climate model simulations of the 20th century. 20CR uses an ensemble filter data assimilation  
189 method which directly estimates the most likely state of the global atmosphere every three hours and  
190 estimates the uncertainty in that analysis. The most recent version of this reanalysis, 20CRv3, provides  
191 8-times daily estimates of global tropospheric variability across 75 km grids, spanning 1836 to 2015  
192 (with an experimental extension from 1806 to 1835). The present study uses monthly SSR data of  
193 20CRv3 (NOAA /CIRES /DOE 20CR, 80 members) from 1955-2015. [We selected all 80 members of](#)  
194 [the 20CR as input \(1 for evaluation and to test reconstruction, the other 79 for training the CNN model\).](#)  
195 The SSR of 20CRv3 has a spatial resolution of  $0.7^\circ \times 0.7^\circ$  (Last accessed: May 2022). The download is  
196 available at <https://portal.nersc.gov/archive/home/projects/incite11/>.

### 197 2.2.2 CMIP6 models output

198 3) CMIP6 models output (data for AI model training): the Coupled Model Intercomparison Project,  
199 driven by the World Climate Research Program, is now in its 6th phase. [Specifically, CMIP6 is](#)  
200 [considered as the current state of the art way of producing future climate simulations, including predicting](#)  
201 [future SSR based on different climate scenarios](#) (Zhou et al., 2018b). It provides an [important](#)  
202 [resource](#)~~excellent resource~~ for studying current and future climate change (Eyring et al., 2016). The  
203 historical simulations of CMIP6 are designed to reproduce observed climate and climate change,  
204 constrained by radiative forcing. Its historical simulation spans between 1850 and 2014. In this study,  
205 [we selected 125 members out of a total of 507 members from several CMIP6 large ensemble models](#)  
206 [\(with more than 10 realizations/runs\) with high correlation coefficients with observations as input to train](#)  
207 [and validate the CNN model \(1 for evaluation and to test reconstruction, the other 124 for training the](#)  
208 [CNN model\)](#)~~we selected 125 members from historical simulations of a large sample (a total of 507~~  
209 ~~members). These 125 members match better with the *in situ* observations than the other (507-125)~~  
210 ~~members~~. We selected the monthly downward shortwave radiation from 1955 to 2014 (see Table S1 in  
211 the Supplemental Material (SM)). Last access July 2022. Download at: <https://esgf->  
212 [node.llnl.gov/search/cmip6](https://esgf-node.llnl.gov/search/cmip6).

## 213 3 Methods

### 214 3.1 Data Quality Control (QC) and homogenization

215 The SSR data homogenization method is only applied to the two inhomogenized *in-situ* observations  
216 datasets (GEBA and WRDC). The Quality Control (QC) and homogenization flowchart (Figure 1) is  
217 divided into three steps: 1. QC; 2. Homogenization; 3. Integration and consolidation.

#### 218 3.1.1 QC

219 The QC of SSR data includes the following steps:

220 1) Simple integration: integration of the GEBA (2445) and WRDC (1136) datasets removing stations  
221 with no data and leaving 2681 stations.

222 2) Removing duplicate stations: a. Stations with similar latitude and longitude. We consider two  
223 stations with totally identical latitude and longitude to be the same station; b. Stations less than 10km  
224 apart. We averaged the duplicate stations in this a and b case; c. Special duplicate stations: Stitching  
225 together data of the duplicate stations based on metadata from CMA.

226 3) Remove stations or years /months for which a climatic analysis cannot be established: we remove  
227 stations with records of less than ten years and values more than ~~three~~five times [\(3 \$\sigma\$  criterion \(Olanow  
228 and Koller, 1998\)](#) the standard deviation of the SSR anomalies.

229 4) Candidate stations (487) with a record length greater than 15 years in the period 1971-2000 are  
230 selected. We added stations (715) with more than 10 years of SSR records to increase the number of  
231 available stations for a better homogenization of the candidate stations (Figure 2).

#### 232 3.1.2 Station series homogenization

233 This paper uses the RHtestV4 software package to test and adjust the SSR station data for homogeneity  
234 (<http://etccdi.pacificclimate.org/software.shtml>) (Wang and Feng, 2013). The package is based on the  
235 empirical penalty functions PMF (Wang, 2008b) and PMT (Wang, 2008a; Wang et al., 2007) for the  
236 homogenization test. It takes into account the lag-1 autocorrelation of the time series. It embeds a multiple  
237 linear regression algorithm to significantly reduce the problem of an unbalanced distribution of pseudo-  
238 identification rates and test efficacy. Also, RHtestV4 uses the QM algorithm (Vincent et al., 2012; Wang  
239 et al., 2010) and Mean-Adjustments to adjust the identified change points.

240 The specific steps are as follows:

- 241 1) Building the reference series
- 242 a. We processed the data from all stations series (715) into the annual first differences (FD) series
- 243  $e_i$  (Eq. (1)) (Peterson et al., 1998).
- 244 b. We calculated the correlation of the annual FD series between the series from the potential reference
- 245 pool and the candidate stations.
- 246 c. We calculated the distance between the potential reference pool stations and candidate stations.
- 247 d. We selected potential stations according to the correlation coefficient ( $CC \geq 0.6$ ) between the series
- 248 from potential reference pool and candidate stations. And the potential stations also satisfy the limits in
- 249 distances ( $\leq 500\text{km}$ ) between the potential pool stations and candidate stations.
- 250 e. We obtain the reference FD series ( $Re$ ) based on the  $m$  potential reference series ( $Pe_i$ ) and the CCs
- 251 ( $c_i$ ) between the potential reference series ( $Pe_i$ ) and candidate stations series (Eq. (2)).
- 252 f. The synthesized reference FD series ( $Re$ ) (Eq. (2)), plus the average of all potential reference series
- 253 ( $\bar{R}$ ), yields the final annual reference series ( $R$ ) (Eq. (3)).

$$e_i = x_i - x_{i+1} \quad i=1, 2, \dots, n-1 \quad (1)$$

$$R_e = \frac{\sum_{i=1}^m Pe_i * c_i^2}{\sum_{i=1}^m c_i^2} \quad (2)$$

$$R = R_e + \bar{R} \quad (3)$$

- 254  $e_i$  Annual FD series,
- 255  $x_i$  Raw observational station SSR in the year  $i$ ,
- 256  $Re$  Final reference series,
- 257  $Pe_i$  Potential reference series,
- 258  $c_i$  CC between the potential reference series and the candidate stations series.

259 2) Testing and adjusting the candidate series

260 The homogenization test algorithm used in this paper is the PMT. This method is a reference series-

261 dependent test for a normalized candidate series. It assumes that the linear trend of the time series is zero

262 and uses the degree of mean deviation at different points in the series to find change points. Furthermore,

263 it eliminates the effect of different sample lengths on the test results. At the same time, the method

264 introduces an empirical penalty factor, which effectively improves detection. We used the PMT to test

265 the homogeneity of the candidate series based on the reference series established in 1). We then adjusted

266 the statistically significant( $p>0.05$ ) changepoints obtained using the mean adjustment method ( $p>0.05$ ).  
267 We homogenize the monthly series for 66 stations (see Figure S1 in the SM).

### 268 **3.1.3 Integration and consolidation**

269 As can be seen from Figure 1, the candidate stations (487) are relatively sparse. To better adapt deep  
270 learning methods for the dataset reconstruction later, we adjusted, added and integrated station series  
271 based on the results of homogenized data from other scholars: 1) We added stations with more than 10a  
272 overall (1955-2018) records but no more than 15a during the 1971-2000 period, and removed those  
273 stations that were clearly inhomogeneous (25) and some years of the station (3); 2) We subsequently  
274 integrate monthly SSR series for 116 stations based on the results of homogenization by other scholars  
275 (China (56), Japan (8), Europe (2) and Italy (50)). After the above steps, we end up with a homogenized  
276 dataset containing 944 stations (Figure 3). The details of the processing and classification are shown in  
277 Table S2 (see in the SM).

### 278 **3.2 CNN model reconstruction methods**

279 The CNN deep learning model network architecture uses a U-shaped structure similar to the U-net  
280 (Ronneberger et al., 2015). The advantage of using this model is: 1) both high and low-frequency  
281 information of the picture can be retained, and when reconstructing the SSR data, not only the grid point  
282 information close to the missing measurement point will be considered, but also information from more  
283 distant locations (which may be remotely correlated with that missing measurement point); 2) This makes  
284 the model convergence faster and more economical in terms of computational resources. The upper part  
285 of the U-shaped structure, which has no down samples or a low number of down samples, represents the  
286 high-frequency information of the graph. These sections contain much of the detail in the graph and the  
287 relationships between similar grid points are conveyed by this section. The lower half of the U-shaped  
288 structure is down-sampled more often and represents the lower frequency information of the graph. The  
289 global radiation of a wide range of undulations is transmitted by it, and then the information at the various  
290 levels of the U-shaped structure is connected and transmitted through the skip connection, allowing the  
291 whole network to remember all the information of the picture very well. The model uses nearest  
292 neighbour upsampling in the decoding phase, the skip links will concatenate two feature maps and two  
293 masks as the feature and mask inputs for the next part of the convolution layer. The input to the last part

294 of the convolution layer will contain the original input image concatenated with the holes and the original  
295 mask, allowing the model to replicate the ~~non-hole~~gap-free pixels. The complex and variable nature of  
296 the sea-land boundary then has a significant impact on the reconstruction, when we reconstruct the global  
297 land SSR data. Therefore, we use partial convolution at the image boundaries with a suitable image  
298 padding, ensuring that the padding content at the image boundaries is not affected by values outside the  
299 image. The deep learning models' convolutional layers and loss functions have been described [in SM in](#)  
300 [the SM](#).

301 We further reconstruct a long-term (1955-2018) global SSR anomalies dataset (SSRIH<sub>20CR</sub>) by using  
302 improved partial CNN deep learning methods based on a “perfect” dataset. CNN consists of three parts.  
303 A convolutional layer to reduce the number of weights by extracting local features, a pooling layer to  
304 reduce peakeeping and prevent overfitting, and a fully connected layer to output the desired result. In  
305 this paper, a modified CNN network is used to model the reconstruction of the SSR data, with the  
306 convolutional layer replaced by a partial convolution method and mask update. This method is the latest  
307 in image restoration effects and can restore irregular holes, an advantage over other image restoration  
308 methods that can only restore rectangular holes. Therefore, this paper uses the modified CNN model  
309 (Kadow et al., 2020) to recover the missing part of the global terrestrial SSR (except Antarctica). The  
310 specific reconstruction steps and processes are as in Figure 4.

### 311 **3.2.1 Data pre-processing**

312 The homogenized station data is converted to grid box anomalies using the Climate Anomalies Method  
313 (CAM) (Jones et al., 2001). CAM is a commonly used method for converting station anomaly data to  
314 gridded data. We divide all global areas into a  $5^\circ \times 5^\circ$  grid, after which we calculate the SSR anomalies  
315 (relative to 1923-2020) within the grid box by averaging the anomalies of all stations (at least 1 station  
316 in it). If there are more than one site exists in the same grid box, the record length of this grid box is the  
317 total length of all sites in that grid box. Finally, we removed the values that were more than five-three  
318 times the standard deviation of the SSR anomaly time series after gridding. SSRs are all processed as  
319 daily average anomalies, i.e., monthly anomalies divided by 30 (each month is approximated as 30 days).  
320 We multiplied all the values by 30 again when the reconstruction is complete. The global land (except  
321 for Antarctica) distribution and coverage of SSRs after gridding are shown in Figure 5 a, b.

322 As seen in Figure 5a, the SSR is spatially sparsely distributed across South America and Africa. As  
 323 shown in Figure 5b, SSR coverage increased yearly from 1950 until the mid-1970s, when it slowly  
 324 decreased. In 2013, the coverage rate decreased sharply due to untimely data submission. Considering  
 325 the SSR coverage above, we only kept the years (1955-2018) with data coverage of more than 8% of  
 326 global land (except for Antarctica) areas.

327 Comparisons show that the ERA5 has high spatial resolution and relatively reliable performance in  
 328 the temporal variations and long-term trends (Liang et al., 2022; Jiao et al., 2022). To obtain a higher  
 329 data coverage and ensure that the AI model runs well, we used the ERA5 to fill the SSR of homogenized  
 330 global gridded SSR in the Antarctic and ocean areas. However, if we use the SSR of ERA5 to directly  
 331 fill the SSR of homogenized global gridded SSR ( $SSRIH_{grid}$ ) in the Antarctic and on the ocean areas,  
 332 then the relatively weaker ocean SSR variations (variabilities, decadal changes, trends, etc.) from ERA5  
 333 will inevitably introduce certain systematic biases in land SSR reconstruction due to the SSRs have the  
 334 lower coverage on the land. Therefore, we designed an algorithm to avoid excessive diffusion of SSR  
 335 system bias in terrestrial areas: we first calculated the ratios  $\gamma_i(i=1, 2, 3, \dots, n)$  between the SSR from  
 336 ERA5 and from  $SSRIH_{grid}$  on the land in all  $n$  years. For a single grid box, the  $\gamma_i$  have small changes  
 337 and are regarded as a constant  $\gamma_{median}$  (Eq (4)), and the  $\gamma_{median}$  vary by latitude and longitude both on  
 338 the marine and the land areas. We then extrapolated the  $\gamma_{median}$  for all the grid boxes along the land  
 339 and sea boundaries. If there is no observation there, then the adjacent ocean ERA5 SSR is used to take  
 340 its place after it is adjusted according to the differences between the SSR variations (represented by the  
 341 linear trends) for the different underlying surfaces (Eq (5)).

$$\gamma_{median} = Median\left(\frac{OBS_{i\_land}}{ERA5_{i\_land}}\right), \quad (4)$$

$$OBS_{i\_O\&L}(land) = ERA5_{i\_O\&L}(Ocean) * \gamma_{median} * \frac{T_O}{T_L}, \quad (5)$$

$$i = 1, 2, 3, \dots, n$$

342  $\gamma_{median}$ : The median value of the ratios of OBS and ERA5 land SSR series,

343  $OBS_{i\_land}$ : Land SSR for the year  $i$  from  $SSRIH_{grid}$  in a single grid,

344  $ERA5_{i\_land}$ : Land SSR for the year  $i$  from ERA5 in a single grid,

345  $OBS_{i\_O\&L}(land)$ : Land SSR along the sea-land boundary (land) for the year  $i$  from  $SSRIH_{grid}$ ,

346  $ERA5_{i\_O\&L}(Ocean)$ : Ocean SSR along the sea-land boundary for the year  $i$  from ERA5,

347  $T_O$ : Trend of ERA5 SSR on ocean areas in all  $n$  years,

348  $T_l$ : Trend of ERA5 SSR on areas in all  $n$  years.

### 349 **3.2.2 AI Model reconstruction**

350 We use a server (configured with processor Intel (R) Core (TM) i7-8700 CPU @ 3.20GHz 3.19 GHz,  
351 RAM 32G, 64-bit OS, GPU model 516.94, NVIDIA GeForce 1080T version, Python 3.9.12 64-bit,  
352 CUDA 10.1) for AI models training. The specific training steps are as follows:

353 1) A total of 768 missing value masks (monthly masks between 1955 and 2018) were prepared for  
354 training and validation using '1' for existing and '0' for missing values;

355 2) The 20CRv3 /CMIP6 training set (monthly values between 1955 and 2015 /2014) and missing value  
356 masks are fed into the 20CR-AI /CMIP6-AI model for training;

357 3) We perform 1,500,000 training sessions with an interval of 10,000 sessions for the training output  
358 model.

359 Afterwards, the two AI models are validated against the root mean squared error (RMSE) /CCs of the  
360 reconstructed SSRs ( $SSR_{20CR}/SSR_{CMIP6}$ ). The validation set SSRs, and the optimal number of training  
361 cycles is 1,100,000 (see Figure S2, Figure S3 and Figure S4 in the SM). The initial hyper-parameters of  
362 the model are set as follows; learning rate of  $2e-4$  and learning finetune of  $5e-5$ . [First, we set the batch  
363 size to 16 in the first 500000 iterations and fine-tuned it to 18 in the last 1000000 iterations, for a total  
364 of 1500000 iterations, to suppress the overfitting phenomenon generated during the training process, and  
365 validate the model every 10000 times and early stopping if the validation shows a decreasing trend, the  
366 final number of training times used is 1100000. Second, L2 regularization is also added to regulate the  
367 loss function \(see Eq. \(9\) in the SM\).](#)

368 The training result models generated by the different AI models are obtained separately for the  
369 different training sets. The model is first used to reconstruct a reanalysis validation set with the same  
370 missing value mask as the original observation dataset. This is followed by a validation of the  
371 reconstruction against the original reanalysis dataset (calculation of CC and RMSE) to understand the  
372 discrepancies in the model reconstruction.

## 373 **4 Data homogenization and verification**

374 We homogenized the original monthly stations /gridded SSR time series ( $SSRIH_{station}/SSRIH_{grid}$ ) using  
375 the method in section 3.1.2. We selected six continental regions, excluding Antarctica and the Arctic,

376 from the eight continents of the world defined by Xu et al. (Xu et al., 2018) (Asia, Africa, South America,  
377 Europe, North America, Australia, Antarctica and the Arctic). The decreasing trend of the  $SSRIH_{grid}$  is  
378 consistent with the original gridded SSR series ( $SSRI_{grid}$ ) during 1955-1991 while the increasing trend  
379 during 1991-2018 is weaker. At the regional scale, the  $SSRIH_{grid}$  has a generally similar variation to the  
380  $SSRI_{grid}$ , and the  $SSRIH_{grid}$  is usually more representative of climate change than  $SSRI_{grid}$  at individual  
381 stations.

382 Figure S5 (see in the SM) illustrates the long-term variations of global (Figure S5 (a) in the SM) and  
383 continental land SSR (Figure S5 (b) in the SM) from the  $SSRI_{grid}$  and  $SSRIH_{grid}$  (except for Antarctica)  
384 during 1955-2018. The most prominent change revolves around the adjustment around 1992: the SSR  
385 anomalies were systematically adjusted upward from 1987 to 1992, while the SSR anomalies were  
386 systematically adjusted downward from 1993 onwards. Thus, there is a significant decreasing trend for  
387 both global land  $SSRI_{grid}$  ( $-1.995 \pm 0.251$  W/m<sup>2</sup> per decade) and global land  $SSRIH_{grid}$  ( $-1.776 \pm 0.230$   
388 W/m<sup>2</sup> per decade) (except for Antarctica) from 1955 to 1991. While the increasing trend of the global  
389 land  $SSRIH_{grid}$  from 1991 to 2018 is  $0.851 \pm 0.410$  W/m<sup>2</sup> per decade, slightly smaller than the increasing  
390 trend of the  $SSRI_{grid}$  ( $0.999 \pm 0.504$  W/m<sup>2</sup> per decade). It is worth noting that 1992 happened to be the  
391 second year of the eruption of Mount Pinatubo, and the homogenized SSR data integrated in this paper  
392 may be affected by this event. But overall, the homogenization also has limited effects on the global SSR  
393 variations from Figure S5 (see in the SM), which is consistent with the influence of data homogenization  
394 on a wide range of surface air temperatures (Brohan et al., 2006; Xu et al., 2013).

395 At the regional scale, the differences between the  $SSRIH_{grid}$  and  $SSRI_{grid}$  are more pronounced in Asia  
396 and Europe (see Figure S5(b) in the SM). Asia's homogenized SSR show that the regional average SSR  
397 has been declining significantly over the period 1958-90; this dimming trend mostly diminished over the  
398 period 1991-2005 and was replaced by a brightening trend in the recent decade. The  $SSRIH_{grid}$  in Asia is  
399 higher than the  $SSRI_{grid}$  from 1985 to 1990 and lower than the  $SSRI_{grid}$  from 2012 to 2015. The  $SSRIH_{grid}$   
400 shows a more moderate short-term increase in Europe from 1960 to 1980. Note also that the Australian  
401 raw data prior to 1988 were artificially detrended because at the time the Australia Weather Service was  
402 afraid that the instruments would drift. Therefore, they detrended them and unfortunately did not store  
403 the raw data, and the SSR evolution in Australia is artificial with no trend (Wild et al., 2005). In addition,  
404 the  $SSRI_{station}$  and  $SSRIH_{station}$  comparisons for all 66 stations are shown in Figure S1 (see in the SM).

## 405 5 AI reconstruction and comparison

### 406 5.1 Training of the AI model

407 We produce two (20CRv3 /CMIP6) separate training and validation sets: we select the 1th member  
408 data of the reanalysis data and the model data, respectively, as the validation set, and the remaining 79  
409 (124) ensemble members as the training sets, where each ensemble member included 732 (720) months  
410 of SSR data. Each validation set included 732 (720) samples, while the training sets contained 57828  
411 (89280) ensemble members. All the above data, including the *in-situ* observations, are then resampled to  
412 monthly anomalies of  $5^\circ \times 2.5^\circ$ .

413 We reconstruct the SSR of 20CRv3 /CMIP6 with missing values based on 20CRv3 /CMIP6 datasets  
414 using the method in section 3.2 and obtain two reconstructions,  $SSR_{20CR}$  and  $SSR_{CMIP6}$ , respectively. The  
415 SSR of 20CRv3/CMIP6 with missing values uses the  $SSRIH_{grid}$  mask between 1955 and 2015 /2014. We  
416 compare the global land (except for Antarctica) /regional annual anomalies variation of  $SSR_{20CR}$   
417 / $SSR_{CMIP6}$ . The results show that  $SSR_{20CR}$  is significantly more consistent with the validation set than  
418  $SSR_{CMIP6}$ .

419 Figure 6(a) shows that the RMSE/CC of the  $SSR_{20CR}$  (0.25-247 W/m<sup>2</sup> /0.970 W/m<sup>2</sup>) are smaller /larger  
420 than those of  $SSR_{CMIP6}$  (0.52-518 W/m<sup>2</sup> /0.937 W/m<sup>2</sup>) with the original 20CR /CMIP6 dataset. The  
421 20CR-AI model has a better reconstruction ability for SSR at the global land (except for Antarctica) scale.  
422 The RMSEs of the  $SSR_{20CR}$  ( $SSR_{CMIP6}$ ) are 1.460 (2.413) W/m<sup>2</sup>, 1.44-109 (1.83829) W/m<sup>2</sup>, 2.22-219  
423 (2.60596) W/m<sup>2</sup> and 1.29-286 (2.24235) W/m<sup>2</sup> in North America, Europe, Asia, and Northern  
424 Hemisphere, whereas these values are 1.42-116 (1.77766) W/m<sup>2</sup>, 0.622 (1.602) W/m<sup>2</sup>, 1.88-877 (1.84839)  
425 W/m<sup>2</sup> and 0.772 (1.68679) W/m<sup>2</sup> in South America, Africa, Australia, and Southern Hemisphere  
426 concerning the original 20CR /CMIP6 dataset, respectively. In other words, the RMSEs of the  $SSR_{20CR}$   
427 are smaller than those of  $SSR_{CMIP6}$  for the original 20CR /CMIP6 dataset except for Australia. In  
428 addition, the CCs of the  $SSR_{20CR}$  ( $SSR_{CMIP6}$ ) are 0.96-958 (0.830) W/m<sup>2</sup>, 0.96-958 (0.99987) W/m<sup>2</sup>, 0.89  
429 886 (0.67669) W/m<sup>2</sup>, 0.930 (0.97965) W/m<sup>2</sup>, 0.94-938 (0.930) W/m<sup>2</sup>, 0.943 (0.92916) W/m<sup>2</sup>, 0.94-936  
430 (0.88875) W/m<sup>2</sup> and 0.903 (0.822) W/m<sup>2</sup> in North America, Europe, Asia, Northern Hemisphere, South  
431 America, Africa, Australia, and Southern Hemisphere with respect to the original 20CR /CMIP6  
432 dataset, respectively. That is, the CCs of the  $SSR_{20CR}$  are larger than those of  $SSR_{CMIP6}$  to the original  
433 20CR /CMIP6 dataset except for Europe.

434 Based on the above comparison, the higher uncertainty for CMIP6 model output possibly biases the  
435 CMIP6-AI method. Thus, the accuracy of the SSR<sub>20CR</sub> is higher than that of the SSR<sub>CMIP6</sub> at both global  
436 land (except for Antarctica) and regional scales. Therefore, we choose the reconstruction results of the  
437 20CR-AI model as the final AI reconstruction dataset, and subsequent analysis in the following sections  
438 is only based on this dataset.

## 439 **5.2 Comparison of the spatial and temporal variation characteristics**

440 We investigate the long-term trends and spatial and temporal variation of the SSR<sub>IH<sub>20CR</sub></sub>, compare the  
441 differences between the SSR<sub>IH<sub>20CR</sub></sub> and SSR<sub>IH<sub>grid</sub></sub>, and suggest: the area and magnitude of the high and  
442 low centres of the SSR<sub>IH<sub>20CR</sub></sub> are the same as those of the SSR<sub>IH<sub>grid</sub></sub>; the results of the global land (except  
443 for Antarctica) reconstruction are consistent with "dimming and brightening"; the global dimming is  
444 primarily dominated by decreasing trends in Asia, Europe Africa and North America, whereas Europe  
445 and North America are contributors to the increasing trends.

446 Figure 7 shows the spatial distribution of the SSR<sub>IH<sub>grid</sub></sub> and SSR<sub>IH<sub>20CR</sub></sub> for the three months (July 1960,  
447 July 1980, and July 2000). Figure S6 (see in the SM) displays the spatial distribution of annual SSR<sub>IH<sub>grid</sub></sub>  
448 and SSR<sub>IH<sub>20CR</sub></sub> from 1955 to 2018. Figure 7 also shows the area and the magnitude of the high and low  
449 centres in the SSR<sub>IH<sub>20CR</sub></sub> are the same as in the SSR<sub>IH<sub>grid</sub></sub>. The SSR<sub>IH<sub>20CR</sub></sub> is mainly positive anomalies  
450 in Africa and the Eurasian continent in July 1960, especially in India and the Middle East. Afterwards,  
451 India showed a continuous and steady decline in SSR. This confirms the well-known phenomenon of  
452 global dimming over India (Wild et al., 2009; Soni et al., 2016; Soni et al., 2012; Padma Kumari et al.,  
453 2007; Kambezidis et al., 2012). In Australia, the SSR<sub>IH<sub>20CR</sub></sub> is dominated by negative anomalies in July  
454 1980 and positive anomalies in July 1960 and July 2000. In Greenland, the SSR<sub>IH<sub>20CR</sub></sub> shows a large  
455 positive anomaly during three months. In northern Russia, there is a high value in July 2000. The  
456 reconstruction can better reflect the anomaly distribution of observation information, and the grid boxes  
457 with the missing values are infilled and reconstructed, which has high reliability.

458 Figure 8 illustrates global land (except for Antarctica) annual anomalies variation and long-term trend  
459 of the SSR<sub>IH<sub>20CR</sub></sub> for the period of 1955-2018, 1955-1991 and 1991-2018. [Table S3 in the SM](#)  
460 [demonstrates the trends assessment of global SSR change evaluation in for various data sources global](#)  
461 [SSR change from on different scales](#). Also, we compare the differences between the SSR<sub>IH<sub>20CR</sub></sub> and  
462 SSR<sub>IH<sub>grid</sub></sub>. The minimum value of the SSR<sub>IH<sub>20CR</sub></sub> occurred in 1991 (-2.411 W/m<sup>2</sup>). The decreasing trend

463 of the  $SSRIH_{20CR}$  from 1955 to 1991 ( $-1.276 \pm 0.205$  W/m<sup>2</sup> per decade) is slightly lower than that of the  
464  $SSRIH_{grid}$  ( $-1.776 \pm 0.230$  W/m<sup>2</sup> per decade). After that, the  $SSRIH_{20CR}$  turns to an increasing trend of  
465  $0.697 \pm 0.359$  W/m<sup>2</sup> per decade from 1991 to 2018. This suggests that the difference between  $SSRIH_{20CR}$   
466 and  $SSRIH_{grid}$  may be caused by the results observed in limited data coverage (such as in Africa and  
467 North America) (Figure 9). After homogenization and reconstruction, the trend ( $-1.276$  W/m<sup>2</sup> per decade)  
468 from 1955 to 1991 corresponds to an overall reduction of  $-4.6$  W/m<sup>2</sup> over the dimming period, while that  
469 ( $0.697$  W/m<sup>2</sup> per decade) from 1991 to 2018 correspond to an overall increase of  $2$  W/m<sup>2</sup> over the  
470 brightening period. This is in amazing agreement with the  $-4$  W/m<sup>2</sup> for the dimming period and the  $2$   
471 W/m<sup>2</sup> for the brightening period based on an overall surface energy budget assessment ((Wild, 2012) see  
472 their Figure 1). Also, similar conclusions (incomplete coverage of observational data lead to an  
473 underestimation of global warming trends) have been confirmed in global warming research (Gulev et  
474 al., 2021; Li et al., 2021).

475 Figure 9 demonstrates the long-term annual anomaly variations of the  $SSRIH_{20CR}$  in different regions  
476 and its results compared to the  $SSRIH_{grid}$ . [Table S4 in the SM shows the trends-evaluation in continental  
477 and hemispheric  \$SSRIH\_{20CR}\$  change trends from on different scales.](#) The  $SSRIH_{20CR}$  shows a similar  
478 annual anomaly variation to the global land (except for Antarctica) average trend in North America and  
479 Asia, reaches a minimum in the late 1970s or early 1990s, and follows a moderate reversal. In Europe,  
480 the  $SSRIH_{20CR}$  shows a decrease ( $-2.180 \pm 1.866$  W/m<sup>2</sup> per decade) between 1963 and 1978 before  
481 turning to brightening ( $1.081 \pm 0.312$  W/m<sup>2</sup> per decade). In South America and Australia (Southern  
482 Hemisphere), the  $SSRIH_{20CR}$  shows no significant variation. In Africa, the  $SSRIH_{20CR}$  has a dimming  
483 trend ( $-1.506 \pm 0.496$  W/m<sup>2</sup> per decade) from the 1950s to the 1990s, after which it remains levelled off  
484 ( $0.340 \pm 0.998$  W/m<sup>2</sup> per decade). The  $SSRIH_{20CR}$  shows a decreasing trend ( $-1.457 \pm 0.246$  W/m<sup>2</sup> per  
485 decade) until the 1990s in the Northern Hemisphere and a brightening ( $0.887 \pm 0.415$  W/m<sup>2</sup> per decade)  
486 afterwards. The annual average anomaly variations in regions and globally show that Asia, Africa,  
487 Europe and North America are the four contributors to the global dimming, while Europe and North  
488 America are two major contributors to the “brightening”. This is in general agreement with the results  
489 obtained by previous machine learning (Yuan et al., 2021). In addition, the discrepancy between the  
490  $SSRIH_{20CR}$  and  $SSRIH_{grid}$  is more significant in low-coverage areas (right) than in high-coverage regions  
491 (left). It is particularly pronounced before 1980 and in South America. This suggests that the limited  
492 surface observations are not representative of the continental variation in SSR.

493 To sum up, the AI reconstruction of this paper helps to decrease the uncertainties in SSR variations in  
494 both spatial scales. Further, it shows that there may be a sampling error in the variations of the global  
495 land (except for Antarctica) and regional SSR before reconstruction, leading to a systematic deviation in  
496 the long-term trend of global land (except for Antarctica) or regional SSR.

## 497 **6 Data availability**

498 Both the SSRIH<sub>grid</sub> (the homogenized monthly gridded SSR data over 1923-2020) and the SSRIH<sub>20CR</sub>  
499 (the monthly 20CR-AI model reconstructed SSR data for 1955-2018) are currently publicly available on  
500 the figshare website under DOI at <https://doi.org/10.6084/m9.figshare.21625079.v1> (Jiao and Li, 2023).  
501 These datasets are also available at <http://www.gwpu.net> for free.

## 502 **7 Conclusion**

503 In this study, we integrate global station observations based on the raw observational SSRs from GEBA  
504 and WRDC, combined with existing homogenized SSR datasets from other scholars. Also, we  
505 homogenize the globally distributed station data using the RHtestV4 software package. An improved  
506 CNN deep learning algorithm is subsequently used to reconstruct the SSR anomalies. Thus, a  
507 reconstructed SSR anomaly dataset, SSRIH<sub>20CR</sub>, is obtained based on training sets (20CRv3), for the  
508 years 1955-2018, with a resolution of  $5^{\circ} \times 2.5^{\circ}$ . The main results are as follows:

509 1) The first integrated and homogenized global SSR monthly dataset is developed, which contains 944  
510 stations in total and covers the longest periods (from the 1920s to recent years). A  $5^{\circ} \times 5^{\circ}$  grid boxes  
511 version of the monthly SSR anomalies dataset is derived.

512 2) This paper develops  $5^{\circ} \times 2.5^{\circ}$  full-coverage monthly land (except for Antarctica) SSR anomalies  
513 reconstructed datasets based on the above observations, using the 20CRv3 to train the AI model.  
514 Comparative validations /evaluations show that the SSRIH<sub>20CR</sub> provides a reliable benchmark for global  
515 SSR variations.

516 3) On average, the global annual SSR variations based on the SSRIH<sub>grid</sub> are not significantly different,  
517 except that the increasing (brightening) trend after 1991 is a little smaller for the latter. The short-term  
518 brightening SSR in Europe from the 1970s- to the 1980s disappear at the regional scale. At the same time,  
519 the brightening SSR after the 1990s in Asia slowed or postponed.
