Surface solar radiation (SSR) is an essential factor in the flow of surface energy, enabling accurate capturing of long-term climate change and understanding the energy balance of Earth's atmosphere system. However, the long-term trend estimation of SSR is subjected to significant uncertainties due to the temporal inhomogeneity and the uneven spatial distribution of the *in situ* observations. This paper develops an observational integrated and homogenized global-terrestrial (except for Antarctica) stational SSR dataset (SSRIH_{station}) by integrating all available SSR observations, including the existing homogenized SSR results. The series is then interpolated in order to obtain a $5^{\circ} \times 5^{\circ}$ resolution gridded dataset (SSRIH_{grid}). On this basis, we further reconstruct a long-term (1955-2018) global land (except for Antarctica) SSR anomalies dataset with a $5^{\circ} \times 2.5^{\circ}$ resolution (SSRIH_{20CR}) by training improved partial convolutional neural network deep learning methods based on the reanalysis 20CRv3. Based on this, we analysed the global land (except for Antarctica) /regional scale SSR trends and spatiotemporal variations: The reconstruction results reflect the distribution of SSR anomalies and have high reliability in filling and reconstructing the missing values. At the global land (except for Antarctica) scale, the decreasing trend of the SSRIH_{20CR} (-1.276 ± 0.205 W/m² per decade) is smaller than the trend of the SSRIH_{grid} (-1.776 ± 0.230 W/m² per decade) from 1955 to 1991. The trend of SSRIH_{20CR} (0.697 ± 0.359 W/m² per decade) from 1991 to 2018 is also marginally lower than that of the SSRIH_{grid} (0.851 ± 0.410 W/m² per decade). At the regional scale, the difference between the SSRIH_{20CR} and SSRIH_{grid} is more significant in years and areas with insufficient coverage. Asia, Africa, Europe and North America cause the global dimming of the SSRIH_{20CR}, while Europe and North America drive the global brightening of the SSRIH_{20CR}. Spatial sampling inadequacies have largely contributed to a bias in the long-term variation of global /regional SSR. This paper's homogenized gridded dataset and the Artificial Intelligence reconstruction gridded dataset (Jiao and Li, 2023) are all available at <https://doi.org/10.6084/m9.figshare.21625079.v1>.

40 **1 Introduction**

41 Energy flows at the Earth's surface play an essential role in climate change and human activity and link
42 to physical processes such as global warming, glacier retreating, hydrological cycle, and carbon budget
43 (Hoskins and Valdes, 1990; Peixoto et al., 1992; Trenberth and Fasullo, 2013; Wild, 2012). As a critical
44 factor characterizing surface energy flows, Surface Solar Radiation (SSR) largely determines the climatic
45 conditions and ecological environment in which we live. Therefore, a more accurate and comprehensive
46 analysis of the SSR fluxes will help better understand the Earth's atmospheric system. *In situ* observations
47 provide the most accurate baseline data for measuring SSR. They allowed for the first time the detection
48 of decadal changes in SSR known as “dimming and brightening” (Wild et al., 2005), especially
49 considering that they cover a longer period concerning another type of data like for example satellite data
50 (Pfeifroth et al., 2018). Even observational data often have uneven distribution and missing data with
51 respect to the satellite data, especially in areas with complex orography (Manara et al., 2020).

52 The sources of *in situ* SSR observations are mainly collected from the Global Energy Balance Archive
53 (GEBA) (Wild et al., 2017) and the World Radiation Data Centre (WRDC) (Tsvetkov et al., 1995).
54 Furthermore, other SSR station series are obtained from the high quality Baseline Surface Radiation
55 Network (BSRN) (Driemel et al., 2018) and the data centres of individual national hydrometeorological
56 services. However, two issues still need to be addressed: 1) the inhomogeneity of station data resulting
57 from station relocations and instrumentation changes severely impacts the climate change assessment.
58 For the regions with a relatively high density of stations, like Europe (Manara et al., 2019; Manara et al.,
59 2016; Sanchez-Lorenzo et al., 2013a; Sanchez-Lorenzo et al., 2015; Sanchez-Lorenzo et al., 2013b),
60 Japan (Ma et al., 2022) and China (Ju et al., 2006; Wang, 2014; Wang et al., 2015; Wang and Wild, 2016;
61 Yang et al., 2018b; You et al., 2013), much previous work has redefined the degree and timing of
62 “dimming and brightening” by addressing the inhomogeneity of the SSR data series. For example, in
63 Spain, the average annual homogenized SSR series has a significant increasing trend (+ 3.9 W/m² per
64 decade) during the 1985–2010 period (Sanchez-Lorenzo et al., 2013a). The period of dimming observed
65 in Italy’s homogenized SSR series is not apparent in the 1960s and early 1970s when the raw series
66 (inhomogenized) are taken into account (Manara et al., 2016). The direct measurements of SSR show a
67 level trend from 1961 to 2014 over Japan, while their homogenization series display a decreasing trend
68 (0.8-1.6 W/m² per decade) (Ma et al., 2022). In China, homogenization largely eliminated the dramatic

69 non-climatic rise of the early 1990s and also reduced the increasing trend from 1990 to 2016 (Yang et
70 al., 2018b). However, most of the research was still limited to regional scales. 2) The issue of limited
71 spatial sampling of long observational stations and their uneven distribution especially over areas with
72 complex orography. Considerable efforts have been devoted to filling in /interpolating the missing values
73 in climate datasets ("spatial analysis") (Collins, 1996; Erxleben et al., 2002; Scudiero et al., 2016). The
74 traditional spatial interpolation methods commonly used include Inverse Distance Weighted (Fisher et
75 al., 1993; Shepard, 1968), Kriging (Krige, 1951), Thin-Plate Splines (Bookstein, 1989) et cetera. Since
76 the 1980s, physical parametric interpolation (Feng and Wang, 2021; Tang et al., 2019) and Bayesian
77 fusion schemes (Aguiar et al., 2015) based on multi-source observational data were widely used, when
78 the emergence of highly accurate and relatively precise satellite data. However, the resulting fusion
79 datasets cover a too short period to investigate their decadal and multi-decadal variations and to study
80 the underlying causes. The spatial, temporal, and spectral coverage of a single satellite is limited, and
81 multiple satellite data are therefore often used in tandem with each other; however, such a
82 discontinuity in time and space can introduce inhomogeneity into a dataset (Evan et al., 2007; Feng
83 and Wang, 2021; Shao et al., 2022). Reanalysis products are an important complement containing
84 long-term SSR data, therefore have been widely used in climate studies (Huang et al., 2018; Jiao et
85 al., 2022; Urraca et al., 2018; Zhou et al., 2018a; Zhou et al., 2017) due to the dynamically consistent
86 and spatiotemporally complete atmospheric fields with high resolution and open access to data.
87 However, existing studies have shown that reanalysis products generally overestimate multi-year
88 mean SSR values compared to observations over land (He et al., 2021). With the continuous
89 development of climate system simulations, model data from the Coupled Model International
90 Program (CMIP) have become an important resource for conducting climate change research (Gates
91 et al., 1999; Zhou et al., 2019). Previous studies have shown that the models used in CMIP6
92 overestimate the global mean SSR (He et al., 2023; Jiao et al., 2022; Wild, 2020). The rise of deep
93 learning and big data techniques has brought about an explosion of artificial intelligence (AI). Machine
94 learning is increasingly being used in spatial interpolation, such as the spatial reconstruction of surface
95 temperature datasets (Huang et al., 2022; Kadow et al., 2020; Cao et al., 2022), the spatial and temporal
96 reconstruction of turbulence resolution (Fukami et al., 2021), etc. Furthermore, it shows high accuracy
97 and low uncertainty in reproducing and predicting SSR (Leirvik and Yuan, 2021; Tang et al., 2016; Yang
98 et al., 2018a; Yuan et al., 2021). However, long-term homogenized SSR datasets with global terrestrial

99 coverage have yet to be developed, resulting in significant uncertainties in assessing global SSR variation
100 (Jiao et al., 2022).

101 Therefore, developing a more homogeneous and comprehensive global long-term SSR climatic dataset
102 that provides a better benchmark for observational constraints on the global surface energy balance
103 /budget remains a valuable and challenging task. This paper first homogenizes and grids the most
104 extensive collection of available global SSR station observations. Then, the missing grid boxes /years
105 are spatially interpolated using a convolutional neural network (CNN) approach to obtain a globally
106 covered land surface SSR anomalies dataset. Finally, the reconstructed datasets are initially analysed and
107 evaluated. Thus, the paper is divided into seven main sections. The data resources are introduced in
108 Section 2. Section 3 presents the data homogenization, and the CNN model reconstruction methods. The
109 data homogenization and verification are shown in Section 4. Section 5 gives the AI reconstruction results.
110 Section 6 is the availability of the datasets. Conclusions are provided at the end of the paper.

111 **2 Data**

112 Nine SSR datasets are collected to derive the global SSR variable. In particular, six datasets contain data
113 from observational stations (Section 2.1): two global ground-based measurement datasets (GEBA,
114 WRDC) and four homogenized products at regional and country levels (Europe, China, Japan and Italy).
115 Three of the adopted datasets are reanalysis data (Section 2.2.1): Fifth generation European Centre for
116 Medium-Range Weather Forecasts (ECMWF) reanalysis (ERA5), 20th Century Reanalysis version 3
117 (20CRv3) reanalysis data and the Coupled Model Intercomparison Project Phase 6 (CMIP6) historical
118 simulation output (125). Specifically, the ERA5 data are used to fill the data over oceans and Antarctica
119 (Section 3.2.1), 20CRv3 data and CMIP6 simulations are used for the AI model training (Section 5.1)
120 and reconstruction. All have been listed in Table 1.

121 **2.1 In situ observational Data**

122 **2.1.1 Global datasets**

123 There are two main sources of raw SSR data (see Table 1): the ETH Zurich GEBA with monthly data
124 from 2,445 globally distributed stations, starting from 1922 until 2020, and the WRDC dataset with
125 monthly globally distributed data from 1136 stations since 1964. The first one is available for download

126 at <https://geba.ethz.ch> (Last access: 2022.7. 2). The second one published the first SSR radiation balance
127 data in 1965 and then its publication has been issued four times a year since 1993 and is available for
128 download at <http://wrdc.mgo.rssi.ru/> (Last access: July 2021).

129 **2.1.2 National (regional) homogenized station datasets**

130 1) Chinese homogenized SSR dataset

131 The China Meteorological Radiation Fundamental Elements Monthly Value Data Set has been
132 downloaded at <http://www.nmic.cn>. The homogenized SSR dataset in China is released by the National
133 Meteorological Information Centre (NMIC), China Meteorological Administration (CMA) (Yang, 2016).
134 The data are available for the period between Jan 1950 to Dec 2014, and the follow-up data are extended
135 with raw observations from NMIC. They used the sunshine duration (SSD) data from nearby stations to
136 construct an arguably better reference to identify inhomogeneities in the SSR data. Then, a combined
137 metadata and the maximum penalty t-test (PMT) method was used to detect the change points. Finally,
138 they were adjusted by a quantile matching (QM) algorithm (Wang and Feng, 2013). The final
139 homogenized SSR station dataset was converted to gridded data using the first difference method (FDM
140 (Peterson et al., 1998)) and is available for download at <http://www.nmic.cn>. Last Access: September
141 2022.

142 2) Japanese homogenized SSR dataset

143 Ma et al. (Ma et al., 2022) released a Japanese SSR homogenized dataset in 2022 spanning the period
144 between 1870 and 2015. First, they homogenized SSD based on PMF (penalized maximal F test) and
145 QM algorithms. They then used the homogenized SSD from the previous step as a reference series,
146 combined with metadata and PMT, to detect change points. Finally, they adjusted the change points by
147 the QM algorithm. For more details on data descriptions, the adopted methodology and downloading
148 data refer to <https://data.tpdc.ac.cn/en/data/45d73756-3f5a-4d27-82a4-952e268c20e8/>, Last Access:
149 March 2022.

150 3) European homogenized SSR data

151 A homogenized dataset of European SSR stations was developed by Sanchez-Lorenzo et al. (Sanchez-
152 Lorenzo et al., 2015) and is currently available as a full public download at
153 <https://agupubs.onlinelibrary.wiley.com/doi/full/10.1002/2015JD023321>. They selected the 56 longest
154 Central European SSR series available in GEBA dataset with data for the period comprised between

155 1922 and 2012. They adjusted them to ensure temporal homogeneity homogenizing the data with the
156 Standard Normal Homogeneity Test (Alexandersson, 1986) and the Craddock test (Craddock, 1979).

157 4) Italian homogenized SSR dataset

158 The Italian homogenized SSR datasets are those published by (Manara et al., 2019; Manara et al.,
159 2016). As candidate stations to use as reference series, they selected the ten series located in the same
160 area of the series to be tested and that series correlate well with the test one. In particular, they tested the
161 change points with the Craddock test (Manara. et al., 2017) and when a break is identified by more than
162 one reference series the preceding portion of the series is corrected, leaving the most recent portion
163 unchanged. In this way, the SSR stations were homogenized, and then the missing values were
164 interpolated.

165 **2.2 Other datasets**

166 **2.2.1 Reanalysis**

167 ERA5 can be used to fill in SSR data from the oceans and Antarctica and carry out the global
168 reconstruction, taking into account its high spatial resolution and reliable performance of SSR (Jiao et
169 al., 2022; Liang et al., 2022). After the reconstruction, we removed the data for the ocean reanalysis and
170 maintain the data only in the land area (except for Antarctica). In addition, two SSR data products
171 (20CRv3, CMIP6) are used to train AI models. These are:

172 1) ERA5 (space-filling data): ERA5 is the fifth generation of the European Centre for Medium-Range
173 Forecasting reanalysis product, which currently publishes data from 1950 to the present (Hersbach et al.,
174 2020). In addition, ERA5 has an hourly output and an uncertainty estimate from the ensemble. The data
175 is based on the Integrated Forecasting Model Cy41r2 run in 2016, which contains a 4D-Var assimilation
176 scheme. In ERA5, SSR is obtained from a Rapid Radiation Transfer Model (RRTM) (Mlawer et al.,
177 1997). The present study utilizes monthly SSR data for the period 1955-2018 from ERA5 with a
178 resolution of $0.25^\circ \times 0.25^\circ$ (last accessed in July 2022). It can be downloaded at
179 <https://cds.climate.copernicus.eu>

180 2) 20CRv3 (data for AI model training): The 20CR Project is an effort led by NOAA's Physical
181 Sciences Laboratory and CIRES at the University of Colorado, supported by the Department of Energy,
182 to produce reanalysis datasets spanning the entire 20th century and much of the 19th century (Slivinski
183 et al., 2019). 20CR provides a comprehensive global atmospheric circulation data set from 1850 to 2015.

184 Its chief motivation is to provide an observational validation dataset, with quantified uncertainties, for
185 assessing climate model simulations of the 20th century. 20CR uses an ensemble filter data assimilation
186 method which directly estimates the most likely state of the global atmosphere every three hours and
187 estimates the uncertainty in that analysis. The most recent version of this reanalysis, 20CRv3, provides
188 8-times daily estimates of global tropospheric variability across 75 km grids, spanning 1836 to 2015
189 (with an experimental extension from 1806 to 1835). The present study uses monthly SSR data of
190 20CRv3 (NOAA /CIRES /DOE 20CR, 80 members) from 1955-2015. We selected all 80 members of
191 the 20CR as input (1 for evaluation and to test reconstruction, the other 79 for training the CNN model).
192 The SSR of 20CRv3 has a spatial resolution of $0.7^\circ \times 0.7^\circ$ (Last accessed: May 2022). The download is
193 available at <https://portal.nersc.gov/archive/home/projects/incite11/>.

194 **2.2.2 CMIP6 models output**

195 3) CMIP6 models output (data for AI model training): the Coupled Model Intercomparison Project,
196 driven by the World Climate Research Program, is now in its 6th phase. Specifically, CMIP6 is
197 considered as the current state of the art way of producing future climate simulations, including predicting
198 future SSR based on different climate scenarios (Zhou et al., 2018b). It provides an important resource
199 for studying current and future climate change (Eyring et al., 2016). The historical simulations of CMIP6
200 are designed to reproduce observed climate and climate change, constrained by radiative forcing. Its
201 historical simulation spans between 1850 and 2014. In this study, we selected 125 members out of a total
202 of 507 members from several CMIP6 large ensemble models (with more than 10 realizations/runs) with
203 high correlation coefficients with observations as input to train and validate the CNN model (1 for
204 evaluation and to test reconstruction, the other 124 for training the CNN model). We selected the monthly
205 downward shortwave radiation from 1955 to 2014 (see Table S1 in the Supplemental Material (SM)).
206 Last access July 2022. Download at: <https://esgf-node.llnl.gov/search/cmip6>.

207 **3 Methods**

208 **3.1 Data Quality Control (QC) and homogenization**

209 The SSR data homogenization method is only applied to the two inhomogenized *in situ* observations
210 datasets (GEBA and WRDC). The Quality Control (QC) and homogenization flowchart (Figure 1) is
211 divided into three steps: 1. QC; 2. Homogenization; 3. Integration and consolidation.

212 **3.1.1 QC**

213 The QC of SSR data includes the following steps:

214 1) Simple integration: integration of the GEBA (2445) and WRDC (1136) datasets removing stations
215 with no data and leaving 2681 stations.

216 2) Removing duplicate stations: a. Stations with similar latitude and longitude. We consider two
217 stations with totally identical latitude and longitude to be the same station; b. Stations less than 10km
218 apart. We averaged the duplicate stations in this a and b case; c. Special duplicate stations: Stitching
219 together data of the duplicate stations based on metadata from CMA.

220 3) Remove stations or years /months for which a climatic analysis cannot be established: we remove
221 stations with records of less than ten years and values more than [three times \(\$3\sigma\$ criterion \(Olanow and
222 Koller, 1998\)](#) the standard deviation of the SSR anomalies.

223 4) Candidate stations (487) with a record length greater than 15 years in the period 1971-2000 are
224 selected. We added stations (715) with more than 10 years of SSR records to increase the number of
225 available stations for a better homogenization of the candidate stations (Figure 2).

226 **3.1.2 Station series homogenization**

227 This paper uses the RHtestV4 software package to test and adjust the SSR station data for homogeneity
228 (<http://etccdi.pacificclimate.org/software.shtml>) (Wang and Feng, 2013). The package is based on the
229 empirical penalty functions PMF (Wang, 2008a) and PMT (Wang, 2008b; Wang et al., 2007) for the
230 homogenization test. It takes into account the lag-1 autocorrelation of the time series. It embeds a multiple
231 linear regression algorithm to significantly reduce the problem of an unbalanced distribution of pseudo-
232 identification rates and test efficacy. Also, RHtestV4 uses the QM algorithm (Vincent et al., 2012; Wang
233 et al., 2010) and Mean-Adjustments to adjust the identified change points.

234 The specific steps are as follows:

235 1) Building the reference series

236 a. We processed the data from all stations series (715) into the annual first differences (FD) series

237 e_i (Eq. (1)) (Peterson et al., 1998).

238 b. We calculated the correlation of the annual FD series between the series from the potential reference

239 pool and the candidate stations.

240 c. We calculated the distance between the potential reference pool stations and candidate stations.

241 d. We selected potential stations according to the correlation coefficient ($CC \geq 0.6$) between the series

242 from potential reference pool and candidate stations. And the potential stations also satisfy the limits in

243 distances ($\leq 500\text{km}$) between the potential pool stations and candidate stations.

244 e. We obtain the reference FD series (Re) based on the m potential reference series (Pe_i) and the CCs

245 (c_i) between the potential reference series (Pe_i) and candidate stations series (Eq. (2)).

246 f. The synthesized reference FD series (Re) (Eq. (2)), plus the average of all potential reference series

247 (\bar{R}), yields the final annual reference series (R) (Eq. (3)).

$$e_i = x_i - x_{i+1} \quad i=1, 2, \dots, n-1 \quad (1)$$

$$R_e = \frac{\sum_{i=1}^m Pe_i * c_i^2}{\sum_{i=1}^m c_i^2} \quad (2)$$

$$R = R_e + \bar{R} \quad (3)$$

248 e_i Annual FD series,

249 x_i Raw observational station SSR in the year i ,

250 Re Final reference series,

251 Pe_i Potential reference series,

252 c_i CC between the potential reference series and the candidate stations series.

253 2) Testing and adjusting the candidate series

254 The homogenization test algorithm used in this paper is the PMT. This method is a reference series-

255 dependent test for a normalized candidate series. It assumes that the linear trend of the time series is zero

256 and uses the degree of mean deviation at different points in the series to find change points. Furthermore,

257 it eliminates the effect of different sample lengths on the test results. At the same time, the method

258 introduces an empirical penalty factor, which effectively improves detection. We used the PMT to test

259 the homogeneity of the candidate series based on the reference series established in 1). We then adjusted

260 the statistically significant($p>0.05$) changepoints obtained using the mean adjustment method ($p>0.05$).
261 We homogenize the monthly series for 66 stations (see Figure S1 in the SM).

262 **3.1.3 Integration and consolidation**

263 As can be seen from Figure 1, the candidate stations (487) are relatively sparse. To better adapt deep
264 learning methods for the dataset reconstruction later, we adjusted, added and integrated station series
265 based on the results of homogenized data from other scholars: 1) We added stations with more than 10a
266 overall (1955-2018) records but no more than 15a during the 1971-2000 period, and removed those
267 stations that were clearly inhomogeneous (25) and some years of the station (3); 2) We subsequently
268 integrate monthly SSR series for 116 stations based on the results of homogenization by other scholars
269 (China (56), Japan (8), Europe (2) and Italy (50)). After the above steps, we end up with a homogenized
270 dataset containing 944 stations (Figure 3). The details of the processing and classification are shown in
271 Table S2 (see in the SM).

272 **3.2 CNN model reconstruction methods**

273 The CNN deep learning model network architecture uses a U-shaped structure similar to the U-net
274 (Ronneberger et al., 2015). The advantage of using this model is: 1) both high and low-frequency
275 information of the picture can be retained, and when reconstructing the SSR data, not only the grid point
276 information close to the missing measurement point will be considered, but also information from more
277 distant locations (which may be remotely correlated with that missing measurement point); 2) This makes
278 the model convergence faster and more economical in terms of computational resources. The upper part
279 of the U-shaped structure, which has no down samples or a low number of down samples, represents the
280 high-frequency information of the graph. These sections contain much of the detail in the graph and the
281 relationships between similar grid points are conveyed by this section. The lower half of the U-shaped
282 structure is down-sampled more often and represents the lower frequency information of the graph. The
283 global radiation of a wide range of undulations is transmitted by it, and then the information at the various
284 levels of the U-shaped structure is connected and transmitted through the skip connection, allowing the
285 whole network to remember all the information of the picture very well. The model uses nearest
286 neighbour upsampling in the decoding phase, the skip links will concatenate two feature maps and two
287 masks as the feature and mask inputs for the next part of the convolution layer. The input to the last part

288 of the convolution layer will contain the original input image concatenated with the holes and the original
289 mask, allowing the model to replicate the gap-free pixels. The complex and variable nature of the sea-
290 land boundary then has a significant impact on the reconstruction, when we reconstruct the global land
291 SSR data. Therefore, we use partial convolution at the image boundaries with a suitable image padding,
292 ensuring that the padding content at the image boundaries is not affected by values outside the image.
293 The deep learning models' convolutional layers and loss functions have been described in the SM.

294 We further reconstruct a long-term (1955-2018) global SSR anomalies dataset (SSRIH_{20CR}) by using
295 improved partial CNN deep learning methods based on a “perfect” dataset. CNN consists of three parts.
296 A convolutional layer to reduce the number of weights by extracting local features, a pooling layer to
297 reduce peakeeping and prevent overfitting, and a fully connected layer to output the desired result. In
298 this paper, a modified CNN network is used to model the reconstruction of the SSR data, with the
299 convolutional layer replaced by a partial convolution method and mask update. This method is the latest
300 in image restoration effects and can restore irregular holes, an advantage over other image restoration
301 methods that can only restore rectangular holes. Therefore, this paper uses the modified CNN model
302 (Kadow et al., 2020) to recover the missing part of the global terrestrial SSR (except Antarctica). The
303 specific reconstruction steps and processes are as in Figure 4.

304 **3.2.1 Data pre-processing**

305 The homogenized station data is converted to grid box anomalies using the Climate Anomalies Method
306 (CAM) (Jones et al., 2001). CAM is a commonly used method for converting station anomaly data to
307 gridded data. We divide all global areas into a $5^\circ \times 5^\circ$ grid, after which we calculate the SSR anomalies
308 (relative to 1923-2020) within the grid box by averaging the anomalies of all stations (at least 1 station
309 in it). If there are more than one site exists in the same grid box, the record length of this grid box is the
310 total length of all sites in that grid box. Finally, we removed the values that were more than three times
311 the standard deviation of the SSR anomaly time series after gridding. SSRs are all processed as daily
312 average anomalies, i.e., monthly anomalies divided by 30 (each month is approximated as 30 days). We
313 multiplied all the values by 30 again when the reconstruction is complete. The global land (except for
314 Antarctica) distribution and coverage of SSRs after gridding are shown in Figure 5 a, b.

315 As seen in Figure 5a, the SSR is spatially sparsely distributed across South America and Africa. As
316 shown in Figure 5b, SSR coverage increased yearly from 1950 until the mid-1970s, when it slowly

317 decreased. In 2013, the coverage rate decreased sharply due to untimely data submission. Considering
 318 the SSR coverage above, we only kept the years (1955-2018) with data coverage of more than 8% of
 319 global land (except for Antarctica) areas.

320 Comparisons show that the ERA5 has high spatial resolution and relatively reliable performance in
 321 the temporal variations and long-term trends (Liang et al., 2022; Jiao et al., 2022). To obtain a higher
 322 data coverage and ensure that the AI model runs well, we used the ERA5 to fill the SSR of homogenized
 323 global gridded SSR in the Antarctic and ocean areas. However, if we use the SSR of ERA5 to directly
 324 fill the SSR of homogenized global gridded SSR ($SSRIH_{grid}$) in the Antarctic and on the ocean areas,
 325 then the relatively weaker ocean SSR variations (variabilities, decadal changes, trends, etc.) from ERA5
 326 will inevitably introduce certain systematic biases in land SSR reconstruction due to the SSRs have the
 327 lower coverage on the land. Therefore, we designed an algorithm to avoid excessive diffusion of SSR
 328 system bias in terrestrial areas: we first calculated the ratios $\gamma_i(i=1, 2, 3, \dots, n)$ between the SSR from
 329 ERA5 and from $SSRIH_{grid}$ on the land in all n years. For a single grid box, the γ_i have small changes
 330 and are regarded as a constant γ_{median} (Eq (4)), and the γ_{median} vary by latitude and longitude both on
 331 the marine and the land areas. We then extrapolated the γ_{median} for all the grid boxes along the land
 332 and sea boundaries. If there is no observation there, then the adjacent ocean ERA5 SSR is used to take
 333 its place after it is adjusted according to the differences between the SSR variations (represented by the
 334 linear trends) for the different underlying surfaces (Eq (5)).

$$\gamma_{median} = Median\left(\frac{OBS_{i_land}}{ERA5_{i_land}}\right), \quad (4)$$

$$OBS_{i_O\&L}(land) = ERA5_{i_O\&L}(Ocean) * \gamma_{median} * \frac{T_O}{T_L}, \quad (5)$$

$$i = 1, 2, 3, \dots, n$$

335 γ_{median} : The median value of the ratios of OBS and ERA5 land SSR series,

336 OBS_{i_land} : Land SSR for the year i from $SSRIH_{grid}$ in a single grid,

337 $ERA5_{i_land}$: Land SSR for the year i from ERA5 in a single grid,

338 $OBS_{i_O\&L}(land)$: Land SSR along the sea-land boundary(land) for the year i from $SSRIH_{grid}$,

339 $ERA5_{i_O\&L}(Ocean)$: Ocean SSR along the sea-land boundary for the year i from ERA5,

340 T_O : Trend of ERA5 SSR on ocean areas in all n years,

341 T_L : Trend of ERA5 SSR on areas in all n years.

342 **3.2.2 AI Model reconstruction**

343 We use a server (configured with processor Intel (R) Core (TM) i7-8700 CPU @ 3.20GHz 3.19 GHz,
344 RAM 32G, 64-bit OS, GPU model 516.94, NVIDIA GeForce 1080T version, Python 3.9.12 64-bit,
345 CUDA 10.1) for AI models training. The specific training steps are as follows:

346 1) A total of 768 missing value masks (monthly masks between 1955 and 2018) were prepared for
347 training and validation using '1' for existing and '0' for missing values;

348 2) The 20CRv3 /CMIP6 training set (monthly values between 1955 and 2015 /2014) and missing value
349 masks are fed into the 20CR-AI /CMIP6-AI model for training;

350 3) We perform 1,500,000 training sessions with an interval of 10,000 sessions for the training output
351 model.

352 Afterwards, the two AI models are validated against the root mean squared error (RMSE) /CCs of the
353 reconstructed SSRs (SSR_{20CR}/SSR_{CMIP6}). The validation set SSRs, and the optimal number of training
354 cycles is 1,100,000 (see Figure S2, Figure S3 and Figure S4 in the SM). The initial hyper-parameters of
355 the model are set as follows; learning rate of $2e-4$ and learning finetune of $5e-5$. First, we set the batch
356 size to 16 in the first 500000 iterations and fine-tuned it to 18 in the last 1000000 iterations, for a total
357 of 1500000 iterations, to suppress the overfitting phenomenon generated during the training process, and
358 validate the model every 10000 times and early stopping if the validation shows a decreasing trend, the
359 final number of training times used is 1100000. Second, L2 regularization is also added to regulate the
360 loss function (see Eq. (9) in the SM).

361 The training result models generated by the different AI models are obtained separately for the
362 different training sets. The model is first used to reconstruct a reanalysis validation set with the same
363 missing value mask as the original observation dataset. This is followed by a validation of the
364 reconstruction against the original reanalysis dataset (calculation of CC and RMSE) to understand the
365 discrepancies in the model reconstruction.

366 **4 Data homogenization and verification**

367 We homogenized the original monthly stations /gridded SSR time series ($SSRIH_{station}/SSRIH_{grid}$) using
368 the method in section 3.1.2. We selected six continental regions, excluding Antarctica and the Arctic,
369 from the eight continents of the world defined by Xu et al. (Xu et al., 2018) (Asia, Africa, South America,

370 Europe, North America, Australia, Antarctica and the Arctic). The decreasing trend of the $SSRIH_{grid}$ is
371 consistent with the original gridded SSR series ($SSRI_{grid}$) during 1955-1991 while the increasing trend
372 during 1991-2018 is weaker. At the regional scale, the $SSRIH_{grid}$ has a generally similar variation to the
373 $SSRI_{grid}$, and the $SSRIH_{grid}$ usually more representative of climate change than $SSRI_{grid}$ at individual
374 stations.

375 Figure S5 (see in the SM) illustrates the long-term variations of global (Figure S5 (a) in the SM) and
376 continental land SSR (Figure S5 (b) in the SM) from the $SSRI_{grid}$ and $SSRIH_{grid}$ (except for Antarctica)
377 during 1955-2018. The most prominent change revolves around the adjustment around 1992: the SSR
378 anomalies were systematically adjusted upward from 1987 to 1992, while the SSR anomalies were
379 systematically adjusted downward from 1993 onwards. Thus, there is a significant decreasing trend for
380 both global land $SSRI_{grid}$ (-1.995 ± 0.251 W/m² per decade) and global land $SSRIH_{grid}$ (-1.776 ± 0.230
381 W/m² per decade) (except for Antarctica) from 1955 to 1991. While the increasing trend of the global
382 land $SSRIH_{grid}$ from 1991 to 2018 is 0.851 ± 0.410 W/m² per decade, slightly smaller than the increasing
383 trend of the $SSRI_{grid}$ (0.999 ± 0.504 W/m² per decade). It is worth noting that 1992 happened to be the
384 second year of the eruption of Mount Pinatubo, and the homogenized SSR data integrated in this paper
385 may be affected by this event. But overall, the homogenization also has limited effects on the global SSR
386 variations from Figure S5 (see in the SM), which is consistent with the influence of data homogenization
387 on a wide range of surface air temperatures (Brohan et al., 2006; Xu et al., 2013).

388 At the regional scale, the differences between the $SSRIH_{grid}$ and $SSRI_{grid}$ are more pronounced in Asia
389 and Europe (see Figure S5(b) in the SM). Asia's homogenized SSR show that the regional average SSR
390 has been declining significantly over the period 1958-90; this dimming trend mostly diminished over the
391 period 1991-2005 and was replaced by a brightening trend in the recent decade. The $SSRIH_{grid}$ in Asia is
392 higher than the $SSRI_{grid}$ from 1985 to 1990 and lower than the $SSRI_{grid}$ from 2012 to 2015. The $SSRIH_{grid}$
393 shows a more moderate short-term increase in Europe from 1960 to 1980. Note also that the Australian
394 raw data prior to 1988 were artificially detrended because at the time the Australia Weather Service was
395 afraid that the instruments would drift. Therefore, they detrended them and unfortunately did not store
396 the raw data, and the SSR evolution in Australia is artificial with no trend (Wild et al., 2005). In addition,
397 the $SSRI_{station}$ and $SSRIH_{station}$ comparisons for all 66 stations are shown in Figure S1 (see in the SM).

398 5 AI reconstruction and comparison

399 5.1 Training of the AI model

400 We produce two (20CRv3 /CMIP6) separate training and validation sets: we select the 1th member data
401 of the reanalysis data and the model data, respectively, as the validation set, and the remaining 79 (124)
402 ensemble members as the training sets, where each ensemble member included 732 (720) months of SSR
403 data. Each validation set included 732 (720) samples, while the training sets contained 57828 (89280)
404 ensemble members. All the above data, including the *in situ* observations, are then resampled to monthly
405 anomalies of $5^\circ \times 2.5^\circ$.

406 We reconstruct the SSR of 20CRv3 /CMIP6 with missing values based on 20CRv3 /CMIP6 datasets
407 using the method in section 3.2 and obtain two reconstructions, SSR_{20CR} and SSR_{CMIP6} , respectively. The
408 SSR of 20CRv3/CMIP6 with missing values uses the $SSRIH_{grid}$ mask between 1955 and 2015 /2014. We
409 compare the global land (except for Antarctica) /regional annual anomalies variation of SSR_{20CR}
410 / SSR_{CMIP6} . The results show that SSR_{20CR} is significantly more consistent with the validation set than
411 SSR_{CMIP6} .

412 Figure 6(a) shows that the RMSE/CC of the SSR_{20CR} (0.247 W/m² /0.970 W/m²) are smaller /larger
413 than those of SSR_{CMIP6} (0.518 W/m² /0.937 W/m²) with the original 20CR /CMIP6 dataset. The 20CR-
414 AI model has a better reconstruction ability for SSR at the global land (except for Antarctica) scale. The
415 RMSEs of the SSR_{20CR} (SSR_{CMIP6}) are 1.460 (2.413) W/m², 1.109 (1.829) W/m², 2.219 (2.596) W/m²
416 and 1.286 (2.235) W/m² in North America, Europe, Asia, and Northern Hemisphere, whereas these
417 values are 1.116 (1.766) W/m², 0.622 (1.602) W/m², 1.877 (1.839) W/m² and 0.772 (1.679) W/m² in
418 South America, Africa, Australia, and Southern Hemisphere concerning the original 20CR /CMIP6
419 dataset, respectively. In other words, the RMSEs of the SSR_{20CR} are smaller than those of SSR_{CMIP6} for
420 the original 20CR /CMIP6 dataset except for Australia. In addition, the CCs of the SSR_{20CR} (SSR_{CMIP6})
421 are 0.958 (0.830) W/m², 0.958 (0.987) W/m², 0.886 (0.669) W/m², 0.930 (0.965) W/m², 0.938 (0.930)
422 W/m², 0.943 (0.916) W/m², 0.936 (0.875) W/m² and 0.903 (0.822) W/m² in North America, Europe,
423 Asia, Northern Hemisphere, South America, Africa, Australia, and Southern Hemisphere with respect
424 to the original 20CR /CMIP6 dataset, respectively. That is, the CCs of the SSR_{20CR} are larger than those
425 of SSR_{CMIP6} to the original 20CR /CMIP6 dataset except for Europe.

426 Based on the above comparison, the higher uncertainty for CMIP6 model output possibly biases the
427 CMIP6-AI method. Thus, the accuracy of the SSR_{20CR} is higher than that of the SSR_{CMIP6} at both global
428 land (except for Antarctica) and regional scales. Therefore, we choose the reconstruction results of the
429 20CR-AI model as the final AI reconstruction dataset, and subsequent analysis in the following sections
430 is only based on this dataset.

431 **5.2 Comparison of the spatial and temporal variation characteristics**

432 We investigate the long-term trends and spatial and temporal variation of the $SSRIH_{20CR}$, compare the
433 differences between the $SSRIH_{20CR}$ and $SSRIH_{grid}$, and suggest: the area and magnitude of the high and
434 low centres of the $SSRIH_{20CR}$ are the same as those of the $SSRIH_{grid}$; the results of the global land (except
435 for Antarctica) reconstruction are consistent with "dimming and brightening"; the global dimming is
436 primarily dominated by decreasing trends in Asia, Europe Africa and North America, whereas Europe
437 and North America are contributors to the increasing trends.

438 Figure 7 shows the spatial distribution of the $SSRIH_{grid}$ and $SSRIH_{20CR}$ for the three months (July 1960,
439 July 1980, and July 2000). Figure S6 (see in the SM) displays the spatial distribution of annual $SSRIH_{grid}$
440 and $SSRIH_{20CR}$ from 1955 to 2018. Figure 7 also shows the area and the magnitude of the high and low
441 centres in the $SSRIH_{20CR}$ are the same as in the $SSRIH_{grid}$. The $SSRIH_{20CR}$ is mainly positive anomalies
442 in Africa and the Eurasian continent in July 1960, especially in India and the Middle East. Afterwards,
443 India showed a continuous and steady decline in SSR. This confirms the well-known phenomenon of
444 global dimming over India (Wild et al., 2009; Soni et al., 2016; Soni et al., 2012; Padma Kumari et al.,
445 2007; Kambezidis et al., 2012). In Australia, the $SSRIH_{20CR}$ is dominated by negative anomalies in July
446 1980 and positive anomalies in July 1960 and July 2000. In Greenland, the $SSRIH_{20CR}$ shows a large
447 positive anomaly during three months. In northern Russia, there is a high value in July 2000. The
448 reconstruction can better reflect the anomaly distribution of observation information, and the grid boxes
449 with the missing values are infilled and reconstructed, which has high reliability.

450 Figure 8 illustrates global land (except for Antarctica) annual anomalies variation and long-term trend
451 of the $SSRIH_{20CR}$ for the period of 1955-2018, 1955-1991 and 1991-2018. Table S3 in the SM
452 demonstrates the trends of global SSR change evaluation for various data sources on different scales.
453 Also, we compare the differences between the $SSRIH_{20CR}$ and $SSRIH_{grid}$. The minimum value of the
454 $SSRIH_{20CR}$ occurred in 1991 (-2.411 W/m^2). The decreasing trend of the $SSRIH_{20CR}$ from 1955 to 1991

455 (-1.276 ± 0.205 W/m² per decade) is slightly lower than that of the SSRIH_{grid} (-1.776 ± 0.230 W/m² per
456 decade). After that, the SSRIH_{20CR} turns to an increasing trend of 0.697 ± 0.359 W/m² per decade from
457 1991 to 2018. This suggests that the difference between SSRIH_{20CR} and SSRIH_{grid} may be caused by the
458 results observed in limited data coverage (such as in Africa and North America) (Figure 9). After
459 homogenization and reconstruction, the trend (-1.276 W/m² per decade) from 1955 to 1991 corresponds
460 to an overall reduction of -4.6 W/m² over the dimming period, while that (0.697 W/m² per decade) from
461 1991 to 2018 correspond to an overall increase of 2 W/m² over the brightening period. This is in amazing
462 agreement with the -4 W/m² for the dimming period and the 2 W/m² for the brightening period based on
463 an overall surface energy budget assessment ((Wild, 2012) see their Figure 1). Also, similar conclusions
464 (incomplete coverage of observational data lead to an underestimation of global warming trends) have
465 been confirmed in global warming research (Gulev et al., 2021; Li et al., 2021).

466 Figure 9 demonstrates the long-term annual anomaly variations of the SSRIH_{20CR} in different regions
467 and its results compared to the SSRIH_{grid}. Table S4 in the SM shows the evaluation in continental and
468 hemispheric SSRIH_{20CR} change trends on different scales. The SSRIH_{20CR} shows a similar annual
469 anomaly variation to the global land (except for Antarctica) average trend in North America and Asia,
470 reaches a minimum in the late 1970s or early 1990s, and follows a moderate reversal. In Europe, the
471 SSRIH_{20CR} shows a decrease (-2.180 ± 1.866 W/m² per decade) between 1963 and 1978 before turning
472 to brightening (1.081 ± 0.312 W/m² per decade). In South America and Australia (Southern Hemisphere),
473 the SSRIH_{20CR} shows no significant variation. In Africa, the SSRIH_{20CR} has a dimming trend (-1.506 ±
474 0.496 W/m² per decade) from the 1950s to the 1990s, after which it remains levelled off (0.340 ± 0.998
475 W/m² per decade). The SSRIH_{20CR} shows a decreasing trend (-1.457 ± 0.246 W/m² per decade) until the
476 1990s in the Northern Hemisphere and a brightening (0.887 ± 0.415 W/m² per decade) afterwards. The
477 annual average anomaly variations in regions and globally show that Asia, Africa, Europe and North
478 America are the four contributors to the global dimming, while Europe and North America are two major
479 contributors to the “brightening”. This is in general agreement with the results obtained by previous
480 machine learning (Yuan et al., 2021). In addition, the discrepancy between the SSRIH_{20CR} and SSRIH_{grid}
481 is more significant in low-coverage areas (right) than in high-coverage regions (left). It is particularly
482 pronounced before 1980 and in South America. This suggests that the limited surface observations are
483 not representative of the continental variation in SSR.

484 The sources of error in the observational dataset can be divided into three types: (1) station error, the

485 uncertainties of individual station anomalies; Including measurement errors (which are not the focus of
486 the considerations in this manuscript) and errors due to homogenization. The errors due to
487 homogenization adjustment are always approximately normally distributed ((Jones et al., 2008), see
488 their Figure 5; also see Figure S9 in the SM) and therefore have limited impacts on the global average
489 SSR change (Figure S5 a, b). (2) sampling error, the uncertainties in a grid box mean caused by
490 estimating the mean from a small number of point values (Jones et al., 1997) ; and (3) bias error. It
491 generally refers to systematic errors such as urbanization together, which has not been discussed here.
492 However, even the sum of the above errors is much smaller than the errors due to limited data coverage
493 ((Li et al., 2010), see their Figure 5). So, the focus of this study is to eliminate this kind of error through
494 the CNN reconstruction.

495 **6 Data availability**

496 Both the $SSRIH_{grid}$ (the homogenized monthly gridded SSR data over 1923-2020) and the $SSRIH_{20CR}$
497 (the monthly 20CR-AI model reconstructed SSR data for 1955-2018) are currently publicly available on
498 the figshare website under DOI at <https://doi.org/10.6084/m9.figshare.21625079.v1> (Jiao and Li, 2023).
499 These datasets are also available at <http://www.gwpu.net> for free.

500 **7 Conclusion**

501 In this study, we integrate global station observations based on the raw observational SSRs from GEBA
502 and WRDC, combined with existing homogenized SSR datasets from other scholars. Also, we
503 homogenize the globally distributed station data using the RHtestV4 software package. An improved
504 CNN deep learning algorithm is subsequently used to reconstruct the SSR anomalies. Thus, a
505 reconstructed SSR anomaly dataset, $SSRIH_{20CR}$, is obtained based on training sets (20CRv3), for the
506 years 1955-2018, with a resolution of $5^{\circ} \times 2.5^{\circ}$. The main results are as follows:

507 1) The first integrated and homogenized global SSR monthly dataset is developed, which contains 944
508 stations in total and covers the longest periods (from the 1920s to recent years). A $5^{\circ} \times 5^{\circ}$ grid boxes
509 version of the monthly SSR anomalies dataset is derived.

510 2) This paper develops $5^{\circ} \times 2.5^{\circ}$ full-coverage monthly land (except for Antarctica) SSR anomalies
511 reconstructed datasets based on the above observations, using the 20CRv3 to train the AI model.

512 Comparative validations /evaluations show that the SSRIH_{20CR} provides a reliable benchmark for global
513 SSR variations.

514 3) On average, the global annual SSR variations based on the SSRIH_{grid} are not significantly different,
515 except that the increasing (brightening) trend after 1991 is a little smaller for the latter. The short-term
516 brightening SSR in Europe from the 1970s- to the 1980s disappear at the regional scale. At the same time,
517 the brightening SSR after the 1990s in Asia slowed or postponed.

829

830

831

832

833

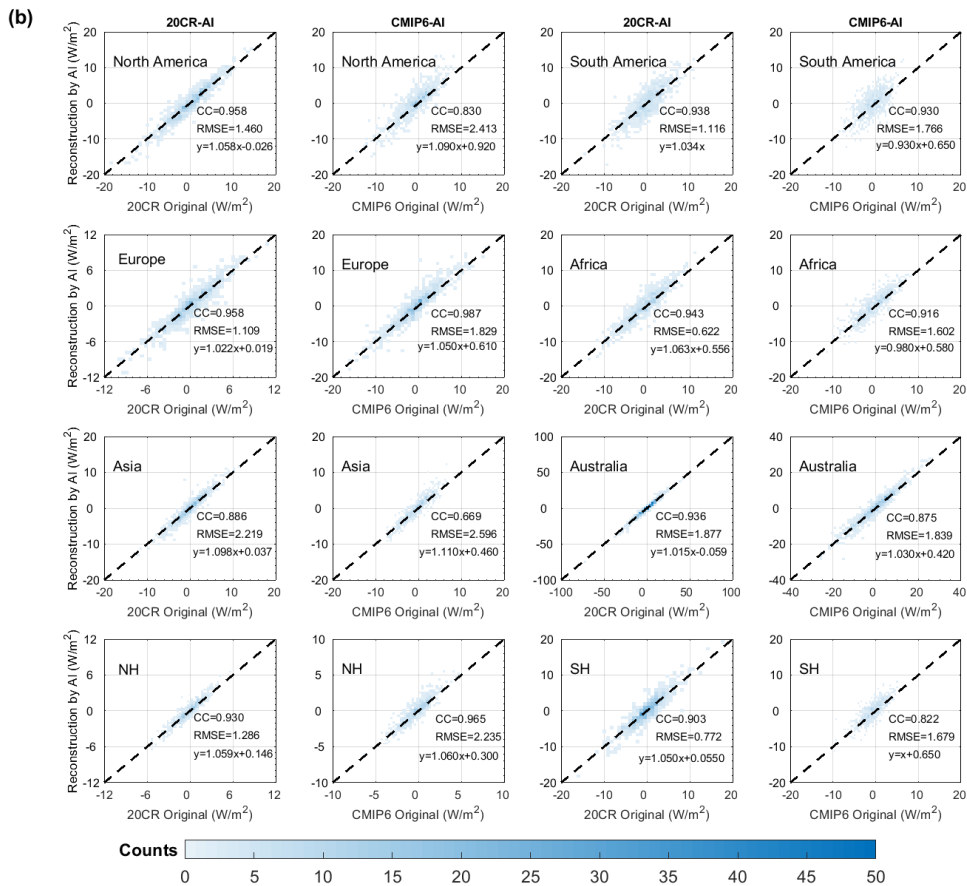

834

Figure 5: (a) Spatial distribution of $5^{\circ}\times 5^{\circ}$ grid boxes ($SSRIH_{grid}$) obtained interpolating the homogenized global land (except for Antarctica) SSR series. The different colours represent the length (the sum of all records) of the station record, Units: Year. (b) Grid box coverage for the homogenized global land (except for Antarctica) SSR ($SSRIH_{grid}$) except for Antarctica.

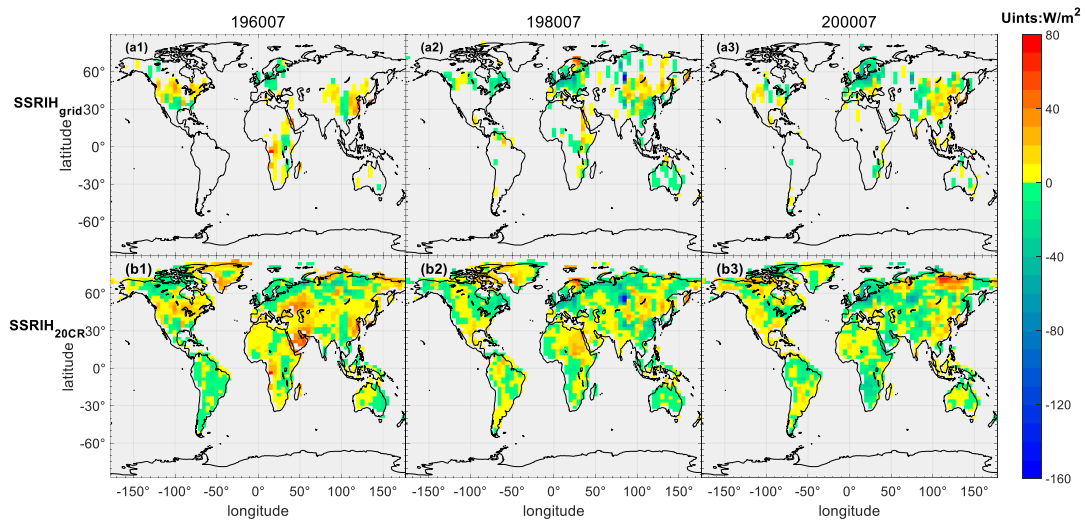

835

836

837 **Figure 6: Reconstruction capabilities of the AI model. (a) Global land (except for Antarctica) means time-**
 838 **series analysis and AI model reconstruction evaluation. The red line is the SSR of the reconstruction based**
 839 **on the 20CR-AI /CMP6-AI model (SSR_{20CR} / SSR_{CMP6}); The grey line is the masked datasets with missing**
 840 **values of the $SSR_{IH_{grid}}$. The solid black line is the 20CR and CMP6 validation set (the SSR from the 1th**
 841 **member of 20CRv3 /CMP6). (b) Comparisons of the SSR_{20CR} (columns 1, 3) / SSR_{CMP6} (columns 2, 4) with**
 842 **the SSR from the 20CR and CMP6 validation set. Colour bars represent counts with the same values for**
 843 **both. Figures also show the SSR_{20CR} (SSR_{CMP6}) correlation coefficient (CC), root mean squared error (RMSE)**
 844 **and fitting equation compared to the original dataset in different regions.**

845

846

847

Figure 7: Spatial distribution of the $SSRIH_{grid}$ (a1-3) and $SSRIH_{20CR}$ (b1-3) in typical months. 1-3 is July 1960, July 1980, and July 2000, respectively.

848

849

Figure 8: Global land (except for Antarctica) annual SSR anomaly variations (relative to 1971-2000)

850

before/after reconstruction. The Black solid line represents the SSRIH_{grid} annual anomalies. The solid blue

851

line represents the SSRIH_{20CR} annual anomalies. The histograms represent the decadal trends of the

852

SSRIH_{grid} /SSRIH_{20CR} (unit: W/m² per decade) and their 95% uncertainty range from 1955 to 1991, 1991-

853

2018 and 1955-2018.

854

855 **Figure 9: Same as Figure 8, but for regional annual anomaly variations. The green colour filling diagram**
 856 **represents the variation in grid box coverage (before reconstruction).**
