#### 32 Abstract

33 This paper presents two metazoan zooplankton datasets obtained by imaging samples collected on the Bay of Biscay continental shelf in spring during the PELGAS integrated surveys, over the 2004-2019 period. The samples 34 35 were collected at night, with a WP2 200 µm mesh size fitted with a Hydrobios (back-run stop) mechanical flowmeter, hauled vertically from the sea floor to the surface with a maximum depth set at 100 m when the 36 37 bathymetry is deeper. The first dataset originates from samples collected from 2004 to 2016, imaged on land with 38 the ZooScan and is composed of 1,153,507 imaged and measured objects. The second dataset originates from 39 samples collected from 2016 to 2019, imaged on board the R/V Thalassa with the ZooCAM and is composed of 40 702,111 imaged and measured objects. The imaged objects are composed of zooplankton individuals, zooplankton pieces, non-living particles and imaging artefacts, ranging from 300 µm to 3.39 mm Equivalent Spherical 41 42 Diameter, individually imaged, measured and identified. Each imaged object is geolocated, associated to a station, 43 a survey, a year and other metadata. Each object is described by a set of morphological and grey level based 44 features (8 bits encoding, 0 = black, 255 = white), including size, automatically extracted on each individual image. 45 Each object was taxonomically identified using the web based application Ecotaxa with built-in, random forest 46 and CNN based, semi-automatic sorting tools followed by expert validation or correction. The objects were sorted 47 in 172 taxonomic and morphological groups. Each dataset features a table combining metadata and data, at the 48 individual object granularity, from which one can easily derive quantitative population and communities 49 descriptors such as abundances, mean sizes, biovolumes, biomasses, and size structure. Each object's individual 50 image is provided along with the data. These two datasets can be used combined together for ecological studies as 51 the two instruments are interoperable, or as training sets for ZooScan and ZooCAM users. The data presented here are available in the SEANOE dataportal: https://doi.org/10.17882/94052 (ZooScan dataset, Grandremy et al., 52 2023c) and https://doi.org/10.17882/94040 (ZooCAM dataset, Grandremy et al., 2023d). 53

#### 57 **1 Introduction**

58 Metazoan planktonic organisms, hereafter referred to as zooplankton, encompass an immense diversity 59 of life forms, which have successfully colonized the entire ocean, from eutrophic estuarine shallow areas to 60 oligotrophic open ocean, from sunlit ocean to hadal depth. Their body sizes span five to six orders of magnitude 61 in length, from um to tens of meters (Sieburth & Smetacek, 1978). Zooplankton plays a pivotal role in marine 62 ecosystem (Banse, 1995). It transfers the organic matter produced in the epipelagic domain by photosynthesis to 63 the deeper layers of the ocean (Siegel et al., 2016), by producing fast sinking aggregates (Turner, 2015), and by 64 diel vertical migration (Steinberg et al., 2000; Ohman & Romagnan, 2016). Zooplankton therefore participates in 65 mitigating the anthropogenic carbon dioxide build up in the atmosphere responsible for climate change. Moreover, zooplankton is an exclusive trophic resource for commercially important fish during their larval stage, where a 66 67 shift in zooplankton species or phenology can have dramatic effects on recruitment (i.e. North Sea cod, Beaugrand 68 et al., 2003). In addition, it is a major trophic resource for adult planktivorous small pelagic fish, known as forage 69 fishes (Van der Lingen, 2006). Recent studies suggest that zooplankton dynamics may have a significant effect on 70 small pelagic fish population dynamics and individual body condition (Brosset et al., 2016; Menu et al., 2023), 71 and therefore impact wasp-waist ecosystem based fisheries and fisheries dependent socio-ecosystems, worldwide 72 (Cury et al., 2000).

73 Despite zooplankton being of such global importance in both climate change effects on ecosystems and 74 management of fisheries (Chiba et al., 2018; Lombard et al., 2019), it is still technically difficult to monitor, with respect to other marine ecological compartments. Zooplankton biomass, diversity and spatio-temporal 75 76 distributions cannot be estimated from spaceborne sensors as phytoplankton's does (Uitz et al., 2010), and 77 zooplankton commercial exploitation data do not exist yet, as fish data does. One noticeable exception is the CPR 78 surveys network that enables zooplankton data generation at spatio-temporal scales resolved enough to study 79 climate change and diversity related zooplanktonic processes (Batten et al., 2019). Yet, generating zooplankton 80 data often requires dedicated surveys at sea, specific sampling instruments and trained taxonomic analysts. 81 Moreover, besides actual observation, modelling zooplankton remains a challenging task due to the diversity of 82 traits such as life forms, life cycles, body sizes and physiological processes exhibited by zooplankton (Mitra & 83 Davis 2010; Mitra et al., 2014). However, over the past two decades the development of imaging and associated 84 machine learning semi-automatic identification tools (Irisson et al., 2022) have greatly improved the capability of 85 scientists to analyse long (Feuilloley et al., 2022), high frequency (Romagnan et al., 2016), or spatially resolved 86 (Grandremy et al., 2023a) zooplankton time series, as well as trait based data (Orenstein et al., 2022). Imaging and 87 machine learning have particularly enabled the increased development of combined size and taxonomy 88 zooplankton ecological studies (i.e. Vandromme et al., 2014; Romagnan et al., 2016; Benedetti et al., 2019). Yet, 89 use of these machine learning tools is not trivial because these require abundant, scientifically qualified, sensor 90 specific, training image data (i.e. learning set and test set, Irisson et al., 2022), and complex hardware and software 91 setups (Panaïotis et al., 2022). One good example of such image dataset is the ZooScanNet dataset (Elineau et al., 92 2018), which features an extensive ZooScan (Gorsky et al., 2010) imaging dataset usable as a training set for 93 ecologists as well as for imaging and machine learning scientists.

94 The objective of this paper is to present two freely available zooplankton imaging datasets, originating
95 from two different instruments, the ZooScan (Gorsky et al., 2010), and the ZooCAM (Colas et al., 2018). These

96 datasets originate from the PELGAS integrated survey in the Bay of Biscay (Doray et al., 2018a), a continental

97 shelf ecosystem supporting major European fisheries (ICES, 2021). Combined together, these datasets make up a

98 16-years time series of sized and taxonomically resolved zooplankton, along with context metadata allowing the

99 calculation of quantitative data, covering the whole Bay of Biscay continental shelf, from the French coast to the

- 100 continental slope, and from the Basque country to southern Brittany, in spring. These datasets can be used for
- 101 ecological studies (Grandremy et al., 2023a), machine learning studies, and modelling studies.

#### 102 **2 Methods**

#### 103 **2.1 Sampling**

Zooplankton samples were collected during the successive PELGAS (PELagique GAScogne) integrated 104 105 surveys carried out over the Bay of Biscay (BoB) French continental shelf, every year in spring from 2004 to 2019 106 on board the R/V Thalassa. The aim of this survey is to assess small pelagic fish biomass and monitor the pelagic 107 ecosystem to inform ecosystem based fisheries management. Fish data, hydrology, phyto- and zoo-plankton 108 samples and megafauna sightings (marine mammals and seabirds) are concomitantly collected to build long-term 109 spatially resolved time series of the BoB pelagic ecosystem. The PELGAS sampling protocols combine day-time 110 en-route data collection (small pelagic fish and megafauna), with night-time, depth integrated hydrology and 111 plankton sampling at fixed points. Detailed PELGAS survey protocols can be found in Doray et al. (2018a) and 112 Doray et al. (2021). The PELGAS survey datasets providing hydrological, primary producers, fish and megafauna data are available as gridded data in the SEANOE dataportal (Doray et al., 2018b) under the following link: 113 114 https://www.seanoe.org/data/00422/53389/.

115 The number of zooplankton samples across years varied between 41 (2005) and 64 (2019), due to adjustments in the sampling strategy and weather conditions, for 889 zooplankton samples collected in total. From 116 117 2004 to 2006, samples were collected in the southern Bay of Biscay until the Loire estuary only (Fig. 1). Sampling 118 was carried out in vertical tows during night time using a 200-µm mesh size WP2 net, generally from 100 m depth 119 (or 5 m above the seabed) to the surface. In 2004 and 2005, the targeted maximum sampling depth was 200 m. In 120 2004, fifteen samples were collected deeper than 100 m, among which eleven were deeper than 120 m; in 2005, 121 twenty samples were collected deeper than 100 m, among which thirteen were deeper than 120 m. Before 2014, 122 the sampled water volume was estimated by multiplying the cable length by the net opening surface (0.25 m<sup>2</sup>) 123 whereas since 2014, the net was equipped with a Hydrobios back-run stop flowmeter. The samples originating 124 from 2004 to 2016 surveys were preserved in 4% formaldehyde (final concentration) and analysed on land in the 125 laboratory with the ZooScan, while since 2016 they were analysed live on board with the ZooCAM.

#### 126 **2.2 Sample processing and analyses**

#### 127 **2.2.1 Digitization with the ZooScan**

Preserved samples were digitized with the ZooScan (Gorsky et al., 2010), a flatbed scanner generating 16-bit gray-level high-resolution images (2400 dpi, pixel size:  $10.56 \mu$ m, image size:  $15\times24$  cm equivalent to 14 200×22 700 pixels). It is well suited for the imaging of preserved organisms ranging in size from 300 µm to several centimeters. The ZooScan is run by the custom made, ImageJ based, ZooProcess software which generates one single large image for each scan that contains up to 2000 organisms depending on the size of the imaged organisms.

134 Prior to digitization, the seawater and formaldehyde solution was filtered through a 180 µm mesh sieve 135 into a trash tank, under a fume hood. The organisms were then gently but thoroughly rinsed with freshwater over the tank, in the sieve. They were then size-fractionated with a 1 mm sieve, into organisms larger and smaller than 136 137 1 mm size fractions. This size splitting step is recommended when using the ZooScan to address the possible 138 under-representation of large objects bias caused by the necessary subsampling. Each size fraction was subsampled 139 separately with a Motoda splitter to obtain two subsamples containing 500-1000 objects for the large organisms 140 size fraction, and 1000-2000 objects for the small organisms size fraction. Each subsample was imaged after 141 manual separation of objects on the scanning tray, to mitigate the number of overlapping objects as recommended 142 in Vandromme et al. (2012). Overall, 699 samples were digitized following this protocol, corresponding to 1397 143 scans (one sample was not size fractioned as it did not contained organisms larger than 1 mm).

145

Figure 1: Metazoan zooplankton sampling locations during the PELGAS cruises in the Bay of Biscay from 2004
to 2019. The years with the poorest coverage are 2005 and 2006 with 41 and 43 sampling stations respectively;

and the years with the best coverage are 2015, 2017 and 2019 with 64, 64 and 65 sampling stations respectively.

#### 149 **2.2.2 Digitization with the ZooCAM**

150 The ZooCAM is an in-flow imaging instrument, designed to digitize preserved as well as live zooplankton samples, on board, immediately after net collection (Colas et al., 2018). The ZooCAM features a cylindrical 151 152 transparent tank in which the zooplankton sample is mixed with filtered seawater. Depending on the richness of 153 the sample, and the subsampling (if necessary), the volume of seawater can be adjusted between 2-7 litres. The organisms were pumped at a 1L.min<sup>-1</sup> from the tank to a flowcell inserted between a CCD camera (pixel size: 10.3 154 155 μm) and a red LED flashing device where they were imaged at 16 fps. Given the flowcell volume, the size of the 156 field of view, the imaging frequency and the flowrate, all the seawater volume containing the organisms was 157 imaged (Colas et al., 2018). Before all the initial volume was imaged, the tank and the tubing were carefully and 158 thoroughly rinsed with filtered seawater to ensure the imaging of all the organisms poured in the tank. For each 159 sample, the ZooCAM generates a stack of small size (~1 Mo) raw images that are subsequently analysed with the ZooCAM software. Depending on the initial water content of the tank and the rinsing, a ZooCAM run can generate 160 161 up to 10k raw images from which the individual organism vignettes will be extracted. A ZooCAM run on a live sample often generates up to 5000-10000 vignettes of individual organisms. It is very important to subsample the 162 163 initial samples with a dichotomic splitter (here a Motoda splitter), to get subsamples with a quantity of objects that reduce the risk of imaging overlapping objects, and avoid any dependency to the water volume imaged to 164 165 reconstruct quantitative estimates of zooplankton as the initial and rinsing volume are variable. Overall, 190 166 samples were digitized live on-board with the ZooCAM.

### 167 **2.3 Images processing**

168 Both instruments generate grey level working images (8 bit encoding, 0 = black, 255 = white). In both cases, image processing consisted in (i) a "physical" background homogenization by subtracting an empty 169 170 background image to each sample image (1 for ZooScan, and as many as raw images for ZooCAM), (ii) a 171 thresholding of each raw image (threshold value: 243 for ZooScan, 240 for ZooCAM), (iii) the segmentation of 172 each object imaged. The ZooProcess software was set to detect and segment objects with an area equal or larger 173 than 631 pixels, whereas the ZooCAM software was set to detect objects with an area equal or larger than 667 174 pixels, which in both cases equals  $300 \,\mu\text{m}$  ESD, or a biovolume of  $0.014 \,\text{mm}^3$  (using a spherical biovolume model, 175 Vandromme et al., 2012).

176 Morphological features were then extracted on each detected object. Features generated by the ZooScan are defined in Gorsky et al. (2010) and those generated by the ZooCAM are defined in Colas et al. (2018). ZooScan 177 178 images were processed with ZooProcess v7.39 (04/10/2020) open source software. ZooCAM images were 179 processed with the proprietary ZooCAM custom made software which uses the MIL (Matrox Imaging Library, 180 Dorval, Québec, Canada) as the individual object processing kernel. Each detected object was finally cropped from 181 the working sample images, and saved as a unique, labelled vignette, in a sample specific folder along with a 182 sample specific single text file containing the objects features arranged as a table with objects arranged in lines 183 and features in columns.

#### 184 **2.4 Touching objects**

185 The ZooProcess features a tool that enable the digital separation of possible touching objects in the final 186 image dataset, for each sample. As touching objects may impair the estimations of abundances and size structure 187 (Vandromme et al., 2012), remaining touching objects were searched for on the individual vignettes from the

- 188 ZooScan and digitally manually separated with the ZooProcess separation tool to improve the quality of further 189 identifications, counts and size structure of zooplankton. The ZooCAM software does not offer such a tool.
- 190 **2.5 Taxonomic identification of individual images**

191 All individual vignettes from both instruments were sorted and identified with the help of the online 192 application Ecotaxa (Picheral et al., 2017), as two instrument-specific separated sets. Ecotaxa features a Random 193 Forest algorithm (Breiman, 2001) and a series of instruments specific tuned spatially sparse Convolutional Neural 194 Networks (Graham, 2014) that were used in a combined approach to predict identifications of unidentified objects. 195 First, an automatic classification of non-identified individual vignettes into coarse zooplankton and non-196 zooplankton categories was carried out. In both cases (ZooScan and ZooCAM), Ecotaxa hosted instrument specific 197 image datasets, previously curated and freely available, that were used as initial learning sets. These initial 198 classifications were then visually inspected, manually validated or corrected when necessary, and taxonomically 199 refined when possible. After a few thousand images were validated in each project, they were used as dataset 200 specific learning sets to improve the initial coarse automatic identifications. This process was iterated until all the 201 individual vignettes were classified into their maximum reachable taxonomical detail. A subsequent quality check 202 of automatic taxonomic identifications has been realized in a two-step process: a first complete review (validation 203 and / or correction) of all individual automatic identifications was done by GN and RJB; then, trained experts (JL 204 and NA) reviewed and curated the ZooScan and the ZooCAM datasets, respectively, at the individual level. 205 Although some identification errors may still remain in the datasets, we consider this double check process as 206 sufficient to provide taxonomically qualified data.

## 207

#### 2.6 Intercalibration of the two instruments

208 The two datasets are usable separately. However, considered together they build a 16 years long spatio-209 temporal time series. A comparison study was done to ensure these datasets are homogeneous and can thus be 210 combined for ecological studies (Grandremy et al., 2023b). All the zooplankton samples from year 2016 (61 211 sampling stations over the whole BoB continental shelf) were imaged with both instruments. In brief, all nonzooplankton and touching objects images were removed from the initial datasets. Then, the interoperable size 212 213 range was determined with an assessment based on the comparison of Normalized Biovolume - Size Spectra (NB-214 SS) for each instrument. This size interval ranges between [0.3-3.39] mm ESD. Finally, the zooplankton 215 communities as seen by the ZooScan and the ZooCAM were compared by taxa and by station using 27 taxonomic 216 groups. Poorly represented taxa as well as non-taxonomically identified objects were not taken into account in the zooplankton variables computation and in community structure analyses. Both instruments showed similar NB-217 218 SS slopes for 58 out of 61 stations; depicted equivalent abundances, biovolumes and mean organisms' sizes, as 219 well as similar community composition for a majority of sampling stations. They also estimated similar spatial 220 patterns of the zooplankton community at the scale of the Bay of Biscay. However, some taxonomic groups showed 221 discrepancies between instruments, which originates from the differences in sample preparation protocols before 222 the image acquisition, the imaging techniques and quality, and whether the samples were imaged live or fixed. For 223 example, the mineralized protists (here, Rhizaria) dissolve in formalin and are considered underestimated in 224 preserved seawater samples (Biard et al., 2016). Also, the random orientation of objects in the ZooCAM flow cell 225 leads to a loss of taxonomic identification accuracy due to the difficulty to spot the specific features needed for the

- identification (Colas et al., 2018; Grandremy et al., 2023b). This is particularly acute for copepods, where the
- 227 ZooScan seems to provide better identification capabilities to experts, as the organisms are imaged in a lateral
- 228 view most of the time whereas the ZooCAM often images them in a non-lateral, randomly-oriented view,
- 229 preventing the visualisation of specific features. A detailed discussion about how to explain the discrepancies
- between the ZooScan and the ZooCAM can be found in Grandremy et al. (2023b). We assume that the two
- 231 presented datasets build a single, 16 years long spatio-temporal time series of abundances (Fig. 2) and sizes of
- 232 zooplanktonic organisms (Fig. 3), from which biovolumes, biomasses, Shannon index (Fig. 4), and zooplankton
- community size structure can be derived (Vandromme et al., 2012).

Figure 2: Gridded maps of total zooplankton abundances expressed as individuals per cubic meters of sampled seawater, during the PELGAS cruises in the Bay of Biscay from 2004 to 2019. The abundances are well within the range of zooplankton abundances seen over other temperate continental shelves. They exhibit a marked coastal to offshore gradient, abundances being higher at the coast. Abundances also show an overall increase over the years. The gridding procedure is presented in Petitgas et al. (2009) and Petitgas et al. (2014). See also Doray et al. (2018c) and Grandremy et al. (2023a) for application examples.

Figure 3: Gridded maps of total zooplankton mean sizes expressed as mm Equivalent Spherical Diameter during the PELGAS cruise in the Bay of Biscay from 2004 to 2019. They exhibit a coastal to offshore gradient as well as a north-south gradient. Mean body sizes are smaller at the coast and usually smaller in the south. In general, mean body sizes show an overall decrease over the years. The gridding procedure is presented in Petitgas et al. (2009) and Petitgas et al. (2014). See also Doray et al. (2018c) and Grandremy et al. (2023a) for application examples.

#### 247 **3 Datasets**

#### 248 **3.1 Taxonomic groups and Operational Morphological Groups**

The ZooScan dataset is composed of 1,153,507 zooplankton individuals, zooplankton parts, non-living 249 250 particles and imaging artefacts individually imaged and measured with the ZooScan and ZooProcess (Gorsky et al., 2010), sorted in 127 taxonomic and morphological groups. The ZooCAM dataset is composed of 702,111 251 252 zooplankton individuals, zooplankton parts, non-living particles and imaging artefacts individually imaged and 253 measured with the ZooCAM (Colas et al., 2018), sorted in 127 taxonomic and morphological or life stages groups. 254 The total number of different groups identified with both instruments combined is 170, among which 84 are in 255 common (Table 1), 43 belong to the ZooScan dataset only and 43 others belong to the ZooCAM dataset only (Table 2). The identified groups were divided into actual taxa and Operational Morphological Groups (OMGs). 256 257 Typically, OMGs are either non-adult life stages of taxa, aggregated morphological groups, or non-living groups 258 (see Tables 1 and 2). Among the groups common to both instruments, 45 are actual taxa, and 39 are OMGs (Table 1). Among the ZooScan only groups, 22 are taxa, and 21 are OMGs, and among the ZooCAM only groups, 18 are 259 taxa, and 25 are OMGs (Table 2). 260

261 The differences in identified groups, in the ratio taxa/OMGs, and in the associated counts arose from 262 several aspects of the data generation. Firstly, the two imaging methods differ in their technical set-up. The main 263 difference is that, on the one hand, fixed organisms are laid down and arranged manually on the imaging sensor 264 and digitized in a lab, steady 2-D, set-up when using the ZooScan. On the other hand, organisms are imaged live, 265 in a moving fluid, in a 3-D environment (the flowcell), on-board when digitized with the ZooCAM. Their position in front of the camera may not enable an identification as precise as when they are laid on the scanner tray 266 267 (Grandremy et al., 2023b; Colas et al., 2018). Secondly, the dataset are sequential in time, the ZooCAM dataset 268 follows the ZooScan's. Zooplankton communities in the Bay of Biscay may have changed over time, even if their 269 biomass as aggregated groups show a remarkable space-time stability (Grandremy et al., 2023a). Thirdly, we 270 cannot guaranty that there is no adverse effect on taxonomic identification, as validation involved several experts 271 (Culverhouse, 2007). Although we paid great attention to homogenize the final detailed datasets, we recommend 272 to aggregate taxa and OMGs and reduce the biological resolution for ecological studies (Grandremy et al., 2023a, 2023b). Additionally, numerous identified and sorted taxa and OMGs do not belong to the metazoan zooplankton, 273 274 or are non-adult life stages, or parts of organisms. Those were included in the presented datasets because they are 275 always found in natural samples. They need to be separated from entire organisms to ensure as accurate as possible 276 abundances estimations, as well as taken into account to ensure accurate biovolumes or biomasses estimations. A 277 good example is the siphonophore issue: numerous swimming bells of degraded siphonophores individuals can be 278 found and imaged in a sample. Determining an accurate siphonophore abundance may not be easy, but this could 279 be overcome by considering the biovolume or biomass of siphonophores by adding up the numerous parts' 280 biovolumes or biomass of the organisms imaged.

- 281 Table 1: ZooCAM and ZooScan common taxa and Operational Morphological Groups (OMGs). Taxa are listed
- in the left column of the table, and OMGs are listed in the right column of the table . OMGs names are spelled as
- they appear in the dataset. Numbers next to each taxa and OMGs are the counts and the percentages (%) for each
- 284 category for each instrument in the whole datasets. Non-zooplanktonic OMGs are highlighted in bold, and genera
- and species are formatted in italics.

- 287 Table 2: ZooCAM and ZooScan not common taxa and Operational Morphological Groups (OMGs). Taxa and
- 288 OMGs appearing exclusively in the ZooCAM dataset are listed in the left column, those appearing exclusively in
- the ZooScan dataset are listed in the right column. OMGs names are spelled as they appear in the dataset. Numbers
- 290 next to each taxa and OMG are the counts and the percentages (%) for each category for each instrument in the
- 291 whole datasets. Non-zooplanktonic taxa and OMGs are highlighted in bold, and genera and species are formatted
- in italics.

- 295 OMGs' names are mainly in the form of two words separated by a "<" character. Although we tried to name them
- as most explicitly as possible, a few potentially needed clarifications can be found in Table 3.
- Table 3: Non-exhaustive list of prefixes, their types (morphological, developmental stage, taxonomical, non-livingand imaging artefact), and content.

| prefix        | type                | content of category   |

300 \* clupeids fish embryo developmental stages according to Ahlstrom (1943) and Moser & Ahlstrom (1985).

Figure 4: Gridded maps of total zooplankton Shannon index (calculated on spherical biovolumes) during the PELGAS cruise in the Bay of Biscay from 2004 to 2019. Shannon index exhibit a coastal to offshore gradient as well as a north-south gradient. Shannon index is larger at the coast and in the south, except in 2014 where it is smaller in the south, offshore. The gridding procedure is presented in Petitgas et al. (2009) and Petitgas et al. (2014). See also Doray et al. (2018c) and Grandremy et al. (2023a) for application examples.

### 307 3.2 Data and images

#### 308 3.2.1 Data

309 The data is divided into two datasets available as tab separated files, one for each instrument. Within each 310 dataset the data is organized as a table containing text data as well as numerical data. Each dataset combines 311 together actual data and metadata at the individual object granularity. For each object, the user will be able to find 312 descriptors originating from the image processing (i.e. features), and sampling metadata (i.e. latitude and longitude 313 of sampling station, date and time of sampling, sampling device, etc.) and sample processing metadata (i.e. 314 subsampling factor, seawater sampled volume, pixel size), in columns, and individual objects in lines. The columns 315 headers are defined in Tables A1 and A2 for ZooCAM and ZooScan datasets respectively. The following prefixes 316 enable the segregation of types of data and metadata: (i) "object", which identifies variables assigned to each object individually; (ii) "sample ", which identifies variables assigned to each sample; (iii) "acq ", which 317 318 identifies variables assigned to each data acquisition for the same sample (note here that this type of variable is found only in the ZooScan dataset as ZooScan samples were splitted in two size fractions corresponding to two 319 320 acquisitions); (iv) "process ", which identifies variables describing key image processing features (i.e. pixel size). 321 Those prefixes originate from the use of the Ecotaxa web application to sort and identify the images (Picheral et 322 al., 2017) that promote this specific formatting. The ZooCAM dataset is shaped as a 72 columns (variables) x 323 702,111 rows (individual imaged objects) matrix and the ZooScan dataset is shaped as a 71 columns (variables) x 324 1,153,507 rows (individual imaged objects) matrix.

325 Among the 70+ variables it is worth noticing the following ones:

- (i) objid: it is a unique individual object numerical identifier that enables to link single data line to a
   327 corresponding single image in the image dataset;
- (ii) taxon: it is the taxonomic or OMG identification of the imaged objects written as they appear in the
   Tables 1 and 2;
- (iii) lineage: it is the full taxonomic lineage of the taxon. Lineage may be used to aggregate taxa at a higher
   taxonomic levels, respecting taxonomic lineages;
- 332 (iv) classif\_id: it is a unique, numerical, taxon identifier;

333 (v) sample\_sub\_part / acq\_sub\_part: those are the subsampling ratios, for ZooCAM and ZooScan

respectively, needed to reconstruct the quantitative estimates of the samples' abundances;

(vi) sample\_fishingvolume / sample\_tot\_vol: those are the total seawater sampled volumes for ZooCAM
 and ZooScan respectively, needed to normalize the samples' concentrations by seawater volume.

337 One can therefore calculate quantitative abundances estimates for a taxon in a sample as follow:

338 ZooCAM: 
$$Ab_{taxon} = \frac{n_{taxon} \times sample\_sub\_part}{sample\_fishingvolume}$$
 (1)

339 ZooScan: 
$$Ab_{taxon} = \frac{(n_{taxon_{acq1}} \times acq\_sub\_part_{acq1}) + (n_{taxon_{acq2}} \times acq\_sub\_part_{acq2})}{sample\_tot\_vol}$$
 (2)

340 Where *Ab* is the abundance in ind.m<sup>-3</sup> and *n* is the number of individuals for "taxon".

#### 341 **3.2.2 Images**

342 Two sets of individual images sorted into folders by categories (Tables 1 and 2) come along with each dataset. For the ZooCAM only, the associated images from years 2016 and 2017 contain printed Region Of Interest 343 344 (ROI) bounding box limits and text at the bottom of each image, and non-homogenised background within and around the ROI bounding box; images from year 2018 contain non-homogenised background within the ROI 345 346 bounding box only; images from 2019 have a completely homogeneous and thresholded background around the 347 object. The differences arose from successive ZooCAM software updates that do not modify the calculation of 348 object's features. The ZooScan images have all a completely homogeneous and thresholded background around 349 the object, no bounding box limits nor text printed in the images. All images for the two instruments datasets have 350 a 1 mm scale bar printed at the bottom left corner.

## 351 4 Data availability

352 The ZooScan dataset can be found as the PELGAS Bay of Biscay ZooScan zooplankton Dataset (2004-2016) in

the SEANOE dataportal following the link: <u>https://www.seanoe.org/data/00829/94052/</u> (doi: 10.17882/94052,
 Grandremy et al., 2023c). Individual objects images can be freely viewed and explored by anyone using the

Grandremy et al., 2023c). Individual objects images can be freely viewed and explored by anyone using the Ecotaxa (https://ecotaxa.obs-vlfr.fr/) web application, without registration, under the tab "explore images", by

356 searching the project name: "PELGAS Bay of Biscay ZooScan zooplankton Dataset (2004-2016)".

357 The ZooCAM dataset can be found as the PELGAS Bay of Biscay ZooCAM zooplankton Dataset (2016-2019) in

the SEANOE dataportal https://www.seanoe.org/data/00828/94040/ (doi: 10.17882/94040, Grandremy et al.,

359 2023d). Individual objects images can be freely viewed and explored by anyone using the Ecotaxa

360 (https://ecotaxa.obs-vlfr.fr/) web application, without registration, under the tab "explore images", by searching

361 the project name: "PELGAS Bay of Biscay ZooCAM zooplankton Dataset (2016-2019)".

362 Each dataset comes as a .zip archive that contains:

#### • One tab separated file containing all data and metadata associated to each imaged and identified object.

- One comma separated file containing the name, type, definition and unit of each field (column)
- One comma separated file containing the taxonomic list of the dataset, with counts and nature of the
   content of the category

A directory "*individual\_images*" containing images of each object, named according to the object id
 *objid* and sorted in subdirectories according to their taxonomic identification, across years and sampling
 stations.

#### 370 **5 Concluding remarks**

Recent studies showed that the small pelagic fish (SPF) communities have suffered from a drastic decrease of condition in the Mediterranean Sea and in the Bay of Biscay (Van Beveren et al., 2014; Doray et al., 2018d; Saraux et al., 2019) over the last 20 years. This loss of condition was especially expressed by the constant decrease of SPF size- and weight-at-age (Doray et al., 2018d; Veron et al. 2020), and possibly explained by a change in SPF trophic resource composition, size and quality (Brosset et al., 2016; Queiros et al., 2019; Menu et al., 2023). Identifying and measuring zooplankton at appropriate temporal and spatial scales is not an easy task, but can be addressed with imaging. These datasets were assembled as an effort to make possible the exploration

of the relationship between SPF observed dynamics in the Bay of Biscay and their main food resource's dynamics, 378 379 the metazoan zooplankton. This zooplankton imaging data series is a significant output of Nina Grandremy PhD 380 (2019-2023), that is currently being exploited (Grandremy et al., 2023a), and is intended to be continued and 381 updated on a yearly basis in the framework of the PELGAS program, to better understand the underlying processes 382 presiding to long-term SPF dynamics. Moreover, those two zooplankton datasets can be associated with the 383 PELGAS survey datasets previously published in 2018, also in the SEANOE dataportal, featuring hydrological, 384 primary producers, fish and megafauna data arranged as gridded data (Doray et al., 2018b). Together, all these 385 datasets allow to study simultaneously all the pelagic ecosystem compartments, with coherent spatial domain (the Bay of Biscay continental shelf), resolution and time series. Nevertheless, a spatial gridding of the data is highly 386 387 recommended (as represented in the Fig. 2, 3 and 4), since the spatial coverage of the sampling protocols can vary between years (Fig. 1), within and between each pelagic ecosystem compartment. A procedure for such batch data 388 spatial smoothing is presented e.g. in Petitgas et al. (2009) and Petitgas et al. (2014). See also Doray et al. (2018c) 389 390 and Grandremy et al. (2023a) for application examples. As several descriptors of the spring zooplankton 391 community (abundances, sizes, biovolumes, biomass) can be derived from this 16 years long spatially resolved 392 time series at several taxonomic levels, these datasets are intended to be used in various ecological studies including the zooplankton compartment, especially modelling studies, where zooplankton is usually 393 394 underrepresented (Mitra, 2010; Mitra et al., 2014). Finally, these datasets can also be used for machine learning 395 applied to plankton studies serving, for example, as consequent learning sets.

#### 396 **Disclaimer**

397 Data are published without any warranty, express or implied. The user assumes all risk arising from his/her use of 398 data. Data are intended to be research-quality, but it is possible that the data themselves contain errors. It is the 399 sole responsibility of the user to assess if the data are appropriate for his/her use, and to interpret the data 400 accordingly. Authors welcome users to ask questions and report problems.

#### 401 Authors' contributions

402 GN scanned and validated most of the ZooScan dataset, assembled the datasets, and led the drafting. BP collected 403 and managed the samples since 2004, and participated in the manual validation of identifications. DE scanned a 404 substantial fraction of the ZooScan samples and participated in the initial sorting of vignettes. DMM participated in the collection of samples, and was involved in the ZooCAM development. DM was chief scientist on the 405 PELGAS surveys and participated in the drafting. DC supervised GN work and participated in the drafting. FB 406 407 developed, improved and maintained the ZooCAM software. JL curated a substantial fraction of the ZooScan 408 dataset manual validation of identifications. HM participated in the collection of samples, lead the DEFIPEL 409 project, and participated in the drafting. LMS participated in the collection of samples, and managed the ZooCAM. 410 NA curated a substantial fraction of the ZooScan and ZooCAM dataset manual validation of identifications. PP 411 supervised GN work and participated in the drafting. PPh participated in the collection of samples and participated 412 in the drafting. RJ supervised the development and improvement of the ZooCAM. TM developed and improved the ZooCAM, and participated in the collection of samples. RJB supervised GN work, participated in the collection 413 414 of samples, curated a substantial fraction of the ZooCAM dataset manual validation of identifications, and lead 415 the drafting.

#### 416 **Competing interests**

417 The authors declare that they have no conflict of interest.

#### 418 Acknowledgements

419 The authors acknowledge receiving funding from the 'France Filière Pêche' DEFIPEL project. NG acknowledges the funding of her PhD by Region Pays de la Loire, FR and Ifremer. The authors wish to thank Jean-Yves Coail, 420 421 Gérard Guyader and Patrick Berriet (Ifremer – REM-RDT-SIIM) for their contribution to the hardware assembly 422 of the ZooCAM. The authors acknowledge the work of Elio Raphalen for scanning year 2005 samples. The authors thank the EMBRC platform PIQs for image analysis. This work was supported by EMBRC-France, whose French 423 424 state funds are managed by the ANR within the Investments of the Future program under reference ANR-10-INBS-02. Finally, the authors wish also to thank the many other students, technicians and scientists who 425 426 participated in the sampling and samples imaging on board, and the successive crews of the R/V Thalassa involved 427 in the PELGAS surveys from 2004 to 2019.

## 589 Appendix A

590 Table A1: ZooCAM dataset columns header – definition of data and metadata fields.

| Column name                | Definition  |  |  |  |
|----------------------------|---|--|--|--|
| object_id                  | name of object and associated image   |  |  |  |
| objid                      | unique ecotaxa internal object identifier                                       |  |  |  |
| object_lat                 | latitude of sampling  |  |  |  |
| object_lon                 | longitude of sampling   |  |  |  |
| object_date                | date of sampling  |  |  |  |
| object_time                | time of sampling  |  |  |  |
| object_depth_min           | minimum sampling depth  |  |  |  |
| object_depth_max           | maximum sampling depth  |  |  |  |
| object_taxon               | taxonomic name  |  |  |  |
| object_lineage             | full taxonomic lineage corresponding to the taxon                               |  |  |  |
| classif_id                 | unique ecotaxa internal taxon identifier  |  |  |  |
| object_area                | object's surface  |  |  |  |
| object_area_exc            | object surface excluding white pixels   |  |  |  |
| object_%area               | proportion of the image corresponding to the object                             |  |  |  |
| object_area_based_diameter | object's Area Based Diameter: 2 * (object_area/pi)^(1/2)                        |  |  |  |
| object_meangreyimage       | mean image grey level   |  |  |  |
| object_meangreyobjet       | mean object grey level  |  |  |  |
| object_modegreyobjet       | modal object grey level   |  |  |  |
| object_sigmagrey           | object grey level standard deviation  |  |  |  |
| object_mingrey             | minimum object grey level   |  |  |  |
| object_maxgrey             | maximum object grey level   |  |  |  |
| object_sumgrey             | object grey level integrated density: object_mean*object_area                   |  |  |  |
| object_breadth             | breadth of the object along the best fitting ellipsoid minor axis               |  |  |  |
| object_length              | breadth of the object along the best fitting ellipsoid majorr axis              |  |  |  |
| object_elongation          | elongation index: object_length/object_breadth                                  |  |  |  |
| object_perim               | object's perimeter  |  |  |  |
| object_minferetdiam        | minimum object's feret diameter   |  |  |  |
| object_maxferetdiam        | maximum object's feret diameter   |  |  |  |
| object_meanferetdiam       | average object's feret diameter   |  |  |  |
| object_feretelongation     | elongation index: object_maxferetdiam/object_minferetdiam                       |  |  |  |
| object compactness         | Isoperimetric quotient: the ration of the object's area to the area of a circle |  |  |  |
| ogoet_compactions          | having the same perimeter   |  |  |  |
| object_intercept0          | the number of times that a transition from background to foreground occurs a    |  |  |  |
|                            | the angle $0^{\circ}$ for the entire object                                     |  |  |  |

| abject intercent/5          | the number of times that a transition from background to foreground occurs a |  |  |  |
|-----------------------------|--|--|--|--|
| object_intercept45          | the angle 45° for the entire object  |  |  |  |
| object intercent90          | the number of times that a transition from background to foreground occurs a |  |  |  |
| object_intercept>0          | the angle 90° for the entire object  |  |  |  |
| object_intercent135         | the number of times that a transition from background to foreground occurs a |  |  |  |
| object_intercept155         | the angle 135° for the entire object   |  |  |  |
| object_convexhullarea       | area of the convex hull of the object  |  |  |  |
| object_convexhullfillratio  | ratio object_area/convexhullarea   |  |  |  |
| object_convexperimeter      | perimeter of the convex hull of the object                                   |  |  |  |
| object_n_number_of_runs     | number of horizontal strings of consecutive foreground pixels in the object  |  |  |  |
| object_n_chained_pixels     | number of chained pixels in the object                                       |  |  |  |
| object_n_convex_hull_points | number of summits of the object's convex hull polygon                        |  |  |  |
| object_n_number_of_holes    | number of holes (as closed white pixel area) in the object                   |  |  |  |
| object_transparence         | ratio object_sumgrey/obejct_area   |  |  |  |
| object_roughness            | measure of small scale variations of amplitude in the object's grey levels   |  |  |  |
| object_rectangularity       | ratio of the object's area over its best bounding rectangle's area           |  |  |  |
| object_skewness             | skewness of the object's grey level distribution                             |  |  |  |
| object_kurtosis             | kurtosis of the object's grey level distribution                             |  |  |  |
| object_fractal_box          | fractal dimension of the object's perimeter                                  |  |  |  |
| object hist25               | grey level value at quantile 0.25 of the object's grey levels normalized     |  |  |  |
| 00jeet_113t25               | cumulative histogram   |  |  |  |
| object hist50               | grey level value at quantile 0.5 of the object's grey levels normalized      |  |  |  |
| object_mstoo                | cumulative histogram   |  |  |  |
| object hist75               | grey level value at quantils 0.75 of the object's grey levels normalized     |  |  |  |
|                             | cumulative histogram   |  |  |  |
| object_valhist25            | sum of grey levels at quantile 0.25 of the object's grey levels normalized   |  |  |  |
| object_vallist25            | cumulative histogram   |  |  |  |
| object_valhist50            | sum of grey levels at quantile 0.5 of the object's grey levels normalized    |  |  |  |
|                             | cumulative histogram   |  |  |  |
| object valhist75            | sum of grey levels at quantile 0.75 of the object's grey levels normalized   |  |  |  |
|                             | cumulative histogram   |  |  |  |
| object_nobj25               | number of objects after thresholding at the object_valhist25 grey level      |  |  |  |
| object_nobj50               | number of objects after thresholding at the object_valhist50 grey level      |  |  |  |
| object_nobj75               | number of objects after thresholding at the object_valhist75 grey level      |  |  |  |
| object_symetrieh            | index of horizontal symmetry   |  |  |  |
| object_symetriev            | index of vertical symmetry   |  |  |  |
| object_thick_r              | maximum object's thickness/mean object's thickness                           |  |  |  |
| object_cdist                | distance between the mass and the grey level object's centroids              |  |  |  |
| object_bord                 | tag for object touching the frame edge                                       |  |  |  |

| sample_id                  | name of the sample from the object originate                               |  |
|----------------------------|--|--|
| sample_ship                | name of the ship used to collect the samples                               |  |
| sample_campaign            | name of the cruise where samples were collected                            |  |
| sample_station             | name of the station where samples were collected                           |  |
| sample_depth               | bottom depth at station  |  |
| sample_device              | net used to collect the sample   |  |
| sample_fishingvolume       | seawater volume sampled  |  |
| sample_sub_part            | subsampling elevation factor   |  |
| process_id                 | name of software/software version used to analysed digitized sample images |  |
| process_resolution_camera_ |  |  |
| micron_par_pixel           | pixei size   |  |

592 Table A2: ZooScan dataset columns header – definition of data and metadata fields

| Column name      | Definition  |
|------------------|---|
| object_id        | name of object and associated image   |
| objid            | unique ecotaxa internal object identifier   |
| object_lat       | latitude of sampling  |
| object_lon       | longitude of sampling   |
| object_date      | date of sampling  |
| object_time      | time of sampling  |
| object_depth_min | minimum sampling depth  |
| object_depth_max | maximum sampling depth  |
| object_taxon     | taxonomic name  |
| object_lineage   | full taxonomic lineage corresponding to the taxon                                 |
| classif_id       | unique ecotaxa internal taxon identifier  |
| object_area      | object's surface  |
| object_mean      | mean object grey level  |
| object_stddev    | object grey level standard deviation  |
| object_mode      | modal object grey level   |
| object_min       | minimum object grey level   |
| object_max       | maximum object grey level   |
| object_perim.    | object's perimeter  |
| object_major     | lenght of major axis of best fitting elipse                                       |
| object_minor     | lenght of minor axis of best fitting elipse                                       |
| object_circ.     | circularity: 4*pi(object_area/object_perim.^2)                                    |
| object_feret     | maximum feret diameter  |
| object_intden    | object grey level integrated density: /object_mean*/object_area                   |
| object_median    | median object grey level  |
| object_skew      | skewness of the object's grey level distribution                                  |
| object_kurt      | kurtosis of the object's grey level distribution                                  |
| object_%area     | proportion of the image corresponding to the object                               |
| object_area_exc  | object surface excluding white pixels   |
| object_fractal   | fractal dimension of the object's perimeter                                       |
| object_skelarea  | surface of the one-pixel wide skeleton of the object                              |
| object_slope     | slope of the cumulated histogram of the object grey levels                        |
| object_histcum1  | the number of times that a transition from background to foreground occurs at the |
|                  | angle 0°  |
| object_histcum2  | grey level at quantiles 0.5 of the histogram of the object grey levels            |
| object_histcum3  | grey level at quantiles 0.75 of the histogram of the object grey levels           |
| object_nb1       | number of objects after thresholding at the object_histcum1 grey level            |
| object_nb2       | number of objects after thresholding at the object_histcum2 grey level            |

| object_symetrieh               | index of horizontal symmetry  |
|--------------------------------|---|
| object_symetriev               | index of vertical symmetry  |
| object_symetriehc              | index of horizontal symmetry after thresholding at the object_histcum1 grey level   |
| object_symetrievc              | index of vertical symmetry after thresholding at the object_histcum1 grey level     |
| object_convperim               | perimeter of the convex hull of the object  |
| object_convarea                | area of the convex hull of the object   |
| object_fcons                   | object's contrast   |
| object_thickr                  | maximum object's thickness/mean object's thickness                                  |
| object_esd                     | object's Equivalent Spherical Diameter: 2 * (object_area/pi)^(1/2)                  |
| object_elongation              | elongation index: major/minor   |
| object_range                   | range of greys: max-min   |
| object_meanpos                 | relative position of the mean grey: (max-mean)/range                                |
| object_centroids               | distance between the mass and the grey level object's centroids                     |
| object_cv                      | coefficient of variation of greys: 100*(stddev/mean)                                |
| object_sr                      | index of variation of greys: 100*(stddev/range)                                     |
| object_perimareaexc            | index of the relative complexity of the perimeter: object_perim/object_area_exc     |
| object_feretareaexc            | another elongation index : object_feret/object_area_exc                             |
| object_perimferet              | index of the relative complexity of the perimeter: object_perim/object_feret        |
| object_perimmajor              | index of the relative complexity of the perimeter: object_perim/object_major        |
| object_circex                  | circularity of object excluding white pixels: 4*pi(object_area_exc/object_perim.^2) |
| object_cdexc                   | distance between the mass and the grey level object's centroids calculated with     |
|                                | object_area_exc   |
| sample_id                      | name of the sample from the object originate  |
| sample_ship                    | name of the ship used to collect the samples  |
| sample_program                 | name of the cruise where samples were collected                                     |
| sample_stationid               | name of the station where samples were collected                                    |
| sample_bottomdepth             | bottom depth at station   |
| sample_net_type                | net used to collect the sample  |
| sample_tot_vol                 | seawater volume sampled   |
| sample_comment                 | comments associated with sampling/sample treatment                                  |
| process_id                     | name of software/software version used to analysed digitized sample images          |
| process_particle_pixel_size_mm | pixel size  |
| acq_id                         | name of subsample if any  |
| acq_min_mesh                   | minimum sieve size of subsample   |
| acq_max_mesh                   | maximum sieve size of subsample   |
| acq_sub_part                   | subsampling elevation factor  |
