34

35 **Abstract**

36 As a key biogeochemical pathway in the marine nitrogen cycle, nitrification (ammonia oxidation
37 and nitrite oxidation) converts the most reduced form of nitrogen – ammonium/ammonia (NH_4^+ /
38 NH_3) into the oxidized species nitrite (NO_2^-) and nitrate (NO_3^-). In the ocean, these processes are
39 mainly performed by ammonia-oxidizing archaea (AOA) and bacteria (AOB), and nitrite-
40 oxidizing bacteria (NOB). By transforming nitrogen speciation and providing substrates for
41 nitrogen removal, nitrification affects microbial community structure, marine productivity
42 (including chemoautotrophic carbon fixation) and the production of a powerful greenhouse gas,
43 nitrous oxide (N_2O). Nitrification is hypothesized to be regulated by temperature, oxygen, light,
44 substrate concentration, substrate flux, pH, and other environmental factors. Although the number
45 of field observations from various oceanic regions has increased considerably over the last few
46 decades, a global synthesis is lacking, and understanding how environmental factors control
47 nitrification remains elusive. Therefore, we have compiled a database of nitrification rates and
48 nitrifier abundance in the global ocean from published literature and unpublished datasets. This
49 database includes 2393 and 1006 measurements of ammonia oxidation and nitrite oxidation rates,
50 and 2242 and 631 quantifications of ammonia oxidizers and nitrite oxidizers, respectively. This
51 community effort confirms and enhances our understanding of the spatial distribution of
52 nitrification and nitrifiers, and their corresponding drivers such as the important role of substrate
53 concentration in controlling nitrification rates and nitrifier abundance. Some conundrums are also
54 revealed including the inconsistent observations of light limitation and high rates of nitrite
55 oxidation reported from anoxic waters. This database can be used to constrain the distribution of
56 marine nitrification, to evaluate and improve biogeochemical models of nitrification, and to
57 quantify the impact of nitrification on ecosystem functions like marine productivity and N_2O
58 production. This database additionally sets a baseline for comparison with future observations and
59 guides future exploration (e.g., measurements in the poorly sampled regions such as the Indian
60 Ocean; method comparison/standardization). The database is publicly available at Zenodo
61 repository: <https://doi.org/10.5281/zenodo.8355912> (Tang et al., 2023).

62

63 **Introduction**

64 Nitrification (ammonia oxidation and nitrite oxidation) converts the most reduced form of nitrogen
65 (N) – ammonium/ammonia ($\text{NH}_4^+/\text{NH}_3$) into the oxidized compounds nitrite (NO_2^-) and nitrate
66 (NO_3^-). Ammonia oxidation is conducted by ammonia oxidizing archaea (AOA) and bacteria
67 (AOB) with AOA dominating in most marine environments (Francis et al., 2005; Wuchter et al.,
68 2006). Marine AOA are often separated into a few major ecotype groups including water column
69 group A, water column group B and *Nitrosopumilus*-like (Beman et al., 2008; Tolar et al., 2020),
70 with a diverse group of AOA remaining to be characterized (Alves et al., 2018). Marine nitrite
71 oxidation is carried out by nitrite-oxidizing bacteria (NOB) such as *Nitrospina*, *Nitrospira*,
72 *Nitrococcus* and *Nitrobacter*, with *Nitrospina* as the dominant group (Mincer et al., 2007;
73 Pachiadaki et al., 2017). Complete ammonia-oxidizing (comammox) bacteria within the bacterial
74 genus *Nitrospira* have been identified in freshwater, terrestrial, and coastal environments but not
75 yet been found in the open ocean (Daims et al., 2015; Van Kessel et al., 2015; Xia et al., 2018).

76
77 Nitrification and nitrifiers are thought to be regulated by light/solar radiation, oxygen, temperature,
78 substrate concentration, pH, and other environmental factors (Ward, 2008), many of which are
79 experiencing dramatic changes in the ocean. For example, light is generally found to inhibit
80 nitrifier growth and nitrification rate (Olson, 1981b; Merbt et al., 2012; Xu et al., 2019). In
81 addition, ocean acidification decreases ammonia oxidation rates (Beman et al., 2011; Breider et
82 al., 2019) partly due to the decreased availability at lower pH of NH_3 , which is the actual substrate
83 for ammonia oxidation (Suzuki et al., 1974). In contrast, ocean warming shifts the $\text{NH}_4^+/\text{NH}_3$
84 equilibrium towards NH_3 by decreasing the pK_a (Emerson et al., 1975) and is observed to enhance
85 enzyme activity (Zheng et al., 2017; Zheng et al., 2020), further complicating the effect of climate
86 change on nitrification.

87
88 Although nitrification does not directly change the absolute inventory of bioavailable N, it can
89 control the relative availability of substrates (NH_4^+ , NO_2^- and NO_3^-) for phytoplankton growth.
90 Since prokaryotic phytoplankton preferentially assimilate NH_4^+ while eukaryotic phytoplankton
91 are better able to exploit NO_3^- in the sunlit surface ocean (Berthelot et al., 2018; Fawcett et al.,
92 2011), variations in the relative supply of NH_4^+ versus NO_3^- can influence phytoplankton
93 community composition and ecosystem functionalities. Because the uptake of NH_4^+ and NO_3^- is

94 often used to differentiate regenerated and new production (Eppley and Peterson, 1979),
95 production of NO_3^- by nitrification in the surface ocean may bias the estimate of new production
96 (Yool et al., 2007). NO_2^- and NO_3^- are also involved in denitrification and anammox, which remove
97 bioavailable N from the ocean. Thus, nitrification can indirectly affect the size of the bioavailable
98 N pool, marine productivity and ultimately the atmospheric CO_2 concentration (Falkowski, 1997).
99 As a chemoautotrophic process, nitrification in the ocean water column is estimated to supply
100 $\sim 0.13\text{-}1.4 \text{ Pg C yr}^{-1}$ of organic matter, which is critical to support the heterotrophic microbial
101 community/metabolism in the dark ocean (Bayer et al., 2022; Middelburg, 2011; Pachiadaki et al.,
102 2017; Zhang et al., 2020). Nitrification could also contribute to the oxygen consumption and the
103 development of hypoxia or anoxia (Hsiao et al., 2014; Beman et al., 2021). In addition, nitrification
104 is the major global ocean source of N_2O , a potent greenhouse gas and dominant ozone-depleting
105 agent, thus connecting the marine N cycle directly to the Earth's climate system (Freing et al.,
106 2012; Ji et al., 2018).

107
108 Considering the important role of nitrification and nitrifiers in marine N and C cycles and Earth's
109 climate, a better understanding of its distribution and regulating factors is highly desirable.
110 Historical observations of nitrification and nitrifiers cover a wide range of environmental gradients
111 and biogeography in the ocean, ranging from cross-Atlantic (e.g., Clark et al., 2008; Clark et al.,
112 2022), western Pacific (e.g., Wan et al., 2021; Wan et al., 2018), polar oceans (e.g., Shiozaki et
113 al., 2019; Mdutyana et al., 2020) to oxygen minimum zones (e.g., Peng et al., 2015; Santoro et al.,
114 2021). This study aims to introduce the newly constructed database of nitrification and nitrifiers
115 in the marine water column and to guide future research efforts in field observations and model
116 development of nitrification. This new global synthesis significantly expands upon what was
117 possible with earlier more limited datasets (Yool et al. 2007; Ward, 2008). Additional reviews on
118 marine nitrification and nitrifiers can be found elsewhere (Schleper and Nicol, 2010; Daims et al.,
119 2016; Ward, 2011b).

120

121 **Methods**

122 **Data sources and compilation**

123 Nitrification rates including ammonia oxidation and nitrite oxidation, and abundances of ammonia
124 oxidizers and nitrite oxidizers were extracted directly from the literature published between 1984
125 and 2022 when the data were presented in tables or supplementary materials from publications;
126 otherwise, data were provided by the coauthors. Some previously unpublished data were also
127 included in the database. Table 1 and Table 2 summarize the origin, methods and locations of
128 nitrification rate and nitrifier abundance measurements, sorted in alphabetical order by lead author.
129 The metadata format contains geographical sampling information (date, latitude, longitude, and
130 depth) and concurrent measurements of environmental conditions such as light intensity,
131 temperature, salinity, water density, N concentration (NH_4^+ , NO_2^- and NO_3^-), pH and oxygen
132 concentration if available. In total, there are 2393, 1006, 2242, and 631 measurements of ammonia
133 oxidation rate, nitrite oxidation rate, ammonia oxidizer abundance and nitrite oxidizer abundance,
134 respectively. However, not all measurements of nitrification rates or nitrifier abundance are
135 accompanied by all the environmental factors because such factors were often not reported in the
136 literature or recorded during the measurements/sample collections. Rates, nitrifier abundances and
137 environmental parameters below the methodological detection limits are noted as BDL. NM
138 represents parameters that were not measured. Empty/NA means that data are not available or
139 reported. The database is deposited into Zenodo repository following the Findable, Accessible,
140 Interoperable and Reusable (FAIR) principles for data management (Wilkinson et al., 2016). We
141 encourage authors and readers to contact us to report an update to or an error in the database.

142

143 Table 1. Summary of the number of observations for nitrification rates in alphabetical order of the
144 lead author. The method (e.g., substrate tracer addition vs product dilution), sampling regions and
145 whether nitrifier abundance is quantified are listed. Methods used for data collection are described
146 in the next section.

153

154 We applied Chauvenet's criterion for quality control to flag outliers in nitrification rates and
155 nitrifier abundance (Glover et al., 2011). Chauvenet's criterion is commonly applied to normally
156 distributed datasets to identify outliers whose deviations from the mean have a probability of less
157 than $1/(2n)$, where n is the number of data points (Buitenhuis et al., 2013). We applied the criterion
158 acknowledging the fact that the data were collected at different environmental conditions. After
159 removing measurements of zero and below detection limit (277, 132, 51, 240, 6 and 11
160 observations for ammonia oxidation, nitrite oxidation, AOA *amoA*, AOB *amoA*, 16S rRNA of
161 *Thaumarchaeota* and *Nitrospina*), nitrification rates and nitrifier abundances were log₁₀
162 transformed before further analysis. Nitrification rates and nitrifier abundances reported at 0 or
163 below detection limit are noted separately in the database and following analysis. Although we did
164 not find outliers for ammonia oxidation and nitrite oxidation rates, there are some extreme values
165 worth noting. For example, an extremely high ammonia oxidation rate of 4900 nmol L⁻¹ d⁻¹ was

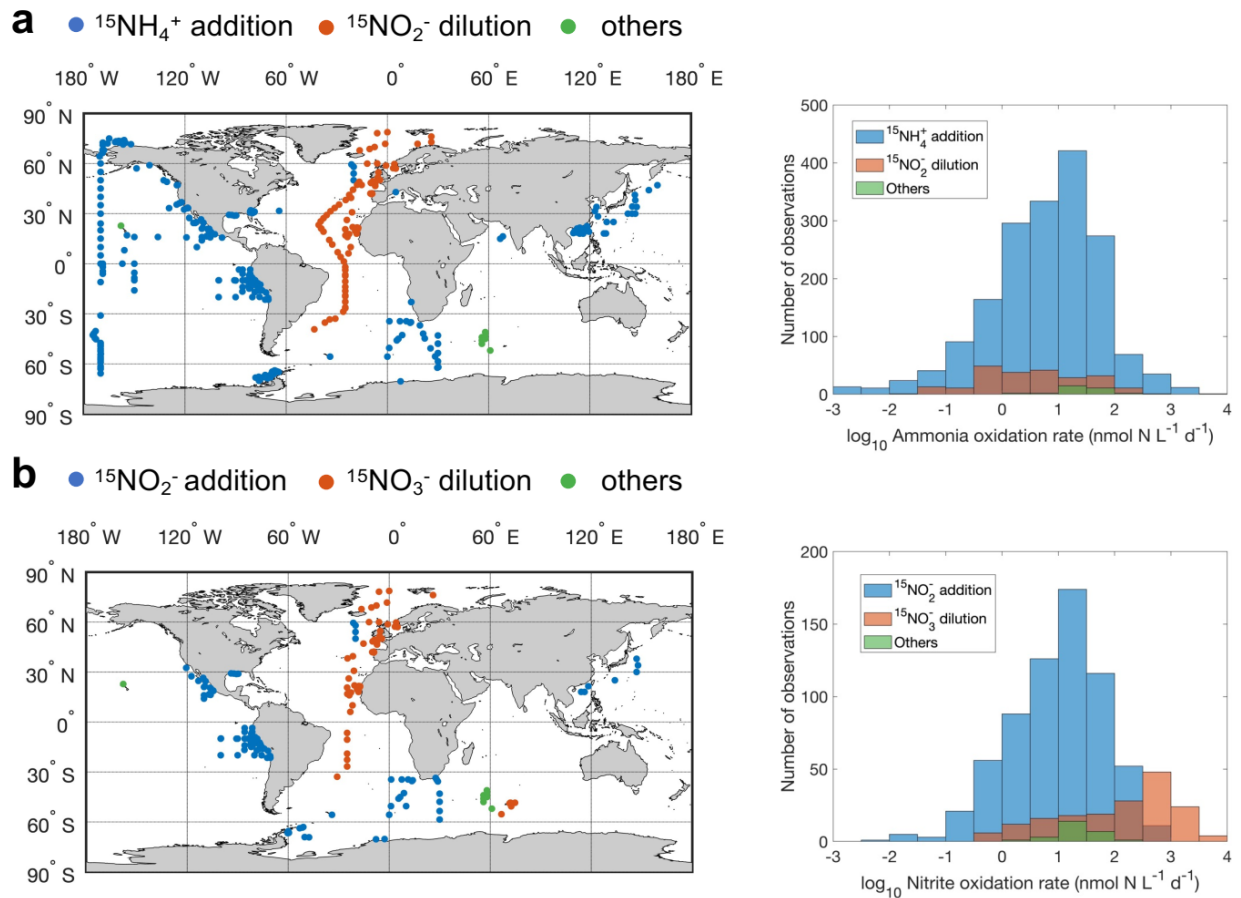

166 observed in the Peruvian oxygen minimum zone (Lam et al., 2009). Low but detectable rates below
167 0.01 nmol L⁻¹ d⁻¹ were observed in the Eastern Tropical North Pacific oxygen minimum zone (Frey
168 et al., 2022), South Atlantic Bight (Liu et al., 2018) and western Pacific (Xu et al., 2018). Some
169 outliers were identified by Chauvenet's criterion for ammonia oxidizers (1 for AOB *amoA* and 1
170 for 16S rRNA of *Thaumarchaeota*). An abnormally high abundance of the bacterial *amoA* gene
171 (10⁸ copies L⁻¹) was observed in the South Pacific oxygen minimum zone (Kalvelage et al., 2013),
172 which was removed from the following analysis. A low abundance of 16S rRNA of
173 *Thaumarchaeota* (25 copies L⁻¹) was found in the surface water of the western Pacific (Zhang et
174 al., 2020). In addition, the low-ammonia concentration AOA ecotype (or water column group B
175 AOA) at 2 copies L⁻¹ was reported in the Arctic Ocean (Sintes et al., 2013). Measurements of
176 nitrification rate and nitrifier abundance of 0 or below detection limit were not included in the
177 analysis of outlier identification. For example, AOA abundance at 0 or below detection limit
178 (varies among studies) has been reported in surface waters of South Atlantic Bight (Damashek et
179 al., 2018), equatorial Pacific (Santoro et al., 2017) and North Pacific (Shiozaki et al., 2016).

180

181 **Methods for measuring ammonia oxidation and nitrite oxidation rates**

182 Ammonia oxidation rate is commonly measured by comparing the change in nitrite (NO₂⁻) and
183 nitrate (NO₃⁻) concentration in controls versus an experimental treatment containing a nitrification
184 inhibitor (e.g., Dore and Karl, 1996), by tracking the oxidation of ¹⁵NH₄⁺ into the NO₂⁻ and NO₃⁻
185 pool (Olson, 1981a), or by the dilution of ¹⁵NO₂⁻ (Clark et al., 2007). Similarly, nitrite oxidation
186 rate can be measured by the change in NO₃⁻ concentration, by tracking the oxidation of ¹⁵NO₂⁻ into
187 the NO₃⁻ pool, or by the dilution of ¹⁵NO₃⁻ (Ward et al., 1989). In addition, nitrification has also
188 been estimated from the incorporation of ¹⁴C tracer due to the chemoautotrophic metabolism of
189 nitrifiers (Bianchi et al., 1997). There is a large uncertainty, however, in the conversion factor from
190 carbon fixation to nitrification (Bayer et al., 2022). A more detailed description of methods for
191 measuring nitrification can be found in Ward, 2011a. The spatial distribution of different methods
192 used to measure nitrification and the frequency distribution of measured rates by different methods
193 are shown in Figure 1. Rates measured with the substrate tracer addition method (¹⁵NH₄⁺ and
194 ¹⁵NO₂⁻) outnumbered other methods globally but the product dilution method (¹⁵NO₂⁻ and ¹⁵NO₃⁻)
195 dominated in the Atlantic Ocean. The ammonia oxidation rates measured by different methods
196 have similar median values. However, the median nitrite oxidation rate measured by the ¹⁵NO₃⁻

197 dilution method is significantly higher than the rate measured by the $^{15}\text{NO}_2^-$ addition method (200.3
 198 vs $7.4 \text{ nmol N L}^{-1} \text{ d}^{-1}$). These comparisons, however, are between samples aggregated from
 199 measurements taken at different sites. It is thus unclear whether the differences arise from
 200 differences in the measurement approaches (e.g., in sensitivity) or in the sites where measurements
 201 were made. A direct methods comparison is recommended for future exploration.
 202

203
 204 Figure 1. Distribution of different methods used to measure ammonia oxidation (a) and nitrite
 205 oxidation (b). Others include ^{14}C incorporation and concentration change methods. Note the colors
 206 change slightly where they overlap in the histograms.

207
 208 Incubations to measure nitrification rates have been conducted in polycarbonate and glass bottles,
 209 exetainers and plastic bags. Seawater is directly transferred from the Niskin bottle into the
 210 incubation containers to minimize temperature, oxygen and other perturbations. These incubation
 211 containers are usually kept in an incubator with light filters to mimic the ambient temperature and

212 light conditions. After incubating for 3 hours to over 24 hours depending on the estimated
213 magnitude of nitrification rates, the incubation is terminated by filtering via GF/F or 0.22 μm filters
214 (e.g., Baer et al., 2017; Wan et al., 2018). The filtrate is then frozen at -20°C or -80°C until further
215 analysis on land. The incubation has also been terminated by subsampling and freezing without
216 filtration (e.g., Damashek et al., 2018). Alternatively, the incubation is preserved by adding
217 mercury chloride or zinc chloride (Kalvelage et al., 2013; Frey et al., 2020). This method allows
218 gas measurements like N_2O and N_2 production before nitrification analysis. Detailed incubation
219 conditions for each study are presented in the database file.

220

221 Various approaches have been developed to measure the N isotopes of NO_2^- and NO_3^- . For
222 example, 1) dissolved NO_2^- is extracted by formation of an azo dye. The resulting dye is filtered
223 onto precombusted GF/F or GF/C filters and its $^{15}\text{N}:^{14}\text{N}$ ratio is analyzed by elemental analyzer
224 isotope ratio mass spectrometry (Ward et al., 1982; Olson, 1981a). NO_3^- can be reduced to NO_2^-
225 by cadmium reduction and then extracted using the azo dye method described above. 2) Dissolved
226 NO_2^- is converted to Sudan-1 and Sudan-1 is collected via solid-phase extraction. The sample is
227 then purified by HPLC and derivatized before analysis by GC/MS (Clark et al., 2007). Similarly,
228 NO_3^- can be reduced to NO_2^- by cadmium prior to conversion to Sudan-1 for nitrogen isotope
229 analysis. 3) NO_2^- can be converted to N_2 with sulfamic acid and subsequently measured by isotope
230 ratio mass spectrometry (Dalsgaard et al., 2012; Bristow et al., 2016). 4) NO_2^- can also be
231 converted into N_2O by the azide method and subsequently measured by isotope ratio mass
232 spectrometry (Mcilvin and Altabet, 2005). The N isotopes of NO_2^- and NO_3^- can be measured via
233 the denitrifier method (Sigman et al., 2001; Weigand et al., 2016) where both NO_2^- and NO_3^- are
234 converted into N_2O . In addition, the $\delta^{15}\text{N}$ of NO_3^- alone can be measured using the denitrifier
235 method after removing NO_2^- with sulfamic acid (Granger and Sigman, 2009). The azide and
236 denitrifier methods require smaller sample volumes and offer a higher sensitivity of nitrogen
237 isotope detection.

238

239 Many factors may complicate the interpretation of rate measurements, e.g., isotope dilution by
240 regeneration of the ^{15}N -labeled substrates and stimulation of nitrification by substrate addition
241 (Lipschultz, 2008). For instance, the amount of tracer addition varied substantially from <10 nM
242 to 5 μM , enriching the ambient pool by $<10\%$ to over 1000%. The excess addition of substrates

243 will likely enhance the nitrification rate, which will then reflect a potential rate instead of an
 244 in situ rate. In addition, the measurement of NO_2^- compared to $\text{NO}_2^- + \text{NO}_3^-$ could also lead to
 245 variations in the estimates of the ammonia oxidation rates. Specifically, $^{15}\text{NO}_2^-$ produced from
 246 $^{15}\text{NH}_4^+$ may be further oxidized to $^{15}\text{NO}_3^-$, especially when samples are low in NO_2^- concentration.
 247 Ammonia oxidation rate may be underestimated if only $^{15}\text{NO}_2^-$ is measured instead of measuring
 248 both $^{15}\text{NO}_2^-$ and $^{15}\text{NO}_3^-$ (Santoro et al., 2013; Peng et al., 2015). Therefore, NO_2^- carrier (to increase
 249 the NO_2^- pool and trap the produced $^{15}\text{NO}_2^-$) may be added to the sample before incubation or both
 250 NO_2^- and NO_3^- should be measured after incubation when ambient NO_2^- concentration is low. The
 251 $^{15}\text{NO}_2^-$ isotope dilution method may overestimate ammonia oxidation rates because NO_2^- could
 252 also be released from phytoplankton after assimilative nitrate reduction (Lomas and Lipschultz,
 253 2006). These confounding factors may be difficult to quantify but worth recording and reporting
 254 in publications for the sake of comparison among studies. In addition, a variety of approaches have
 255 been applied to calculate nitrification rates. The following equations are commonly used to
 256 estimate nitrification measured by the tracer addition (Equation 1; e.g., Peng et al., 2015) or tracer
 257 dilution method (Equation 2; e.g., Clark et al., 2007; Cavagna et al., 2015). However, these
 258 equations do not account for the effect of other processes such as the isotope dilution on rate
 259 estimates. Please refer to other studies for the detailed rate correction processes (e.g., Lipschultz
 260 et al., 1986; Santoro et al., 2010; Kanda et al., 1987).

261
$$\text{Rate} = \frac{\Delta[^{15}\text{NO}_x^-]}{F \times \Delta t} \quad \text{Equation 1}$$

262 where $\Delta[^{15}\text{NO}_x^-]$ represents the change in concentration of $^{15}\text{NO}_2^-$ or $^{15}\text{NO}_3^-$ between the end
 263 and start of the incubation. F represents the fraction of ^{15}N such as $(\frac{^{15}\text{NH}_4^+}{^{15}\text{NH}_4^+ + ^{14}\text{NH}_4^+} \text{ or } \frac{^{15}\text{NO}_2^-}{^{15}\text{NO}_2^- + ^{14}\text{NO}_2^-})$
 264 in the initial substrate pool (NH_4^+ or NO_2^-). Δt is the length of incubation time.

265
$$\text{Rate} = \frac{\ln(\frac{R_t}{R_0})}{\ln(\frac{[\text{NO}_x^-]_t}{[\text{NO}_x^-]_0})} \times (\frac{[\text{NO}_x^-]_0}{\Delta t}) \quad \text{Equation 2}$$

266 where R_t and R_0 represent ratios of $^{15}\text{NO}_x^-$ to $^{14}\text{NO}_x^-$ after and before the incubation, respectively.
 267 NO_x^- is either NO_2^- or NO_3^- , which are used for calculating ammonia oxidation and nitrite
 268 oxidation rates, respectively. $[\text{NO}_x^-]_t$ and $[\text{NO}_x^-]_0$ are NO_x^- concentration after and before the
 269 incubation, respectively. Δt is the length of incubation time.

270

271 Nitrification supported by organic N substrates like urea and cyanate has been observed in the Gulf
 272 of Mexico (Kitzinger et al., 2018), Pacific (Santoro et al., 2017; Wan et al., 2021), off the east

273 coast of the United States (Laperriere et al., 2020; Tolar et al., 2017), and in the polar oceans
 274 (Alonso-Saez et al., 2012; Shiozaki et al., 2021). The number of these observations remains limited
 275 compared to ammonia oxidation. They can be included in future editions of the database (i.e., not
 276 included in the current database) and their role in the marine N cycle deserves future investigations.
 277

278 **Methods for quantifying ammonia oxidizers and nitrite oxidizers**

279 We summarize the primers used to quantify nitrifier abundance based on both functional genes
 280 and 16S rRNA genes using quantitative PCR (qPCR) (Table 3). The cell abundance and biomass
 281 can be subsequently estimated based on the gene abundance, number of genes per cell and specific
 282 cell biomass (e.g., Kitzinger et al., 2020; Khachikyan et al., 2019). The oxidation of ammonia to
 283 hydroxylamine is catalyzed by ammonia monooxygenase, which is a multisubunit enzyme
 284 partially encoded by the *amoA* gene. Primers have been designed to quantify both bacterial and
 285 archaeal *amoA* genes (Rotthauwe et al., 1997; Francis et al., 2005; Hornek et al., 2006; Wuchter
 286 et al., 2006; Beman et al., 2008; Mosier and Francis, 2011; Sintes et al., 2013). Archaeal ammonia
 287 oxidizers are also separated into different ecotypes including Water Column ecotypes A and B
 288 (WCA and WCB), which preferentially inhabit the surface vs deep ocean, respectively, or high-
 289 ammonia concentration vs low-ammonia concentration groups, which dominate in high ammonia
 290 vs low ammonia concentration environments, respectively. The *nxrB* gene, which encodes the beta
 291 subunit of nitrite oxidoreductase for nitrite oxidation, has been used to quantify *Nitrospira* (Pester
 292 et al., 2014). However, no primers targeting *nxr* genes are available for other groups of nitrite
 293 oxidizers such as *Nitrospina*, which is the dominant group of nitrite oxidizers in the ocean (Beman
 294 et al., 2013; Pachiadaki et al., 2017). Primers have also been designed to quantify the 16S rRNA
 295 gene abundance of *Thaumarchaeota*, *Nitrospira*, and *Nitrospina* (Mincer et al., 2007; Graham et
 296 al., 2007). The abundance of nitrifiers can be useful for inferring and interpreting nitrification rates.
 297 In addition to qPCR, amplicon sequencing and quantitative metagenomics are also useful to
 298 determine the abundance of nitrifiers (Tolar et al., 2020; Lin et al., 2019; Satinsky et al., 2013) but
 299 these analyses are not included in the database.

303 **Results and Discussion**

304 **Summary of the database**

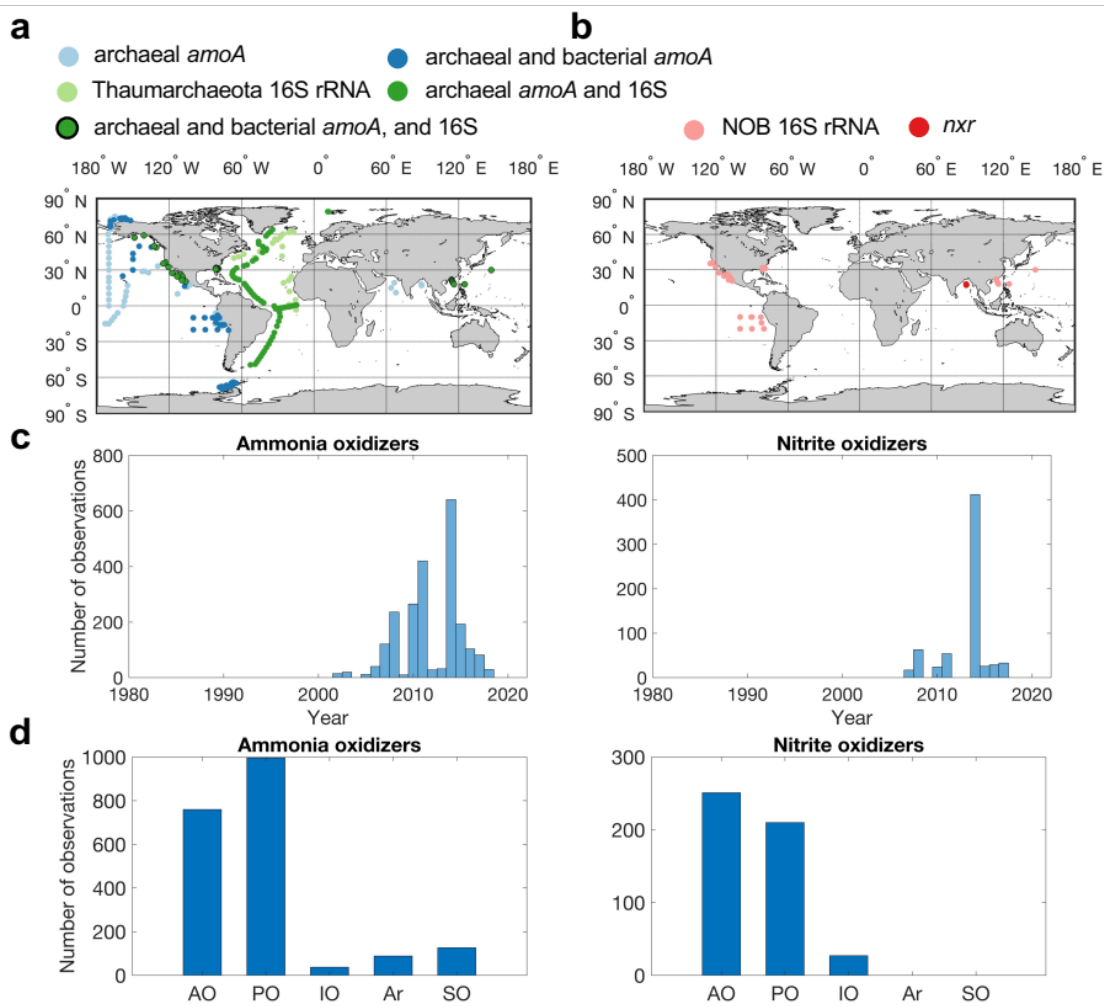

305

306 Figure 2. Map showing the distribution of sampling locations for nitrification rate measurements
307 (a), the number of observations each year (b) and the number of observations in different ocean
308 basins (c) (AO: Atlantic Ocean; PO: Pacific Ocean; IO: Indian Ocean; Ar: Arctic Ocean; SO:
309 Southern Ocean). Blue points: only ammonia oxidation is measured; red points: only nitrite
310 oxidation is measured. Green points: both ammonia oxidation and nitrite oxidation are measured.

311

312 In total, there are 2393 and 1006 measurements of ammonia oxidation and nitrite oxidation,
313 respectively (Figure 2). Ammonia oxidation and nitrite oxidation have been concurrently measured
314 at 418 locations. The Pacific Ocean has the largest number of nitrification observations followed
315 by the Atlantic Ocean, Southern Ocean and Indian Ocean. Particularly, meridional transects across
316 ocean basins and biomes have been conducted in the North Pacific and Atlantic (Shiozaki et al.,
317 2016; Clark et al., 2008; Clark et al., 2022). Observations have recently expanded into oxygen
318 minimum zones (Beman et al., 2012; Beman et al., 2013; Frey et al., 2020; Frey et al., 2022; Peng
319 et al., 2015; Peng et al., 2016; Santoro et al., 2021; Sun et al., 2017) and polar oceans (Cavagna et
320 al., 2015; Shiozaki et al., 2019; Smith et al., 2022; Mduyana et al., 2022a and b; Mduyana et al.,
321 2020; Flynn et al., 2021). Nitrification rates are more frequently measured after 2010 (Figure 2b).
322

323

324 Figure 3. Maps showing the distribution of sampling locations for ammonia oxidizers (a) and
 325 nitrite oxidizers (b), the number of observations each year (c) and the number of observations in
 326 different ocean basins (d) (AO: Atlantic Ocean; PO: Pacific Ocean; IO: Indian Ocean; Ar: Arctic
 327 Ocean; SO: Southern Ocean). (a) light blue points: only archaeal *amoA* was quantified. Dark blue
 328 points: both archaeal and bacterial *amoA* genes were quantified. Light green points: 16S rRNA
 329 gene of *Thaumarchaeota* was quantified; dark green points: both archaeal *amoA* and 16S rRNA
 330 gene of *Thaumarchaeota* were quantified. (b) pink points: 16S rRNA of nitrite oxidizers was
 331 quantified; red points: *nxr* gene of nitrite oxidizers was quantified.

332

333 In total, there are 2242 and 631 measurements of ammonia oxidizer and nitrite oxidizer abundance,
 334 respectively (Figure 3). Most of the nitrifier quantifications have been conducted in the tropical
 335 and subtropical oceans (Figure 4a). Data are sparse in the central Pacific, Indian Ocean and
 336 Southern Ocean (with the exception of the West Antarctic Peninsula). Both archaeal *amoA* and
 337 16S rRNA genes of *Thaumarchaeota* were quantified on a transect across the Atlantic (Sintes et
 338 al., 2016). There are far fewer observations of nitrite oxidizers compared to ammonia oxidizers.
 339 Notably, there are only 27 observations of *nxr* genes. The quantification of nitrifier abundance
 340 starts to accumulate after 2002 (Figure 3c). Most of the observations of nitrite oxidizers originate
 341 from one study where samples were collected in 2014 (Liu et al., 2018). Nitrification rate and
 342 nitrifier abundance are sometimes determined at the same location, which allows us to assess the
 343 relationship between biogeochemical rate and the abundance of functional groups (e.g., Peng et
 344 al., 2015; Shiozaki et al., 2019; Santoro et al., 2021).

345

346 Distribution of ammonia oxidation

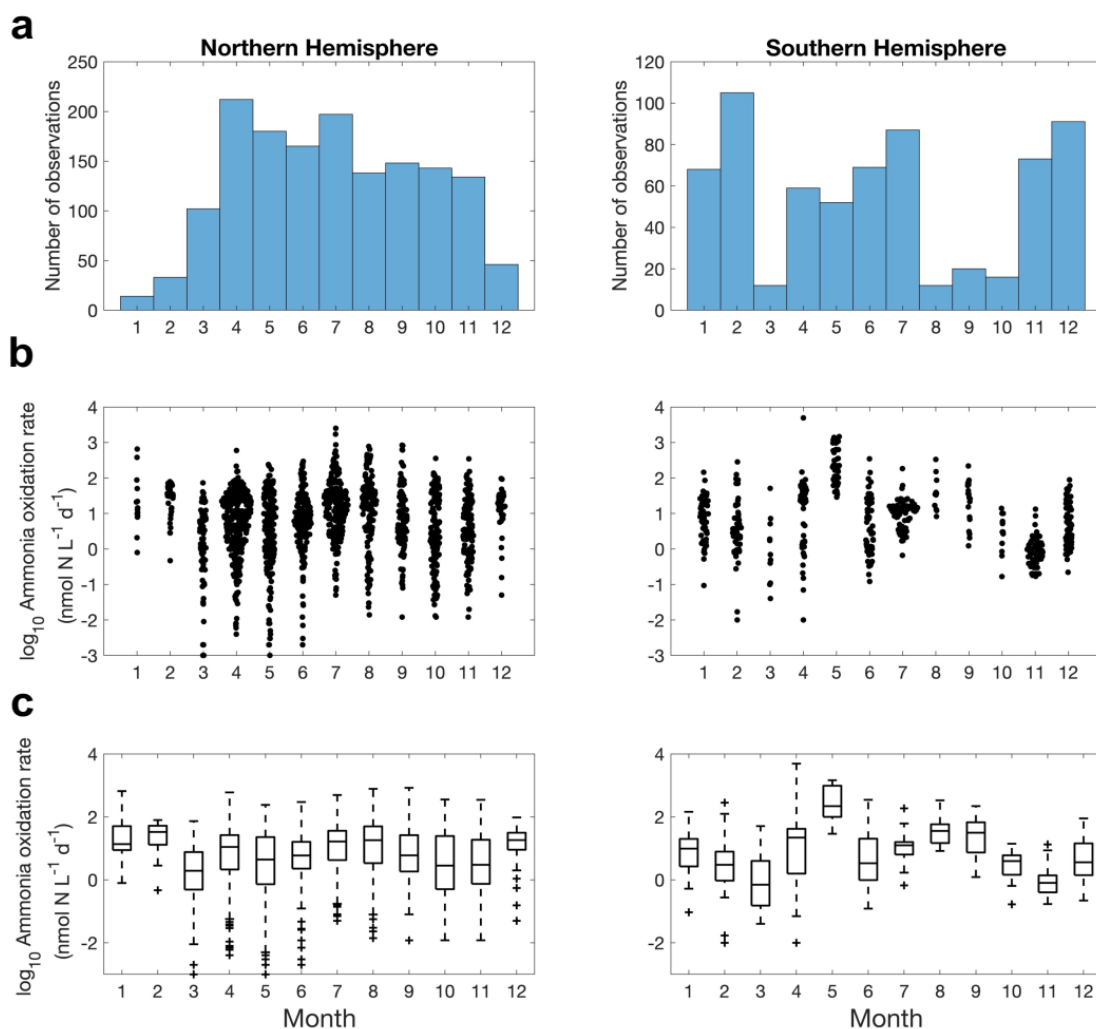

347

348 Figure 4. Number of ammonia oxidation observations (a) and ammonia oxidation rates (b-c) within
349 latitudinal bands. For the boxplot in this figure and figures throughout the manuscript, the black
350 line in each box is the median. The bottom and top of each box are the 25th and 75th percentiles
351 of the observations, respectively. The error bars represent 1.5 times the interquartile range away
352 from the bottom or top of the box, with black + signs showing outliers beyond that range.

353

354 A large number of observations exist for the tropical and temperate oceans (Figure 4), particularly
355 in the 30-40°N band where rates were measured in offshore waters of Georgia and California
356 (Tolar et al., 2020; Liu et al., 2018). Ammonia oxidation rates vary from <0.01 to over 1000 nmol
357 $\text{N L}^{-1} \text{d}^{-1}$ with a median value of $7.7 \pm 9.8 \text{ nmol N L}^{-1} \text{d}^{-1}$. There is no clear latitudinal trend in the
358 ammonia oxidation rates. In contrast, Clark et al. (2022) found higher ammonia oxidation rates in
359 the southern hemisphere along the north-south transect in the Atlantic Ocean. This latitudinal
360 pattern is hypothesized to be explained by the difference in the supply of dissolved organic
361 nitrogen (DON) by lateral transport into the gyre interior from the eastern boundary upwelling
362 (Clark et al., 2022). The stimulation of ammonia oxidation rates by a lateral DON supply has also
363 been observed in the Western Pacific (Xu et al., 2018).

364

365
 366 Figure 5. Monthly variation (1-12: January to December) of ammonia oxidation observations (a)
 367 and ammonia oxidation rates (b-c) divided into observations taken in the Northern Hemisphere
 368 (left panels) and Southern Hemisphere (right panels). Jitter according to data density is added in
 369 subplot b.

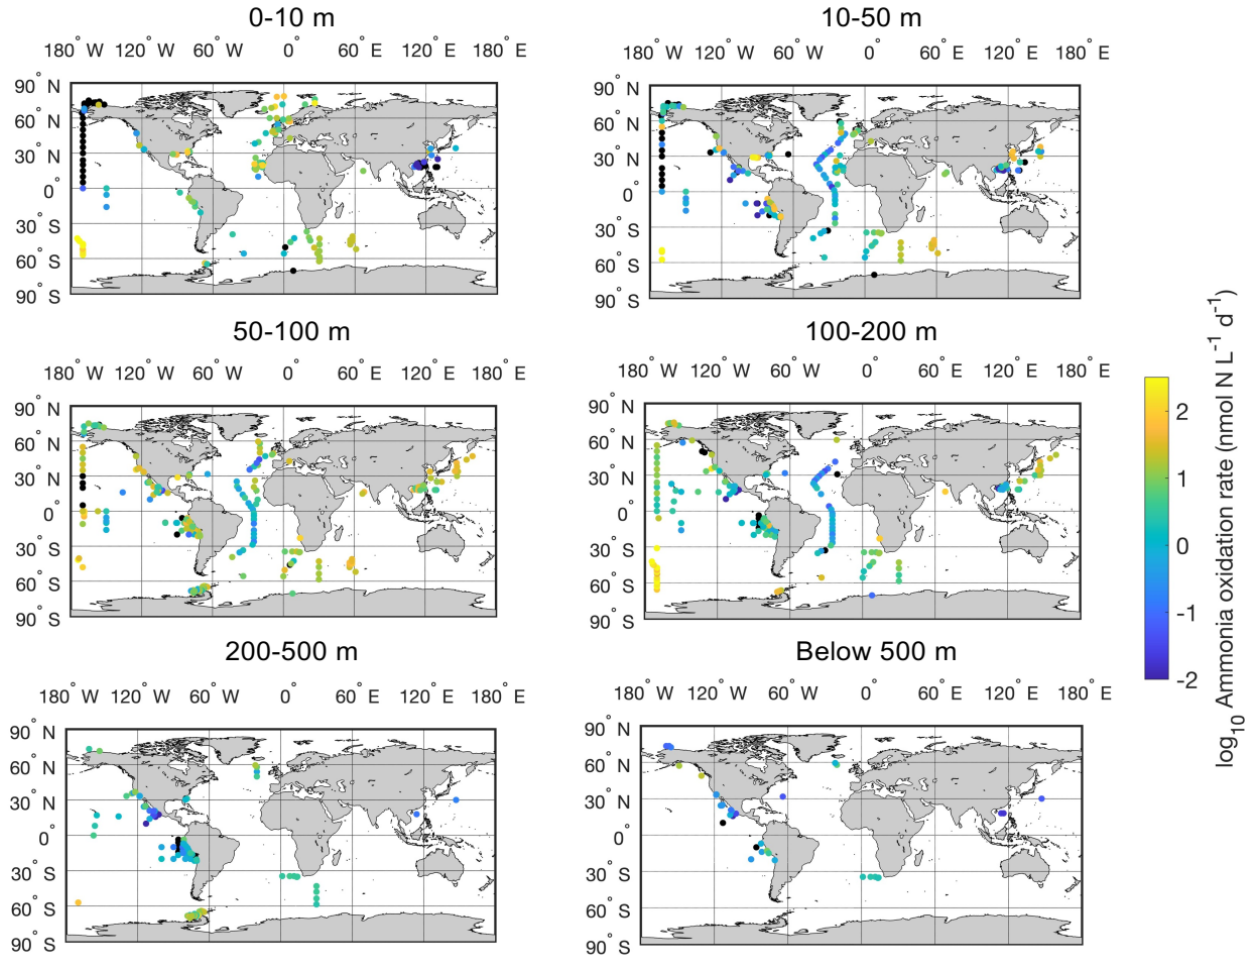

370
 371 More ammonia oxidation measurements were conducted in summer in both hemispheres (Figure
 372 5) which is likely due to the more challenging weather conditions in winter for field explorations.
 373 The northern hemisphere has more observations compared to the southern hemisphere. Although
 374 no clear seasonal pattern is apparent for ammonia oxidation rates at a global scale, seasonal
 375 variation in ammonia oxidation has been seen at time-series stations near and offshore of
 376 California (Ward, 2005; Tolar et al., 2020; Laperriere et al., 2020). In addition, ammonia oxidation

377 showed a substantial seasonal pattern in the polar ocean with higher rates observed in the NH_4^+ -
378 enriched dark winter season (Baer et al., 2017; Mdotyana et al., 2020; Mdotyana et al., 2022b).
379

380
381 Figure 6. Vertical variation of ammonia oxidation observations (a) and ammonia oxidation rates
382 (b-c). Note the axis breaks at 500 m depth in subplots a and b.
383

384 Most of the ammonia oxidation rate measurements were made shallower than 500 m, accounting
385 for ~96% of the total measurements (Figure 6). Ammonia oxidation rates often reach a maximum
386 near the base of the euphotic zone or in the 50-100 m layer before decreasing with depth below
387 the euphotic zone. Although nitrification is thought to be inhibited by light, high ammonia
388 oxidation rates $>100 \text{ nmol N L}^{-1} \text{ d}^{-1}$ have been observed within the euphotic zone (Raes et al.,
389 2020; Bianchi et al., 1997), suggesting complex regulation of nitrification in the surface ocean.
390 This complicates the interpretation of the source of NO_3^- in the euphotic zone and further the NO_3^-
391 -supported new production (Diaz and Raimbault, 2000; Yool et al., 2007; Grundle et al., 2013;
392 Mdotyana et al. 2020).
393

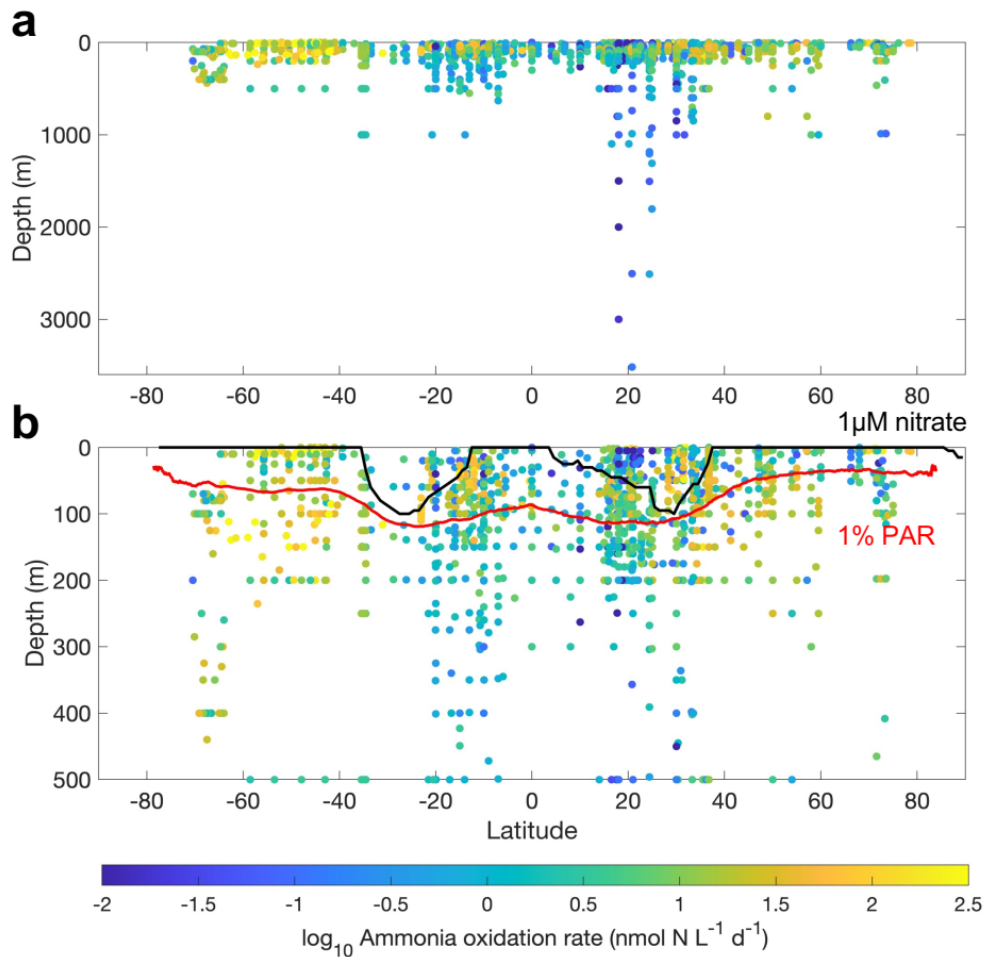

395

396 Figure 7. Spatial distribution of ammonia oxidation rates in six depth intervals in the global ocean.
 397 Locations with rates below the detection limit are shown in the black circles.

398

399 There is a large spatial and vertical variation in ammonia oxidation rates (Figure 7). Some hotspots
 400 with rates $>100 \text{ nmol N L}^{-1} \text{ d}^{-1}$ include the subpolar North Atlantic (Clark et al., unpublished),
 401 Southern Ocean (Mdutyana et al., 2020), and coastal waters off California and Georgia (Tolar et
 402 al., 2020; Liu et al., 2018). Particularly, there are extremely high ammonia oxidation rates >1000
 403 $\text{nmol N L}^{-1} \text{ d}^{-1}$ observed in the surface Pacific Southern Ocean (Raes et al., 2020), deserving further
 404 studies to confirm this pattern. In contrast, some low rates $<0.01 \text{ nmol N L}^{-1} \text{ d}^{-1}$ or rates below the
 405 detection limit are found in the surface sunlit North Pacific, which is likely caused by the light
 406 limitation of nitrifiers, and nitrifier competition with phytoplankton for NH_4^+ in well-lit areas
 407 (Smith et al., 2014). For example, peak ammonia oxidation rates are often found in regions/depths

408 where NO_3^- is present or light levels are low such that competition of nitrifiers with phytoplankton
409 for NH_4^+ diminishes (Figure 8; Wan et al., 2021). Additionally, low rates are found in oxygen-
410 depleted waters of the eastern tropical Pacific where ammonia oxidation is likely limited by
411 oxygen availability (Peng et al., 2016).
412

413
414 Figure 8. Latitudinal and vertical distribution of ammonia oxidation rates in the whole water
415 column (a) and from the top 500 m (b). The climatological depths of the euphotic zone (1% PAR)
416 obtained from MODIS satellite observations and 1 μM nitrate obtained from World Ocean Atlas
417 2018 (García et al., 2019) are shown by the red line and black lines, respectively.
418

419 Distribution of nitrite oxidation

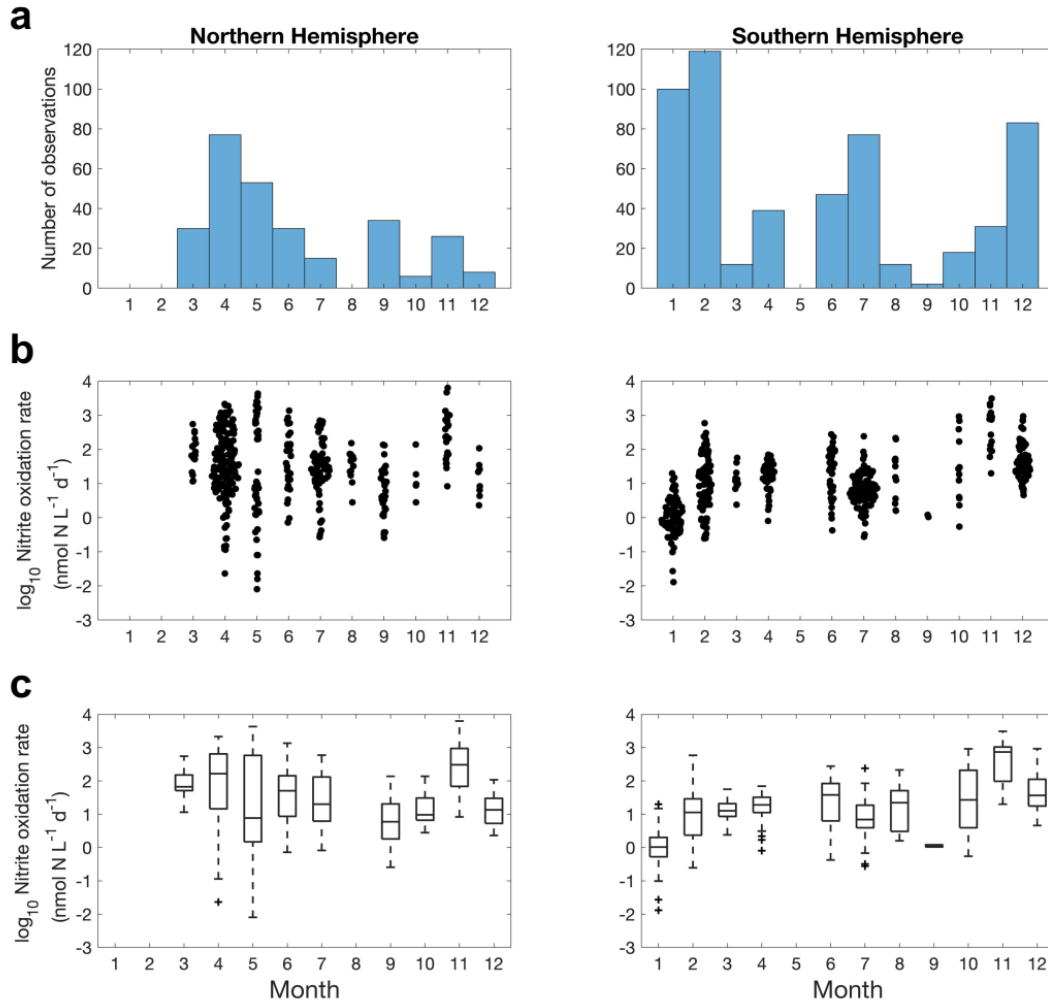

420

421 Figure 9. Number of nitrite oxidation observations (a) and nitrite oxidation rates (b-c) within
422 latitudinal bands.

423

424 Similar to ammonia oxidation, the majority of the nitrite oxidation observations were conducted
425 in the tropical and subtropical oceans (Figure 9), particularly in the eastern tropical Pacific oxygen
426 minimum zones (Ward et al., 1989; Peng et al., 2015; Kalvelage et al., 2013; Santoro et al., 2021).
427 Recent observations extended into the Southern Ocean (Cavagna et al., 2015; Mduyana et al.,
428 2020; Mduyana et al., 2022a; Flynn et al., 2021). The rates vary from 0.01 to >1000 nmol N L⁻¹
429 d⁻¹ with a median value at 15.9±10.7 nmol N L⁻¹ d⁻¹. Nitrite oxidation rates seem to increase from
430 the southern hemisphere to northern hemisphere. The lowest median rates were found in the
431 Southern Ocean south of 60°S, which is hypothesized to be regulated by low iron availability
432 (Mduyana et al., 2022a). Overall, more measurements of nitrite oxidation over a large spatial scale
433 are desired to resolve the latitudinal distribution of nitrite oxidation rates.

434

435
 436 Figure 10. Monthly variation (1-12: January to December) in the number of nitrite oxidation
 437 observations (a) and nitrite oxidation rates (b-c).

438
 439 Nitrite oxidation measurements are limited in winter in the northern hemisphere (Figure 10). No
 440 clear seasonal pattern is found for nitrite oxidation rates at a global scale, except for some of the
 441 lowest rates detected in January in the Southern Ocean (austral summer). In addition to iron
 442 limitation, light inhibition and competition with phytoplankton for nitrite during the growing
 443 season may be important factors driving these low rates. Unlike ammonia oxidation, there is no
 444 time-series study of nitrite oxidation to show its seasonal variations.

445

446

447

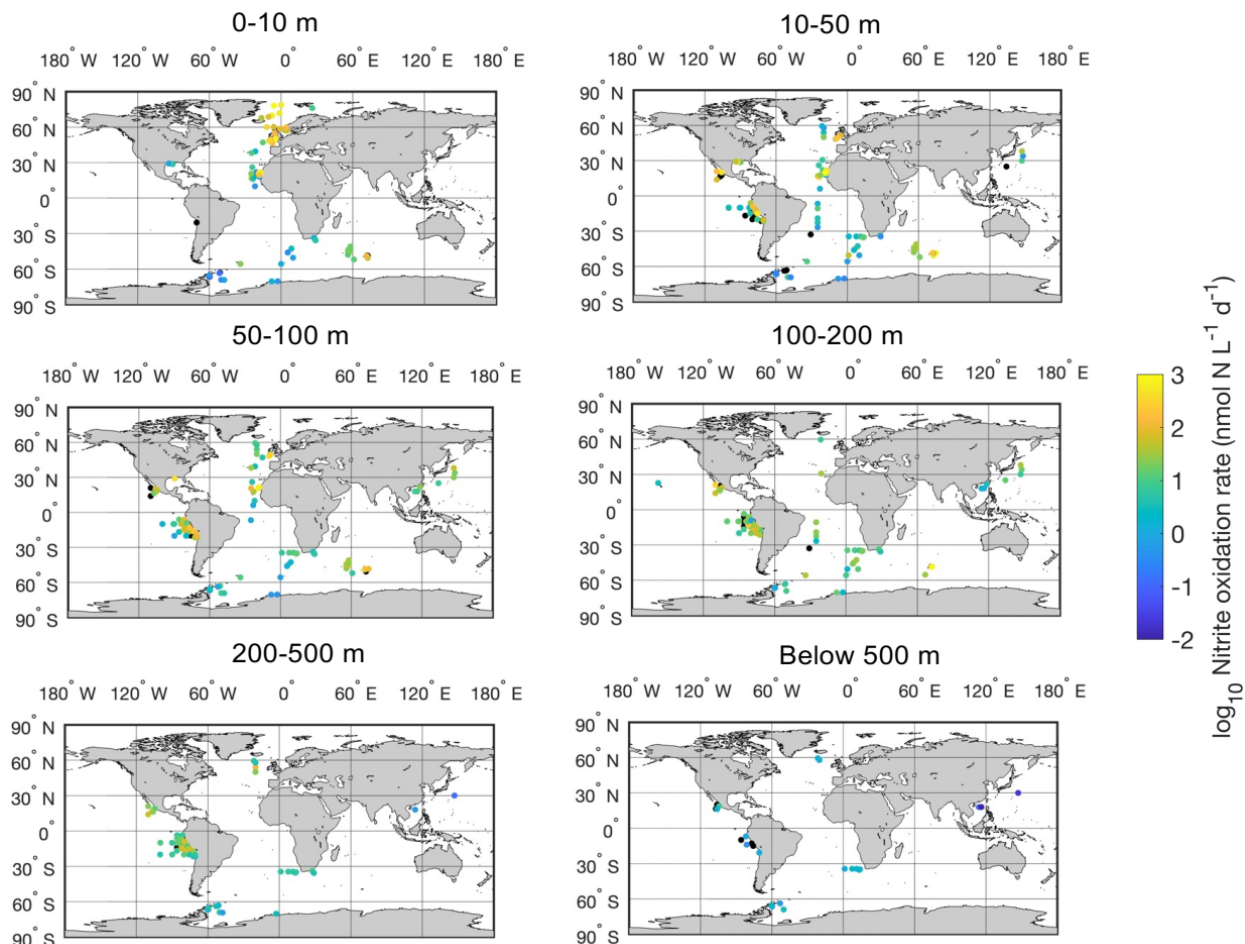

448 Figure 11. Vertical variation of nitrite oxidation observations (a) and nitrite oxidation rates (b-c).
449 Note the axis breaks at 500 m depth in subplots a and b.

450

451 Most of the nitrite oxidation rates were also measured at depths shallower than 500 m, accounting
452 for ~94% of the total measurements (Figure 11). There is a large spatial variation in the nitrite
453 oxidation observations and rates (Figure 12). Observations are lacking in the central Pacific Ocean
454 and Indian Ocean outside of the oxygen minimum zones. Nitrite oxidation rates decrease with
455 depth. Globally, the highest median nitrite oxidation rates were found in the surface water (0-10
456 m layer), which is mainly attributed to the high surface rates observed over the United Kingdom
457 shelves, subpolar North Atlantic and Mauritanian upwelling system (Figure 12; Clark et al.,
458 unpublished; Clark et al., 2016). After removing these high surface nitrite oxidation rates, the depth
459 profiles of nitrite oxidation often show a subsurface maximum that is slightly deeper than the
460 subsurface maximum of ammonia oxidation (Figure 13). This difference may be related to the
461 higher sensitivity of nitrite oxidizers/nitrite oxidation to light (Wan et al., 2021; Olson, 1981b).
462 Interestingly, some deep peaks of nitrite oxidation rates have been found in the oxygen-depleted
463 waters in the oxygen minimum zones (Peng et al., 2015; Babbin et al., 2020; Ward et al., 1989;
464 Beman et al., 2013). These high rates stand out in depths below the 1 μM nitrate threshold and
465 above the 1% PAR level between 20°N and 20°S (Figure 14). Many hypotheses (Sun et al., 2023)
466 have been proposed to explain the observed “anaerobic” nitrite oxidation, including alternative
467 oxidants like iodate (Babbin et al., 2017), distinct nitrite oxidizers that are only present in the
468 OMZs and adapted to the low oxygen conditions (Sun et al., 2021), nitrite dismutation ($2\text{H}^+ +$
469 $5\text{NO}_2^- \rightarrow \text{N}_2 + 3\text{NO}_3^- + \text{H}_2\text{O}$; van de Leemput et al., 2011; Babbin et al., 2020; Tracey et al., 2022),

470 and oxygen intrusions (Buchanan et al., 2023). Whether nitrite oxidation is truly anaerobic and
471 how nitrite oxidation is sustained in oxygen depleted waters remain to be determined.

472

473

474 Figure 12. Spatial distribution of nitrite oxidation rates in six depth intervals in the global ocean.

475 Locations with rates below the detection limit are shown in the black circles.

476

477

478 Figure 13. Depth profiles of ammonia oxidation (a) and nitrite oxidation (b) in the top 1000 m.

479 Only depth profiles with five or more measurements/depths are included in this figure. The grey

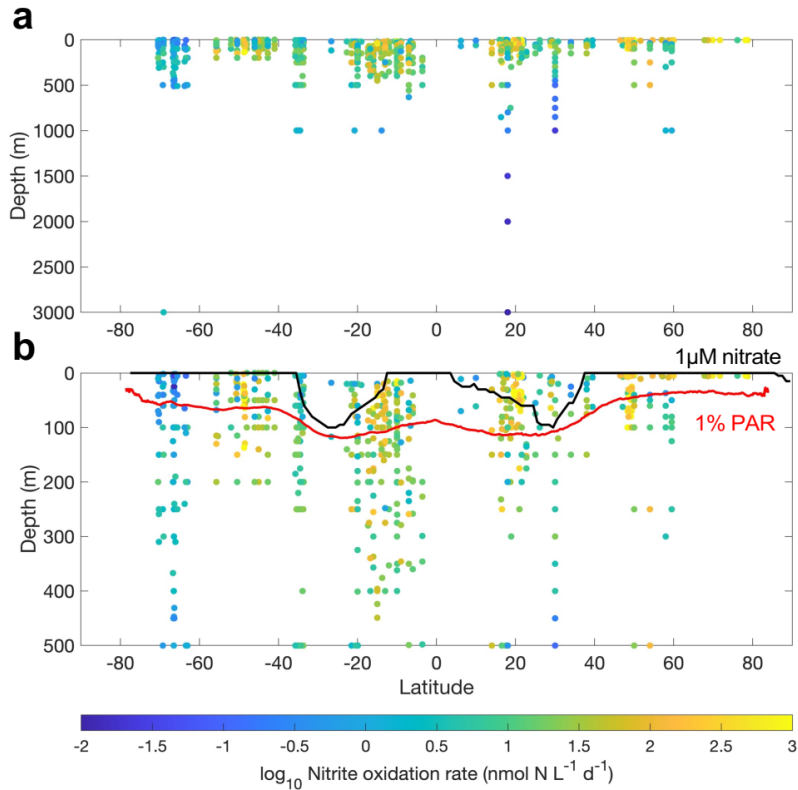

480 lines and black lines show non-paired and paired profiles (i.e., ammonia oxidation and nitrite

481 oxidation were measured concurrently), respectively. The median profiles of ammonia oxidation

482 and nitrite oxidation are shown in red lines, highlighting the maximum of nitrite oxidation deeper

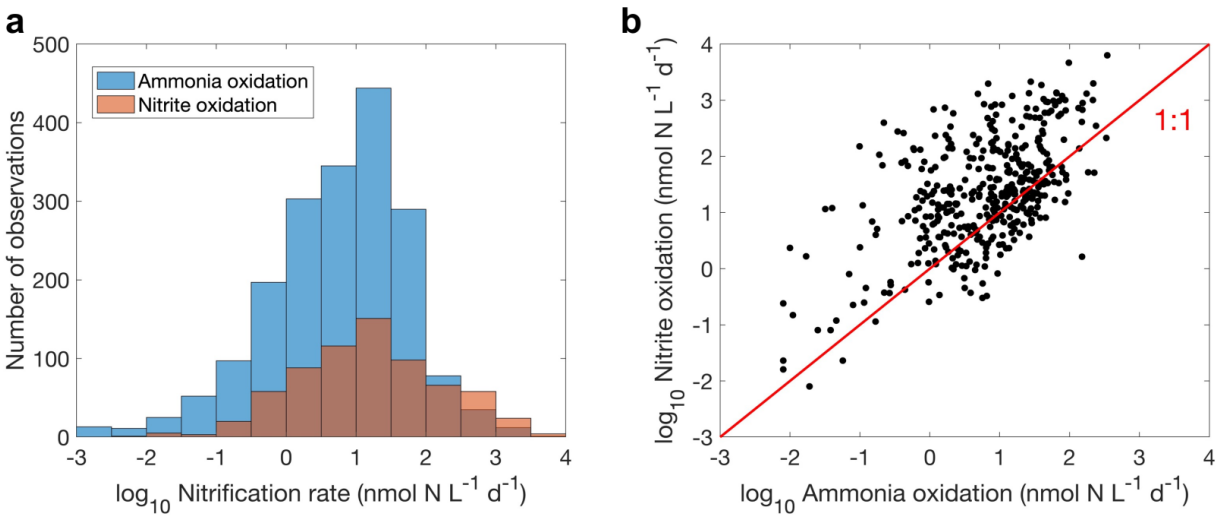

483 than the maximum of ammonia oxidation.

484

485
 486 Figure 14. Latitudinal and vertical distribution of nitrite oxidation rates in the whole water column
 487 (a) and from the top 500 m (b). The lower panel shows data from the top 500 m. The climatological
 488 depth of the euphotic zone (1% PAR) and 1 μM nitrate are shown by the red and black lines
 489 respectively.

490

491
 492 Figure 15. Comparison between ammonia oxidation and nitrite oxidation. (a) Histogram of both
 493 rates globally. Note the colors change slightly where they overlap in the histograms. (b)

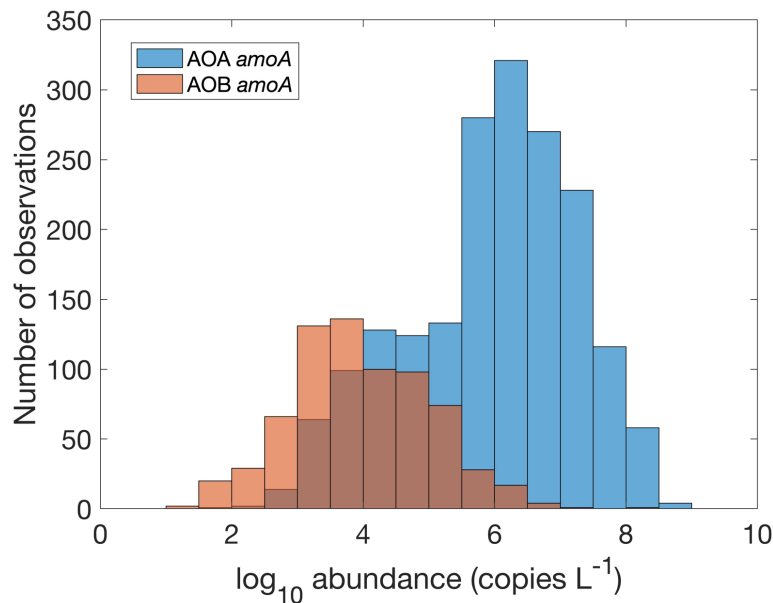

494 Relationship between ammonia oxidation and nitrite oxidation measured at the same locations and
495 time ($\log_{10}y = 0.53 \times \log_{10}x + 0.91$, $r = 0.5$, $p < 0.01$).

496

497 Overall, there are fewer nitrite oxidation rate measurements compared to ammonia oxidation
498 measurements (Figure 15a). Ammonia oxidation and nitrite oxidation are generally of similar
499 magnitude (Figure 15b), leading to the low concentration of NO_2^- in most of the ocean. However,
500 ammonia oxidation and nitrite oxidation could be decoupled. For example, higher ammonia
501 oxidation rates than nitrite oxidation rates (Lomas and Lipschultz, 2006) and competition between
502 ammonia oxidation and phytoplankton ammonium assimilation (Zakem et al. 2018) may both
503 partly explain the presence of the primary nitrite maximum. The median nitrite oxidation rate is
504 higher than the median ammonia oxidation rate (15.9 vs 7.7 $\text{nmol N L}^{-1} \text{d}^{-1}$), which may be related
505 to nitrite production pathways from urea and cyanate oxidation in addition to ammonia oxidation
506 (Wan et al., 2022; Kitzing et al., 2018). Consistently, when comparing ammonia oxidation and
507 nitrite oxidation rates measured at the same locations and same time, nitrite oxidation rates are
508 mostly higher (Figure 15b). Mechanisms driving the decoupling of ammonia oxidation and nitrite
509 oxidation deserve further investigations.

510

511 **Distribution of ammonia oxidizers**

512

513 Figure 16. Comparison between the gene abundance of AOA *amoA* and AOB *amoA*. AOA *amoA*
 514 represent the total abundance of archaeal *amoA* gene abundance or the sum of WCA and WCB.
 515 Note the colors change slightly where they overlap in the histograms.
 516

517
 518 Figure 17. Comparison between AOA *amoA* and *Thaumarchaeota* 16S rRNA gene abundances
 519 ($\log_{10}y = 0.78 \times \log_{10}x + 1.66$, $r = 0.9$, $p < 0.01$).
 520

521 There are 1893, 892, 1073 measurements of the abundance of AOA *amoA* gene, AOB *amoA* and
 522 16S rRNA of *Thaumarchaeota*, respectively. Within the measurements of AOA *amoA* abundance,
 523 1204 and 1101 measurements were separately conducted for water column ecotype A (WCA)
 524 *amoA* and water column ecotype B (WCB) *amoA*. Thus, the total *amoA* gene abundance was
 525 calculated by summing the abundance of WCA and WCB when available. The AOA *amoA*
 526 abundance with median of 1.34×10^6 copies L^{-1} is substantially higher than AOB *amoA* gene
 527 abundance with median of 7.96×10^3 copies L^{-1} (Figure 16), confirming the dominance of archaeal
 528 ammonia oxidizers in the ocean. We also found that *Thaumarchaeota* 16S rRNA gene abundance
 529 positively correlates with but slightly outnumbered the *amoA* gene abundance (Figure 17). This may
 530 suggest that not all the *Thaumarchaeota* contain the *amoA* genes to oxidize NH_4^+ or some
 531 organisms containing *amoA* genes (such as the *Nitrosopumilus*-like group) may have been missed

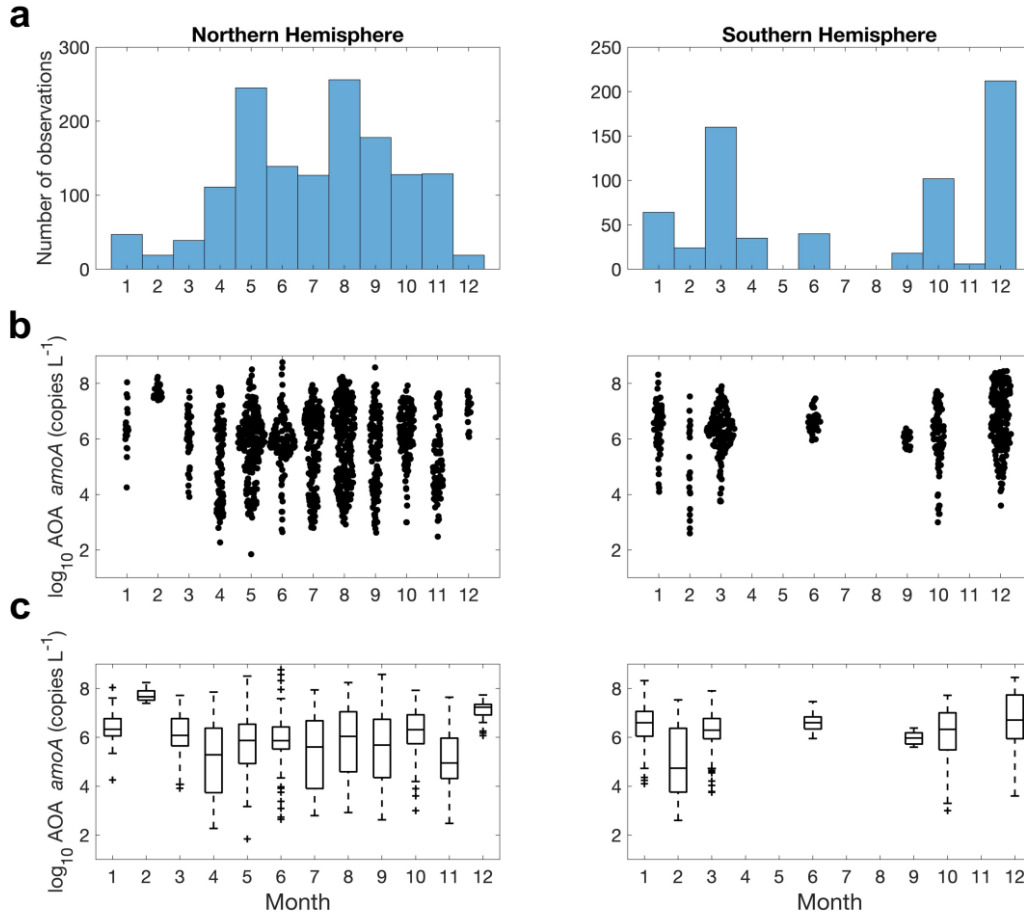

532 due to primer bias (Sintes et al., 2016; Hiraoka et al., preprint), Since total AOA *amoA* genes have
 533 the largest number of observations and better represent ammonia oxidation capability, we will use
 534 it to show the spatial and vertical distribution of ammonia oxidizer abundance.
 535

536
 537 Figure 18. Number of observations of archaeal ammonia oxidizers (a) and the abundance of
 538 archaeal ammonia oxidizers (b-c) within latitudinal bands.

539
 540 The eastern Pacific Ocean and Atlantic Ocean have the majority of the observations for ammonia
 541 oxidizers, particularly in the 30-40°N band where ammonia oxidizers were measured in the coastal
 542 waters off California and Georgia (Liu et al., 2018; Tolar et al., 2020). In contrast, observations in
 543 the Indian Ocean and Southern Ocean are scarce. The AOA *amoA* gene abundance varies from a
 544 few copies per liter in the surface ocean to over 10^8 copies L^{-1} in the subsurface of equatorial
 545 Atlantic. There is no clear latitudinal trend in the abundance of ammonia oxidizers.

546

547

548 Figure 19. Monthly variation (1-12: January to December) in the number of the observation (a)
 549 and abundance (b-c) of archaeal *amoA*.

550

551 There are substantially more observations in the northern hemisphere than the southern
 552 hemisphere. We do not see a clear seasonal trend in nitrifier abundance due to the large monthly
 553 variation. A time-series study in the Monterey Bay shows that seasonality can be observed for the
 554 top 200 m while the overall community of ammonia oxidizers was stable at 500 m (Tolar et al.,
 555 2020). In addition, mid-summer peaks in *Thaumarchaeota* abundance have been observed at the
 556 coast off Georgia (Hollibaugh et al., 2013). More time-series studies with high-frequency sampling
 557 would be useful for characterizing the response of the nitrifier community to seasonal changes in
 558 environmental drivers.

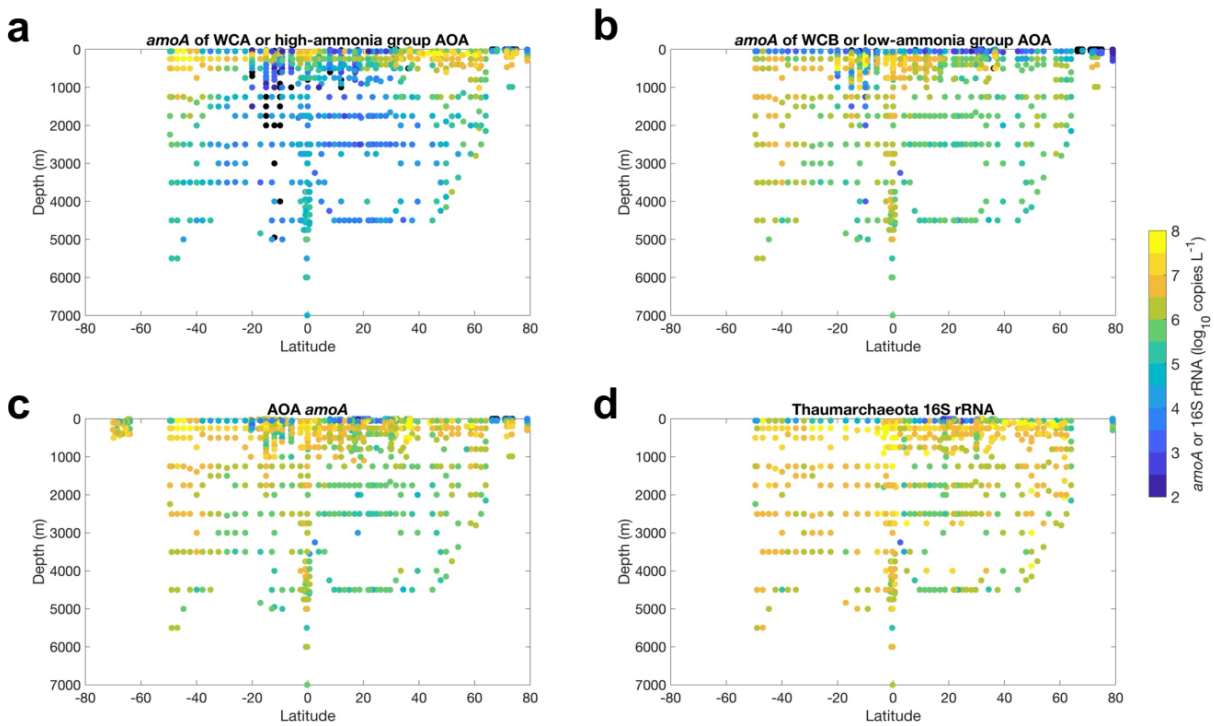

559

560

561 Figure 20. Vertical distribution of archaeal *amoA* observations (a) and archaeal *amoA* gene
 562 abundance (b-c). Note the axis breaks at 1000 m depth in subplots a and b.

563

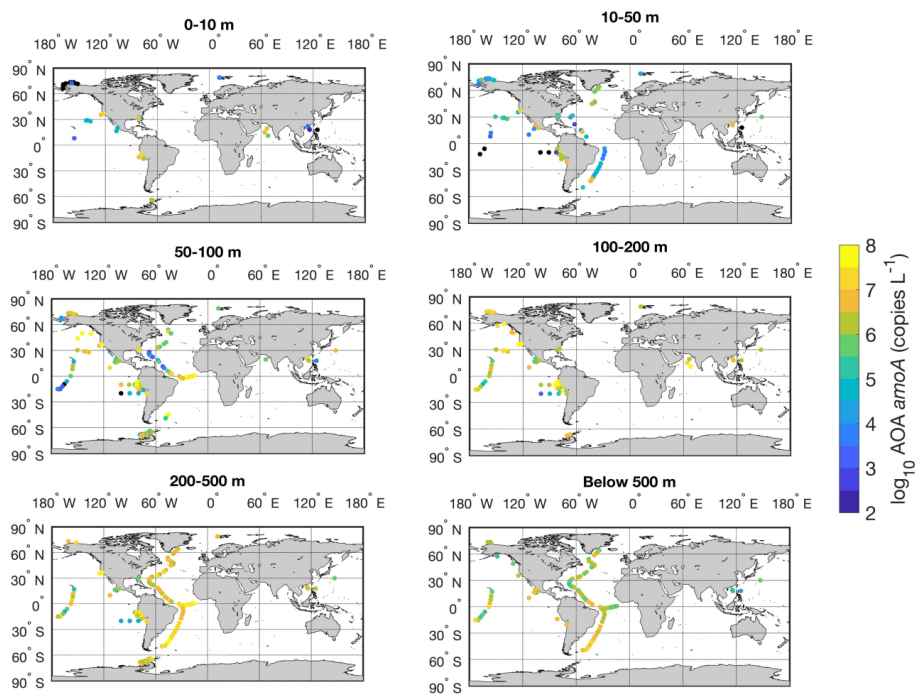

564

565 Figure 21. Vertical distribution of AOA *amoA* gene abundance (a-c) and 16S rRNA of
 566 *Thaumarchaeota* (d) across the latitudinal gradient. WCA and high-ammonia concentration groups
 567 (a) are shown together while WCB and low-ammonia concentration groups (b) are shown together.
 568 The total AOA *amoA* or the sum of WCA and WCB is shown in (c).

569

570 Most of the abundance measurements of ammonia oxidizers were made in the top 1000 m (Figure
 571 20). Median ammonia oxidizer abundance increases from $\sim 10^5$ copies L^{-1} in the 0-10 m depth layer
 572 to $\sim 10^7$ copies L^{-1} in the 100-200 m layer, then decreases with depth and remains relatively

573 constant at $\sim 10^6$ copies L^{-1} in the deep ocean below 500 m depth. We noticed that *amoA* abundance
 574 and ammonia oxidation rates appear to have different depth distributions, particularly for the top
 575 200 m (Figure 6c and Figure 20c): *amoA* abundance in 0-10 m layer is lower than in 100-200 m
 576 layer while ammonia oxidation rates in 0-10 m layer are comparable to the rates observed in 100-
 577 200 m layer. These distributions may suggest depth differences in cell-specific activity which
 578 might be interesting for future investigation. The archaeal *amoA* is sometimes quantified separately
 579 for two ecotypes including water column groups A and B. Water column group A dominates the
 580 upper 200 meter while water column group B is more abundant in the mesopelagic and
 581 bathypelagic deep ocean below 500 m (Figure 21), likely reflecting their different affinities for
 582 NH_4^+ (Beman et al., 2008; Sintes et al., 2016). The vertical distribution of ammonia oxidizers is
 583 similar to the vertical distribution of ammonia oxidation rates (Figure 13).
 584

585
 586 Figure 22. Spatial distribution of AOA *amoA* gene in six depth intervals in the global ocean.
 587 Locations with abundance below the detection limit are shown in the black circles.

588
 589 There is a large spatial variation in the abundance of ammonia oxidizers (Figure 22). High
 590 abundances are found in the tropical Atlantic and eastern tropical Pacific where upwelling drives
 591 high rates of marine primary production. In contrast, some of the lowest abundances of ammonia

592 oxidizers are found in the South China Sea and oligotrophic subtropical Pacific. Therefore, the
593 distribution of marine productivity and organic matter production and export may play an
594 important role in regulating the distribution of ammonia oxidizers because ammonia oxidizers rely
595 on the supply of NH_4^+ , which is generated by of organic matter decomposition.

596

597 **Distribution of nitrite oxidizer abundance**

598 There are only seven studies available reporting the abundance of nitrite oxidizers in the ocean.
599 One study used the *nxr* marker gene and the other six studies used 16S rRNA gene of either
600 *Nitrospina* or *Nitrospira*. Since *Nitrospina* is the dominant nitrite oxidizer in the ocean (Beman et
601 al., 2013; Pachiadaki et al., 2017) and accounts for most of the observations, we use it to show the
602 distribution of nitrite oxidizers.

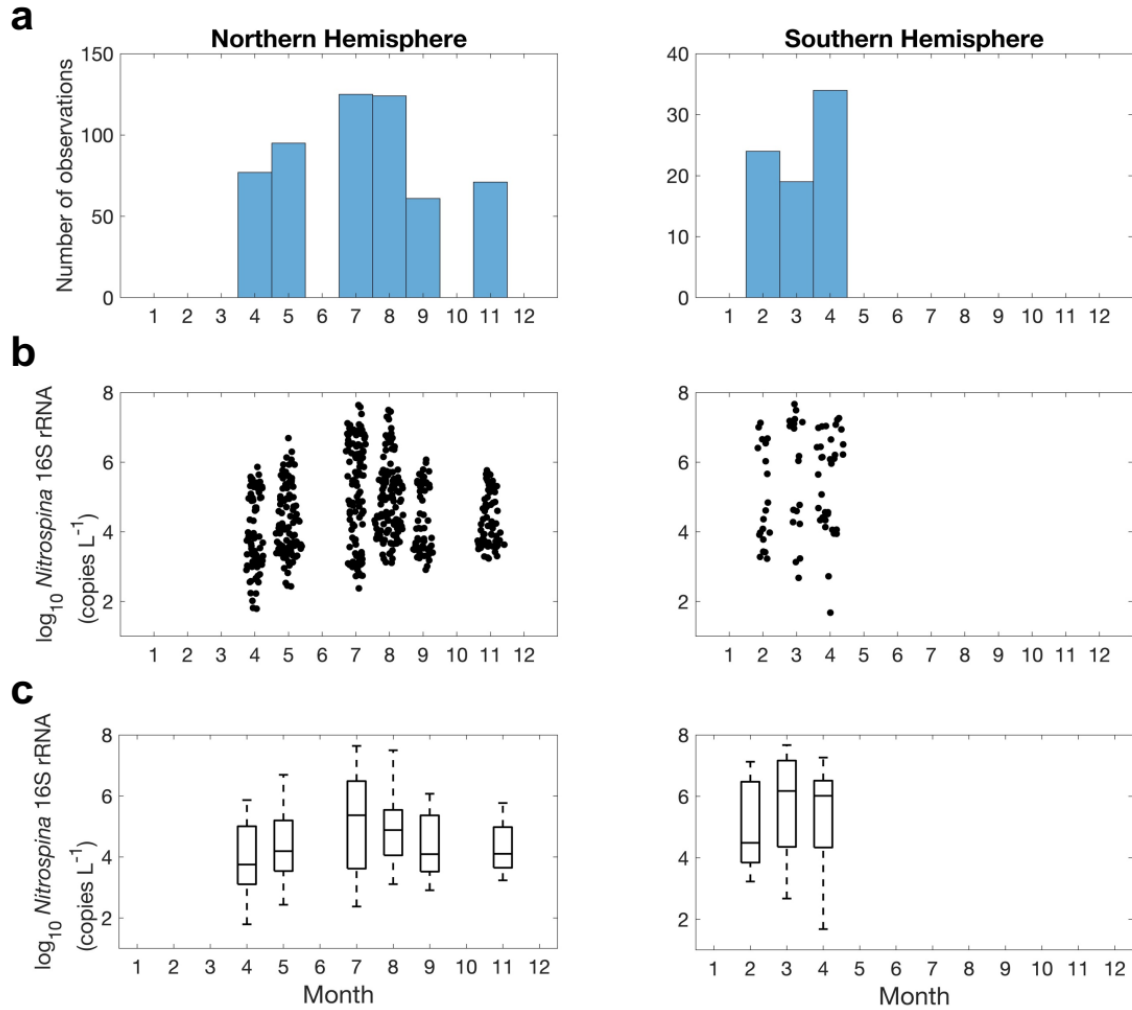

603

604

605 Figure 23. Number of observations (a) and abundance (b-c) of *Nitrospina* within latitudinal bands.

606

607

608 Figure 24. Monthly variation (1-12: January to December) in the number of observations (a) and
 609 abundance (b-c) of *Nitrospina*.

610

611 Quantification of nitrite oxidizers using the 16S rRNA gene is limited to a few locations between
 612 40°N to 40°S including the coastal waters off California and Georgia, the eastern tropical South
 613 Pacific, Bay of Bengal, and western Pacific (Figure 23). The number of observations is dominated
 614 by one study conducted near the coast of Georgia (Liu et al., 2018). The highest abundance of 4.68
 615 $\times 10^7$ copies L^{-1} was found in the eastern tropical South Pacific. No clear latitudinal or seasonal
 616 trend can be determined based on the limited number of observations (Figures 23-24).

617

618

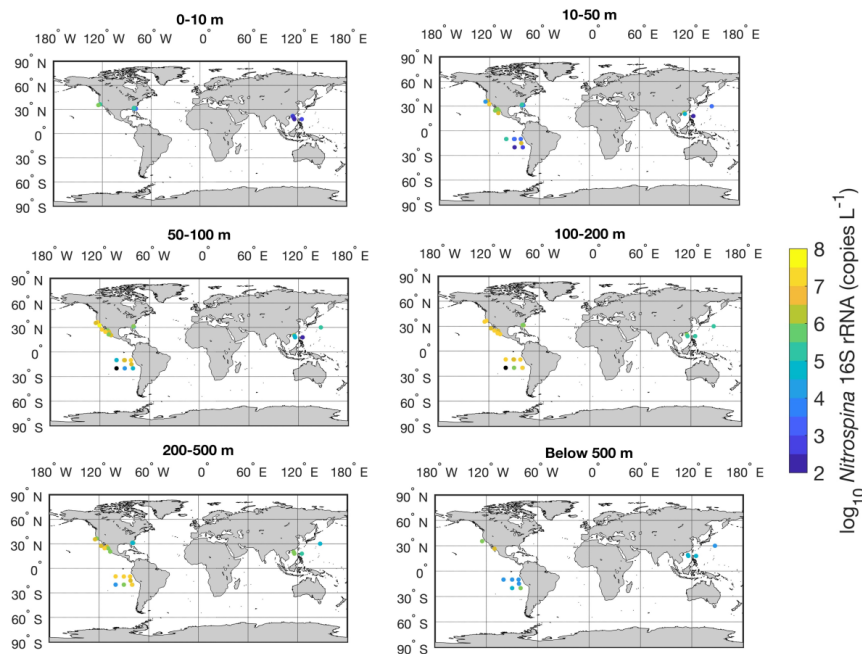

619

620 Figure 25. Vertical distribution of *Nitrospina* observations (a) and gene abundance (b-c). Note the
621 axis breaks at 1000 m depth in subplots a and b.

622

623 The vertical distribution of nitrite oxidizers resembles the vertical distribution of ammonia
624 oxidizers: increases from $\sim 10^4$ copies L^{-1} in the surface 0-10 m depth layer to a maximum of $\sim 10^6$
625 copies L^{-1} in the 100-200 m layer, then decreases to $\sim 10^{4.5}$ copies L^{-1} in the deep ocean below 500
626 m (Figures 25-26). However, data below 500 m are insufficient to describe the distribution of
627 nitrite oxidizers in the deep ocean. The vertical distribution of nitrite oxidizers qualitatively
628 matches the vertical distribution of nitrite oxidation rates (Figure 13).

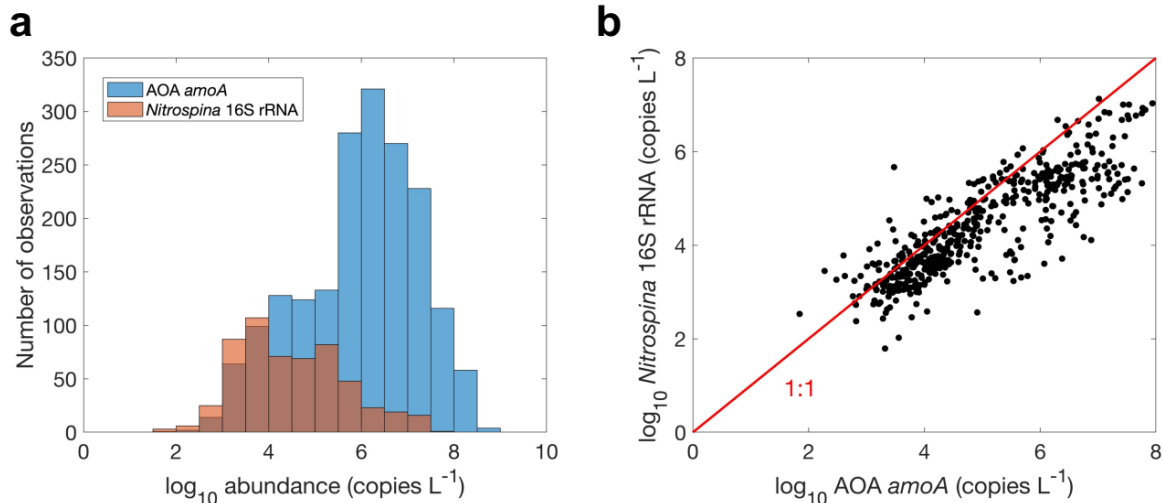

629

630

631 Figure 26. Spatial distribution of *Nitrospina* in six depth intervals in the global ocean. Locations
632 with abundances below the detection limit are shown in the black circles.

633

634

635 Figure 27. Comparison between the number of observations (a) and the correlation between the
636 abundance (b) of the archaeal *amoA* gene and *Nitrospina* 16S rRNA gene ($\log_{10}y =$
637 $0.68 \times \log_{10}x + 1$, $r = 0.85$, $p < 0.01$). Note the colors change slightly where they overlap in the
638 histograms.

639

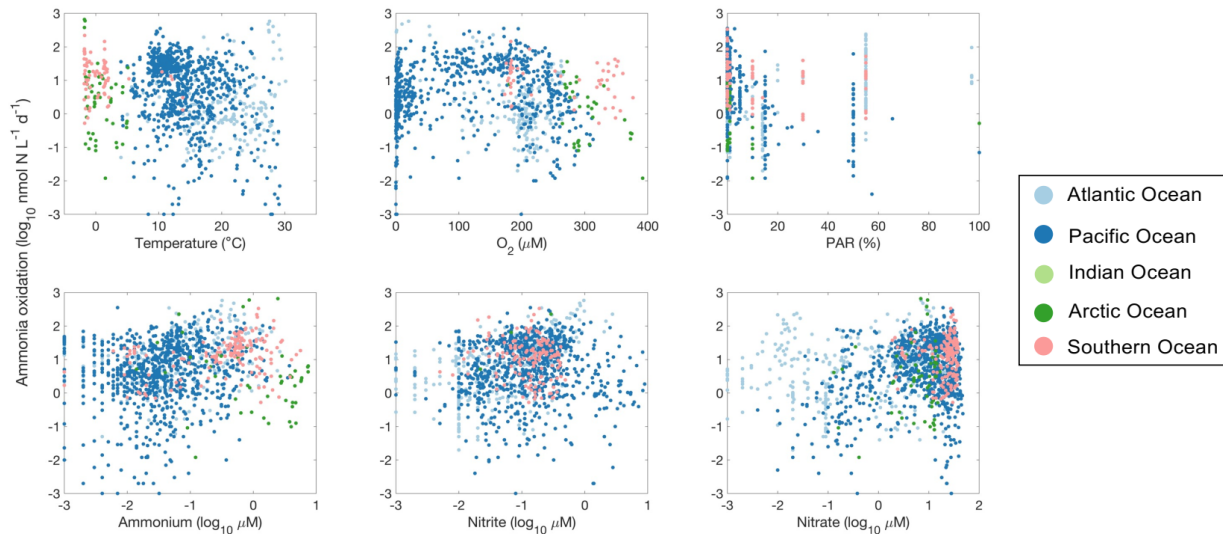

640 When comparing ammonia oxidizers with nitrite oxidizers, median abundance of ammonia
641 oxidizers of 1.34×10^6 copies L⁻¹ is approximately two orders of magnitude higher than the median
642 nitrite oxidizer of 2.14×10^4 copies L⁻¹. The difference in their abundance has been predicted by
643 the relative biomass yields and cell quotas (Zakem et al., 2018; Zakem et al., 2022) and
644 alternatively is explained by the difference in the mortality/loss rates between AOA and *Nitrospina*
645 (Kitzinger et al., 2020). In addition, there is a positive relationship between the abundance of
646 ammonia oxidizers and nitrite oxidizers (Figure 27) as previously shown in observations from the
647 Pacific (Santoro et al., 2019), indicating their coexistence under most conditions.

648

649 Environmental controls on nitrification rates and the abundance of nitrifiers

650 We compared the measured nitrification rates and nitrifier abundance with concurrently measured
651 or available environmental factors including temperature, oxygen, light, and N concentration
652 (NH_4^+ , NO_2^- , NO_3^-) to assess the environmental controls on nitrification and nitrifiers (Figures 28-

653 31). We acknowledge that nitrification rates and nitrifier abundance are regulated by multiple
 654 environmental factors, which may not be revealed by the simple correlation analysis with
 655 individual factors. The new database will facilitate more sophisticated future analyses.
 656

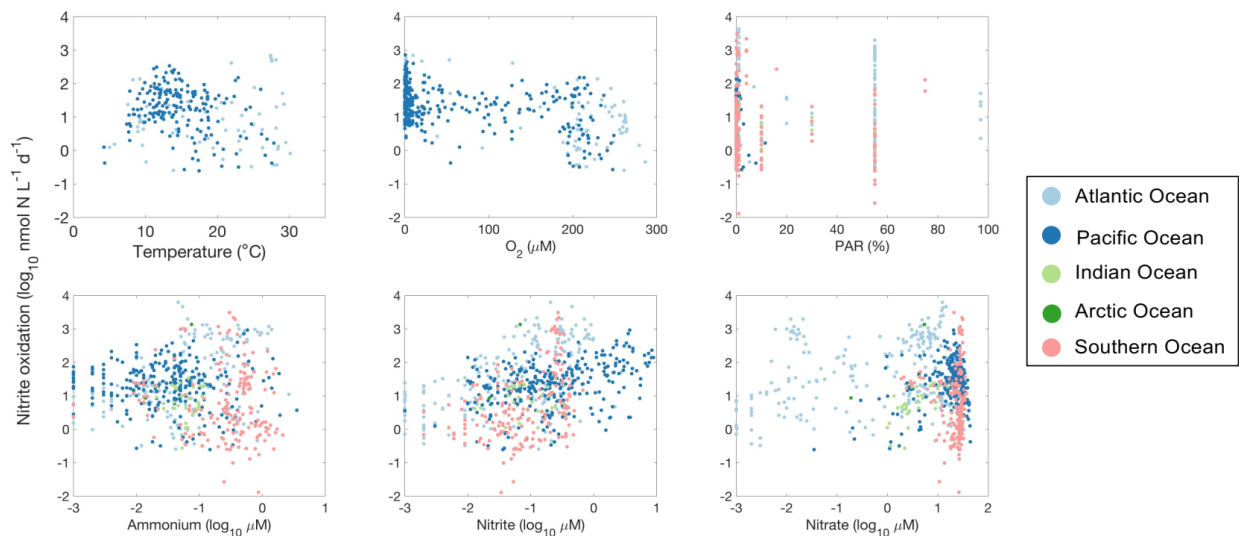

657
 658 Figure 28. Relationship between ammonia oxidation rates and environmental factors observed in
 659 different ocean basins.

660
 661 Ammonia oxidation rates showed a weak negative correlation with temperature ($r = -0.22$, $p <$
 662 0.01 ; Figure 28). Some of the high rates are found below 0°C , and at around 10°C and 25°C .
 663 Temperature manipulation experiments showed varying temperature sensitivity of ammonia
 664 oxidation in different regions or among natural assemblages (Baer et al., 2014; Horak et al., 2018;
 665 Zheng et al., 2020). The highest ammonia oxidation rates were found in the oxygen range between
 666 100 and $200 \mu\text{M}$ ($p > 0.01$). But ammonia oxidation has also been detected in low oxygen waters
 667 (e.g., $<10 \mu\text{M}$) in the oxygen minimum zones (Bristow et al., 2016a; Peng et al., 2015), reflecting
 668 the high affinity of ammonia oxidizers for oxygen. Oxygen production by ammonia-oxidizing
 669 archaea may support their presence and activity in the oxygen minimum zones (Kraft et al., 2022).
 670 Ammonia oxidation generally decreases at relatively high light intensity (PAR% relative to surface
 671 PAR) due to light inhibition and substrate competition with phytoplankton (but the negative slope
 672 is not significant, $p > 0.01$). Nevertheless, high ammonia oxidation rates have been measured in
 673 the euphotic zone at 55% PAR in the Atlantic Ocean (Clark et al., 2008; Clark et al., unpublished).
 674 Although light manipulation experiments have shown clear light inhibition of nitrification rate at

675 specific locations (e.g., Xu et al., 2019; Shiozaki et al., 2019), the relationship between nitrification
 676 and light intensity is ambiguous at the global scale, which may be related the compounding factors
 677 on nitrification. For example, the covarying ammonium availability would complicate the impact
 678 of change in light intensity. Ammonia oxidation increases with N nutrient concentration ($p < 0.01$).
 679 NH_4^+ is the substrate while NO_2^- is the product of ammonia oxidation. The Michaelis-Menten-like
 680 kinetics of ammonia oxidation rate have been observed in various ocean regions (Frey et al., 2022;
 681 Newell et al., 2013; Horak et al., 2013; Xu et al., 2019; Zhang et al., 2020; Mduyana et al., 2022a
 682 and b). High concentrations of NH_4^+ and NO_2^- likely reflect intense recycling of organic matter
 683 and remineralization. The presence of high NO_3^- concentration may relieve the competition
 684 between ammonia oxidizers and phytoplankton for NH_4^+ , therefore leading to high ammonia
 685 oxidation rates (Wan et al., 2018). In addition, recent studies have shown that AOA have a high
 686 requirement for iron and copper, which may affect the distribution of nitrification in the ocean
 687 (Shafiee et al., 2019; Shafiee et al., 2021).

688

689

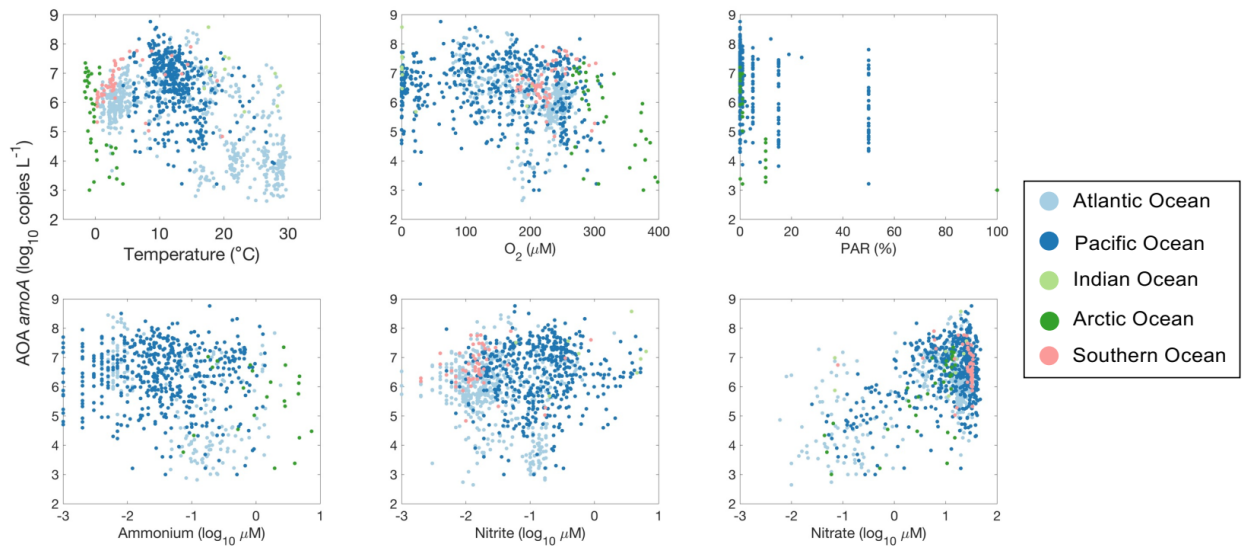

690 Figure 29. Relationships between nitrite oxidation rates and environmental factors observed in
 691 different ocean basins.

692

693 High nitrite oxidation rates are found between 10°C and 20°C (Figure 28). Surprisingly, some of
 694 the highest nitrite oxidation rates were measured in the oxygen minimum zones even with oxygen
 695 levels below detection limits (Ward et al., 1989; Sun et al., 2017; Sun et al., 2021). Nitrite oxidation
 696 in anoxic waters has been observed to be inhibited (Sun et al., 2017) or stimulated (Bristow et al.,

2016a) by the addition of oxygen. The mechanisms for apparently anaerobic nitrite oxidation remain to be determined (Sun et al., 2023). Similar to ammonia oxidation, nitrite oxidation is often reported to be inhibited by high light levels, but the relationship is not statistically significant across the database ($p > 0.01$; Figure 29) partly due to the presence of high nitrite oxidation rates in the euphotic zone (e.g., Clark et al., 2016). High nitrite oxidation rates are often observed in regions with high NO_2^- concentration ($r = 0.23$, $p < 0.01$). For example, the highest nitrite oxidation rates were observed at NO_2^- concentrations near $0.5 \mu\text{M}$ (Figure 29).

704

705

706 Figure 30. Relationship between archaeal *amoA* gene abundance and environmental factors
707 observed in different ocean basins.

708

709 We use *amoA* gene abundance to represent the abundance of ammonia oxidizers with the caveat
710 that the number of gene copies may not equal the cell numbers. Ammonia oxidizers are adapted to
711 a wide range of environmental conditions (Figure 30). Their abundance reaches a maximum at
712 around 10°C. Ammonia oxidizers are also present in low oxygen waters and the euphotic zone
713 with slightly lower abundance. Interestingly, ammonia oxidizers show relatively constant
714 abundance across the NH_4^+ concentration gradient while ammonia oxidation rates are low under
715 low NH_4^+ concentration (e.g., $<0.01 \mu\text{M}$). A large portion of the *amoA* observations were
716 conducted in the deep ocean where nitrate concentration was above $10 \mu\text{M}$. Some of the highest
717 *amoA* abundance were found in these NO_3^- enriched waters.

718

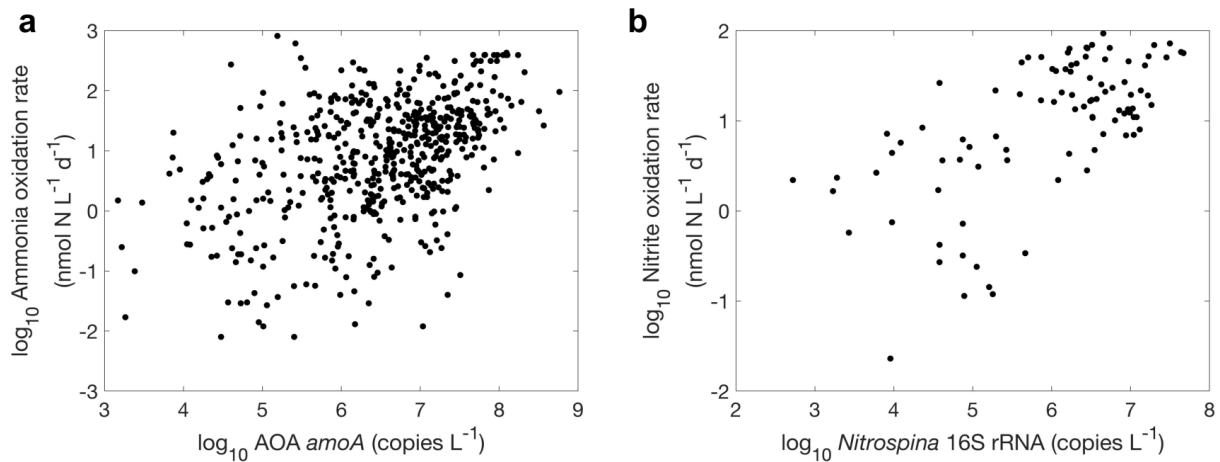

719

720 Figure 31. Relationships between *Nitrospina* 16S rRNA gene abundance and environmental
 721 factors observed in different ocean basins.

722

723 It is difficult to evaluate the relationship between nitrite oxidizers and environmental factors due
 724 to the limited number of observations (Figure 31). Nevertheless, one interesting pattern is the
 725 presence of high *Nitrospina* abundance in oxygen depleted waters. The nitrite oxidizers present in
 726 the oxygen depleted waters are distinct from those found in oxygenated waters or currently
 727 cultivated strains (Sun et al., 2019; Sun et al., 2021). Similar to *amoA* abundance, *Nitrospina* 16S
 728 rRNA gene abundance also increased with NO₃⁻ concentration.

729

730

731 Figure 32. Relationships between nitrifier abundance and nitrification rate. (a) ammonia oxidation
 732 vs AOA *amoA* gene abundance ($\log_{10}y = 0.43 \times \log_{10}x - 1.92$, $r = 0.46$, $p < 0.01$); (b) nitrite

733 oxidation vs *Nitrospina* 16S rRNA gene abundance ($\log_{10}y = 0.45 \times \log_{10}x - 1.65$, $r = 0.65$, p
734 < 0.01).

735

736 There is a positive correlation between AOA *amoA* gene abundance and ammonia oxidation rates
737 ($r = 0.46$, $p < 0.01$), and between *Nitrospina* 16S rRNA abundance and nitrite oxidation rate ($r =$
738 0.65 , $p < 0.01$) (Figure 32) even though the correlation is weak. This lack of a strong relationship
739 has also been found in regional studies (Tolar et al., 2020), which may be caused by the
740 perturbation of the microbial community during rate measurement incubations. Furthermore, the
741 addition of nitrogen substrate during rate measurement incubations may stimulate the growth of
742 nitrifiers and the subsequently measured nitrification rate. Overall, using functional gene
743 abundances to predict their functional activity needs to be conducted with caution since the
744 presence of genes only reflects the functional potentials.

745

746 **Applications of the database and suggestions for future research**

747 This database will be useful for a broad scientific community who are interested in marine
748 biogeochemistry and marine microbial ecology. Potential applications include but are not limited
749 to: 1) Compare future measurements of nitrification rates or nitrifier abundance in a specific region
750 to previous measurements conducted in the same regions, and contextualize new measurements at
751 the global scale. 2) Meta-analysis of environmental controls on the distribution of nitrification and
752 nitrifier abundance at regional and global scales. The simple correlation analyses provided here
753 only considered individual environmental drivers separately while other drivers are changing
754 simultaneously. Analysis with environmental assemblages could complement laboratory culture
755 experiments. 3) Help to validate and improve model parametrization of nitrification and nitrifiers.
756 For example, ammonia oxidation has been modeled as a function of substrate concentration and
757 specific ammonia oxidation rate (Yool et al., 2007). However, nitrification has been found to be
758 regulated by temperature, oxygen, light and many other environmental factors that are not
759 considered in that model. A better representation of nitrification in ocean biogeochemical models
760 could help to constrain the estimates of marine new production, N₂O production and many other
761 key processes. 4) Guide future nitrification studies, e.g., conducting measurements in poorly
762 sampled regions or seasons.

763

764 Based on the historical measurements of nitrification and nitrifiers, we provide recommendations
765 for future research below.

766

767 1. Method standardization is useful for comparison among studies. Nitrification has been mostly
768 measured by ^{15}N substrate tracer addition and product dilution methods. The ^{15}N product dilution
769 method tends to yield higher rates relative to the ^{15}N substrate tracer addition method (Figure 1).
770 This is perhaps to be expected since the ^{15}N product dilution method measures all the NO_2^-
771 production pathways including ammonia oxidation (and organic N oxidation) and nitrate reduction
772 instead of only NO_2^- production from ammonia oxidation as is measured by the $^{15}\text{NH}_4^+$ tracer
773 addition method. Comparison between different methods should be conducted to resolve the
774 difference or even correct some of the previous measurements.

775

776 Additionally, the amount of tracer added should be recorded and reported because the increased
777 substrate concentration may enhance nitrification rate. Therefore, the measured rates should be
778 interpreted as potential rates rather than in-situ rates when the amount of tracer addition is large
779 compared to the ambient substrate concentration. If possible, substrate kinetic experiments should
780 be conducted for in-situ rate calibration (e.g., Wan et al., 2018; Mdutyana et al., 2022a and b).

781

782 The measured product of ammonia oxidation should also be reported (e.g., either only NO_2^- or
783 $\text{NO}_2^- + \text{NO}_3^-$). When ambient NO_2^- concentration is low, the $^{15}\text{NO}_2^-$ produced from $^{15}\text{NH}_4^+$ tracer
784 may be further oxidized to $^{15}\text{NO}_3^-$. Thus, nitrification may be underestimated if only NO_2^- is
785 measured. Alternatively, NO_2^- carrier may be added into the incubation to ‘trap’ the produced
786 $^{15}\text{NO}_2^-$. In addition to only measuring ammonia oxidation, more observations of nitrite oxidation
787 are desirable to evaluate mechanisms controlling the coupling or decoupling of the two steps of
788 nitrification.

789

790 Furthermore, measurements with at least three time points are preferred during the incubation time
791 courses in order to examine whether the rate has changed during the incubation period. Depending
792 on the incubation period, nitrification rates are reported as either $\text{nmol N L}^{-1} \text{d}^{-1}$ or $\text{nmol N L}^{-1} \text{h}^{-1}$.
793 A conversion factor (e.g., 12 or 24 hours) is required to obtain the same unit. The choice of the
794 conversion factor may be critical if there is a diel cycle of nitrification rate, e.g., in the euphotic

795 zone where light/solar radiation varies diurnally (Wan et al., 2021). Therefore, incubation
796 conducted under both light and dark conditions may be preferable to obtain the daily nitrification
797 rates. The detection limit of rate measurements should also be estimated and reported (Santoro et
798 al., 2013) instead of presenting rates that are below detection limit as zero.

799

800 For in-situ rate measurements, incubations should mimic the in-situ environmental conditions as
801 closely as possible, e.g., using light filters to simulate in-situ light/solar radiation intensity and
802 quality; using a temperature-controlled incubator to simulate the in-situ temperature. Particularly
803 for samples collected in the oxygen minimum zones, oxygen concentration in the incubation
804 containers should be measured or monitored throughout the incubation because oxygen
805 contamination is common during the sampling process (Garcia-Robledo et al., 2021). Samples
806 collected from the anoxic layer of the oxygen minimum zones need to be purged with helium or
807 nitrogen gas to remove any oxygen contamination before incubation.

808

809 2. Various primers have been designed to target ammonia oxidizers. However, current primers
810 miss the *Nitrosopumilus*-like *amoA* (Tolar et al., 2013; Hiraoka et al., preprint) and this group
811 accounts for a large fraction of the AOA based on 16S rRNA sequencing (Tolar et al., 2020). New
812 primers or techniques need to be developed to cover the diverse groups of ammonia oxidizers. In
813 addition, the quantification of nitrite oxidizers is limited. Developing primers for *nxr* genes may
814 be useful to untangle the relative contribution of different nitrite oxidizers particularly for the
815 unique ones found in the oxygen minimum zones. The report of qPCR assay should follow the
816 MIQE guidelines (Bustin et al., 2009) including the amplification conditions, amplification
817 efficiency, detection limit and other parameters. Alternatively, the abundance of nitrifiers may be
818 determined with quantitative metagenomics (Lin et al., 2019; Satinsky et al., 2013). In comparison
819 to the gene presence, gene expression and protein synthesis may be better linked to the activity of
820 nitrifiers (Tolar et al., 2016; Frey et al., 2022; Saito et al., 2020), deserving more observations.

821

822 3. Future observations should target regions that have been poorly sampled and regions that are
823 experiencing or expected to experience dramatic changes. For example, the Indian Ocean has the
824 fewest number of observations of nitrification and nitrifiers. With regards to change, oxygen
825 minimum zones are projected to change under future climate (Breitburg et al., 2018; Busecke et

826 al., 2022). Polar oceans (Arctic Ocean and Southern Ocean) are experiencing warming, ice melt
827 (which affects light/solar radiation availability) and ocean acidification (Meredith et al., 2019).
828 Upward nutrient supply into the subtropical gyres may be affected due to enhanced stratification
829 (Li et al., 2020). How nitrification will respond to these changes deserves further exploration.

830

831 Time-series studies, observations across a large-scale transect, and observations at a mesoscale or
832 submesoscale would be desirable for investigating the temporal and spatial variation of
833 nitrification rates and nitrifier abundances. When possible, both nitrification rates and nitrifier
834 abundance should be measured at the same locations. While this approach incurs logistical and
835 financial complications in requiring collaborations among laboratories with different expertise, the
836 benefit to comprehensive process description is manifold.

837

838 4. Incubation conditions (mentioned in point 2) and ambient environmental conditions associated
839 with rate measurements or gene quantification should be recorded and reported (e.g., temperature,
840 light, substrate concentration, oxygen). This information would be helpful for comparison among
841 different studies and future meta-analyses of environmental controls on nitrification and nitrifiers.
842 For example, light/solar radiation should be reported as both absolute light/solar radiation intensity
843 and relative light/solar radiation intensity to the surface ocean. Analysis of trace metals like iron
844 and copper concentration will be useful to assess their impact on nitrification. Standard notation
845 should be used to denote measurements below detection limit or measurements not conducted,
846 e.g., BDL for below detection limit, NM for not measured, empty/NA for data not available. A
847 data compilation template is provided for anyone who is interested in contributing to the database
848 with new datasets or datasets currently not included in the database. We encourage the scientific
849 community to contact us with suggestions to improve the database and to contribute to the database
850 with new datasets or datasets currently not included in the database.

851

852 **Data availability**

853 Data described in this manuscript can be accessed at Zenodo repository under data doi:

854 <https://doi.org/10.5281/zenodo.8355912> (Tang et al., 2023).

855

856 **Conclusions**

857 We present a newly compiled database of nitrification rate and nitrifier abundance measurements
858 in the global ocean. This database sheds light on the spatial and temporal patterns of nitrification
859 and nitrifiers even though the spatial and temporal coverages remain limited. In recent years,
860 observations have expanded into oxygen minimum zones and polar oceans while the Indian Ocean
861 and Pacific Basin remain poorly sampled, especially with regard to nitrite oxidation and nitrite
862 oxidizers. This database can be applied to assess the environmental controls on nitrification at
863 regional and global scales, to validate and develop biogeochemical models, to guide future
864 observational efforts, and to better constrain the distribution of nitrification and assess its impact
865 on the marine ecosystem and climate. This database has been deposited into the Zenodo repository
866 and can be updated with new datasets.

867

868 **Author contributions**

869 Weiyi Tang and Bess Ward designed the study with input from Fabien Paulot and Charles Stock.
870 Weiyi Tang compiled the database with data contribution from coauthors, and Weiyi Tang
871 analyzed the database. Weiyi Tang and Bess Ward wrote the manuscript with contribution from
872 coauthors.

873

874 **Competing interests**

875 No competing interest is declared.

876

877 **Acknowledgements**

878 We want to thank all the authors who have kindly shared data for this community effort. Weiyi
879 Tang, Bess Ward, Fabien Paulot, and Charles Stock are funded by Cooperative Institute for
880 Modeling the Earth System (CIMES). Gerhard J. Herndl is funded by the Austrian Science Fund
881 (FWF) project DEPOCA (P 35587-B).
