

18 **Abstract:** The lack of long-term and high-quality solar radiation data has been an  
19 obstacle for scientific and industrial fields. In this study, a dense station-based long-  
20 term and high-accuracy dataset of daily surface solar radiation was developed using  
21 two surface radiation models. One is the model developed by Yang et al. (2006) for  
22 global radiation estimation, and the other is the model developed by Tang et al. (2018)  
23 for direct radiation estimation. The main inputs for the development of the dataset are  
24 surface pressure, air temperature, relative humidity, horizontal visibility, and sunshine  
25 duration, which are the routine meteorological variables observed at the 2743 China  
26 Meteorological Administration (CMA) weather stations. Validation against in-situ  
27 observations and comparisons with two satellite-based radiation products show that our  
28 station-based radiation dataset clearly outperforms the satellite-based radiation  
29 products at both daily and monthly scales. In addition, our dataset is available for more  
30 than 60 years and includes three radiation components of global, direct, and diffuse  
31 radiation, which is not possible with satellite products. This station-based radiation  
32 dataset will contribute to the climate change research and solar energy engineering  
33 applications in the future. The station-based dataset is now available at  
34 <https://doi.org/10.11888/Atmos.tpdc.300461> and  
35 <https://data.tpdc.ac.cn/en/disallow/55fc9768-ea6a-4d16-9207-28f6aed4900b> (Tang,  
36 2023).

37 **Keywords:** Global radiation; Direct radiation; Diffuse radiation; High-accuracy; Long-  
38 term; Dataset.

## 39 **1. Introduction**

40 Solar radiation provides energy to everything on Earth, drives the water, energy  
41 and carbon cycles of the Earth's climate system, and largely determines the climatic  
42 conditions of human habitats (Wild et al., 2009). Therefore, solar radiation information  
43 at the Earth's surface is crucial in research of agriculture, hydrology, ecology, climate  
44 change, and simulations of land surface processes (Wang et al., 2012). Solar radiation  
45 reaching the horizontal surface is called as total solar radiation or global radiation ( $R_g$ ),  
46 and is composed of direct radiation ( $R_{dir}$ ) and diffuse radiation ( $R_{dif}$ ). Global radiation  
47 is an important component of the surface energy budgets (Wild et al., 2015), and  
48 accurate global radiation data will contribute to the simulation of land surface-related  
49 processes, such as ecological, hydrological, agricultural, and glacial simulations (Tang  
50 et al., 2019a). In addition, both direct and diffuse radiation provide energy for plant  
51 photosynthesis and transpiration, and are essential for hydrological and agricultural  
52 studies (Lee et al., 2017). Due to its multidirectional nature, diffuse radiation penetrates  
53 in the vegetation canopy more than direct radiation, and more diffuse radiation can  
54 increase light energy use efficiency of the canopy (Mercado et al., 2009, Yang et al.,  
55 2019). For example, under the same global radiation condition, increasing the  
56 proportion of diffuse radiation can increase the light energy use efficiency of different  
57 vegetation types by 6-180% (Gu et al., 2002; Alton et al., 2007).

58 In addition to basic scientific research, the distribution and intensity of surface  
59 solar radiation is urgently needed for solar energy applications. All three components  
60 of solar radiation, i.e., global radiation, direct radiation, and diffuse radiation, are

61 prerequisites for the siting, design, evaluation, and optimization of different solar  
62 energy systems (Karakoti et al., 2011; Mellit et al., 2010). For example, photovoltaic  
63 (PV) power systems rely on global radiation to generate electricity, and global radiation  
64 on arbitrarily oriented PV panels can be calculated by direct and diffuse radiation, while  
65 concentrated solar power systems use only direct radiation to generate electricity  
66 (Boland et al., 2013; Tang et al., 2018). In addition, recently developed bifacial PV  
67 panels also use the backside of the PV panel to generate electricity, and the source of  
68 solar radiation on the backside is diffuse radiation (Rodríguez-Gallegos et al., 2018;  
69 Pelaez et al., 2019).

70 In-situ measurements are considered the most effective and direct means of  
71 obtaining surface solar radiation data. However, the number of radiation observation  
72 stations is very low due to high maintenance and calibration costs. For example,  
73 radiation fluxes measured at about 2500 stations worldwide are stored in the Global  
74 Energy Balance Archive (GEBA), a database that stores the different components of  
75 the surface energy budget from different data sources, such as national meteorological  
76 services, various experimental observation networks, and project reports (Wild et al.,  
77 2017). Among the GEBA, there are only about 100 radiation stations (Jiang et al. 2020a),  
78 which are provided by the China Meteorological Administration (CMA). Another issue  
79 is that the radiation observation stations are very unevenly distributed, with most of  
80 radiation stations being located in flat and densely populated areas, and with a very  
81 small number of stations being located in the complex terrain areas and sparsely  
82 populated areas. In addition, almost all radiation stations include global radiation

83 observations, but most of them do not include direct radiation and diffuse radiation  
84 observations. In addition, radiation measurements are considered to be more prone to  
85 problems and unreliable data than those of other meteorological variables. For example,  
86 erroneous or spurious data were frequently found in the CMA radiation observations  
87 (Shi et al., 2008; Tang et al., 2011). Therefore, the lack of long-term and dense solar  
88 radiation observations has become a tough challenge.

89         Satellites can provide continuous spatiotemporal observations, and retrieval based  
90 on satellite remote sensing is considered one of the most effective and commonly used  
91 means to fill the gap in ground-based radiation measurements (Lu et al., 2011; Zhang  
92 et al., 2014; Huang et al., 2019; Wang et al., 2022; Letu et al., 2021). In the past,  
93 satellite-based retrieval algorithms and corresponding radiation products have emerged,  
94 and the retrieval accuracy of the corresponding products has improved (Huang et al.,  
95 2019). In particular, retrievals applied to the new generation of geostationary satellites  
96 have improved in temporal resolution, spatial resolution, and accuracy to varying  
97 degrees (Tang et al., 2019b; Letu et al., 2020). Especially, Li et al. (2023) produced a  
98 high-spatiotemporal-resolution radiation product based on the new generation of  
99 geostationary satellites from the United States and Japan, with accuracy higher than  
100 other existing satellite products. In general, the accuracy of the satellite-based radiation  
101 product is higher than that of the reanalysis product (Jiang et al., 2020b). In addition,  
102 Hao et al. (2020) developed a global radiation product based on the unique Deep Space  
103 Climate Observatory (DSCOVR) satellite, whose orbit is at the Lagrange point. Despite  
104 the obvious advantages, there are still several problems with satellite-based radiation

105 products. First, the time series of satellite radiation products are generally not long  
106 enough to meet the demand for long time series data, such as for climate change studies.  
107 Second, the updating of satellite sensors and the fusion of multi-source satellites would  
108 lead to inconsistent data quality and introduce large uncertainties into the analysis of  
109 long-term variations (Feng and Wang, 2021a; Shao et al., 2022). Third, most satellite  
110 radiation products only provide global radiation, but do not include direct and diffuse  
111 radiation, because the uncertainty in algorithms for estimating direct and diffuse  
112 radiation is much larger than the uncertainty in global radiation.

113         Alternatively, estimation based on meteorological variables observed at routine  
114 weather stations is another effective solution that can overcome the scarcity of radiation  
115 data, since the number of routine weather stations is much denser than that of radiation  
116 stations (Feng and Wang, 2021b). For example, the number of radiation stations  
117 maintained by the CMA is only about 100, but the number of routine weather stations  
118 with long-term observations is much denser, exceeding 2400 stations. Empirical models  
119 for estimating global radiation using surface meteorological variables were usually  
120 found in the hydrological and agricultural fields (Wang et al., 2016), and these models  
121 can be broadly classified into three types: air temperature-based models, sunshine  
122 duration-based models, and cloud cover-based models (Liu et al., 2009; Ehnberg &  
123 Bollen, 2005). In general, a well-calibrated sunshine duration-based model was  
124 considered to perform better than the other two types of models (Pohlert, 2004).  
125 Although the above empirical models, especially the Ångström-Prescott relationships  
126 (Ångström, 1924; Prescott, 1940), have been widely used and have achieved great

127 success, these models require ground radiation observations for calibration and the  
128 calibrated parameters are usually site-dependent, which poses significant risks and  
129 challenges when applied in areas with sparse or no radiation observations.

130 Yang et al. (2001) developed a hybrid model to estimate daily global radiation by  
131 combining pure physical processes under clear skies and a parameterization formula  
132 for cloud transmission under cloudy skies. The hybrid model has been shown to work  
133 well without local calibration (Yang et al., 2006; Yang et al., 2010). Tang et al. (2013)  
134 used this hybrid model to construct a dataset of daily global radiation at 716 CMA  
135 weather stations during 1961-2010, and also found that its accuracy was generally  
136 higher than that of locally calibrated empirical models and satellite-based retrievals.  
137 However, few studies have focused on the development of empirical models for direct  
138 and diffuse radiation estimates. Fortunately, Tang et al. (2018) also developed a similar  
139 hybrid model to estimate daily direct radiation by adopting the strategy of Yang et al.  
140 (2001) to estimate global radiation. Therefore, these two hybrid models provide us with  
141 an opportunity to construct daily surface solar radiation at routine weather stations, once  
142 the observations of meteorological variables are available. The constructed dataset will  
143 contribute to simulations of land surface processes, climate change analysis, and solar  
144 energy applications.

145 In this study, based on our previous study by Tang et al. (2013) for global radiation  
146 estimation, we expanded the number of stations, radiation elements and time length,  
147 and finally developed a dense station-based long-term and high-accuracy daily surface  
148 solar radiation dataset in China, which includes three elements: global radiation, direct

149 radiation, and diffuse radiation. This long-term dataset will contribute to the analysis of  
150 long-term variations in surface process simulations and solar energy applications, such  
151 as the assessment of solar energy potential, the determination of the optimal angle for  
152 solar PV panels and their long-term variation analysis, as well as the assessment of  
153 historical extreme events on solar energy systems. The rest of the paper is organized as  
154 follows. The methods used to estimate daily global, direct, and diffuse radiation at  
155 weather stations are presented in Section 2, and Section 3 describes the input data used  
156 to drive the station-based models, the in-situ data used to validate the accuracy of the  
157 developed dataset, and two satellite-based radiation products used for comparison with  
158 our products. The performance of our dataset and two satellite-based radiation products  
159 against the in-situ data is evaluated in Section 4, and the information on data availability  
160 is described in Section 5. Finally, Section 6 presents the summary of this study.

161

## 162 **2. Methods**

163 In this study, daily global radiation and daily direct radiation were estimated using  
164 the hybrid model of Yang et al. (2006) and the method developed by Tang et al. (2018),  
165 respectively. Finally, daily diffuse radiation was calculated by subtracting direct  
166 radiation from global radiation. The methods for estimating daily global, direct, and  
167 diffuse radiation can be simply described by the following five mathematical formulas:

$$168 \quad R_g = (R_{b,clr} + R_{d,clr})\tau_{c,g}, \quad (1)$$

$$169 \quad R_b = R_{b,clr}\tau_{c,b}, \quad (2)$$

$$170 \quad R_d = R_g - R_b, \quad (3)$$

171  $\tau_{c,g} = 0.2505 + 1.1468 \left(\frac{n}{N}\right) - 0.3974 \left(\frac{n}{N}\right)^2,$  (4)

172  $\tau_{c,b} = 0.4868 \left(\frac{n}{N}\right) + 0.5132 \left(\frac{n}{N}\right)^2,$  (5)

173 where  $R_g$ ,  $R_b$ , and  $R_d$  [ $\text{W m}^{-2}$ ] are the daily all-sky global, direct, and diffuse radiation  
 174 at the horizontal surface, respectively.  $R_{b,clr}$  and  $R_{d,clr}$  [ $\text{W m}^{-2}$ ] are the daily clear-sky  
 175 global and direct radiation at the horizontal surface, respectively.  $\tau_{c,g}$  and  $\tau_{c,b}$  are the  
 176 cloud transmittance for the daily global and direct radiation, respectively.  $n$  and  $N$  are  
 177 the actual sunshine duration and the maximum possible sunshine duration, respectively.  
 178 The daily clear-sky global and direct radiation ( $R_{b,clr}$  and  $R_{d,clr}$ ) at the horizontal  
 179 surface are calculated by the following equations:

180  $R_{b,clr} = \frac{1}{24\text{hours}} \int_{t_1}^{t_2} I_0 \bar{\tau}_b dt,$  (6)

181  $R_{d,clr} = \frac{1}{24\text{hours}} \int_{t_1}^{t_2} I_0 \bar{\tau}_d dt,$  (7)

182  $\bar{\tau}_b \approx \max(0, \bar{\tau}_o \bar{\tau}_w \bar{\tau}_g \bar{\tau}_r \bar{\tau}_a),$  (8)

183  $\bar{\tau}_d \approx \max(0, 0.5 \bar{\tau}_o \bar{\tau}_w \bar{\tau}_g (1 - \bar{\tau}_r \bar{\tau}_a)),$  (9)

184  $\bar{\tau}_o = \exp[-0.0365(ml)^{0.7136}],$  (10)

185  $\bar{\tau}_g = \exp[-0.0117(m_c)^{0.3139}],$  (11)

186  $\bar{\tau}_w = \min[1.0, 0.909 \ln(mw)],$  (12)

187  $\bar{\tau}_r = \exp[-0.008735m_c(0.547 + 0.014m_c - 0.00038m_c^2 +$   
 188  $4.6 \times 10^{-6}m_c^3)^{-4.08}],$  (13)

189  $\bar{\tau}_a = \exp\{-m\beta[0.6777 + 0.1464(m\beta) - 0.00626(m\beta)^2]^{-1.3}\},$  (14)

190  $m = 1/[\sin(h) + 0.15(57.296h + 3.885)^{-1.253}],$  (15)

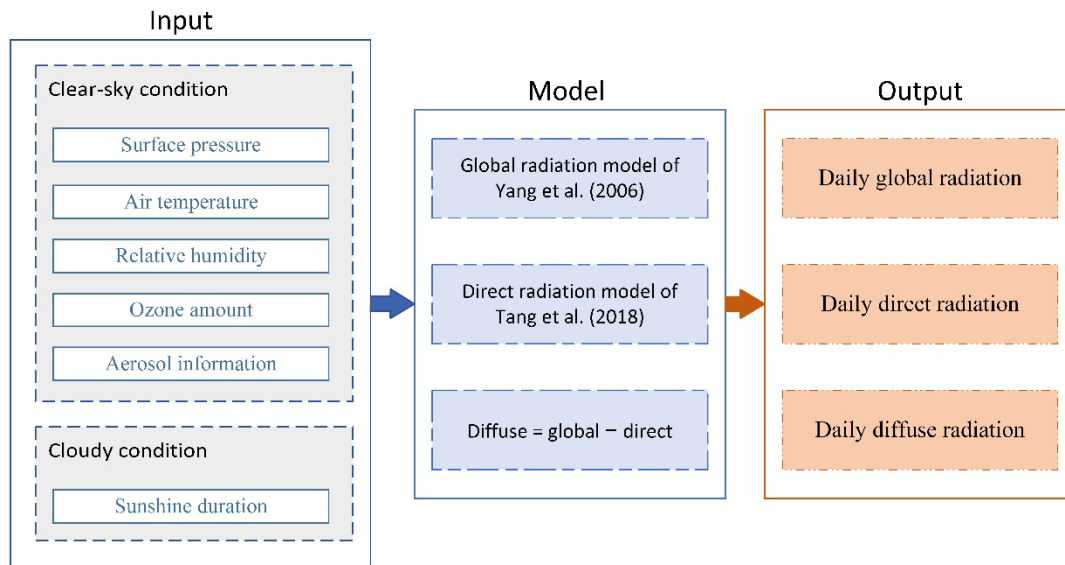

191  $m_c = mp_s/p_0,$  (16)

192 where  $I_0$  [ $\text{W m}^{-2}$ ] is the horizontal solar radiation at the top of the atmosphere (TOA),

193 and  $t1$  [hour] and  $t2$  [hour] are the times of sunrise and sunset, respectively.  $\bar{\tau}_b$  and  $\bar{\tau}_d$   
194 are the transmittances for the daily direct and diffuse radiation under clear skies,  
195 respectively.  $\bar{\tau}_o$ ,  $\bar{\tau}_g$ ,  $\bar{\tau}_w$ ,  $\bar{\tau}_r$ , and  $\bar{\tau}_a$  are transmittances due to ozone absorption,  
196 permanent gas absorption, water vapor absorption, Rayleigh scattering, and aerosol  
197 absorption and scattering in the atmospheric layer, respectively.  $m$  is the air mass, and  
198  $l$  (cm) is ozone layer thickness.  $m_c$  is the pressure-corrected air mass, and  $w$  (cm), is  
199 the precipitable water.  $\beta$  and  $h$  [radian] are the Ångström turbidity coefficient and the  
200 solar elevation angle, respectively.  $p_0$  [Pa] is the standard atmospheric pressure, and  $p_s$   
201 [Pa] is the surface pressure.

202 The overall flowchart for the estimation of the station-based radiation products is  
203 shown in Figure 1, which consists mainly of input, model and output sections. The  
204 inputs are surface pressure, air temperature, relative humidity, ozone amount, aerosol  
205 data and sunshine duration. Air temperature and relative humidity are used to estimate  
206 precipitable water. The aerosol Ångström turbidity is mainly converted from horizontal  
207 visibility observations measured at weather stations using the method of Tang et al.  
208 (2017a). The ozone amount is obtained from the zonal means of the Total Ozone  
209 Mapping Spectrometer (TOMS). The outputs are daily global, direct and diffuse  
210 radiation, respectively. For more detailed information on the above methods, we can  
211 refer to the articles by Yang et al. (2006) and Tang et al. (2018).

212

213

214 **Figure 1** Flowchart of data production, including input, model, and output sections.

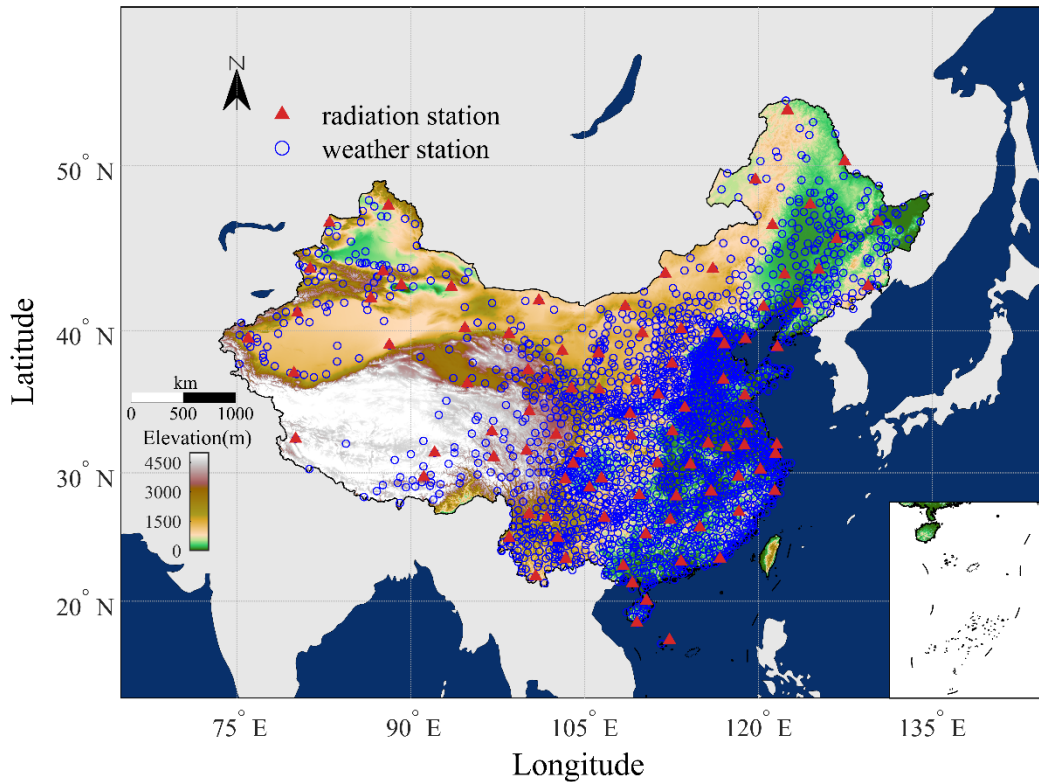

215

### 216 **3 Data**

#### 217 **3.1 Input data**

218 The inputs to the above methods for estimating daily global, direct, and diffuse  
 219 radiation are mainly surface pressure, air temperature, relative humidity, horizontal  
 220 visibility, sunshine duration, and ozone amount. Except for ozone, all input data are  
 221 observed at the 2473 CMA routine meteorological stations, where the estimation  
 222 methods can work well. Here, the ozone amount was used from the climatological data  
 223 obtained from the TOMS zonal means. Figure 2 shows the spatial distribution of these  
 224 routine meteorological stations, indicated by the small blue circles, with characteristics  
 225 of a dense distribution in the eastern and southern regions of China and a sparse  
 226 distribution in the western and northern regions of China.

227

228

229 **Figure 2** Spatial distribution of China Meteorological Administration weather station  
 230 and radiation station. Red triangles represent radiation stations, and blue  
 231 circles denote weather stations without radiation observation.

232 Finally, in this study, a dataset of more than 60 years of daily global, direct and  
 233 diffuse radiation was constructed using the methods described above at the 2473 CMA  
 234 routine meteorological stations from the 1950s to 2021, with most stations covering the  
 235 period of 1961-2021.

236

### 237 **3.2 In-situ radiation data**

238 Due to the extensive renewal and replacement of radiation instruments in 1993,  
 239 and because more erroneous observations were found before 1993, radiation  
 240 observations during the period 1993-2010 were used to evaluate the performance of our  
 241 developed station-based radiation dataset and the other two satellite-based radiation

242 products. Among the 2473 CMA routine meteorological stations, there are about 96  
243 radiation stations (denoted by the upper red triangle in Figure 2) where radiation  
244 observations have been carried out in addition to routine meteorological observations  
245 since 1993. Among the 96 CMA radiation stations, there are only 19 stations where  
246 direct and diffuse radiation observations are carried out in addition to global radiation  
247 observations.

248 One issue to note is that we did not use the direct radiation observations as  
249 validation basis, but the value obtained by subtracting the diffuse radiation observations  
250 from the global radiation observations, because the quality of the direct radiation  
251 observations is significantly lower than those of the global and diffuse radiation  
252 observations (Tang et al., 2018). Another issue that we need to be aware of is that  
253 obviously erroneous or false values have usually been found in the CMA radiation data  
254 (Shi et al., 2008), although a preliminary quality check of the raw radiation observations  
255 was carried out before release. Therefore, we further applied the quality control  
256 procedures developed by Tang et al. (2010) to the raw radiation observations and  
257 filtered out the corresponding spurious and erroneous observations. More detailed  
258 information on the quality control scheme can be found in the article by Tang et al.  
259 (2010).

260

### 261 **3.3 Satellite-based radiation products**

262 In this study, two satellite-based radiation products (Jiang et al., 2020a; Tang et  
263 al., 2019a) were used for comparison with our station-based radiation dataset estimated

264 at 2743 CMA routine meteorological stations.

265 One is the product of Jiang et al. (2020a), which provides hourly global radiation  
266 and diffuse radiation in China with a spatial resolution of ~5 km and a time span from  
267 2007 to 2018. The product was generated using a deep learning algorithm developed  
268 by Jiang et al. (2019) to retrieve global radiation, and a transfer learning approach to  
269 retrieve diffuse radiation from Multi-functional Transport Satellites (MTSAT) imagery.  
270 The algorithm successfully tackled spatial adjacency effects induced by photon  
271 transport through convolutional neural networks, resulting in excellent performance in  
272 instantaneous radiation retrieval, especially for diffuse radiation (Jiang et al., 2020c).

273 The other is the high-resolution global product of global radiation developed by  
274 Tang et al. (2019a) based on the latest cloud products of the International Satellite  
275 Cloud Climatology Project H-series pixel-level global (ISCCP-HXG), routine  
276 meteorological variables of the ERA5 reanalysis data, aerosol optical thickness of the  
277 MERRA-2 reanalysis data, and albedo of the MODIS and CM-SAF products with the  
278 physical algorithm of Tang et al. (2017b). This global product has a spatial resolution  
279 of 10 km, a temporal resolution of 3 hours, and spans the period of 1983.7-2018.12.  
280 Global comparative validation with observations shows that the accuracy of this global  
281 radiation product is generally better than several global satellite radiation products, such  
282 as the Earth's Radiant Energy System (CERES; Kato et al., 2013), the Global Energy  
283 and Water Cycle Experiment surface radiation budget (GEWEX-SRB; Pinker and  
284 Laszlo, 1992), and the ISCCP flux dataset (ISCCP-FD; Zhang et al., 2004).

285 In this study, these two satellite-based radiation products were first averaged to

286 daily and monthly means, and then validated against observations collected at the CMA  
287 radiation stations, and finally compared with our station-based radiation dataset in  
288 China.

289

## 290 **4 Results and Discussion**

291 The station-based radiation dataset was first validated against the CMA radiation  
292 observations at daily and monthly scales, respectively, then compared with two other  
293 satellite-based radiation products, and finally its spatial distribution characteristics were  
294 further analyzed. These are described in detail in the following four subsections. In this  
295 study, we used the statistical metrics of mean bias error (MBE), relative MBE (rMBE),  
296 root mean square error (RMSE), relative RMSE (rRMSE) and correlation coefficient  
297 (R) to measure the accuracies of our station-based dataset and the other two satellite-  
298 based radiation products.

299

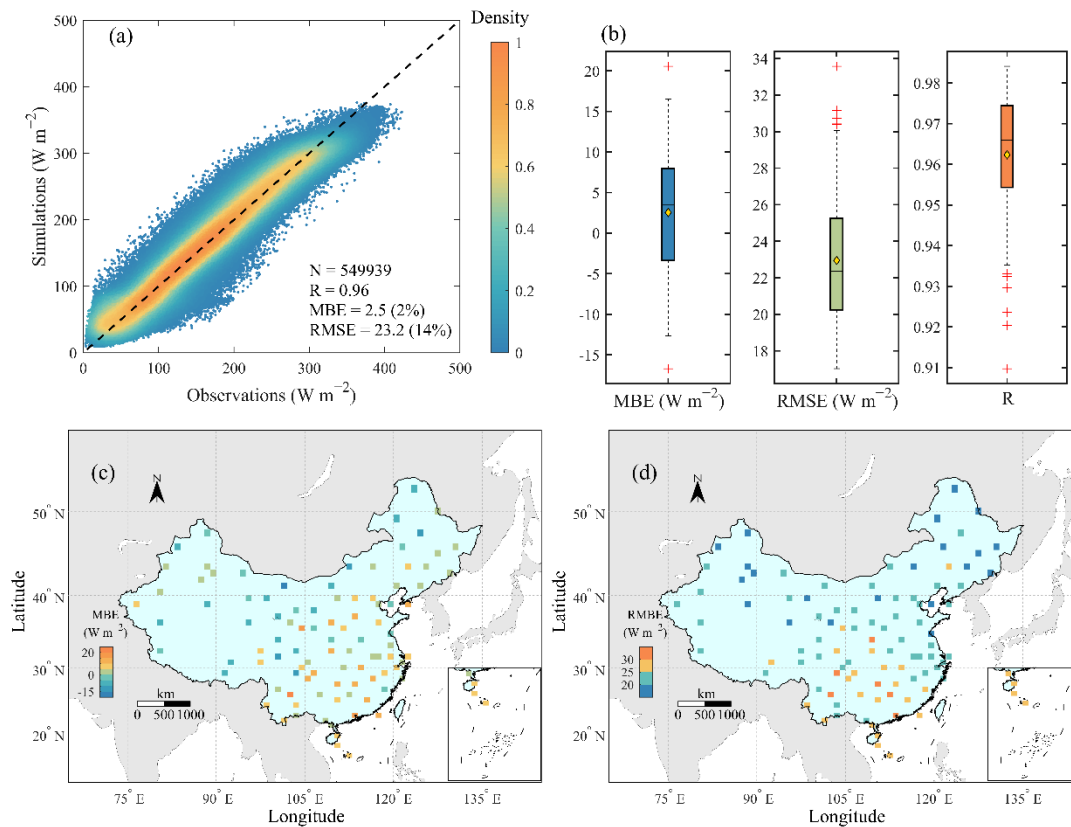

### 300 **4.1 Validation at daily scale**

301 Figure 3 shows the validation results for the daily global radiation estimates  
302 against observations from 96 CMA radiation stations over the period of 1993-2010.  
303 Overall, our station-based estimates over China perform well, with an MBE of 2.5 W  
304  $\text{m}^{-2}$ , a RMSE of 23.2 W  $\text{m}^{-2}$ , and an R of 0.96 (Figure 3 a). This indicates that the  
305 accuracy of our station-based estimates is significantly higher than that of almost all of  
306 the satellite products (such as, ISCCP-FD, GEWEX-SRB, CERES, GLASS and  
307 ISCCP-HXG) and reanalysis data (such as, ERA5 and MERRA-2), as well as other

308 regional satellite-based radiation products from Tang et al. (2016), Jiang et al. (2020a),  
309 and Letu et al. (2021). Therefore, we would expect our station-based estimates to be  
310 more accurate than the five global radiation products mentioned by Li et al. (2021), as  
311 CERES generally performs best among them. Of course, this speculation needs to be  
312 further verified with in-situ measurements collected in China in the future. In terms of  
313 MBE, there is a slight positive deviation, but the relative deviation is close to 2%, which  
314 is within the tolerance range of the PV potential assessment.

315 In addition, we also calculated the statistical metrics for each radiation station and  
316 their boxplots and spatial distributions are shown in Figure 3 (b)-(d). It can be seen that  
317 most of the stations had MBE between  $-4$  and  $8 \text{ W m}^{-2}$ , RMSE less than  $25 \text{ W m}^{-2}$ , and  
318 R greater than 0.95. The stations with relatively large errors were mainly found in the  
319 southern and eastern regions of China. This is largely due to the fact that these regions  
320 have more cloud cover and overcast skies, making it difficult to use sunshine duration  
321 to accurately parameterize cloud transmission. In addition, the uncertainty in the aerosol  
322 data would also partly contribute to the large errors.

323

324 **Figure 3** Validation results for our station-based daily global radiation dataset against

325 observations collected at 96 CMA radiation stations during 1993-2010. (a)

326 Comparison of daily global radiation between our dataset and observations,

327 (b) Boxplots of three statistical error metrics (MBE, RMSE and R), (c) spatial

328 distribution of MBE for individual radiation station, and (d) spatial

329 distribution of RMSE for individual radiation station.

330

331 Similar evaluations for the daily direct and diffuse radiation estimates are

332 presented in Figure 4 and Figure 5, respectively. Averaged over 19 CMA radiation

333 stations, our estimates for daily direct radiation produces an MBE of 7.4 W m<sup>-2</sup>, a

334 RMSE of 27.2 W m<sup>-2</sup> and an R of 0.92, respectively; while our estimates for daily

335 diffuse radiation produces an MBE of -3.3 W m<sup>-2</sup>, a RMSE of 19.2 W m<sup>-2</sup> and an R of

336 0.83, respectively. Both accuracies for direct and diffuse radiation are lower than for  
337 global radiation, as can be seen from their rRMSE and rMBE. The absolute rMBE for  
338 global radiation is about 2%, while those for direct and diffuse radiation are about 9%  
339 and 4%, respectively. The rRMSE for global radiation is about 14%, while those for  
340 direct and diffuse radiation are about 33% and 22%, respectively. We found that there  
341 is a slight overestimation for direct radiation, with an MBE of about  $7.4 \text{ W m}^{-2}$ . This  
342 may be due to the presence of high clouds, in which case the cloud transmission for  
343 direct radiation cannot be well parameterized by the sunshine duration (Tang et al.  
344 2018). For direct radiation, the RMSE at most stations is less than  $29 \text{ W m}^{-2}$  and the R  
345 at most stations is greater than 0.91; for diffuse radiation, the RMSE at most stations is  
346 less than  $21 \text{ W m}^{-2}$  and the R at most stations is greater than 0.81. The largest RMSE  
347 for both direct and diffuse radiation is found at the Lhasa station, where popcorn clouds  
348 were common, posing a major challenge to the simulation of cloud transmittance with  
349 sunshine duration.

350

351

**Figure 4** Same as **Figure 3**, but for daily direct radiation.

352

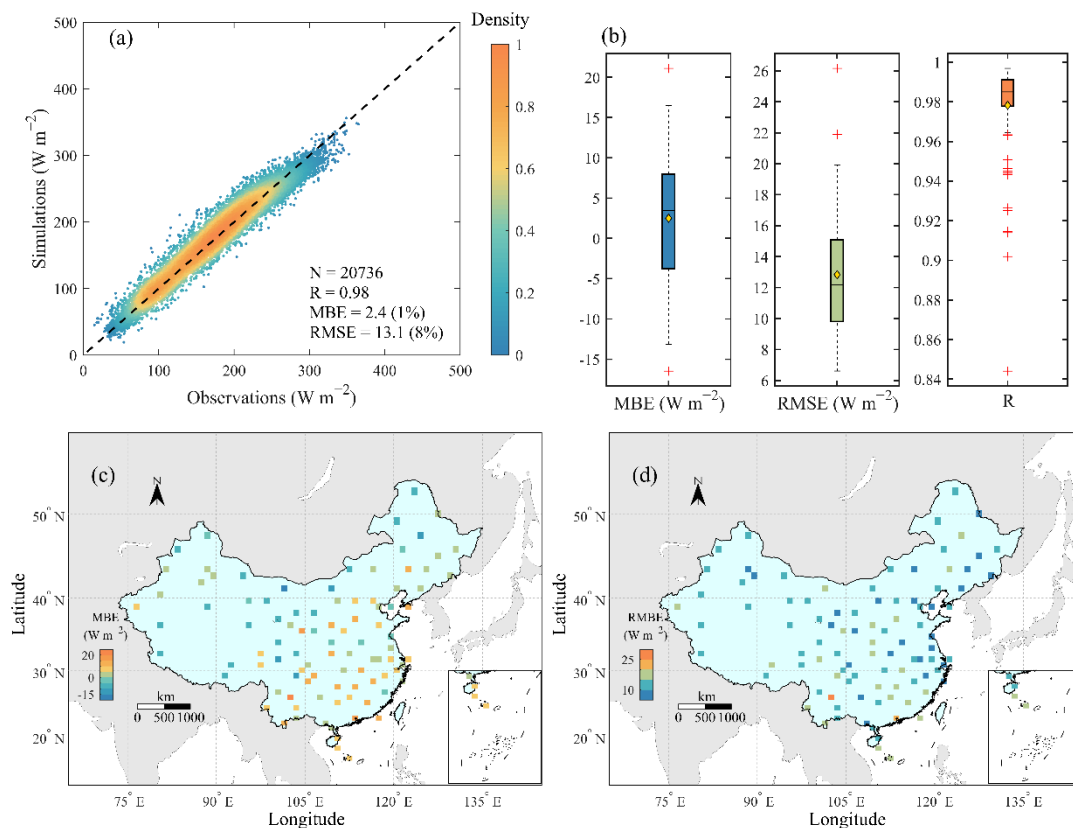

353

**Figure 5** Same as **Figure 3**, but for daily diffuse radiation.

354 **4.2 Validation at monthly scale**

355 Based on the daily estimates, we also calculated their monthly averages and  
356 validated them against observations. Figure 6 shows the validations for the estimates of  
357 monthly global radiation against observations at the CMA radiation stations. Averaged  
358 over all stations, the monthly global radiation estimates give an MBE of  $2.4 \text{ W m}^{-2}$ , a  
359 RMSE of  $13.1 \text{ W m}^{-2}$  and an R of 0.98. The rRMSE is about 8%. From the boxplots of  
360 the error indicators, R was greater than 0.98 and RMSE was less than  $15 \text{ W m}^{-2}$  at most  
361 stations. The spatial distribution features of MBE and RMSE are similar to those for  
362 daily global radiation, with relatively larger errors in the southern and eastern regions  
363 of China, and the largest MBE and RMSE are both found at Panzhihua station (with  
364 longitude of  $101.717^\circ$  and latitude of  $26.583^\circ$ ).

365

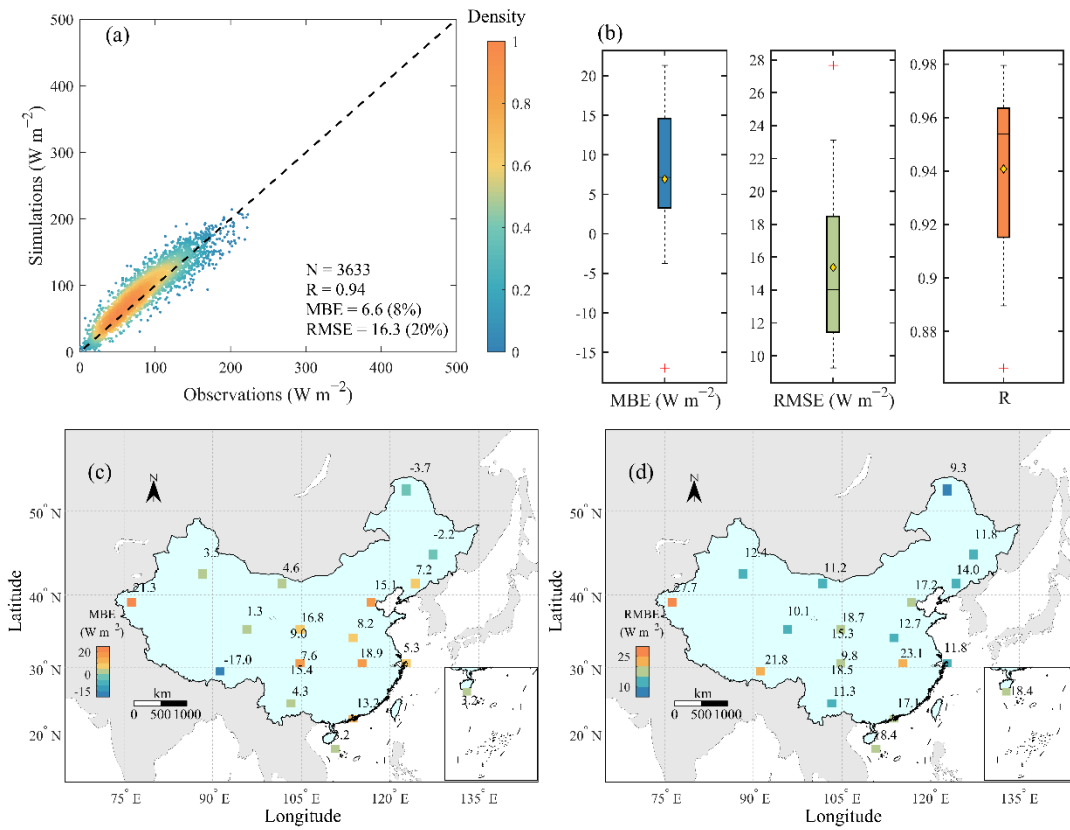

366

367 **Figure 6** Same as **Figure 3**, but for monthly global radiation.

368

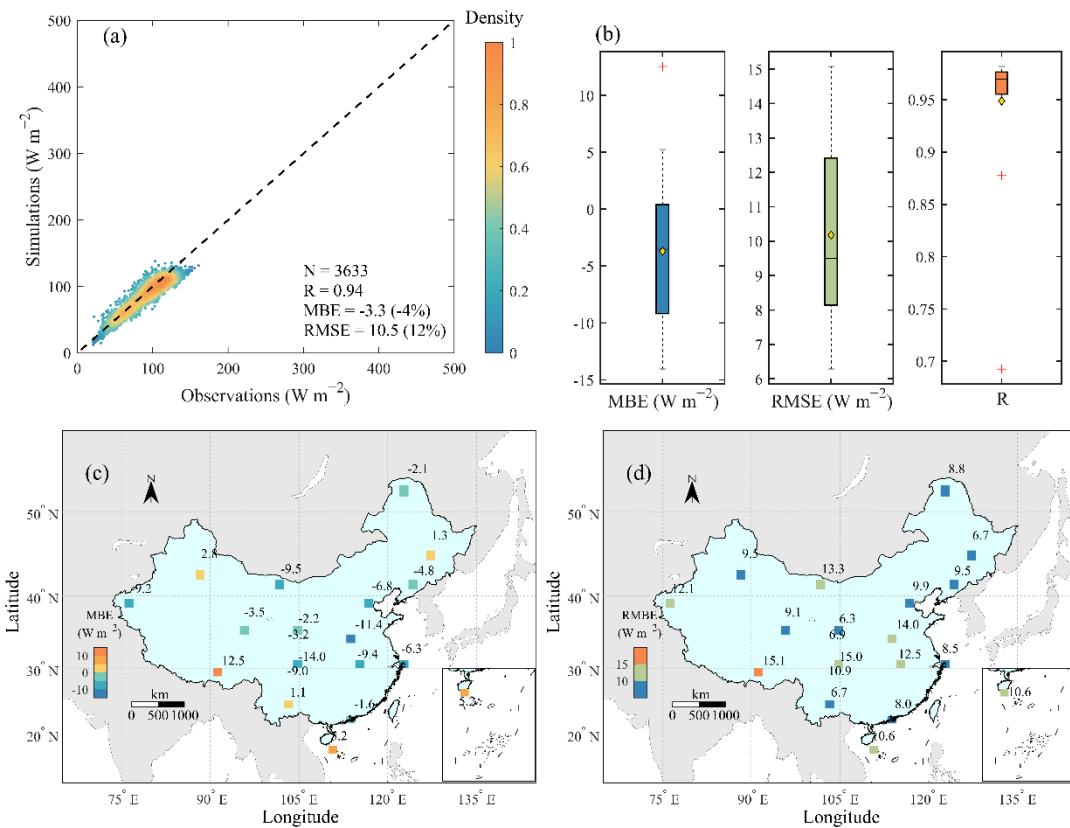

369 Figure 7 and Figure 8 also show the validation results for monthly direct and  
370 diffuse radiation against 19 CMA radiation stations. The rRMSE values for monthly  
371 direct and diffuse radiation are 20% and 12%, respectively. The MBE, RMSE and R for  
372 monthly direct radiation are  $6.6 \text{ W m}^{-2}$ ,  $16.3 \text{ W m}^{-2}$  and 0.94, respectively, while the  
373 MBE, RMSE and R for monthly diffuse radiation are  $-3.3 \text{ W m}^{-2}$ ,  $10.5 \text{ W m}^{-2}$  and 0.94,  
374 respectively. Similar to the case of the daily scale, a slight overestimation is also found  
375 for the monthly direct radiation. The RMSE for monthly direct and diffuse radiation is  
376 less than  $18 \text{ W m}^{-2}$  and  $13 \text{ W m}^{-2}$ , respectively, at most stations, while R for monthly  
377 direct and diffuse radiation is greater than 0.91 and 0.95, respectively, at most stations.  
378 The spatial distribution characteristics of MBE and RMSE are similar to those of daily  
379 conditions for both direct and diffuse radiation.

380

381

**Figure 7** Same as **Figure 3**, but for monthly direct radiation.

382

383

**Figure 8** Same as **Figure 3**, but for monthly diffuse radiation.

### 384 **4.3 Comparison with satellite-based products**

385 To demonstrate the superiority of the station-based radiation dataset developed in  
386 this study, we compared the station-based dataset with two widely used satellite-based  
387 radiation products. One is the product developed with deep learning and trained with  
388 surface radiation observations (Jiang et al., 2020a), and the other is the long-term global  
389 product of global radiation (Tang et al., 2019a), which was mainly developed based on  
390 the latest ISCCP-HXG cloud products with the improved physical algorithm (Tang et  
391 al., 2017b). The former can provide hourly global, direct and diffuse radiation, while  
392 the latter can only provide the 3-hourly global radiation. Here, we use a  $3 \times 3$  spatial  
393 window to smooth the raw radiation product from Tang et al. (2019a), as its accuracy  
394 is clearly improved when upscaled to 30 km. As we only have access to the CMA  
395 radiation observations up to 2010, the time period chosen for comparison is 2000-2010.  
396 Table 1 and Table 2 present the comparison of the evaluation results among the three  
397 radiation products against the observations measured at all CMA radiation stations, for  
398 daily and monthly conditions, respectively.

399 For daily data comparisons, our station-based estimate for daily global radiation  
400 obviously outperforms the other two satellite-based radiation products, with MBE of  
401  $2.7 \text{ W m}^{-2}$ , RMSE of  $23.2 \text{ W m}^{-2}$  and R of 0.96, followed by the product of Tang et al.  
402 (2019a) (with MBE of  $6.7 \text{ W m}^{-2}$ , RMSE of  $26.8 \text{ W m}^{-2}$  and R of 0.95) and the product  
403 of Jiang et al. (2020a) (with MBE of  $4.4 \text{ W m}^{-2}$ , RMSE of  $33.6 \text{ W m}^{-2}$  and R of 0.92).  
404 Our station-based estimates for daily direct radiation are also apparently more accurate  
405 than the satellite-based product of Jiang et al. (2020a), with the former producing a

406 lower RMSE and a higher R. The RMSE of our estimates is about  $9 \text{ W m}^{-2}$  lower than  
 407 that of the product of Jiang et al. (2020a).

408 For the daily diffuse radiation, our estimate is comparable to the diffuse radiation  
 409 product of Jiang et al. (2020a). It should be noted that the CMA radiation observations  
 410 were used to train the deep learning model of Jiang et al. (2020a), while no observations  
 411 were used in our estimates. Overall, these results indicate that the station-based  
 412 estimates of global, direct, and diffuse radiation generally outperform those from  
 413 satellite retrievals.

414  
 415 **Table 1.** Accuracy comparisons of our estimates in this study with other two satellite-  
 416 based products at daily scale. The units of MBE and RMSE are both  $\text{W m}^{-2}$ .  
 417 Observations of global radiation measured at 96 CMA radiation stations, and  
 418 observations of direct radiation and diffuse radiation measured at 19 CMA radiation  
 419 stations during 2000-2010 are used.

	This study			Jiang et al. (2020a)			Tang et al. (2019a)
	global	direct	diffuse	global	direct	diffuse	global (30 km)
MBE	2.7	8.6	-3.8	4.4	8.6	0.1	6.7
RMSE	23.2	27.6	19.6	33.6	36.6	20.1	26.8
R	0.96	0.92	0.83	0.92	0.85	0.84	0.95
N	328977	43630	43630	328977	43630	43630	328977

420

421 For the monthly comparisons, we also found that our estimate of monthly global

422 radiation is clearly more accurate than the two satellite products. The MBE and RMSE  
 423 of our estimate are  $2.6 \text{ W m}^{-2}$  and  $13.4 \text{ W m}^{-2}$ , respectively, which are lower than those  
 424 of the two satellite products, with MBE and RMSE values of  $4.6 \text{ W m}^{-2}$  and  $18.5 \text{ W m}^{-2}$   
 425 <sup>2</sup> for the Jiang et al. (2020a) product and  $6.7 \text{ W m}^{-2}$  and  $16.3 \text{ W m}^{-2}$  for the Tang et al.  
 426 (2019a) product. The R of our estimate is 0.98, which is higher than those of the two  
 427 satellite products. Our direct radiation estimate also outperforms the satellite product of  
 428 Jiang et al. (2020a), with the former having lower RMSE and MBE and higher R.  
 429 Similar to the daily comparison, the two monthly diffuse products are comparable to  
 430 each other.

431

432 **Table 2.** Accuracy comparisons of our estimates in this study with other two satellite-  
 433 based products at monthly scale. The units of MBE and RMSE are both  $\text{W m}^{-2}$ .  
 434 Observations of global radiation measured at 96 CMA radiation stations, and  
 435 observations of direct radiation and diffuse radiation measured at 19 CMA radiation  
 436 stations during 2000-2010 are used.

	This study			Jiang et al. (2020a)			Tang et al. (2019a)
	global	direct	diffuse	global	direct	diffuse	global (30 km)

437

#### 438 4.4 Spatial distribution features of solar radiation in China

439 Based on the developed station-based solar radiation dataset, Figure 9 present the  
440 spatial distributions of the multi-year average global, direct, and diffuse radiation in  
441 China during 1961 -2021. The spatial distribution of direct radiation is similar to that  
442 of global radiation, with the highest value over the Tibetan Plateau and the lowest value  
443 over the Sichuan Basin. However, the spatial distribution of diffuse radiation is very  
444 different from that of global radiation, with the highest value being found at the  
445 southernmost tip of China, and the lowest value being found in northeastern China. In  
446 general, clear-sky days correspond to more direct radiation and cloudy days correspond  
447 to more diffuse radiation, mainly because the scattering effect of aerosols is much  
448 smaller than the scattering effect of clouds. Therefore, high direct radiation is usually  
449 found in areas with frequent sunny days, such as Northwest China, North China, and  
450 Inner Mongolia, while low direct radiation is usually found in areas with frequent cloud  
451 cover, such as East China and South China. The opposite is true for diffuse radiation.

452 It should be noted that our station-based products are spatially discontinuous,  
453 especially in northwestern China, which may introduce significant uncertainty when  
454 applied to the assessment of solar power system potential. However, the uncertainty  
455 caused by spatial discontinuity in flat areas would be relatively small, as the spatial  
456 representation of a station on flat ground is generally larger than 25 km (Hakuba et al.,  
457 2013). Fortunately, most solar power systems are built on land with slopes of less than  
458 3%. In contrast, applications over complex terrain will introduce large uncertainties.  
459 Combining station-based data with satellite products will be a good solution in the  
460 future to improve the accuracy of solar energy potential assessment.

462

463 **Figure 9** Spatial distribution of the multi-year mean (a) global radiation, (b) direct  
 464 radiation, and (c) diffuse radiation from the station-based radiation dataset in  
 465 China during 1961-2021.

466

467 The spatial distribution of the multi-year average ratio of direct radiation to global  
 468 radiation in China during the period of 1961-2021 is also shown in Figure 10. Direct  
 469 radiation is mainly greater than diffuse radiation (ratio < 50%) in northern China,  
 470 northeastern China, northwestern China, and the Tibetan Plateau, while diffuse  
 471 radiation dominates in eastern and southern China. This information can guide the  
 472 planning of solar PV power and concentrating solar power (CSP) in China. For example,  
 473 regions such as Xinjiang, Inner Mongolia, Gansu, and the Tibetan Plateau with a high

474 proportion of direct radiation are suitable for the construction of CSP projects. Regions  
475 such as Hainan, Yunnan, Guangxi, and Guangdong with relatively high global and  
476 diffuse radiation are suitable for the use of bifacial PV panels, as both sides of the panels  
477 can be used to generate electricity and the main source on the back is from diffuse  
478 radiation. Conversely, in areas with low diffuse radiation, it may not be necessary to  
479 use bifacial PV panels.  
480

481  
482 **Figure 10** Spatial distribution of the multi-year mean ratio of direct radiation to global  
483 radiation from the station-based radiation dataset in China during 1961-  
484 2021.

485

## 486 **5 Data availability**

487 The dense station-based long-term dataset of daily global, direct, and diffuse  
488 radiation product with high-accuracy is stored at the National Tibetan Plateau Data  
489 Center (<https://data.tpsc.ac.cn/en/disallow/55fc9768-ea6a-4d16-9207-28f6aed4900b>  
490 and <https://doi.org/10.11888/Atmos.tpsc.300461>, Tang, 2023), Institute of Tibetan  
491 Plateau Research, Chinese Academy of Sciences.

492

## 493 **6 Summary**

494 In this study, we have developed a dense station-based long-term dataset of daily  
495 surface solar radiation in China with high-accuracy. The dataset consists of estimates  
496 of three radiation components (global, direct and diffuse radiation) at the 2473 CMA  
497 meteorological stations during the period from the 1950s to 2021, with most stations  
498 covering the period of 1961-2021. The methods used to develop the dataset are the  
499 global radiation estimation model of Yang et al. (2006) and the direct radiation  
500 estimation model of Tang et al. (2018), and the main inputs are the five meteorological  
501 variables of surface pressure, air temperature, relative humidity, horizontal visibility,  
502 and sunshine duration measured at the meteorological stations. The developed dataset  
503 was evaluated against in-situ measurement collected at 96 CMA radiation stations, and  
504 further compared with other two satellite-based radiation products.

505 Averaged over all radiation stations and the time period of 1993-2010, the total  
506 RMSE values for daily global, direct and diffuse radiation are 23.2, 27.6 and 19.6 W  
507 m<sup>-2</sup>, respectively. At the monthly mean scale, our estimates give RMSE values of about  
508 13.4, 16.5 and 10.9 W m<sup>-2</sup>, respectively, for monthly global, direct and diffuse radiation.

509 These error indicators on both daily and monthly scales are generally lower than those  
510 of the satellite radiation products, especially for global and direct radiation.  
511 Comparisons with the satellite-based radiation products indicate that our station-based  
512 estimates have a clear advantage in terms of accuracy and length of time series.  
513 However, our dataset does not provide radiation data beyond the weather stations.  
514 Merging the station-based estimates with the satellite-based retrievals will have good  
515 potential to improve the accuracy of the radiation products in the future. We expect that  
516 our station-based radiation dataset to contribute significantly to relevant basic research,  
517 engineering applications and fusion with satellite-based retrievals in the future.

518

519 **Author contributions.** All authors discussed the results and contributed to the  
520 manuscript. WT calculated the dataset, analyzed the results, and drafted the manuscript.  
521 JH drew the figures.

522

523 **Competing interests.** The authors declare that they have no conflicts of interest.

524

525 **Acknowledgments.** The ISCCP-HXG global product of global radiation was provided  
526 by the National Tibetan Plateau Data Center (TPDC). The radiation product of Jiang et  
527 al. (2016) was available from the Pangaea at  
528 <https://doi.org/10.1594/PANGAEA.904136>, and the CMA routine meteorological  
529 variables and radiation data were obtained from the CMA Meteorological Information  
530 Center. The authors would like to thank the staff of the data management and production

531 organizations for their valuable work.

532

533 **Financial support.** This work was supported by the National Natural Science  
534 Foundation of China (Grant No. 41988101 and 42171360), and Development Program  
535 of China (Grant No. 2022YFB4202104).
