9 **Abstract.** Land surface temperature (LST) is a key variable within the Earth’s climate system and a necessary input parameter  
10 required by numerous land-atmosphere models. It can be directly retrieved from satellite thermal infrared (TIR) observations,  
11 which contain many invalid pixels mainly caused by cloud contamination. To investigate the spatial and temporal variations  
12 of LST in China, long-term, high-quality, and spatiotemporally continuous LST datasets (i.e., all-weather LST) are urgently  
13 needed. Fusing satellite TIR LST and reanalysis datasets is a viable route to obtain long time-series all-weather LST. Among  
14 satellite TIR LSTs, the MODIS LST is the most commonly used and a few corresponding all-weather LST products have been  
15 reported recently. However, the publicly reported all-weather LSTs were not available during the temporal gaps of MODIS  
16 between 2000 and 2002. In this study, we generated a daily (four observations per day) 1-km all-weather LST dataset for the  
17 Chinese landmass and surrounding areas–TRIMS LST, which begins on the first day of the new millennium (January 1, 2000).  
18 We used the Enhanced Reanalysis and Thermal infrared remote sensing Merging (E-RTM) method to generate the TRIMS  
19 LST dataset with the temporal gaps being filled, which had not been achieved by the original RTM method. Specifically, we  
20 developed two novel approaches, i.e., the Random-Forest based Spatio-Temporal Merging (RFSTM) approach and Time-  
21 Sequential LST-based Reconstruction (TSETR) approach, respectively, to produce Terra/MODIS-based and Aqua/MODIS-  
22 based TRIMS LSTs during the temporal gaps. We also conducted a thorough evaluation of the TRIMS LST. A comparison  
23 with the GLDAS and ERA5-Land LST demonstrates that the TRIMS LST has similar spatial patterns but higher image quality,  
24 more spatial details, and no evident spatial discontinuities. The results outside the temporal gap show consistent comparisons  
25 of TRIMS LST with MODIS LST and AATSR LST, with mean bias deviation (MBD) of 0.09 K/0.37 K and standard deviation  
26 of bias (STD) of 1.45 K/1.55 K. Validation based on *in-situ* LST at 19 ground sites indicate that the TRIMS LST has a mean  
27 bias error (MBE) ranging from -2.26 K to 1.73 K and a root mean square error (RMSE) ranging from 0.80 K to 3.68 K. There  
28 is no significant difference between the clear-sky and cloudy conditions. For the temporal gap, it is observed that RFSTM and  
29 TSETR perform similarly to the original RTM method. Additionally, the differences between Aqua and Terra remain stable  
30 throughout the temporal gap. The TRIMS LST has already been used by scientific communities in various applications such  
31 as soil moisture downscaling, evapotranspiration estimation, and urban heat island modeling. The TRIMS LST is freely and  
32 conveniently available at <https://doi.org/10.11888/Meteoro.tpd.271252> (Zhou et al., 2021).

## 34 **1 Introduction**

35 Land surface temperature (LST) is a key variable related to the energy exchange at the interface between the land surface and  
36 the atmosphere. It is the result of the thermal feedback of various ground surfaces to incident solar radiation and atmospheric  
37 downward radiation. Therefore, it is a necessary input parameter required by numerous land-atmosphere models (Jiang and  
38 Liu, 2014; Li et al., 2013b, 2023c). LST has been widely used in a variety of studies, such as surface evapotranspiration (ET)  
39 estimation (Anderson et al., 2011; Ma et al., 2022), urban heat island (UHI) modeling (Alexander, 2020; Liao et al., 2022),  
40 drought monitoring (Zhang et al., 2017), and ecological assessment (Sims et al., 2008).

41 In the past four decades, especially since the beginning of the new millennium (i.e., 2000), China and its surrounding areas  
42 have experienced rapid economic development and population growth, accompanied by notable changes to the natural  
43 environment (Yang and Huang, 2021). Meanwhile, China has adopted a series of interventions to protect the environment  
44 since the 1980s, such as the Grain for Green Program (Wang et al., 2017), Three-North Shelter Forest Program (Zhai et al.,  
45 2023), and Red Lines of Cropland (a policy to ensure that Chinese arable land does not drop below 120 million hectares).  
46 These interventions have played a key role in changing land use/cover and regulating the climate (Chen et al., 2019a). In  
47 addition, with the warming climate, extreme weather and meteorological disasters occur frequently in China and its  
48 surrounding areas (Chen et al., 2019b). Since LST is highly sensitive to land cover change, heat waves, droughts, and  
49 vegetation information (Li et al., 2023a; Su et al., 2023), making it an important indicator of global climate change (Mildrexler  
50 et al., 2018; Peng et al., 2014). Therefore, it is important to investigate the spatial and temporal variations of LST for these  
51 areas, which requires a long-term, high-quality, and spatio-temporally continuous LST dataset.

52 LST can be obtained through *in-situ* observations, model simulations, and remote sensing retrievals. However, LST is spatially  
53 and temporally heterogeneous and highly affected by various factors such as land cover, soil type, topography, and climatic,  
54 and meteorological conditions (Liu et al., 2006; Zhan et al., 2013). *In-situ* observations based on spatial 'point measurement'  
55 are not able to obtain spatially continuous LST, and the current model simulation suffers from coarse spatial resolution. In  
56 contrast, satellite remote sensing, which has the advantages of better spatial continuity, larger coverage, good ability for  
57 repeating observations, and much higher spatial resolution, has become an important way to obtain LST for large areas (Li et  
58 al., 2013b).

59 Satellite thermal infrared (TIR) remote sensing can directly obtain the regional and global LST efficiently. A series of satellite  
60 TIR LST products are currently available to users. For example, the Moderate-resolution Imaging Spectroradiometer (MODIS)  
61 LST products are the most widely used because of their global coverage, long time-series (since February 24, 2000, for Terra  
62 and since July 4, 2002, for Aqua), high quality, and good accuracy (Aguilar-Lome et al., 2019; Sandeep et al., 2021; Wan,  
63 2014). However, they generally have significant spatial absences due to cloud contamination, especially in low and middle  
64 latitudes in China (e.g., the Tibet Plateau and southern China) (Duan et al., 2017), increasing high uncertainties for their

65 spatially-continuous applications (Li et al., 2023c). Meanwhile, there is a temporal discontinuity (hereafter termed the temporal  
66 gap) in Terra/Aqua MODIS during 2000-2002, further limiting their long-time applications.

67 To fill these drawbacks, scholars have developed a variety of methods to generate gapless LST (Jia et al., 2022b; Zhang et al.,  
68 2022; Li et al., 2023c; Quan et al., 2023). These methods can be generally divided into three groups, i.e., spatio-temporal  
69 interpolation, surface energy balance (SEB), and multisource data fusion methods (Ding et al., 2023; Li et al., 2023c). The  
70 spatio-temporal interpolation methods take advantage of the temporal and spatial variation patterns inner the LST to get gapless  
71 LST data (Ding et al., 2023). For example, Zhang et al. (2022) proposed a spatio-temporal fitting framework to generate a 1-  
72 km spatial resolution dataset from 2003 to 2020 over global land, which is the only seamless LST dataset, to the best of our  
73 knowledge, on Google Earth Engine for free applications. Nevertheless, the results using the spatio-temporal interpolation  
74 methods may contain some uncertainties under cloudy-sky conditions (Martins et al., 2019). The SEB-based methods are a  
75 group of physical methods, that can recover LST under cloudy conditions, considering longwave radiation and solar radiation  
76 as influences on the LST (Jin and Dickinson, 2000). For example, Martins et al. (2019) used the SEB-based method to  
77 successfully fill the missing LST, based on land surface parameters from the European Satellite Application Facility on Land  
78 Surface Analysis (LSA-SAF), to generate the all-weather LST product (MSG All-Sky Land Surface Temperature, MLST-AS).  
79 In addition, a general approach that incorporates the clear-sky LST into the SEB model has recently been developed, based on  
80 the MODIS and Visible Infrared Imaging Radiometer (VIIRS) data, to estimate the LSTs under cloud-contaminated regions  
81 (Jia et al., 2021).

82 Multisource data fusion methods mainly integrate TIR LST with satellite passive microwave (PMW) observation or reanalysis  
83 data to generate seamless all-weather LST and have been widely used. PMW data can be used for estimating all-weather LST  
84 retrievals because they are less affected by the atmosphere and clouds (Holmes et al., 2009; Zhou et al., 2017). However, there  
85 are limitations in obtaining all-weather LST from PMW observations. First, the spatial resolution of PMW data differs  
86 significantly from TIR, such as the Advanced Microwave Scanning Radiometer 2 (AMSR2) with ~10 km spatial resolution.  
87 Second, the spatial coverage of the PMW data is incomplete because there are orbital gaps. Third, the temperature retrieved  
88 from PMW observations contains information from the subsurface, which differs from the TIR LST that exclusively represents  
89 skin temperature (Zhou et al., 2017). Compared with the PMW data, reanalysis data can provide spatially continuous LST and  
90 related surface parameters; thus, it can act as an alternative basis to obtain the all-weather LST (Long et al., 2020; Ding et al.,  
91 2022). One typical method is the Reanalysis and Thermal infrared remote sensing Merging (RTM) method proposed by Zhang  
92 et al. (2021) for integrating the Global Land Data Assimilation System assimilation (GLDAS) and Aqua/MODIS LST for the  
93 Tibetan Plateau. The theoretical foundation of the RTM method lies in the temporal component decomposition model of LST  
94 (Zhan et al., 2014; Zhang et al., 2019b). Upon comparing with independent TIR LST and validating *in-situ* LST, significant  
95 agreement between RTM LST and TIR LST was observed, demonstrating the effectiveness of the RTM method in all weather  
96 conditions. RTM method fully utilizes reanalysis data and TIR data to produce prospective, high-resolution, and reliable LST  
97 records on regional, continental, and global scales for the long term.

98 Various all-weather LST datasets using the aforementioned three typical methods have been released in recent years (Duan et  
99 al., 2017; Hong et al., 2022; Jia et al., 2022a; Jia et al., 2022b; Li et al., 2021a; Metz et al., 2017; Muñoz-Sabater et al., 2021;  
100 Yao et al., 2023; Yu et al., 2022). However, all-weather LST datasets with both high temporal resolution (4 observations per  
101 day or higher) and high spatial resolution (1 km or higher) since 2000 for the Chinese landmass and the surrounding areas are  
102 still lacking.

103 In this study, we proposed the enhanced RTM (E-RTM) method to produce a daily (four observations per day) 1-km all-  
104 weather LST dataset for the Chinese landmass and its surrounding areas (19°N–55°N, 72°E–135°E), which was named as the  
105 Thermal and Reanalysis Integrating Moderate-resolution Spatial- seamless LST (TRIMS LST), a successor to the work of  
106 Zhang et al. (2021). The E-RTM method includes three modules (Sect.3). First, the original RTM method was used to produce  
107 the TRIMS LST from DOY 55 of 2000 (DOY 185 of 2002) to DOY365 of 2022. Then, Terra/MODIS-based and  
108 Aqua/MODIS-based TRIMS LST during the temporal gaps were produced, based on the physical properties of the LST time  
109 component decomposition model. Finally, the accuracy of the TRIMS LST was evaluated based on observations from *in-situ*  
110 sites.

## 111 2 Datasets

### 112 2.1 Satellite data and reanalysis data

113 In this study, the main satellite data we used were the 1-km daily MODIS LST/emissivity product (MOD11A1: February 2000  
114 to December 2022; MYD11A1: July 2002 to December 2022) in version 6.1, which was produced based on the generalized  
115 split-window algorithm and has good accuracy for homogeneous surfaces (Wan, 2014). This product was used as a basis data  
116 for producing the TRIMS LST. The other MODIS datasets we used include (1) the 1-km 16-day Normalized Difference  
117 Vegetation Index (NDVI) product (MOD13A2: February 2000 to December 2022), (2) the 500-m daily Normalized Difference  
118 Snow Index (NDSI) product (MOD10A1F: February 2000 to December 2022) (<https://modis-snow-ice.gsfc.nasa.gov/>), and  
119 (3) the 500-m daily MODIS land surface albedo product (MCD43A3: February 2000 to December 2022) in version 6.1. All  
120 of the above products except MOD10A1F are available at EARTHDATA (<https://earthdata.nasa.gov/>). To generate and  
121 evaluate the all-weather LST, we also collected (1) the 90-m Shuttle Radar Topography Mission Digital Elevation Model data  
122 (SRTM DEM; <http://srtm.csi.cgiar.org>), (2) global 1-km daily Maximum Value Composite Synthesis of ‘Satellite Pour  
123 l'Observation de la Terre’ (SPOT) VEGETATION (VGT) Images (VGT-S1) (January 2000 to February 2000) (<https://spot-vegetation.com/en>) (Toté et al., 2017), (3) 0.05° 8-day Global Land Surface Satellite (GLASS) Albedo product (January 2000  
124 to February 2000) (<http://www.glass.umd.edu/Albedo/MIX/>) (Feng et al., 2016), (4) the 30-m yearly China Land Cover  
125 Dataset (2000-2015) from Zenodo (CLCD, <https://doi.org/10.5281/zenodo.4417810>) (Yang and Huang, 2021), and (5) the 1-  
126 km daily ENVISAT/AATSR LST product (July 2004–April 2012) (<https://climate.esa.int/>).

128 The main reanalysis data we used in this study were the GLDAS data provided by the Goddard Earth Sciences Data and  
129 Information Services Center (GES DISC) (Rodell et al., 2004). GLDAS utilizes an analysis increment, which is obtained

130 through the optimal interpolator using the observed-minus-forecast value for the skin temperature calculated by GLDAS. This  
 131 analysis increment, along with the bias correction term, is subsequently provided to the land surface models code for energy  
 132 budget considerations. The bias correction ensures that the modeled state is continually adjusted towards the observed values,  
 133 thereby improving the accuracy of the skin temperature calculations on an incremental, semi-daily, or daily basis (Radakovich  
 134 et al., 2001). The accuracy of GLDAS LST has been demonstrated by various studies with MBE ranging from -4.27 K to 8.65  
 135 K and RMSE ranging from 3.0 K to 6.02 K (Zhang et al.,2021; Xiao et al.,2023). Specifically, the 0.25° 3-hourly LST from  
 136 the GLDAS Noah model between January 2000 and December 2022 was used as another input of the RTM method. In addition,  
 137 we also collected the 0.1° hourly ERA5-Land LST datasets (Muñoz-Sabater et al., 2021), and its LST will be compared with  
 138 the generated TRIMS LST.

## 139 2.2 Ground measurements

140 Table I shows 19 ground sites that recorded longwave radiation data for different periods. According to geographical locations  
 141 and land cover types provided in Table I, it is clear that they are distributed in different climate zones.

142  
 143 **Figure 1: The study area and the selected 19 ground sites. A, B, C, D, E, and F are subareas exhibiting a single land cover type with**  
 144 **no change in T1 and T2 (January 1, 2000 to January 3, 2005).**

145 This indicates that they encompass a wide range of land surface and climatic situations for sufficient validation of the TRIMS  
 146 LST. The measurement device at the selected ground station includes a long-wave radiometer and four-component radiometers,  
 147 including CNR1, CNR4, and CG4 (Kipp & Zonen, Netherlands; <https://www.kippzonen.com/>). According to the specifications  
 148 of these radiometers, the uncertainties in the daily total for longwave radiation measurements are 3%–10% (Wang et al., 2020).

149 With the measured incoming and outgoing longwave radiation, the LST of the land cover type within the field-of-view (FOV)  
150 of the radiometer can be calculated through the radiative transfer equation in the form of the Stephan-Boltzmann's law (Ma et  
151 al., 2023, 2021). Considering the uncertainties of the longwave radiation measurement, the uncertainties of the calculated *in-*  
152 *situ* LST are approximately 0.6 K–1.2 K (Xu et al., 2013; Yang et al., 2020; Ma et al., 2021).

153 Spatial representativeness of ground sites has different degrees of influence on the validation of TIR-based LST using *in-situ*  
154 LST. In this study, to quantify the spatial representativeness, we calculated the standard deviation (STD) of  $33 \times 33$  Landsat  
155 LST within MODIS pixels containing ground sites. Specifically, the Landsat LST is the 30-m Landsat-7 ETM+ Collection 2  
156 Level-2 LST provided by the United States Geological Survey (U.S. Geological Survey, 2021). For the 19 sites, the STD  
157 ranged from 0.64 K to 1.53 K, indicating good to acceptable representativeness of these sites for the validation of a 1-km LST  
158 (Zhang et al., 2021; Duan et al., 2019). Abnormal measurements, caused by short-term disturbances such as instantaneous  
159 shadow from small clouds and birds, were excluded from the ground measured longwave radiation through a quality check.  
160 This quality check involved removing the outgoing or incoming longwave radiation that deviated by more than  $3\sigma$  (standard  
161 deviations) from their respective one-hour averages (Göttsche et al., 2016).

162

**Table I: Details of the 19 selected ground sites and their measurements.**

Site	Latitude and Longitude (°N, °E)	Elevation (m)	Radiometers	Height of radiometer (m)	Diameter of radiometer's FOV (m)	Land cover type	Period	STD of 30-m Landsat LST (K)	Source

Note: \*this height is the instrument's average height above the tree canopy. The ground sites were operated by different field campaigns or programs. CERN: Chinese Ecosystem Research Network (Fu et al., 2010; Pastorello et al., 2020); CEOP-CAMP: the Coordinated Energy and Water Cycle Observation Project (CEOP) and Asia-Australia Monsoon Project (CAMP) (Ma et al., 2006; Liu et al., 2004); China Flux (Pastorello et al., 2020; Yu et al., 2014; Zhang and Han, 2016); HHE: HaiHe Experiment in the Hai River Basin, China (Guo et al., 2020; Liu et al., 2013b); HiWATER: Heihe Watershed Allied Telemetry Experimental Research (Che et al., 2019; Li et al., 2013a; Liu et al., 2011, 2018, 2023); NIEER-CAS: Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences (Wen et al., 2011). The datasets from HiWATER and HHE were downloaded from the National Tibetan Plateau Data Center (TPDC) (<https://data.tpdc.ac.cn/>); the datasets from China Flux and CERN were downloaded from the China Flux Network (<http://www.chinaflux.org/>); the datasets from CEOP-CAMP were downloaded from the Earth Observing Laboratory of National Center for Atmospheric Research (<https://data.eol.ucar.edu/dataset/>); and the dataset of MQU was downloaded from the link: <http://tpwrr.nieer.cas.cn/>.

165

170

### 172 3. Methodology

173 TRIMS LST was generated through the E-RTM method, consisting of three modules depicted in Fig.2. Module I runs the  
174 original RTM method (Zhang et al., 2021) to merge MOD11A1 (MYD11A1) and GLDAS LST, producing daily all-weather  
175 LST at the Terra (Aqua) satellite overpass time from DOY 55 of 2000 (DOY 185 of 2002) to DOY 365 of 2022. Module II  
176 employs a Random-Forest-based Spatio-Temporal Merging (RFSTM) approach to extend the beginning date of the MOD11A1  
177 LST-based all-weather LST to January 1, 2000. Finally, Module III utilizes a Time-Sequential LST-based Reconstruction  
178 (TSETR) approach to extend the beginning date of the MYD11A1 LST-based all-weather LST to January 1, 2000.

#### 179 3.1 Module I: the RTM method

180 Details of the RTM method can be found in Zhang et al. (2021). For the convenience of readers, a brief description of RTM is  
181 provided here. In the temporal dimension, the time series of LST can be expressed as:

$$182 \quad LST(t_d, t_{avg}, t_{ins}) = LFC(t_d, t_{avg}) + HFC(t_d, t_{avg}, t_{ins}) + HFC_{cld}(t_d, t_{ins}), \quad (1)$$

183 where  $t_d$  is the day of the year (DOY);  $t_{ins}$  is the overpass time of a satellite TIR sensor (i.e., MODIS) and  $t_{avg}$  is the average  
184 observation time calculated from  $t_{ins}$ ;  $LFC$  is the low-frequency component that represents the intra-annual variation component  
185 of the LST under ideal clear-sky conditions;  $HFC$  is the high-frequency component, which represents the sum of the diurnal  
186 LST variation and the weather variation component (WTC) under ideal clear-sky conditions;  $HFC_{cld}$  is a correction term  
187 representing the impact on LST triggered by cloud contamination under cloudy conditions; and  $HFC_{cld}$  is equal to zero under  
188 clear-sky conditions.

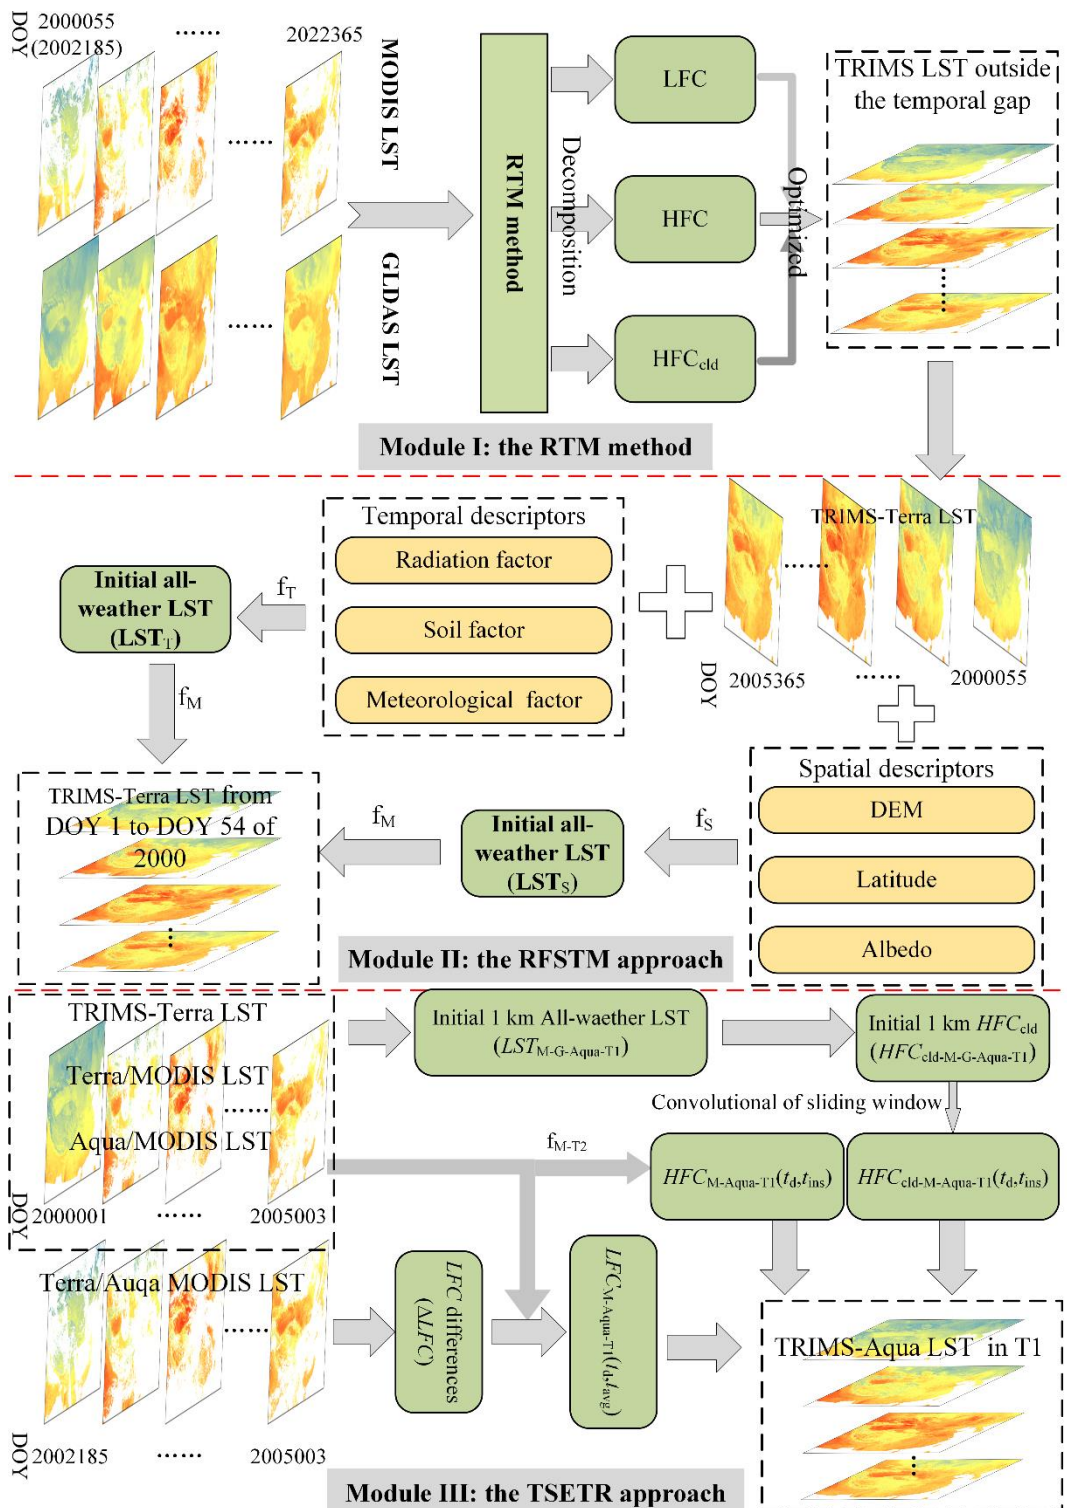

189 In the RTM method,  $LFC$ ,  $HFC$ , and  $HFC_{cld}$  in Eq. (1) are first determined from the MODIS LST and the GLDAS LST. Then,  
190 the optimized models are determined for the three components according to their characteristics and their quality is improved  
191 by inputting their descriptors. Finally, three optimized components are integrated to generate the all-weather LST.

#### 192 3.2 Module II: the RFSTM approach

193 The RFSTM approach was developed to predict the all-weather LST during the period of DOY 1-54 2000 during which the  
194 Terra MODIS LST was not available. It is based on the fact that (i) the LST of a pixel in the temporal dimension is strongly  
195 affected by the meteorological conditions as well as the underlying surface and (ii) the LST of many pixels at a certain time  
196 are closely related to their underlying surfaces (Ma et al., 2021). Therefore, RFSTM has two stages, namely, the temporal stage  
197 and the spatial stage.

198

199  
200

Figure 2: Flowchart of the E-RTM method. Note that the date in this figure is in the format of YYYY+DOY.

201 In the temporal stage, the daily LST ( $\mathbf{LST}_T$ ) of a pixel Q in a certain period is modeled as:

$$\begin{aligned}
 & \mathbf{LST}_T = f_T(\mathbf{X}_T) \\
 202 \quad & \mathbf{X}_T = [\mathbf{P}_{T,1} \ \mathbf{P}_{T,2} \ \dots \ \mathbf{P}_{T,m}]^T, \tag{2} \\
 & = \begin{bmatrix} p_{T,1}(t_{d,1}) & p_{T,1}(t_{d,2}) & \dots & p_{T,1}(t_{d,n}) \\ p_{T,2}(t_{d,1}) & p_{T,2}(t_{d,2}) & \dots & p_{T,2}(t_{d,n}) \\ \dots & \dots & \dots & \dots \\ p_{T,m}(t_{d,1}) & p_{T,m}(t_{d,2}) & \dots & p_{T,m}(t_{d,n}) \end{bmatrix}
 \end{aligned}$$

203 where the subscript T denotes the temporal stage; the function  $f_T$  expresses the mapping in temporal dimensions from  
 204 descriptors to LST;  $\mathbf{X}_T$  denotes the matrix including LST descriptors' time series ( $\mathbf{P}_{T,i}$ ,  $i=1, 2, \dots, m$ ); and  $n$  is the number of  
 205 days within the temporal gap of Terra MODIS LST.

206 We used the mapping function  $f_T$  to predict the 1-km all-weather LST, since the MODIS LST is not available as a reference  
 207 for reconstruction and it is impossible to identify the different weather conditions (e.g., clear-sky and cloudy conditions).  
 208 However, the relationship between LST and its descriptors cannot be analytically expressed currently. Fortunately, machine  
 209 learning has been reported to be effective in enhancing the spatial resolution of remote sensing images. Specifically, the random  
 210 forest (RF) algorithm has shown good performance in mapping the correlation between LST with finer resolution and its  
 211 descriptors with coarser resolution (Xiao et al., 2023; Li et al., 2021a; Xu et al., 2021; Zhao and Duan, 2020; Yoo et al., 2020).  
 212 Therefore, the RF algorithm was employed here to realize  $f_T$ . The temporal descriptors of LST include the net longwave  
 213 radiation, downwelling long-wave radiation, soil moisture/ temperature profile (e.g., surface, 0–10 cm, and 10–40 cm in  
 214 GLDAS NOAH model-based data), canopy surface water, snow depth water equivalent, surface skin temperature, wind-speed,  
 215 and air temperature. The training period for  $f_T$  with RF was set as DOY 55 of 2000 to DOY 55 of 2005, and the prediction  
 216 period for  $\mathbf{LST}_T$  was from DOY 1 of 2000 to DOY 55 of 2000.

217 Considering that LST varies in both spatial and temporal dimensions, the spatial descriptors of LST should also be considered.  
 218 In the spatial stage, the LST ( $\mathbf{LST}_S$ ) at  $t_d$  in the prediction period is expressed as:

$$219 \quad \mathbf{LST}_S = f_S[N_{S,1}(t_d) \ N_{S,2}(t_d) \ \dots \ N_{S,k}(t_d)], \tag{3}$$

220 where the subscript S denotes the spatial stage; the function  $f_S$  expresses the mapping in spatial dimensions from the descriptors  
 221 to LST;  $k$  is the number of spatial descriptors of LST; and  $N_S$  denotes the 1-km spatial descriptor of LST ( $N_{S,i}$ ,  $i=1, 2, \dots, k$ ).

222 The spatial descriptors of LST include the DEM, latitude, and albedo. The selected descriptors in the spatial stage are all from  
 223 the ancillary data with a 1 km resolution. Albedo serves as a descriptor that informs about land surface, including factors such  
 224 as vegetation growth, surface/sub-surface moisture distribution, and land surface cover type. We used GLASS albedo data as  
 225 a substitution in the prediction step to fill the temporal gaps in MODIS LST because these temporal gaps are also effective in  
 226 other MODIS products (including the MODIS albedo). Specifically, the GLASS albedo data is the best substitution for MODIS  
 227 albedo data that we can find since they are strongly correlated with each other and have close accuracies according to existing  
 228 studies (He et al., 2014; Wang et al., 2014; Chen et al., 2017; Lu et al., 2021).

229 To involve all spatio-temporal LST descriptors and guarantee the best performance of the output, the LST ( $\mathbf{LST}_T$  and  $\mathbf{LST}_S$ )  
 230 need to be merged to derive the final 1-km LST ( $\mathbf{LST}_M$ ):

$$231 \quad \mathbf{LST}_M = f_M(\mathbf{LST}_T, \mathbf{LST}_S), \quad (4)$$

232 where  $f_M$  denotes the RF-based mapping which indicates the contributions to the  $\mathbf{LST}_M$  from  $\mathbf{LST}_T$  and  $\mathbf{LST}_S$ , respectively.  
 233 For a single 1-km pixel, the RF-based regression contribution function is trained using  $\mathbf{LST}_T$  (obtained by Eq. 2),  $\mathbf{LST}_S$   
 234 (obtained by Eq. 3), and TRIMS LST in the training period. Then,  $f_C$  is applied to estimate the 1-km all-weather LST in the  
 235 prediction period via Eq. (4).

### 236 3.3 Module III: the TSETR approach

237 The TSETR approach was developed to estimate the all-weather LST during the period from DOY 1 of 2000 to DOY 184 of  
 238 2002 during which the Aqua/MODIS LSTs were not available (with a temporal gap of 915 days). Previous studies have shown  
 239 that it is possible to convert between the Terra/MODIS LST and Aqua/MODIS LST, considering land cover types, geolocation,  
 240 and season (Coops et al., 2007). Therefore, Terra/MODIS LST from 2000-2002 could be transformed into Aqua/MODIS LST  
 241 (Li et al., 2018). Since the Terra/MODIS LST (MOD11A1) is available as a reference in the temporal gap, we generated an  
 242 all-weather LST based on the TSETR approach, which is reconstruction rather than prediction.

243 According to Eq. (1), the LST time series can be decomposed into  $LFC$ ,  $HFC$ , and  $HFC_{\text{old}}$  under all weather conditions.  
 244 Therefore, the TSETR approach has three stages. In the first stage, we need to estimate the  $LFC$  during the temporal gap at the  
 245 Aqua overpass time. In this case, the temporal gap period was set as T1, and DOY 185 of 2002 to DOY 3 of 2005 was set as  
 246 T2 (Fig.3). According to the analytical expression and physical meaning of  $LFC$ , there are no underlying trends of change  
 247 within the three annual parameters ( $T_{\text{avg}}$ ,  $A$  and  $\omega$ ) except for the periodic variation in the LST, which means that the  $LFC$  is  
 248 cyclic-stationary over a short period (Bechtel, 2015; Weng and Fu, 2014; Zhu et al., 2022). Once the three annual parameters  
 249 are determined, the  $LFC$  can be calculated for a given day.

250 Therefore, in the TSETR approach, we assume that the  $LFC$  differences ( $\Delta LFC$ ) between the Terra and Aqua overpass times  
 251 in T1 and T2 are also cyclic-stationary. In T2, the  $LFC$  at the Terra/MODIS and Aqua/MODIS pixels are determined separately.  
 252 In T1, the  $LFC$  at the Aqua overpass time of the pixel M can be expressed as:

$$253 \quad \begin{cases} LFC_{M\text{-Aqua-T1}}(t_d, t_{\text{avg}}) = LFC_{M\text{-Terra-T1}}(t_d, t_{\text{avg}}) + \Delta LFC_M(t'_d, t_{\text{avg}}) \\ \Delta LFC_M(t'_d, t_{\text{avg}}) = LFC_{M\text{-Aqua-T2}}(t'_d, t_{\text{avg}}) - LFC_{M\text{-Terra-T2}}(t'_d, t_{\text{avg}}) \end{cases}, \quad (5)$$

254 where  $t_d$  is a specific day in T1;  $t'_d$  is a specific day corresponding to  $t_d$  in T2;  $LFC_{M\text{-Aqua-T1}}(t_d, t_{\text{avg}})$  and  $LFC_{M\text{-Terra-T1}}(t_d, t_{\text{avg}})$   
 255 denote the  $LFC$  corresponding to the Aqua/Terra overpass time in T1, respectively; and  $LFC_{M\text{-Aqua-T2}}(t'_d, t_{\text{avg}})$  and  $LFC_{M\text{-Terra-T2}}(t'_d, t_{\text{avg}})$   
 256 denote the  $LFC$  corresponding to the Aqua and Terra overpass time in T2, respectively.

257  
258 **Figure 3: Schematic diagram for estimating  $LFC$  at daytime Aqua overpass time in T1.**

259  $HFC$  is estimated in the original RTM method using a nonlinear mapping established by multiple descriptors. In the second  
 260 stage of E-RTM, the  $HFC$  within T1 at the Aqua overpass time can be estimated by using its descriptors through RF (Xu et  
 261 al., 2021). With Module I and Module II, we have obtained TRIMS-Terra LST in T1. However, it is unfeasible to directly  
 262 model an RF mapping based on Terra/MODIS LST and its corresponding descriptors in T1. An important concern that needs  
 263 to be addressed is the timing discrepancy between Terra and Aqua observations, which results in distinct variations in the  
 264 pattern of LST changes. When there is no valid Aqua/MODIS LST available, we have made improvements to the procedure  
 265 for calculating the HFC in the original RTM method as follows:

$$266 \begin{cases} HFC_{M-Aqua-T1}(t_d, t_{ins-Aqua-T1}) = HFC_{M-Terra-T1}(t_d, t_{ins-Terra-T1}) + \Delta HFC_{M-Terra-Aqua-T1} \\ \Delta HFC_{M-Terra-Aqua-T1}(t_d, t_{ins}) = f_{M-T2}(g_M, DEM_M, NDVI_M(t_d), slp_M(t_d), \alpha_M(t_d), v_M(t_d), \Delta LFC_M, \Delta DTC_M), \\ \Delta DTC_M = \Delta DTC_{M-Aqua}(t_d, t_{ins}, t_{avg}) - \Delta DTC_{M-Terra}(t_d, t_{ins}, t_{avg}) \end{cases} \quad (6)$$

267 where  $\Delta LFC$  characterizes the systematic deviation of the steady state component;  $g_M$  is geospatial code (Yang et al., 2022);  
 268  $DEM_M$ ,  $NDVI_M$ ,  $slp_M$ ,  $\alpha_M$ ,  $\Delta t_M$ , and  $v_M$  are the DEM, NDVI, slope, albedo, difference between  $t_{ins}$  and  $t_{avg}$ , and the atmospheric  
 269 water vapour content, respectively;  $\Delta DTC$  characterizes the warming effect of solar radiation, and the weather effect can be  
 270 characterized by the atmospheric water vapor content. According to Zhang et al. (2021), the HFC characterizes the change in  
 271 LFC with  $\Delta DTC$  and WTC superimposed under ideal clear-sky conditions. The detailed calculation of  $\Delta DTC$  can be found in  
 272 Zhang et al. (2019).

273  $f_{M-T2}$  is constructed as follows. Initially, the correlation image of the target pixel M is determined within the T2 period and the  
 274 following two conditions need to be satisfied by the correlation image: (i) the mean bias deviation (MBD) of the DTC estimated  
 275 from its corresponding GLDAS LST (10:00-14:00 and 21:00-3:00 local solar time) should be lower than 1 K, and (ii) the  
 276 difference in the average observation time between the GLDAS pixels should not exceed 0.5 h. Using the correlation image,  
 277 the similar image family S of the target pixel M is determined. Subsequently, in the correlation image, using similar land cover  
 278 type criteria, the similar image family S of the target pixel M within the GLDAS pixels is identified. S needs to meet the  
 279 following two conditions: (i) it should have the same land cover type as M and (ii) R of the Terra/MODIS LST time series  
 280 corresponding to S and M need to be greater than 0.8.

281 In the third stage, we need to estimate the  $HFC_{\text{cld}}$  within the temporal gap period at the Aqua overpass time.  $HFC_{\text{cld}}$  is  
 282 essentially an atmospheric correction term and it is obtained from the GLDAS LST in the RTM method. According to the  
 283 parameterization scheme of the RTM method, the clear-sky MODIS pixels and their corresponding GLDAS LST are the  
 284 necessary inputs for the estimation of  $HFC_{\text{cld}}$ . It is not possible to obtain  $HFC_{\text{cld}}$  directly in this stage due to the lack of  
 285 Aqua/MODIS in T1.

286 Inspired by the Temporal Component Decomposition (TCD) method (Zhang et al., 2019b) and other methods integrating  
 287 PMW and TIR LST (Parinussa et al., 2016; Zhang et al., 2020), the initial value of the 1-km  $HFC_{\text{cld}}$  can be expressed as:

$$288 \quad HFC_{\text{cld-M-G-Aqua-T1}}(t_d, t_{\text{ins}}) = LST_{\text{M-G-Aqua-T1}}(t_d, t_{\text{ins}}) - LFC_{\text{M-Aqua-T1}}(t_d, t_{\text{avg}}) - HFC_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}), \quad (7)$$

289 where  $HFC_{\text{cld-M-G-Aqua-T1}}$  is the initial 1-km  $HFC_{\text{cld}}$  of M; and  $LST_{\text{M-G-Aqua-T1}}$  is the initial 1-km LST of M under all-weather  
 290 conditions.

291 Based on the findings of Yao et al. (2023), we established the method for acquiring the initial 1-km all-weather LST. Initially,  
 292 the GLDAS LST that corresponded to the Aqua overpass time is corrected for systematic bias using the cumulative distribution  
 293 function matching (Xu and Cheng., 2021). In the T1 period, since Aqua/MODIS LST is unavailable, we employed MODIS  
 294 LST from 2003-2022 to guarantee an adequately large sample size of MODIS LST. We then downscaled the GLDAS LST to  
 295 1 km through the following two steps.

296 (i) Calculating the LST differences between the MODIS and GLDAS:

$$297 \quad \begin{cases} \Delta LST_{\text{M-G-Aqua-T1}}(t_d, t_{\text{ins}}) = LST_{\text{G-Aqua-T1}}(t_d, t_{\text{ins}}) - LST_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}) \\ LST_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}) = LFC_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}) + HFC_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}) \end{cases}, \quad (8)$$

298 where  $LST_{\text{G-Aqua-T1}}$  is GLDAS LST;  $LST_{\text{M-Aqua-T1}}$  is ideal MODIS clear-sky LST.  $LST_{\text{M-G-Aqua-T1}}$  is an LST difference image.  
 299 One pixel in GLDAS LST corresponds to 625 ( $25 \times 25$ ) pixels in MODIS LST. The LST differences are calculated as GLDAS  
 300 LST minus 625-pixel average MODIS LST. LST difference image was then directly resampled to 1 km.

301 (ii) Downscaling of GLDAS LST:

$$302 \quad LST_{\text{M-G-Aqua-T1}}(t_d, t_{\text{ins}}) = \Delta LST_{\text{M-G-Aqua-T1}}(t_d, t_{\text{ins}}) + LST_{\text{M-Aqua-T1}}(t_d, t_{\text{ins}}), \quad (9)$$

303 where  $LST_{\text{M-G-Aqua-T1}}$  is the initial 1-km downscaled GLDAS LST. The heterogeneity of the underlying land surface within a  
 304  $0.25^\circ$  grid is reflected by MODIS LST, and the downscaled GLDAS LST also exhibits the same characteristic. This is based

305 on the hypothesis that the spatial variations in MODIS LST are the same as that of GLDAS LST. However,  $LST_{M-G-Aqua}$  and  
 306  $HFC_{cld-M-G-Aqua-T1}$  in the results of Eq. (9) may still contain systematic errors due to inadequate downscaling (Eq. 8). Therefore,  
 307 a convolutional implementation of a sliding window was used here to reduce the systematic error contained in  $HFC_{cld-M-G-Aqua-}$   
 308  $T1$  (Chen et al., 2011; Wu et al., 2015; Zhang et al., 2019b).

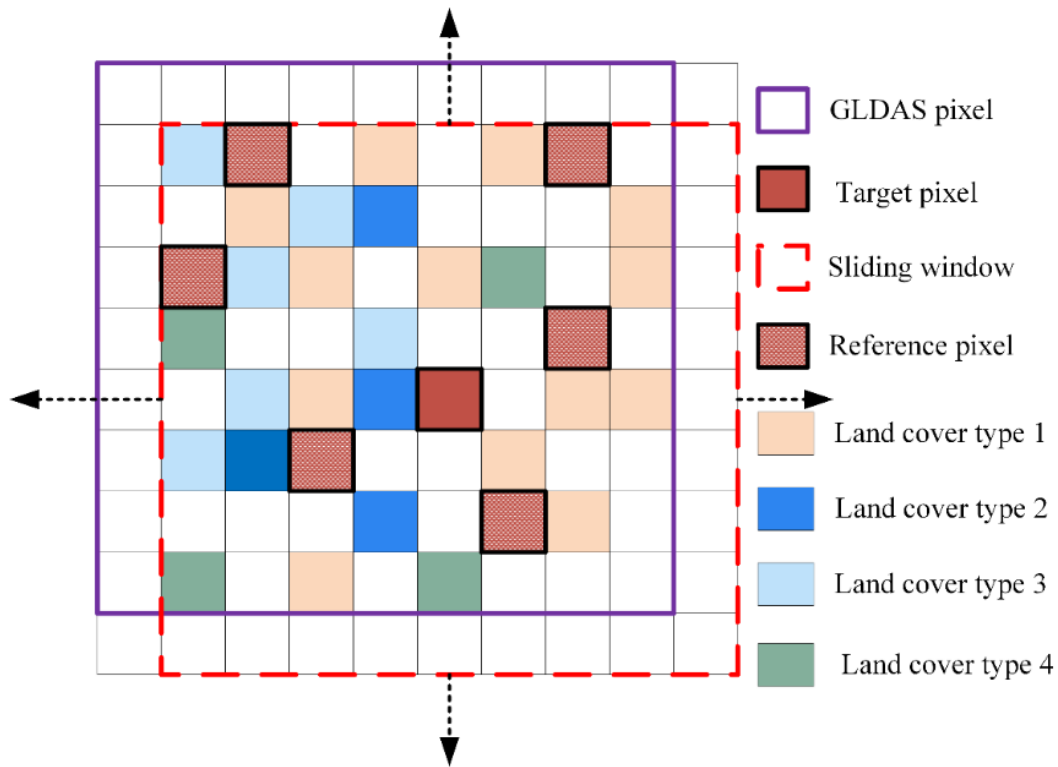

309 The schematic diagram of the convolutional implementation of the sliding window is shown in Fig.4. To fully reduce the  
 310 systematic bias, the size of the sliding window should be slightly larger than a GLDAS pixel ( $26 \times 26 \text{ km}^2$ ). According to  
 311 Zhang et al. (2019, 2021),  $HFC_{cld}$  after optimization of M (i.e.,  $HFC_{cld}$  after eliminating the systematic errors) can be obtained  
 312 by convolving the  $HFC_{cld}$  of the surrounding similar pixels by combining geological factors (e.g., land cover type, spatial  
 313 distance, and topography). This method is based on the interrelationship of different LSTs: neighboring  $HFC_{cld}$  are correlated  
 314 in a limited spatial domain. Previous studies have shown that the approaches analogous to the convolutional implementation  
 315 of sliding windows have a good ability to improve both the accuracy and the image quality of the merged LST (Ding et al.,  
 316 2022; Long et al., 2020; Zhang et al., 2019b). Similar pixels (termed as S) need to meet the following criteria: (i) they are  
 317 within the same sliding window as the target pixel, and (ii) their land cover type does not differ from the target pixel. Therefore,  
 318 the target pixel itself is also a reference pixel. Eventually, the  $HFC_{cld}$  of the target pixel can be expressed as:

$$319 \quad HFC_{cld-M-Aqua-T1}(t_d, t_{ins}) = \sum_{i=1}^n HFC_{cld-S_i}(t_d, t_{ins}) \cdot w_{S_i}, \quad (10)$$

320 where  $n$  is the number of similar pixels;  $HFC_{cld-S}$  denotes  $HFC_{cld-M-Aqua-T1}$  of the similar pixels; and  $w_s$  is the contribution of  
 321 similar pixels to M, which can be expressed as:

$$322 \quad \begin{cases} w_{S_i} = D_{S_i} \cdot H_{S_i} \cdot N_{S_i} / \left( \sum_n D_{S_i} \cdot H_{S_i} \cdot N_{S_i} \right) \\ D_{S_i} = (1/d_{S_i}) / \sum_{i=1}^n 1/d_{S_i} \\ d_{S_i} = \sqrt{(x_{S_i} - x_M)^2 + (y_{S_i} - y_M)^2} \\ H_{S_i} = |DEM_{S_i} - DEM_M| \\ N_{S_i} = |NDVI_{S_i} - NDVI_M| \end{cases}, \quad (11)$$

323 where  $D_s$ ,  $H_s$ , and  $N_s$  are the differences between the similar pixels and M in terms of the spatial distance, DEM, and NDVI,  
 324 respectively.

325

326 **Figure 4: Schematic of the  $HFC_{cd}$  convolutional optimization.**

### 327 **3.4 Implementation of E-RTM**

328 A detailed description of the implementation process of the RTM method is provided by Zhang et al. (2021) and it is only  
 329 briefly described in this section. Here, Module II and Module III's implementation is explained in detail.

#### 330 **Stage I: Data preprocessing and spatio-temporal matching**

331 In this stage, the data are preprocessed and spatio-temporal matching. First, valid MODIS LSTs are selected with the following  
 332 two standards: (i) the quality control of the pixel was flagged as “good” and (ii) the view angle of the pixel was lower than  
 333  $60^\circ$ . Second, the selected temporal descriptors from GLDAS data were temporally interpolated using the cubic spline function  
 334 to observe the time of MODIS LST for temporal matching. Third, the observation times for cloudy pixels and temporal gaps  
 335 were recovered using a 16-day revisiting period. Fourth, the 90-m DEM, 500-m albedo, and 500-m NDSI were upscaled to 1  
 336 km to match the MODIS LST. Fifth, the GLDAS water vapor was extended to 1 km by cubic convolution interpolation. During  
 337 the temporal gap (DOY 1–54 2000), SPOT VGT served as the NDVI, GLASS albedo was extended to a 1 km resolution using  
 338 cubic convolution interpolation, and the NDSI was determined by taking the average of the corresponding days in 2001 and  
 339 2002. The 16-day 1-km NDVI is temporally interpolated to daily resolution. The daily missing albedo caused by the cloud is  
 340 filled up through Statistics-based Temporal Filter (Liu et al., 2013a). In addition, all data are spatially matched.

341

342 **Stage II: Implementation of the RTM**

- 343 (i) For the target MODIS pixel, its annual-scale LST time series are extracted and fitted to obtain the *LFC* component.
- 344 (ii) The *HFC* components of all comparable pixels are estimated.
- 345 (iii) To create a mapping model of the *HFC* components and corresponding spatial descriptors, a machine-learning approach
- 346 is implemented.
- 347 (iv) The trained mapping model is utilized to determine the *HFC* under clear-sky conditions.
- 348 (v) Bias correction of the GLDAS LST to match that of the MODIS LST.
- 349 (vi) Calculate the  $HFC_{\text{cld}}$  present in the GLDAS LST.
- 350 (vii) Estimate the  $HFC_{\text{cld}}$  of the target pixel.
- 351 (viii) To achieve the estimation of LST under clear-sky conditions. ( $LFC+HFC$ ).
- 352 (ix) Implement the estimation of LST under cloudy conditions. ( $LFC+HFC+HFC_{\text{cld}}$ ).
- 353 (x) Repeat the above steps for every pixel of MODIS LST to achieve the fusion of TIR LST and GLDAS LST.

354

355 **Figure 5: Implementation flow of the RTM method**

356

357 **Stage III: Implementation of the RFSTM**

358 (i) For a single 1-km pixel, training the RF regression relationship (i.e.,  $f_T$ ) between TRIMS-Terra LST and the temporal  
359 descriptors from GLDAS data via Eq. (2). The RF parameters were set as follows: n estimators=85, max depth=18, max  
360 features=3, and min samples leaf=1. In the temporal stage of RFSTM, all-weather samples from 2000 to 2005 were compiled.  
361 Two-thirds of the samples are used for model training and the remaining are for model validation (Breiman, 2001).

362 (ii) For a specific day ( $t_d$ ), using the 1-km NDVI (Sobrino et al., 2004) and NDSI to classify the study area into several subareas,  
363 including thick vegetation ( $NDVI > 0.5$ ), sparse vegetation ( $0.2 \leq NDVI \leq 0.5$ ), barren land areas ( $NDVI < 0.2$ ), and snow-ice areas  
364 ( $NDSI > 0.1$ ) (Zhang et al., 2019a) and water ( $NDVI < 0$ ). Then, for each subarea, the spatial descriptors of LST are input into  
365  $f_S$  via Eq. (3). The RF parameters were set as follows: n estimators=420, max depth=43, max features=9, and min samples  
366 leaf=1. Note that  $f_S$  with RF is trained with the 1-km LST and spatial descriptors of a day, with the same observation time as  $t_d$   
367 and the smallest difference in the number of days between  $t_d$ .

368 (iii) For a single 1-km pixel, train the RF-based regression contribution function (i.e.,  $f_M$  in Eq. 4) using  $LST_T$ ,  $LST_S$ , and  
369 TRIMS-Aqua LST under clear-sky conditions. Then, estimate the 1-km TRIMS-Aqua LST during the period of DOY 1-54  
370 2000 by applying  $f_M$  to clear-sky and cloudy conditions, respectively.

371

372 **Stage IV: Implementation of the TSETR**

373 (i) For a single Aqua-MODIS pixel M in T1, determine its LFC in Eq. (5) using Aqua/MODIS LST (T2) and Terra/MODIS  
374 LST (T1 and T2).

375 (ii) Train the RF measuring ( $f_{M-T2}$ ) between all of  $\Delta HFC$  and its descriptors (see section 3.3) of all similar pixels. The RF  
376 measuring function tools are also provided by the MATLAB platform. The RF parameters were set as follows: n estimators =  
377 100, max depth = 20, max feature = 4, min samples leaf = 1. Determine the reconstructed HFC of M through Eq. (6) by  
378 applying the descriptors of HFC in M to  $f_{M-T2}$ .

379 (iii) Implement the bias correction for GLDAS LST of the target GLDAS grid by using cumulative distribution function  
380 matching. Then, downscale the GLDAS LST to 1 km through Eqs. (8) and (9).

381 (iv) Determine the initial 1-km  $HFC_{clid}$  of M through Eq. (7). Finally, determine the  $HFC_{clid}$  of M through Eqs. (10) and (11).

382 **3.5 Evaluation strategies**

383 As can be seen from Fig. 2, TRIMS LST can be divided into two parts according to the period of data coverage: data within  
384 the temporal gap period and data outside the temporal gap period. There are differences in the evaluation strategies within the  
385 two periods due to the different availability of validation data.

386 For outside the temporal gap period, the TRIMS LST was compared with LSTs derived from two reanalysis datasets (i.e.,  
387 GLDAS and the independent ERA5-Land) and retrievals from two different satellite TIR sensor (i.e., MODIS and the  
388 independent AATSR). In comparing different LSTs, samples with time differences greater than five minutes were excluded

389 (Freitas et al., 2010; Göttsche et al., 2016; Jiang and Liu, 2014). The quantitative metrics used in comparison analyses include  
 390 the MBD, STD of bias, and coefficient of determination ( $R^2$ ). Then, the TRIMS LST was validated under different weather  
 391 conditions based on *in-situ* LST from the ground sites listed in Table I. The three metrics used the mean bias error (MBE),  
 392 root-mean-square-error (RMSE), and  $R^2$ .

393 During the temporal gap period, the TRIMS LST was tested using three methods. Firstly, the results of the original RTM  
 394 method were cross-referenced and validated empirically with RFSTM and TSETR. In 2003, RFSTM was utilized to merge  
 395 GLDAS LST and Terra/MODIS LST, resulting in a 1-km all-weather LST. Additionally, the TSETR method was employed  
 396 to generate TRIMS-Aqua LST for the periods of 2003–2005 and 2013–2015. For the actual data generated for the period 2000-  
 397 2002, specifically Aqua LST, the similarity of the TRIMS LST time series was quantified to examine the reliability of TRIMS  
 398 LST during the Aqua/MODIS temporal gap. The time series angle (TSA), inspired by the spectral angle that is widely used to  
 399 measure the similarity between spectral curves (Kruse et al., 1993), was used to quantify the similarity of the TRIMS LST  
 400 time series. The TSA is defined as:

$$401 \quad \theta = \cos^{-1} \frac{\mathbf{LST}_{\text{TRIMS-Aqua}} \cdot \mathbf{LST}_{\text{TRIMS-Terra}}}{\|\mathbf{LST}_{\text{TRIMS-Aqua}}\| \cdot \|\mathbf{LST}_{\text{TRIMS-Terra}}\|}, (12)$$

402 where  $\theta$  is the TSA (unit: degree);  $\mathbf{LST}_{\text{TRIMS-Aqua}}$  and  $\mathbf{LST}_{\text{TRIMS-Terra}}$  are time series of TRIMS-Aqua and TRIMS-Terra LSTs,  
 403 respectively. From this formula, we know that a smaller TSA denotes higher similarity.

404 Based on the CLCD described in Section 2.1, six subareas with a single land cover type and no land cover change in T1 and  
 405 T2 (January 1, 2000 to January 3, 2005) were selected to extract the corresponding TRIMS-Terra and TRIMS-Aqua LST time  
 406 series. These six subareas (Fig.1) were recorded as A (82.30°N–83.16°N, 39.63°E–40.03°E, barren land), B (124.73°N–  
 407 125.17°N, 51.51°E–51.95°E, forest), C (111.84°N–112.30°N, 42.47°E–42.85°E, grassland), D (100.78°N–101.53°N, 39.92°E  
 408 –40.44°E, barren land), E (98.14°N–98.61°N, 33.92°E–34.25°E, grassland), and F (91.73°N–92.22°N, 31.7°E–32.01°E,  
 409 grassland). Then, the TSA was calculated to quantify the similarity between the TRIMS-Terra and TRIMS-Aqua LST time  
 410 series.

411 Finally, we evaluated percentage of valid pixels in TRIMS LST and MODIS LST to prove the continuity of TRIMS LST  
 412 during the temporal gaps. Furthermore, we analysed the fluctuations in LST during the connectivity period (February and  
 413 March 2000 for Terra; June and July 2002 for Aqua) to demonstrate the uninterrupted TRIMS LST sequence at the conclusion  
 414 of the filled duration.

## 415 **4. Results and discussion**

### 416 **4.1 Comparison of the TRIMS LST with reanalysis data**

417 With the E-RTM method, TRIMS LST products from January 1 2000 to December 31 2022 were generated. The spatial  
418 resolution was 1 km. The temporal resolution was four observations per day, which is the same as the Terra/MODIS and  
419 Aqua/MODIS. Fig. 6 shows the daytime TRIMS-Aqua LST on DOY 1, 91, 181, and 271 as examples.

420 Fig. 6 shows that the TRIMS-Aqua LST has a similar spatial pattern as the GLDAS LST since the latter is an input for the  
421 former. Good agreement in the spatial pattern in different seasons can also be observed between TRIMS-Aqua LST and the  
422 independent ERA5-Land LST. A careful observation of Fig. 6 demonstrates that the TRIMS LST is spatially seamless and its  
423 spatial patterns are as expected. Southern China as well as southeast Asia and the south Asian subcontinent in low latitudes  
424 are warm in all seasons because of additional absorbed solar radiation. The Tibetan Plateau, with much higher elevation and  
425 regions in high latitudes, is much cooler than other regions. In spring (DOY 1), summer (DOY 181), and autumn (DOY 271),  
426 northwestern China, where the dominant land cover type is barren land, is much warmer than other regions. Further comparison  
427 indicates that TRIMS LST is generally slightly warmer than the GLDAS LST and the ERA5-Land LST. For example, on DOY  
428 1 of 2000, the LST is generally below 278 K in the eastern Tibetan Plateau, while the GLDAS LST and the ERA5-Land LST  
429 are approximately 3–5 K lower. In the generation scheme of the TRIMS LST, the MODIS LST, which is generally warmer  
430 than the LST provided by reanalysis data, is an important input as well as a reference to ‘calibrate’ the GLDAS LST. This  
431 induces the ‘merged’ TRIMS LST to be warmer than the GLDAS LST as well as the ERA5-Land LST.

432 To further examine the image quality of the TRIMS-Aqua LST, Fig. 7 shows the daytime TRIMS-Aqua LST, GLDAS LST,  
433 and ERA5-Land LST of the subarea shown in Fig. 6 at the Aqua overpass time in 2000. Compared with the GLDAS LST and  
434 the ERA5-Land LST, the TRIMS LST offers more spatial details because of its much higher spatial resolution. Thus, one can  
435 see clear terrain-induced temperature variations. Furthermore, Fig. 7 shows that no evident spatial discontinuities exist in the  
436 TRIMS LST, indicating the E-RTM method performs satisfactorily in addressing the spatial scale mismatch between the  
437 MODIS LST and GLDAS LST (Zhang et al., 2021).

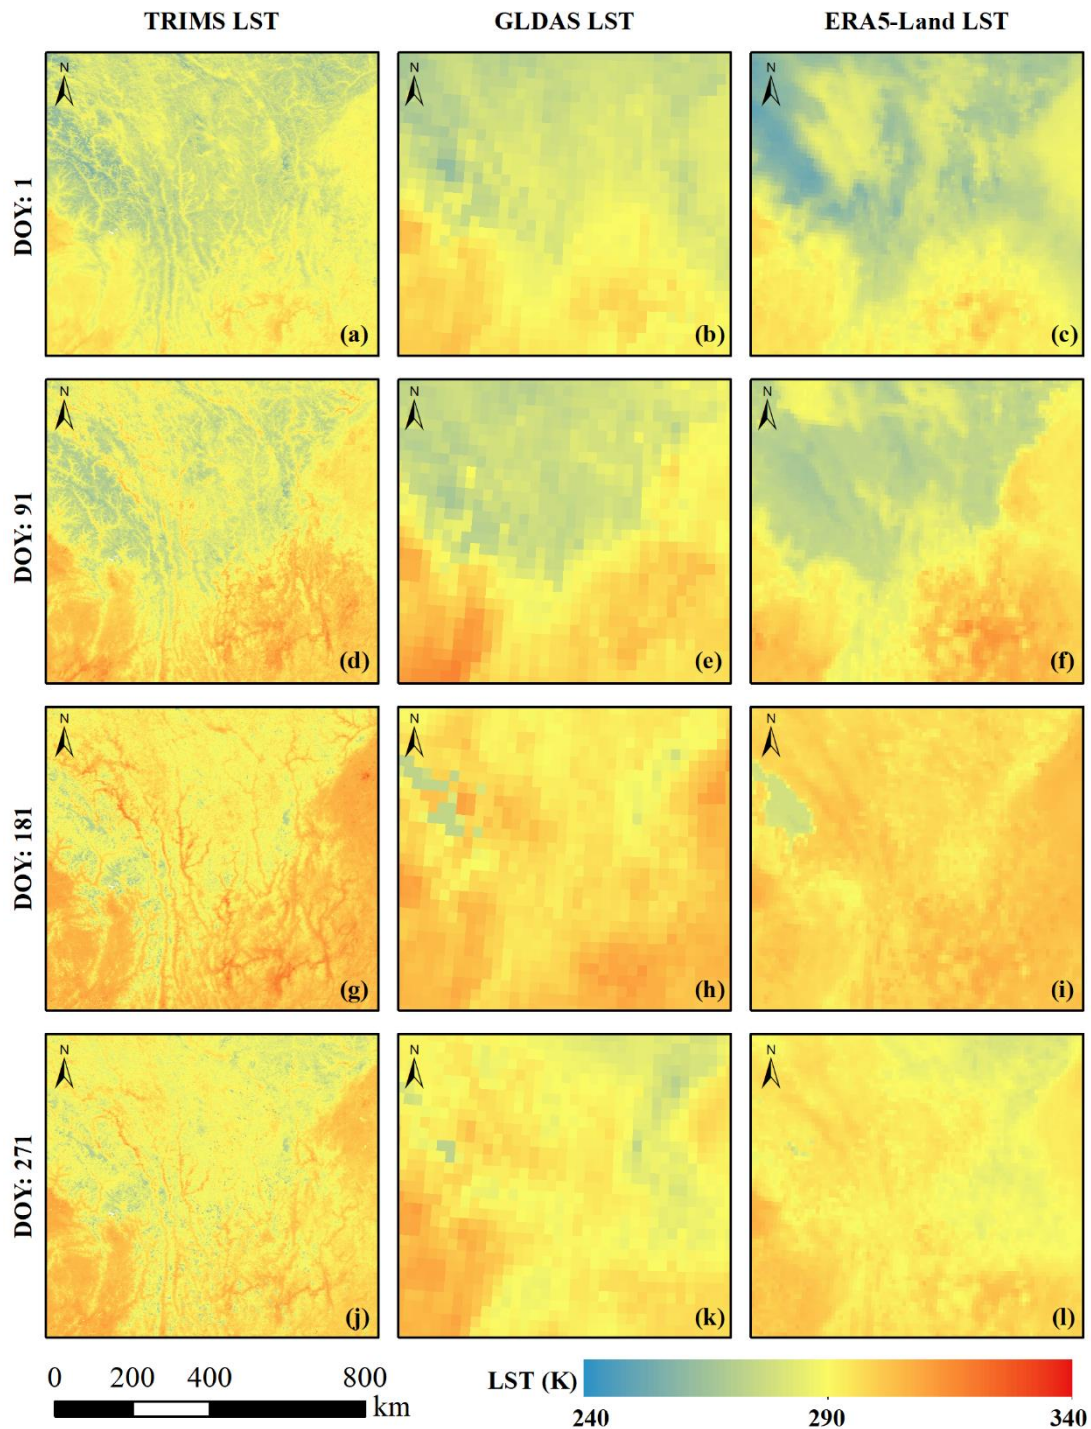

### 438 **4.2 Comparison of the TRIMS LST with satellite TIR LST products**

439 The daily TRIMS LST was compared with the independent ENVISAT/AATSR LST (from 2004 to 2012) and the Terra/Aqua  
440 MODIS LST (from 2000 to 2021 for Terra and from 2002 to 2021 for Aqua). Note that the AATSR and MODIS only have  
441 clear-sky LST. The density plots are shown in Fig. 8. To facilitate the data processing and presentation, 1%/1‰ matched  
442 TRIMS-AATSR/MODIS pairs were randomly extracted. Fig. 8 indicates good consistency between the TRIMS LST and  
443 AATSR/MODIS LST. Compared with AATSR, the overall MBD/STD values of TRIMS were 0.37 K/1.55 K and -0.44 K/1.22  
444 K for daytime and nighttime, respectively; compared with MODIS, the overall MBD/STD values were 0.09 K/1.45 K and -  
445 0.03 K/1.17 K for daytime and nighttime, respectively. Fig. 8 also shows that better agreements exist during nighttime because  
446 of lower thermal heterogeneity.

448

449 **Figure 6: Spatial patterns of the daytime TRIMS-Aqua LST, GLDAS LST, and ERA5-Land LST on four selected days in 2000.**

450  
451 **Figure 7: The daytime TRIMS-Aqua LST, GLDAS LST, and ERA5-Land LST of the subarea (shown in Fig.6) in 2000.**

452

453

454 **Figure 8: Density plots between the TRIMS LST and the AATSR/MODIS LST.**

455  
456 **Figure 9: Histograms of the MBD and STD to compare the TRIMS LST and the AATSR LST.**

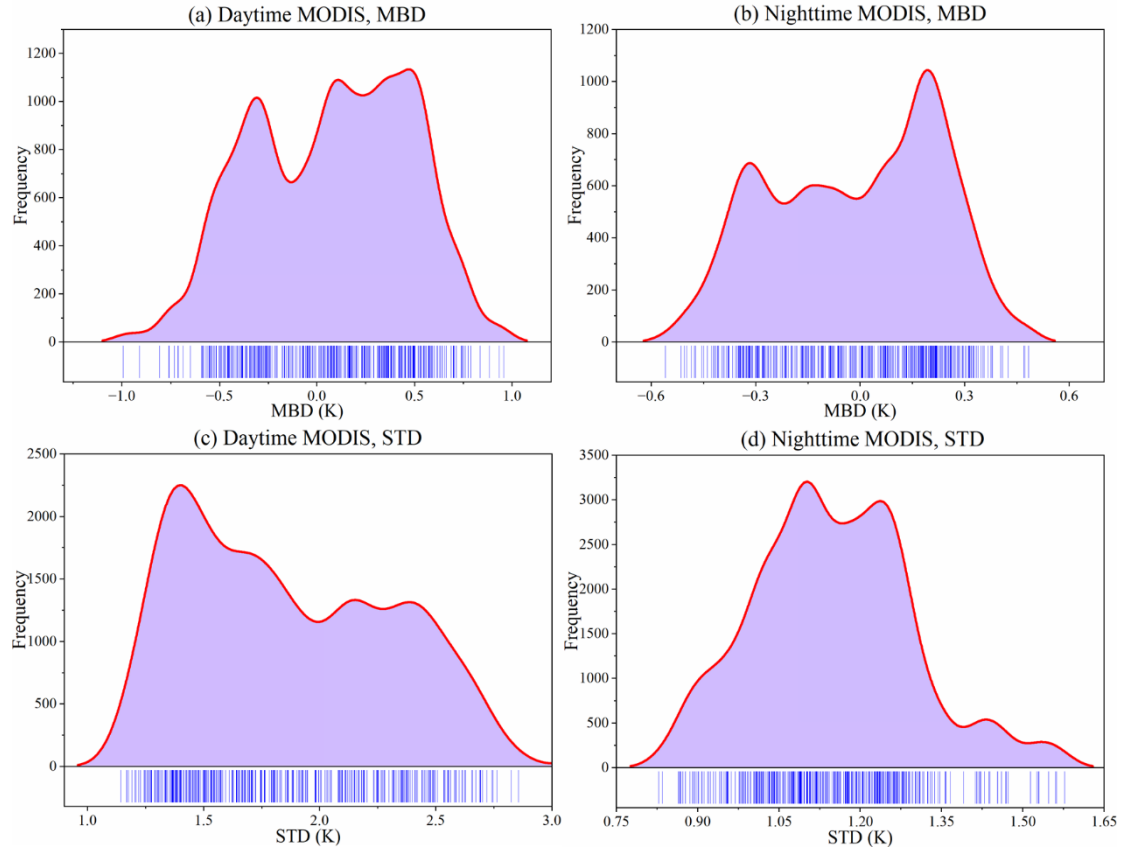

457 To further examine the deviation of the TRIMS LST from the AATSR/MODIS LST, the MBD and STD values were calculated  
458 for each day. Fig. 9 shows the corresponding histograms. For AATSR, the daily daytime MBD and STD were mainly  
459 concentrated in the ranges of 0 K–0.60 K and 1.05 K–1.15 K, respectively; the daily nighttime MBD and STD were mainly  
460 concentrated in the ranges of -0.40 K to 1.0 K and 0.75 K to 1.15 K, respectively. The positive deviation and negative deviation  
461 were consistent with those in Fig. 9 (a) and Fig. 9 (b). For the MODIS case, the daytime MBD was concentrated between -0.6  
462 K and 1.0 K, and STD was concentrated between 1.0 K and 2.50 K; the nighttime MBD was concentrated between -0.6 K and  
463 0.3 K, and STD was concentrated between 0.9 K and 1.50 K (Fig. 10). As shown above, it should be concluded that the daily  
464 differences between the long-term TRIMS LST and AATSR/MODIS LST remain stable.

465

### 466 4.3 Validation against *in-situ* LST outside the temporal gap

467 The TRIMS LST was quantitatively validated against the *in-situ* LST. Remove anomalies caused by transient environmental  
468 factors based on  $3\sigma$  (standard deviation) filtering (Göttsche et al., 2016; Yang et al., 2020). It should be noted that the results  
469 for all sites can be found in Tables B1 and B2. The nineteen ground sites were divided into four groups according to locations

470 and land cover types (Group I: ARO, D105, DSL, EBA, and MQU; Group II: DET, GAZ, GOB, HZZ, and SSW; Group III:  
 471 DAM, DXI, GUT, HLA, and TYU; Group IV: CBS, DHS, QYZ, and SDQ). Table II and Table III show the validation results  
 472 of TRIMS LST against the *in-situ* LST under different sky conditions. In addition, the validation results of the clear-sky  
 473 MODIS LST are provided for comparison.  
 474

475  
 476 **Figure 10: Histograms of the MBD and STD to compare the TRIMS LST and the MODIS LST.**

477 **Table II:  $R^2$ , MBE, and RMSE of the daytime validation for different groups.**

Group	Land cover type	Condition	Amounts	TRIMS LST			MODIS LST		
				MBE (K)	RMSE (K)	$R^2$	MBE (K)	RMSE (K)	$R^2$
I	Grassland	Clear-sky	5370	0.26	2.15	0.95	0.61	2.37	0.95
		Cloudy	6972	0.41	2.18	0.96	—	—	—

		Cloudy	3655	0.68	2.27	0.98	–	–	–

478

479 **Table III:  $R^2$ , MBE, and RMSE of the nighttime validation for different groups.**

Group	Land cover type	Condition	Amounts	TRIMS LST			MODIS LST		
				MBE (K)	RMSE (K)	$R^2$	MBE (K)	RMSE (K)	$R^2$
I	Grassland	Clear-sky	8175	-0.70	1.65	0.98	-0.99	1.69	0.98
		Cloudy	5254	-0.13	1.64	0.97	–	–	–
II	Desert or barren land	Clear-sky	6095	-0.64	1.43	0.99	-0.67	1.53	0.99
		Cloudy	5244	-1.17	1.85	0.99	–	–	–
III	Cropland	Clear-sky	5314	-0.83	1.76	0.98	-0.75	1.60	0.98
		Cloudy	7243	-0.60	1.74	0.98	–	–	–
IV	Forest	Clear-sky	2800	-0.98	1.92	0.98	-0.97	2.09	0.98
		Cloudy	3332	-0.94	1.90	0.99	–	–	–

480

481 Under clear-sky conditions, the TRIMS LST had an accuracy close to that of the MODIS LST as shown in Table II and Table  
482 III. The MBE of the TRIMS LST ranged from -0.98 K to 0.68 K and the RMSE was 1.43 K to 2.46 K. The RMSE of the  
483 TRIMS LST under clear-sky conditions is lower than that of the MODIS LST, except for Group IV. The RMSEs of the MODIS  
484 LST were reduced by 0.22 K (Group I), 0.23 K (Group II), and 0.41 K (Group III), respectively. The nighttime results were  
485 generally better than the daytime results, with an average RMSE of 1.74 K. The  $R^2$  of the TRIMS LST for the four groups of  
486 sites was higher than 0.95 under clear-sky conditions, indicating that the TRIMS LST is in good agreement with the *in-situ*  
487 LST. The improved accuracy of the TRIMS LST may be due to the reduction of the systematic bias of the original MODIS  
488 LST in the E-RTM method by extracting the LFC and HFC (Ding et al., 2022).

489 Under cloudy conditions, the accuracy of TRIMS LST is slightly lower compared to clear-sky conditions, resulting in a 0.35  
490 K increase in the overall RMSE. For TRIMS LST under cloudy conditions, the accuracy is marginally below that under clear-  
491 sky conditions, and the overall RMSE increased by 0.35 K. For the four groups of sites, the MBE values of TRIMS LST were  
492 -0.13 K (Group I), -1.17 K (Group II), -0.60 K (Group III), and -0.94 K (Group IV), revealing that the TRIMS LST is  
493 underestimated under cloudy conditions. According to the parameterization scheme of the E-RTM method, the accuracy of  
494 the estimated  $HFC_{\text{cld}}$  under cloudy conditions is affected by the GLDAS LST, which has a negative deviation from the MODIS  
495 LST as shown in Section 4.1. In contrast, Although the GLDAS LST is bias-corrected, uncertainty may still exist, which is

496 ultimately detrimental to the accurate recovery of the LST for the cloud-contaminated region. Overall, the validation results  
497 indicate that TRIMS LST has good accuracy under cloudy conditions as well as under clear-sky conditions.  
498 For ground sites in Group III with a dominant land cover type of desert or barren land, the nighttime validation shows that the  
499 TRIMS-Aqua LST is systematically underestimated, with an MBE of -1.17 K to -0.64 K. After checking the calculated STD,  
500 we believe the spatial scale mismatch between the ground site and the pixel is not the main reason for the systematic  
501 underestimation. Further examination shows that the clear-sky MODIS LST is significantly underestimated: the MBEs of  
502 Aqua/MODIS LST are -1.88 K, -1.03 K, -1.33 K, and -0.60 K for GOB, HZZ, SSW, and GAZ, respectively. Such a cold bias  
503 in arid and semiarid regions is also been reported by Li et al. (2019) for the MYD11 LST product. The above results indicate  
504 that the accuracy of TRIMS LST is largely dependent on the used MODIS LST.  
505 Reanalysis LST was also validated against *in-situ* LST (Fig. 11). GLDAS LST is generally underestimated compared to *in-*  
506 *situ* LST, with MBE of -0.29 K and RMSE of 5.86 K. Under clear-sky and cloudy conditions, the GLDAS LST exhibits MBE  
507 values of 0.03 K and -0.62 K, respectively. On the other hand, ERA5-Land LST is overestimated compared with *in-situ* LST,  
508 with MBE of 1.60 K and RMSE of 6.37 K. This indicates that the accuracy of the ERA5-Land LST is lower than that of the  
509 GLDAS LST. Notably, this discrepancy is more pronounced under clear-sky conditions. The results of the comparison with  
510 MODIS LST are shown in Fig. 12. GLDAS LST is underestimated relative to MODIS LST with a small deviation, while  
511 ERA5-Land LST is overestimated relative to MODIS LST with a large deviation.

#### 512 **4.4 Validation of TRIMS-Aqua LST and TRIMS-Terra LST during the temporal gap**

513 During the T1 period, there are no independent *in-situ* LST measurements available. Observations of D105 and GAZ began  
514 on DOY275 (October 2) of 2002. To investigate the generalization ability of the RFSTM in the temporal dimension, the method  
515 is implemented as follows: For 2003, the GLDAS LST and Terra/MODIS LST are also merged to generate 1-km TRIMS-  
516 Terra LST. This study utilized the TSETR method to reconstruct the TRIMS-Aqua LST over 915 days. To ensure a  
517 comprehensive analysis, TRIMS-Aqua LST for the years 2003 (DOY1)–2005 (DOY185) and 2013 (DOY1) – 2015 (DOY185)  
518 were generated using the TSETR method. This allowed for the inclusion of a significant number of independent ground sites  
519 for validation purposes.

520 Table IV shows the results of the comparison between the TRIMS-Terra LST generated by the RFSTM-based method and the  
521 TRIMS-Terra LST generated by the RTM-based method. The TRIMS-Terra LST generated by the RTM method and the  
522 TRIMS-Terra LST generated by the RFSTM method have similar accuracies for the sites. The MBEs differ by no more than  
523 0.50 K and the RMSEs differ by no more than 1.2 K. However, the RFSTM method is slightly less accurate than the TRIMS-  
524 Terra LST generated by the RTM method. It is important to note that the RFSTM method is only used in this study to generate  
525 data for 54 days, which has a relatively smaller impact on the overall accuracy of TRIMS LST.

526

527

528  
 529 **Figure 11: Density plots between the reanalysis LST and *in-situ* LST.**

530

531  
532 **Figure 12: Histograms of the MBD to compare reanalysis LST and MODIS LST.**

533  
534 **Table IV: MBE and RMSE from validation results of TRIMS-Terra LST with the *in-situ* LST**

Site	Condition	TRIMS-Terra LST (RTM)				TRIMS-Terra LST (RFSTM)			
		Daytime		Nighttime		Daytime		Nighttime	
		MBE (K)	RMSE (K)	MBE (K)	RMSE (K)	MBE (K)	RMSE (K)	MBE (K)	RMSE (K)
D105	All	1.63	3.15	-1.05	1.94	1.75	3.30	-1.55	2.20
	Clear-sky	1.78	2.17	-1.17	2.04	1.85	3.34	-2.37	2.66
	Cloudy	1.54	3.25	-0.88	1.78	1.04	3.44	-0.40	1.29
GZA	All	0.93	2.61	-0.78	1.76	1.26	3.10	-1.95	2.26
	Clear-sky	0.79	2.51	-0.68	1.70	0.94	2.72	-1.26	2.10
	Cloudy	1.11	3.71	-0.94	1.85	1.61	4.20	-1.47	2.35

535  
536 Combining the results of Table IV and Table V, it can be observed that the TRIMS-Aqua LST generated by the TSETR method  
537 and the TRIMS-Aqua LST generated by the RTM method exhibit similar accuracies at the sites. The differences in MBE and  
538 RMSE between these two methods are not significant, with the MBE differing by no more than 0.40 K and the RMSE differing  
539 by no more than 0.70 K. These findings demonstrate that the TSETR method maintains high accuracy and stability when  
540 generating data over longer periods. Based on this, it can be concluded that the TRIMS-Aqua LST in the T1 period  
541 reconstructed using the TSETR method is reasonably accurate.

542 Table IV and Table V demonstrate the reliability of RFSTM and TSETR. Fig. 13 further shows the quantification results of  
543 the similarity between the TRIMS-Aqua LST and TRIMS-Terra LST time series during the temporal gaps. Overall, the trends  
544 in the time series of TRIMS-Terra and TRIMS-Aqua LST are very consistent, and they generally have a high degree of

545 similarity. The daytime time series shows that the TRIMS-Aqua LST is generally higher than the TRIMS-Terra LST, while  
 546 the opposite is observed for the nighttime. In particular, for subareas E and F, the TRIMS-Aqua LST shows a significant  
 547 systematic deviation from the TRIMS-Terra LST during nighttime. The distribution of the curves in Fig. 13 reveals that the  
 548 daytime LST time series had more large fluctuations, while the nighttime variation is more subdued. The TSA is lower at  
 549 nighttime than daytime, indicating that the time series similarity between the TRIMS-Aqua LST and the TRIMS-Terra LST is  
 550 higher at nighttime. In addition, the TRIMS-Terra and TRIMS-Aqua LST are slightly more similar in the T1 than in T2 among  
 551 these six regions. This situation is as expected since the TRIMS-Aqua LST in T1 is derived from a mapping created by the  
 552 data at the Terra overpass time. The differences in the TSA between T1 and T2 ranged from 0.0080 to 0.0710. The mean  
 553 differences are 0.0465 (daytime) and 0.0433(nighttime). The above results indicate that the similarity of the LST time series  
 554 of T1 and T2 is relatively close. This finding demonstrates that the difference between TRIMS LST at the Aqua and Terra  
 555 overpass times is stable in T1.

556

557

558 **Table V: MBE and RMSE from validation results of TRIMS-Aqua LST with the *in-situ* LST**

Site	Condition	TRIMS-Aqua LST (RTM)				TRIMS-Aqua LST (TSETR)			
		Daytime		Nighttime		Daytime		Nighttime

559

560

561

562 **Figure 13: TRIMS-Terra and TRIMS-Aqua LSTs from January 1, 2000, to January 3, 2005, and statistics of the time series similarity.**

563 Meanwhile, we determined percentage of valid pixels in TRIMS LST and MODIS LST, respectively (Fig. 14). The findings

564 reveal that TRIMS LST is spatio-temporally continuous during the temporal gaps. The percentage of valid pixels in MODIS

565 LST ranges from approximately 10% to 70%, exhibiting substantial seasonal fluctuations. The rise in water vapour, heightened

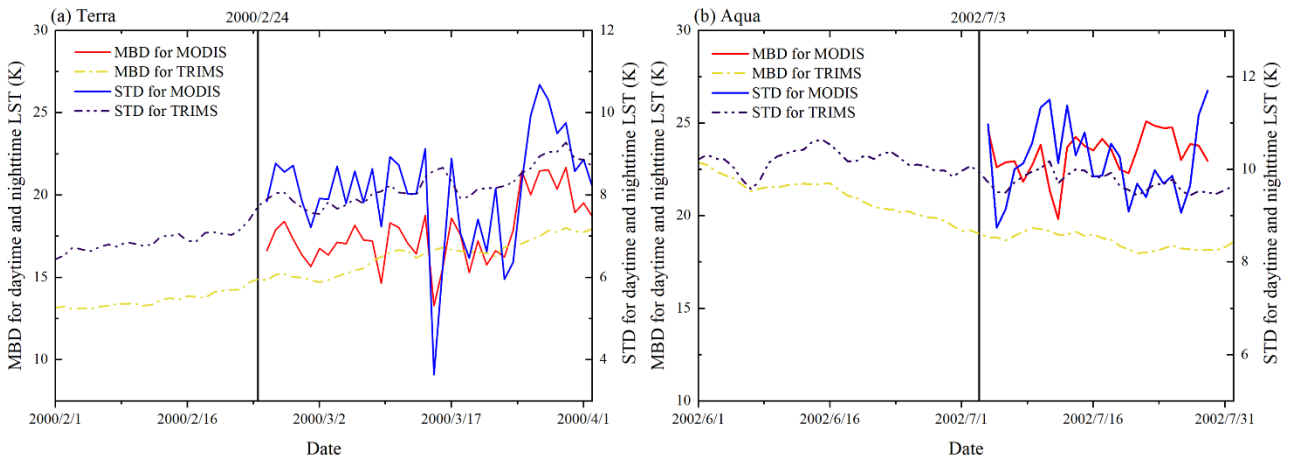

566 convection, and increased cloud cover during summers could account for the reduced number of effective pixels. This condition

567 also clarifies why in most circumstances, fewer valid pixels are evident throughout the daytime than at nighttime. By  
 568 comparison, the number of valid pixels in TRIMS LST changes moderately over time. Approximately 1% pixels were left  
 569 unoccupied for a few days, likely due to the unavailability of reference groups and corresponding pixels within the search  
 570 window during the determination of  $HFC_{\text{cld}}$  for these pixels. However, the percentage of valid pixels almost reached 100%  
 571 following the combination of the RFSTM and the TSETR approach. This phenomenon is a quantitative demonstration of the  
 572 success of the E-RTM method in recovering unspecified LSTs during the temporal gaps.

573  
 574 **Figure 14. Percentage of valid pixels in MODIS LST and TRIMS LST in 2000 (a) and 2002 (b).**

575 Finally, our analysis focused on examining the temporal variations in LST during the connectivity period (February and March  
 576 2000 for Terra; June and July 2002 for Aqua). The outcomes reveal that there is no interruption in the sequence at the  
 577 conclusion of the filled duration (Fig.15).

578  
 579 **Figure 15. MBD and STD for daytime MODIS LST compared to nighttime MODIS LST.**

580 During the connectivity period, we calculated MBD and STD for daytime MODIS LST compared to nighttime MODIS LST.  
581 The MBD and STD for MODIS LST exhibited large fluctuations between dates, whereas the MBD/STD of TRIMS LST  
582 showed smoother overall trends with less fluctuation between dates. This is attributed to the consideration of LFC as the  
583 primary base element in the E-RTM method, particularly during the temporal gap when valid MODIS LST data is lacking.  
584 The trends in MBD/STD for TRIMS LST and MODIS LST are generally consistent outside of the temporal gaps. Specifically,  
585 between 24 February and 31 March 2000, MBD/STD demonstrated a general upward trend, while between 3 July and 31 July  
586 2002, it showed an overall downward trend. Importantly, the trend of MBD/STD changes before and after the connecting dates  
587 is continuous without abrupt changes or breaks, as depicted in Fig. D, indicating uninterrupted LST time series during the  
588 temporal gaps.

589

#### 590 **4.5 Advantages of the TRIMS LST**

591 Recently, several all-weather LST datasets have been released by the scientific communities (see Appendix C). An all-weather  
592 LST product series with a temporal resolution from 15 min (Martins et al., 2019) to monthly (Metz et al., 2017; Zhao et al.,  
593 2020a; Hong et al., 2022; Yao et al., 2023), a spatial resolution from 1 km to 0.5°, and a spatial coverage from a specific region  
594 (Qinghai-Tibet Plateau, China, Asia, Europe and Africa) to globe has been preliminarily formed. All-weather LST products  
595 based on MODIS LST interpolation (Zhang et al., 2022) or fusion with other multi-source data (Xu and Cheng, 2021; Zhang  
596 and Cheng, 2020b; Zhang et al. 2020c; Zhang et al., 2021; Yu et al. 2022) dominate the field. TRIMS LST similarly belongs  
597 to this group. Overall, the uniqueness or advantages of the TRIMS LST are in three main areas:

598 First, the TRIMS LST demonstrates comparable or better accuracy than existing publicly released all-weather/spatially  
599 seamless LST datasets. A thorough comparison with satellite TIR LST products has indicated the effectiveness of TRIMS LST,  
600 with MBD ranging from -1.5 K to 1 K and STD ranging from 1 K to 3 K, thus confirming its accuracy and consistency (Fig.  
601 8, Fig. 9, and Fig. 10). Furthermore, *in-situ* LST evaluations show MBE ranging from -1.64 K to 2.88 K and RMSE ranging  
602 from 1.82 K to 3.48 K (Table II and Table III). Interestingly, no significant difference is observed between clear-sky and  
603 cloudy conditions, indicating the robustness of TRIMS LST across various situations. Furthermore, the RTM technique was  
604 utilized at four top-quality stations and the nearby region (11x11 km): Evora, Gobabeb, KIT-Forest, and Lake Constance  
605 (Meng et al., 2023). The TRIMS LST has performed favorably in validating results across different land cover types, including  
606 barren land, savannas, and forests, with an RMSE range of 1.90 K to 3.10 K. Additionally, over water site, TRIMS LST has  
607 an RMSE of 1.60 K. Thus, based on the results of this study, TRIMS LST can be considered a reliable source of LST.

608 Second, the method employed in this study effectively overcomes the issue of boundary effects in reconstructing the all-  
609 weather process due to the large differences in spatial resolution between different data sources (Zhang et al., 2021; Quan et  
610 al., 2023). This is achieved through the utilization of the E-RTM method, which is based on a temporal decomposition model  
611 of LST. With this model, the *LFC* and *HFC* components can be directly determined from high-resolution MODIS and ancillary  
612 remote sensing data (Eq. 1). Consequently, only spatial downscaling of  $HFC_{\text{cld}}$  is required, eliminating the need for direct

613 downscaling of the GLDAS LST. This method reduces the possibility of insufficient spatial downscaling. Additionally, the E-  
614 RTM method considers the relationship between LSTs of neighboring pixels, resulting in decreased errors during spatial  
615 downscaling (Fig. 4).

616 Third, TRIMS LST offers advantages in effectively recovering LST information and preserving temporal integrity under  
617 cloudy conditions. With a spatial resolution of 1 km, TRIMS LST covers both daytime and nighttime LST from 2000 to 2022,  
618 which is comparable in spatio-temporal resolution to other published seamless LST datasets (Appendix C). The TRIMS LST  
619 dataset will be made publicly available on an annual basis, contingent on availability of pertinent input data for the model. The  
620 E-RTM method effectively recovers temperature information under clouds, ensuring clear physical meaning and high accuracy  
621 and image quality of TRIMS LST. Moreover, TRIMS LST extends the all-weather LST coverage of the MODIS temporal gap.  
622 This enhances the completeness of long-time series LST datasets, creating a unique and valuable collection.

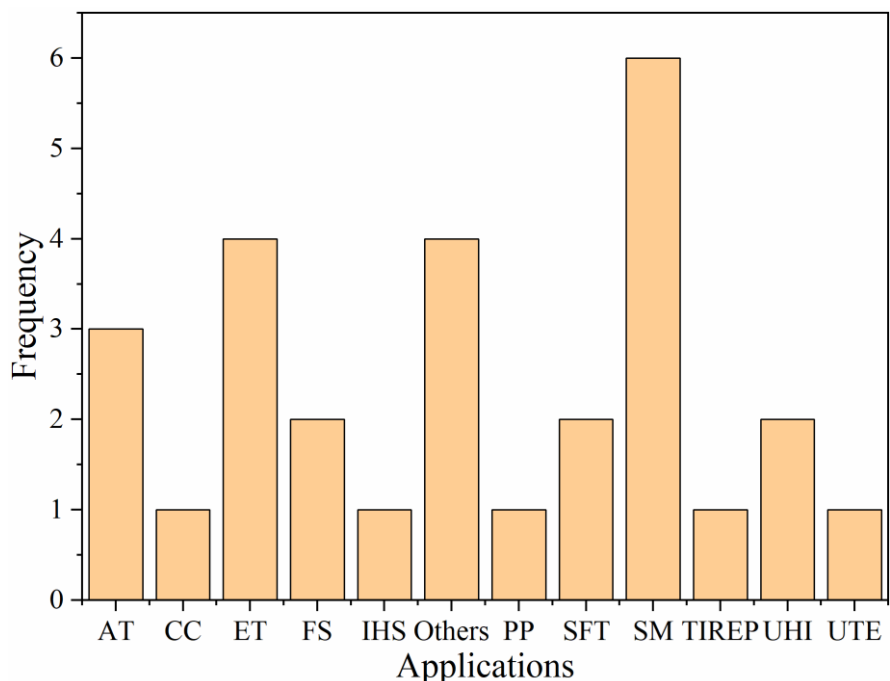

623

#### 624 **4.6 Literature-reported applications of the TRIMS LST**

625 TRIMS LST has already been utilized by the scientific communities in various applications (Fig. 16). A literature survey  
626 indicates that there have been 36 related papers published by journals (as of October 26, 2023), including leading journals such  
627 as Remote Sensing of Environment, Agricultural Water Management, and Science of the Total Environment. Typical  
628 applications include the estimation of soil moisture and surface evapotranspiration as well as the modeling of urban heat islands  
629 and urban thermal environments. A few typical applications are listed below.

630 Satellite TIR LSTs are important input data for obtaining SM estimates with high resolution and high spatial coverage.  
631 However, most satellite TIR LST products can only be used under clear-sky conditions. The availability of all-sky LST  
632 products provides an important opportunity to obtain SMs with spatial seamlessness. Zhang et al. (2023) combined the use of  
633 ERA5-Land and TRIMS LST for the fine-scale assessment of soil moisture in China. They used the model based on 0.1° ERA5  
634 Land and SM data for 1-km TRIMS LST and finally obtained a daily/1-km SM dataset with satisfactory accuracy. Benefiting  
635 from the effective recovery of LST under cloudy conditions, this SM dataset has quasi-full spatial coverage. In addition, Hu  
636 et al. (2022) also used the TRIMS LST as input data to construct a soil moisture downscaling model for the Tibetan Plateau.  
637 The TRIMS LST was found to successfully overcome the challenges of satellite TIR remote sensing detection due to  
638 temporal/spatial gaps and false detections due to clouds and topography. Based on the downscaled soil moisture, they further  
639 published the daily 0.05°×0.05° land surface soil moisture dataset of the Qilian Mountain area (northern and northwestern  
640 Tibetan Plateau) from 2019–2021 (SMHiRes, V2) (Hu et al., 2022; Qu et al., 2021; Chai et al., 2021, 2022a, b).

641

642

643 **Figure 16: Statistics of applications based on TRIMS LST (AT: Air temperature; CC: Climate change; ET: Evapotranspiration;**  
 644 **FS: Frozen soil; IHS: Industrial heat sources; Others: Active layer thickness, Lake Area, Land desertification, and LST downscaling;**  
 645 **PP: Plant Phenology; SFT: Soil freeze/thaw; SM: Soil moisture; TIREP: Thermal Infrared Earthquake Prediction; UHI: Urban**  
 646 **heat island; UTE: Urban Thermal Environment).**

647 LST can also be used to investigate the soil freeze/thaw cycles. Li et al. (2023) used the TRIMS LST to obtain thawing degree  
 648 days and freezing degree days to calculate the soil thermal conductivity and improved the output of the temperature at the top  
 649 of the permafrost model. Due to the characteristics of TRIMS LST: high spatial and temporal resolution, the above two metrics  
 650 can be easily obtained on a spatial scale of 1 km. In addition, the TRIMS LST was also used to evaluate the impact of the LST  
 651 on the classification accuracy of different remote-sensed or model-based freeze/thaw datasets (Li et al., 2022).

652 Based on the TRIMS LST, Li et al. (2021b) investigated the spatial and temporal variations of surface UHI (SUHI) intensity  
 653 (SUHII). The positive performance of the TRIMS LST in obtaining the LST under cloudy conditions enabled the examination  
 654 of the SUHI intensity of 305 Chinese cities, especially the cities located in southern China, where clouds frequently appear.  
 655 Furthermore, Liao et al. (2022) quantified the clear-sky bias of the SUHI intensity by using the MODIS LST based on the  
 656 TRIMS LST. They emphasized the importance of investigating the SUHI phenomenon under cloudy conditions.

## 657 5. Data availability

658 TRIMS LST is available for free and easy access through TPDC: <https://doi.org/10.11888/Meteoro.tpd.271252> (Zhou et al.,  
 659 2021).

## 660 6. Conclusions

661 A long-term 1-km daily all-weather LST dataset is the basis for supporting many applications related to land surface processes  
662 and climate change. Although some all-weather LST datasets have been released, especially in the last two years, users still  
663 lack such data for the period of 2000–2002, during which the MODIS LST is not available. In this study, we report a daily 1-  
664 km all-weather LST dataset for the Chinese landmass and surrounding areas – TRIMS LST. In contrast to many all-weather  
665 LST products, the TRIMS LST begins on the first day of the new millennium (i.e., January 1, 2000).

666 TRIMS LST is produced based on the E-RTM method. The primary input resources are the Terra/Aqua MODIS LST and  
667 GLDAS LST. The TRIMS LST was comprehensively evaluated thoroughly from four aspects, including comparison with  
668 satellite and reanalysis LSTs, validation against the *in-situ* LST, and similarity quantification for the TRIMS-Terra and  
669 TRIMS-Aqua LST time series. The results outside the temporal gap period indicate that the TRIMS LST agrees well with the  
670 original MODIS and GLDAS LST and the independent ERA5 and AATSR LST but with more spatial details and better  
671 spatiotemporal completeness. Validation of TRIMS LST using the *in-situ* LST at 19 ground sites shows that the MBE was -  
672 2.26 K to 1.73 K and the RMSE was 0.80 K to 3.68 K, with slightly better accuracy than the MODIS LST and no obvious  
673 difference under different weather conditions. The results within the temporal gap period show that RFSTM and TSETR have  
674 similar accuracy performance to the original RTM method, with MBE differences not exceeding 0.40 K and RMSE differences  
675 not exceeding 0.7 K. The stability of the TRIMS LST differences for T1 at the Aqua and Terra overpass times is also a side  
676 effect of the excellent quality.

677 The TRIMS LST has already been released to the scientific communities. A series of applications, such as soil moisture  
678 estimation/downscaling, surface evapotranspiration estimation, and UHI modeling, have been reported. The TRIMS LST was  
679 found to successfully address the cloud contamination of satellite TIR LST with good accuracy, long time series, and spatio-  
680 temporal completeness. The TRIMS LST will be continuously updated to satisfy the latest requirements of users.

## Author contribution

WBT implemented the E-RTM method, completed the thorough evaluation, and wrote the earliest version of the manuscript, JZ organized this research, examined the entire process of generation, and release of the TRIMS LST dataset, and provided necessary guidance, JM helped to obtain the measured data and provided the method to quantify the spatial representation, and  
695 XDZ and JZ proposed the original RTM method. All co-authors contributed to the writing and carefully reviewed and revised the manuscript.

## Competing interests

The authors declare that they have no conflict of interest.

## Acknowledgments

700 This work was supported by the National Natural Science Foundation of China under Grants 42271387 and 42201417; by the Science Fund for Distinguished Young Scholars of Sichuan Province under Grant 2023NSFSC1907; by the Fundamental Research Funds for the Central Universities of China, University of Electronic Science and Technology of China under Grant ZYGX2019J069; and by the China Scholarship Council (202306070058). The authors would like to thank EARTH DATA, Goddard Earth Sciences Data and Information Services Center, National Tibetan Plateau Data Center, and Global Flux  
705 Network (<http://www.fluxnet.org>) for providing the MODIS, GLDAS, and ground measurements. We also acknowledge the Centre for Environmental Data Analysis, European Centre for Medium-Range Weather Forecasts, CGIAR Consortium for Spatial Information, Terrascope project, University of Maryland, and Zenodo for providing the AATSR LST, ERA5-Land LST, SRTM DEM, SPOT VGT, GLASS Albedo product, and 30-m yearly China land cover dataset (2000-2015).
