14 **Abstract.** Precise and continuous monitoring on long-term carbon dioxide (CO<sub>2</sub>) and methane (CH<sub>4</sub>) over the globe is of great  
15 importance, which can help study global warming and achieve the goal of carbon neutrality. Nevertheless, the available  
16 observations of CO<sub>2</sub> and CH<sub>4</sub> from satellites are generally sparse, and current fusion methods to reconstruct their long-term  
17 values on a global scale are few. To address this problem, we propose a novel spatiotemporally self-supervised fusion method  
18 to establish long-term daily seamless XCO<sub>2</sub> and XCH<sub>4</sub> products from 2010 to 2020 over the globe at grids of 0.25°. A total of  
19 three datasets are applied in our study, including GOSAT, OCO-2, and CAMS-EGG4. Attributed to the significant sparsity of  
20 data from GOSAT and OCO-2, the spatiotemporal Discrete Cosine Transform is considered for our fusion task. **Validation**  
21 **results show that the proposed method achieves a satisfactory accuracy, with the Standard-Deviation of Bias ( $\sigma$ ) of ~ 1.18 ppm**  
22 **for XCO<sub>2</sub> and 11.3 ppb for XCH<sub>4</sub> against TCCON measurements from 2010 to 2020. Meanwhile, the Determination-**  
23 **Coefficient ( $R^2$ ) of XCO<sub>2</sub> and XCH<sub>4</sub> reach 0.91/0.95 (2010-2014/2015-2020) and 0.9 (2010-2020) after fusion, respectively.**  
24 Overall, the performance of fused results distinctly exceeds that of CAMS-EGG4, which is also superior or close to those of  
25 GOSAT and OCO-2. Especially, our fusion method can effectively correct the large biases in CAMS-EGG4 due to the issues  
26 from assimilation data, such as the unadjusted anthropogenic emission inventories for COVID-19 lockdowns in 2020.  
27 Moreover, the fused results present coincident spatial patterns with GOSAT and OCO-2, which accurately display the long-  
28 term and seasonal changes of globally distributed XCO<sub>2</sub> and XCH<sub>4</sub>. The daily global seamless gridded (0.25°) XCO<sub>2</sub> and  
29 XCH<sub>4</sub> from 2010 to 2020 can be freely accessed at <http://doi.org/10.5281/zenodo.7388893> (Wang et al., 2022b).

## 30 **1 Introduction**

31 As the most abundant greenhouse gases (GHGs) due to human activities, atmospheric carbon dioxide (CO<sub>2</sub>) and methane  
32 (CH<sub>4</sub>) play significant roles in climate change and directly contribute to global warming (Meinshausen et al., 2009; Montzka  
33 et al., 2011; Solomon et al., 2010; Yoro and Daramola, 2020; Shine et al., 2005). For decades, the rising anthropogenic surface  
34 emissions of CO<sub>2</sub> and CH<sub>4</sub> result in their long-term rapid uptrends (Choulga et al., 2021; Moran et al., 2022; Lin et al., 2021;  
35 Petrescu et al., 2021), which have greatly affected the carbon cycle (Battin et al., 2009; Sjögersten et al., 2014) and ecosystem  
36 balance (Liu and Greaver, 2009; Hotchkiss et al., 2015). According to measurements from the Global Greenhouse Gas  
37 Reference Network (<https://gml.noaa.gov/ccgg/>), annual surface CO<sub>2</sub> and CH<sub>4</sub> mole fractions break 412 parts per million (ppm)  
38 and 1878 parts per billion (ppb) in 2020, with growths of ~ 68 ppm and 222 ppb since 1985, respectively. To mitigate global  
39 warming, the Paris Agreement (<https://unfccc.int/process-and-meetings/the-paris-agreement/>) has indicated that the increment  
40 of temperature should not exceed 2 °C (preferably to 1.5 °C) by comparison with the pre-industrial level. This requires all  
41 efforts from the whole society to reach the global peaking of GHGs surface emissions as early as possible, especially for CO<sub>2</sub>  
42 and CH<sub>4</sub>, which eventually create a carbon-neutral world by mid-century. Therefore, it is an urgent need to precisely and  
43 continuously monitor atmospheric CO<sub>2</sub> and CH<sub>4</sub> on a global scale.

44 To date, remote sensing observations have been extensively adopted in plenty of domains (Wang et al., 2021, 2022c; Zhou et  
45 al., 2022), which also emerged as regular techniques to acquire globe-scale atmospheric CO<sub>2</sub> and CH<sub>4</sub> spatial patterns (He et  
46 al., 2022a; Buchwitz et al., 2015; Bergamaschi et al., 2013). For instance, the EnviSat can provide global column-mean dry-  
47 air mole fraction of CO<sub>2</sub> (XCO<sub>2</sub>) and CH<sub>4</sub> (XCH<sub>4</sub>) at a coarse resolution of 30×60 km<sup>2</sup>, with the payload of the Scanning  
48 Imaging Absorption Spectrometer for Atmospheric Cartography (Burrows et al., 1995; Beirle et al., 2018). The Thermal and  
49 Near-Infrared Sensor for carbon Observations - Fourier Transform Spectrometer onboard the Greenhouse Gases Observing  
50 Satellite (GOSAT) (Hamazaki et al., 2005; Velazco et al., 2019) can produce ~ 10-km XCO<sub>2</sub> and XCH<sub>4</sub> over the globe based  
51 on three spectral bands. The Orbiting Carbon Observatory 2/3 (OCO-2/3) (Crisp et al., 2017; Doughty et al., 2022) carries  
52 three-channel grating spectrometers to generate globally covered XCO<sub>2</sub> at a much finer spatial resolution of 1.29×2.25 km<sup>2</sup>.  
53 The Carbon Dioxide Spectrometer named CarbonSpec onboard the TanSat (Liu et al., 2018) of China launched in 2016, which  
54 can accurately map high-resolution (~ 2 km) global XCO<sub>2</sub> spatial distribution.

55 As for long-term observations of XCO<sub>2</sub> and XCH<sub>4</sub>, the operational products from GOSAT and OCO-2 are widely applied in  
56 carbon-related applications, such as the computation of carbon fluxes (Fraser et al., 2013; Wang et al., 2019), inferring carbon  
57 sources and sinks (Deng et al., 2014; Houweling et al., 2015), quantifying CO<sub>2</sub> and CH<sub>4</sub> emissions (Turner et al., 2015;  
58 Hakkarainen et al., 2016), and estimation of terrestrial net ecosystem exchange (Jiang et al., 2022). Nevertheless, large-scale  
59 missing data consists in the XCO<sub>2</sub> and XCH<sub>4</sub> products from GOSAT and OCO-2, which is attributed to the narrow swath of  
60 their observations (Crisp et al., 2017) and contamination of cloud and aerosol (Taylor et al., 2016). Seamless information of

61 XCO<sub>2</sub> and XCH<sub>4</sub> can help better understand the driving factors of long-term variations for CO<sub>2</sub> and CH<sub>4</sub> due to surface  
62 emissions and atmospheric transport (Kenea et al., 2023; Liu et al., 2020). In addition, full-coverage XCO<sub>2</sub> and XCH<sub>4</sub> products  
63 are more useful to analyze carbon source-sink dynamics (Reithmaier et al., 2021; Crosswell et al., 2017) and impacts on climate  
64 changes caused by the elevated CO<sub>2</sub> and CH<sub>4</sub> (Chen et al., 2021; Le Quéré et al., 2019). Hence, it is significant and essential  
65 to assure the spatiotemporal continuity of XCO<sub>2</sub> and XCH<sub>4</sub> products from GOSAT and OCO-2, which is conducive to achieving  
66 the goal of carbon neutrality.

67 A lot of efforts have been made to generate seamless XCO<sub>2</sub> and XCH<sub>4</sub> products for GOSAT and OCO-2. Initially, interpolation-  
68 based methods are widely utilized, such as the fixed rank kriging interpolation (Katzfuss and Cressie, 2011), semantic kriging  
69 interpolation (Bhattacharjee et al., 2014), and space-time kriging interpolation (He et al., 2020; Li et al., 2022). However, the  
70 interpolated results are usually performed at coarse spatial resolutions (e.g., 1°) and tend to show high uncertainties and over-  
71 smoothed distribution due to the extreme sparsity of original data. At present, data fusion techniques (He et al., 2022a, b; Zhang  
72 et al., 2022; Zhang and Liu, 2023; Siabi et al., 2019) have emerged as new methods to acquire full-coverage products for  
73 GOSAT and OCO-2 at a high spatial resolution, which absorb advantages from multisource data. Generally, these methods  
74 exploited machine learning algorithms to train an end-to-end fusion function with multiple seamless data (e.g., model and  
75 reanalysis) as inputs. For example, Siabi et al. (2019) employed multi-layer perceptron and eight environmental variables (e.g.,  
76 net primary productivity and leaf area index) to map full-coverage XCO<sub>2</sub> in Iran; He et al. (2022b) established seamless results  
77 over China using the OCO-2 XCO<sub>2</sub> product, CarbonTracker model data, and auxiliary co-variates based on the light gradient  
78 boosting machine; Zhang et al. (2022) proposed a geographically weighted neural network to produce full-coverage XCO<sub>2</sub>  
79 product across China by fusing the datasets from OCO-2, CAMS-EGG4 (reanalysis), and ERA5; and Zhang and Liu (2023)  
80 adopted multiple datasets, e.g., EnviSat, GOSAT, OCO-2, CarbonTracker, and ERA5, and obtained long-term seamless XCO<sub>2</sub>  
81 product in China through a finely devised neural network.

82 These data fusion approaches provided high-quality results with seamless distribution and greatly enhance the data availability  
83 for GOSAT and OCO-2. Nevertheless, the application areas of current fused products merely target at local or national scales,  
84 which are insufficient for globe-scale researches. Meanwhile, existing data fusion frameworks are regarded as end-to-end  
85 functions, which lack consideration for spatiotemporal self-correlation of original data (e.g., OCO-2). They normally require  
86 massive auxiliary co-variates (e.g., ERA5) as inputs and consume a large time in training procedures. Moreover, only XCO<sub>2</sub>  
87 products are taken into account while the data fusion studies for XCH<sub>4</sub> products are scarce. In conclusion, it is valuable and  
88 imperative to generate long-term globally distributed seamless XCO<sub>2</sub> and XCH<sub>4</sub> products for GOSAT and OCO-2 with an  
89 efficient data fusion method, which considers the knowledge of their spatiotemporal self-correlation.

90 The present study focuses on generating long-term daily global seamless XCO<sub>2</sub> and XCH<sub>4</sub> products from 2010 to 2020 at the  
91 grids of 0.25° via a spatiotemporally self-supervised fusion method. A total of three datasets are utilized in our study without

92 any auxiliary co-variables, including GOSAT, OCO-2, and CAMS-EGG4. CAMS-EGG4 can provide long-term gridded full-  
 93 coverage XCO<sub>2</sub> and XCH<sub>4</sub> datasets over the globe, which is suitable for our fusion task. Since the data from GOSAT and OCO-  
 94 2 is significantly sparse in space-time domain (see Fig. 1), the fusion procedures are difficult to be performed. By contrast,  
 95 frequency domain contains comprehensive information due to its more concentrated signal distribution. Discrete Cosine  
 96 Transform (DCT) (Rao and Yip, 2014) is an efficient algorithm to convert signal into frequency domain. In this study, a novel  
 97 self-supervised fusion method based on spatiotemporal DCT (S-STDCT) is developed for the fusion task. Details of the S-  
 98 STDCT fusion method are presented in Section 3. Validation results show that the S-STDCT fusion method achieves a  
 99 satisfactory performance. Generally, the accuracy of fused results largely exceeds that of CAMS-EGG4, which is also better  
 100 than or close to those of GSOAT and OCO-2.

101  
 102 **Figure 1.** An example of daily spatial footprints for (a) GOSAT XCO<sub>2</sub>, (b) OCO-2 XCO<sub>2</sub>, and (c) GOSAT XCH<sub>4</sub>. Red points signify the  
 103 available data. Background maps are naturally shaded reliefs over the globe.

104 This paper arranges the remaining sections as follows. Section 2 describes the data records employed in our study, including  
 105 the XCO<sub>2</sub> and XCH<sub>4</sub> from in-situ stations, GOSAT, and CAMS-EGG4 and XCO<sub>2</sub> from OCO-2. Section 3 provides the  
 106 specification of the developed S-STDCT fusion method. Section 4 presents the experiment results, which consist of elaborative  
 107 validations against in-situ measurements and assessments of spatial distribution on multi-temporal scales. At last, conclusions  
 108 and future works are summarized in section 5.

## 109 2 Data description

### 110 2.1 GOSAT XCO<sub>2</sub> and XCH<sub>4</sub> products

111 A famous XCO<sub>2</sub> retrieval algorithm devised for GOSAT (Taylor et al., 2022), i.e., the Atmospheric CO<sub>2</sub> Observations from  
 112 Space (ACOS), employs three infrared spectral bands at ~ 0.76, 1.6, and 2.0 μm, which are denoted as Oxygen-A, CO<sub>2</sub> weak,  
 113 and CO<sub>2</sub> strong, respectively. Regarding XCH<sub>4</sub>, the latest retrieval algorithm for GOSAT from the University of Leicester is  
 114 recently updated, which considers the ratio of XCH<sub>4</sub>:XCO<sub>2</sub> as a proxy (Parker et al., 2020). It is based on the theory that the  
 115 impacts from atmospheric scattering and sensor are mostly similar for XCH<sub>4</sub> and XCO<sub>2</sub> in a shared absorption band at ~ 1.6  
 116 μm. The GOSAT XCO<sub>2</sub> and XCH<sub>4</sub> products are both performed at spatial resolutions of 10.5 km (diameter) over the globe  
 117 with revisit times of 3 days. In our study, the scientific data records of “XCO<sub>2</sub>” in ACOS\_L2\_Lite\_FP (level 2, bias-corrected,  
 118 V9r) and “XCH<sub>4</sub>” in UoL-GHG-L2-CH4-GOSAT-OCPR (level 2, V9) are adopted. **Furthermore, the quality assurance (QA)**

119 records of “XCO<sub>2</sub> Quality Flag” and “XCH<sub>4</sub> Quality Flag” are exploited to filter bad data. Relevant information of XCO<sub>2</sub> and  
 120 XCH<sub>4</sub> products from GOSAT is shown in Table 1.  
 121 **Table 1.** Detailed information of the datasets considered in this study.

Source	Scientific data record	Version	Spatial resolution	Temporal resolution	Period
GOSAT	XCO <sub>2</sub> XCO <sub>2</sub> Quality Flag	V9r	10.5 km (diameter)	Daily (~ 13:00 local time)	2010-2014
	XCH <sub>4</sub> XCH <sub>4</sub> Quality Flag	V9			2010-2020
OCO-2	XCO <sub>2</sub> XCO <sub>2</sub> Quality Flag	V10r	1.29×2.25 km <sup>2</sup>	Daily (~ 13:36 local time)	2015-2017
	XCO <sub>2</sub> XCO <sub>2</sub> Quality Flag	V11r			2018-2020
CAMS-EGG4	CO <sub>2</sub> column-mean molar fraction	-	0.75°	3 hours	2010-2020
	CH <sub>4</sub> column-mean molar fraction				

## 122 2.2 OCO-2 XCO<sub>2</sub> product

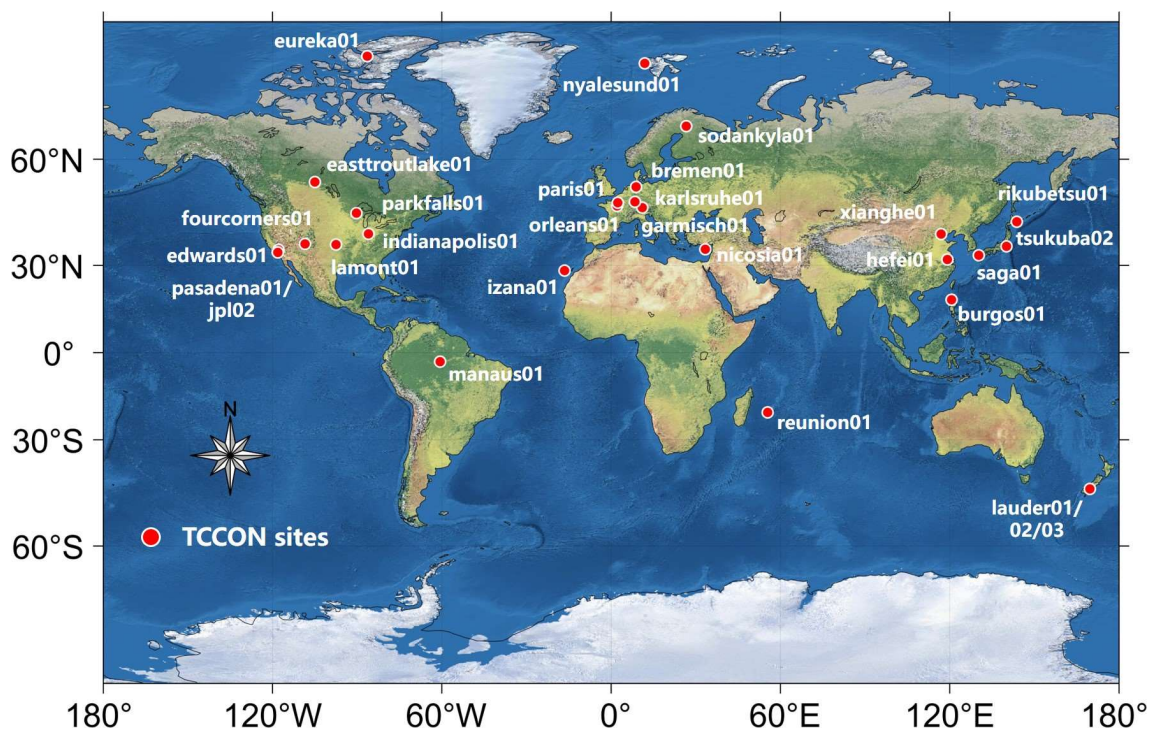

123 Apart from GOSAT, the ACOS XCO<sub>2</sub> retrieval algorithm is also applied to OCO-2 observations (Kiel et al., 2019), which  
 124 utilizes the same bands of the Oxygen-A, CO<sub>2</sub> weak, and CO<sub>2</sub> strong. OCO-2 provides a global XCO<sub>2</sub> product at a high spatial  
 125 resolution of 1.29×2.25 km<sup>2</sup> with a revisit time of 16 days. After 2015, the XCO<sub>2</sub> product from OCO-2 is used for fusion  
 126 instead of GOSAT due to its more observation counts and better accuracy. In this study, the scientific data record of “XCO<sub>2</sub>”  
 127 in OCO2\_L2\_Lite\_FP (level 2, bias-corrected) is applied in the fusion with CAMS-EGG4 using the developed method.  
 128 Moreover, the QA record of “XCO<sub>2</sub> Quality Flag” is adopted to filter bad data. Since the OCO-2 XCO<sub>2</sub> product of the latest  
 129 version (V11r) is still on processing, both data of V10r and V11r are considered in our study. Related information of XCO<sub>2</sub>  
 130 product from OCO-2 is given in Table 1.

## 131 2.3 CAMS-EGG4 GHGs reanalysis datasets

132 CAMS-EGG4 is recent globally distributed operational GHGs reanalysis datasets supported by the European Centre for  
 133 Medium-range Weather Forecasts (Agusti-Panareda et al., 2022). It assimilates the forecasts from the Integrated Forecasting  
 134 System with multiple satellite products, which include Envisat, GOSAT, and Metop-A/B (August et al., 2012), via physical  
 135 and chemistry principles. The CAMS-EGG4 can generate long-term gridded seamless XCO<sub>2</sub> and XCH<sub>4</sub> datasets and related  
 136 fields at spatial and temporal resolutions of 0.75° and 3 hours, respectively. Unfortunately, there are a few limitations in CAMS-  
 137 EGG4, such as the uncorrected anthropogenic emissions for CO<sub>2</sub> and CH<sub>4</sub> during COVID-19 lockdowns, which are  
 138 scheduled to be fixed by the official team in the future (Agusti-Panareda et al., 2022). It is worth noting that the XCO<sub>2</sub> and  
 139 XCH<sub>4</sub> products from GOSAT and OCO-2 employed in this paper are not assimilated in CAMS-EGG4. In our study, the  
 140 scientific data records of “CO<sub>2</sub> column-mean molar fraction” and “CH<sub>4</sub> column-mean molar fraction” are exploited for the  
 141 fusion with GOSAT and OCO-2 through the developed method. Details of CAMS-EGG4 datasets are provided in Table 1.

## 142 2.4 TCCON measurements

143 In our study, the XCO<sub>2</sub> and XCH<sub>4</sub> measurements provided by an international in-situ network, which is named after TCCON  
144 (Wunch et al., 2011) (<https://tccodata.org/>), are utilized to validate the fused results. The in-situ measurements of TCCON  
145 are extensively used in the validation for XCO<sub>2</sub> and XCH<sub>4</sub> products from GOSAT, OCO-2, and CAMS-EGG4 (Hong et al.,  
146 2022; Yoshida et al., 2013; Wunch et al., 2017; Wu et al., 2018; Agusti-Panareda et al., 2022). Figure 2 depicts the spatial  
147 locations of TCCON stations, with the marks of white-edged red circles. The measurements of version GGG2020 (Laughner  
148 et al., 2022) from 29 stations around the world are adopted. Specific information of the stations is listed in Table 2.

149  
150 **Figure 2.** Spatial locations of in-situ stations from TCCON used in the present study. The background map is a naturally shaded relief over  
151 the globe.

## 152 3 Methodology

### 153 3.1 Data pre-processing

154 Data pre-processing is an important procedure to ensure the rationality and reliability of fused results. In this study, the values  
155 of “QA=0” in XCO<sub>2</sub> and XCH<sub>4</sub> from GOSAT and OCO-2 are discarded, which filters the bad data. Besides, the CAMS-EGG4  
156 XCO<sub>2</sub> and XCH<sub>4</sub> at a temporal resolution of 3 hours are averaged in a single day to produce daily datasets. Finally, the spatial  
157 resolutions of XCO<sub>2</sub> and XCH<sub>4</sub> from GOSAT, OCO-2, and CAMS-EGG4 ought to be adjusted to the same value. A globally  
158 covered grid of 721×1441 (0.25°) is employed in our study. The XCO<sub>2</sub> and XCH<sub>4</sub> from GOSAT, OCO-2, and CAMS-EGG4  
159 are re-gridded to 0.25° using the area-weighted aggregation (Wang et al., 2021) and Inverse Distance Weighted (Mueller et al.,  
160 2004) interpolation, respectively.

161 **Table 2.** Detailed information of TCCON in-situ stations adopted in our study. No.: number.

## 162 3.2 Spatiotemporally self-supervised fusion method

163 Since the sparsity of data from GOSAT and OCO-2 is significant in space-time domain (see Fig. 1), it is difficult to perform  
164 fusion procedures for them. In contrast, frequency domain is more suitable because of its concentrated signal distribution. DCT  
165 is an efficient algorithm to transform signal into frequency domain (Rao and Yip, 2014), which has been widely applied in  
166 image compression (Cintra and Bayer, 2011), geophysical data filtering (El-Mahallawy and Hashim, 2013), and remote sensing  
167 data reconstruction (Wang et al., 2012, 2022a; Fredj et al., 2016; Pham et al., 2019). In our study, a novel self-supervised fusion  
168 method based on spatiotemporal DCT, i.e., S-STDCT, is developed for the fusion task, which fully adopts the spatiotemporal  
169 knowledge of self-correlation in GOSAT and OCO-2 products.

### 170 3.2.1 Spatiotemporal DCT

171 A total of eight types of DCT are proposed, among which the second type (type-II) is commonly utilized due to its simple  
172 calculation and broad application range (Rao and Yip, 2014). Hence, the type-II DCT is considered in this study. The  
173 spatiotemporal DCT is a 3-dimensional form (hereafter *STDCT*), which can be expressed as Eq. (1):

$$174 \quad X(u, v, w) = c(u)c(v)c(w) \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} \sum_{t=0}^{P-1} x(i, j, t) \cos \left[ \frac{(i+0.5)\pi}{M} u \right] \cos \left[ \frac{(j+0.5)\pi}{N} v \right] \cos \left[ \frac{(t+0.5)\pi}{P} w \right], \quad (1)$$

$$175 \quad \text{where } c(u) = \begin{cases} \sqrt{\frac{1}{M}}, u = 0 \\ \sqrt{\frac{2}{M}}, u \neq 0 \end{cases}, \quad c(v) = \begin{cases} \sqrt{\frac{1}{N}}, v = 0 \\ \sqrt{\frac{2}{N}}, v \neq 0 \end{cases}, \quad c(w) = \begin{cases} \sqrt{\frac{1}{P}}, w = 0 \\ \sqrt{\frac{2}{P}}, w \neq 0 \end{cases};$$

;  $x$  indicates the original 3-dimensional tensor;  $M, N,$

176 and  $P$  stand for the counts of rows (latitude), columns (longitude), and temporal sequences (days), which equal 721 (0.25°,  
 177 global grids), 1441 (0.25°, global grids), and days of a year (365 or 366), respectively;  $i, j,$  and  $t$  represent the row, column,  
 178 and temporal sequence, respectively ( $i \in [0, M-1], j \in [0, N-1],$  and  $t \in [0, P-1]$ );  $X$  signifies the transformed 3-dimensional  
 179 tensor;  $u, v,$  and  $w$  denote the transformed coordinates in frequency domain, which share the same ranges with  $i, j,$  and  $t$  (e.g.,  
 180  $u \in [0, M-1]$ ), respectively. The inverse transformation of *STDCT* (hereafter *ISTDCT*) is provided in Eq. (2):

$$181 \quad x(i, j, t) = c(u)c(v)c(w) \sum_{u=0}^{M-1} \sum_{v=0}^{N-1} \sum_{w=0}^{P-1} X(u, v, w) \cos \left[ \frac{(i+0.5)\pi}{M} u \right] \cos \left[ \frac{(j+0.5)\pi}{N} v \right] \cos \left[ \frac{(t+0.5)\pi}{P} w \right], \quad (2)$$

### 182 3.2.2 Self-supervised fusion scheme with spatiotemporal knowledge

183 It has been documented that the  $XCO_2$  and  $XCH_4$  products derived from remote sensing satellites generally present better  
 184 accuracy compared to reanalysis datasets (Agusti-Panareda et al., 2022; He et al., 2022a; Parker et al., 2020). Therefore, the  
 185 brand new  $XCO_2$  and  $XCH_4$  products from GOSAT and OCO-2 are regarded as the criteria (or ground truths), which will be  
 186 fused with CAMS-EGG4 datasets. At first, a spatially and temporally varying function relationship (see Eq. (3)) is  
 187 hypothesized between GOSAT/OCO-2 and CAMS-EGG4  $XCO_2/XCH_4$  values.

$$188 \quad XG_s = f(XG_c, Row, Col, Time), \quad (3)$$

189 where  $XG_s$  denotes the  $XCO_2/XCH_4$  values from GOSAT/OCO-2;  $XG_c$  indicates the  $XCO_2/XCH_4$  values from CAMS-EGG4;  
 190  $Row, Col,$  and  $Time$  represent the row (or latitude), column (or longitude), and temporal sequence, respectively. To conveniently  
 191 solve this problem, Eq. (3) is simplified into the scalar product form of  $XG_c$  and a spatially and temporally varying tensor  
 192 (defined as  $\delta$ ), as shown in Eq. (4):

$$193 \quad XG_s = XG_c * \delta(Row, Col, Time), \quad (4)$$

194 Afterward, the factor (i.e.,  $\delta$ ) can be acquired using the  $XCO_2/XCH_4$  values at the grids where the GOSAT/OCO-2 and CAMS-  
 195 EGG4 data are both available. In our study, a self-supervised fusion scheme is introduced to solve Eq. (4) based on the  
 196 spatiotemporal knowledge of self-correlation in GOSAT and OCO-2 products. Due to the large sparsity of data from GOSAT  
 197 and OCO-2 in space-time domain, the *STDCT* is applied for the fusion task.

198 Inspired by previous studies adopting the *STDCT* (Garcia, 2010; Wang et al., 2012, 2022a; Fredj et al., 2016; Pham et al.,  
 199 2019), the S-STDCT fusion method searches for the spatially and temporally varying tensor, i.e.,  $\hat{\delta}$ , that minimizes Eq. (5),  
 200 including a residual (left) and a smoothing (right) term.

$$E(\delta) = \left\| \varphi^{\frac{1}{2}} * (\delta - \hat{\delta}) \right\|^2 + \varepsilon \|\nabla^2 \delta\|^2, \quad (5)$$

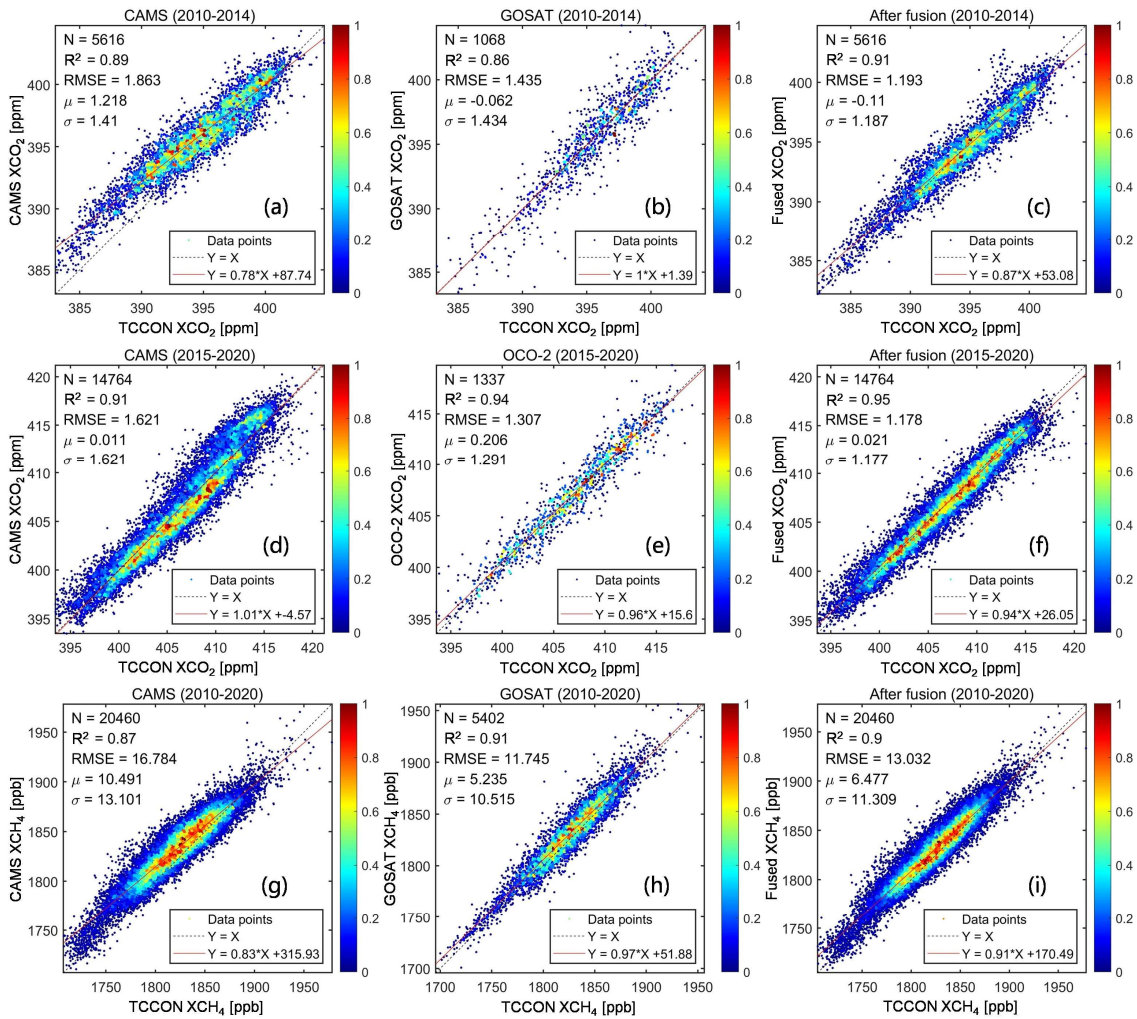

where  $\| \cdot \|$  signifies the Euclidean norm;  $\varphi$  represents the binary mask showing the data is whether available or not;  $\varepsilon$  and  $\nabla^2$  indicate a smoothing factor and the Laplace operator, respectively. This equation can be solved by iterations via Eq. (6):

$$\hat{\delta} = \gamma \text{ISTDCT}(\rho * \text{STDCT}(\varphi * (\delta - \hat{\delta}) + \hat{\delta})) + (1 - \gamma)\hat{\delta}, \quad (6)$$

where  $\gamma$  is a relaxation factor to accelerate convergence;  $\rho$  indicates a 3-dimensional filter related to the smoothing term, which is defined in Eq. (7):

$$\rho(d_1, d_2, d_3) = \frac{1}{1 + \varepsilon \sum_{k=1}^3 2 \left[ 1 - \cos \left( \frac{d_k - 1}{n_k} \pi \right) \right]}, \quad (7)$$

Here,  $d_k$  represents the  $d^{\text{th}}$  value along the  $k^{\text{th}}$  dimension ( $k = 1, 2, \text{ and } 3$ );  $n_k$  denotes the size of  $\delta$  along the  $k^{\text{th}}$  dimension. Namely,  $d_1$ ,  $d_2$ , and  $d_3$  stand for  $u$ ,  $v$ , and  $w$  (see Eq. (1)), respectively. In this study, the number of total iterations,  $\gamma$ , and  $\varepsilon$  are empirically configured to 100, 1.5, and a range from  $10^3$  to  $10^{-1}$  (spaced with 100 intervals), respectively. **It is worth noting that  $\hat{\delta}$  is initialized through the spatiotemporal nearest neighbor interpolation.** More details about the solution steps can be found in Garcia (2010).

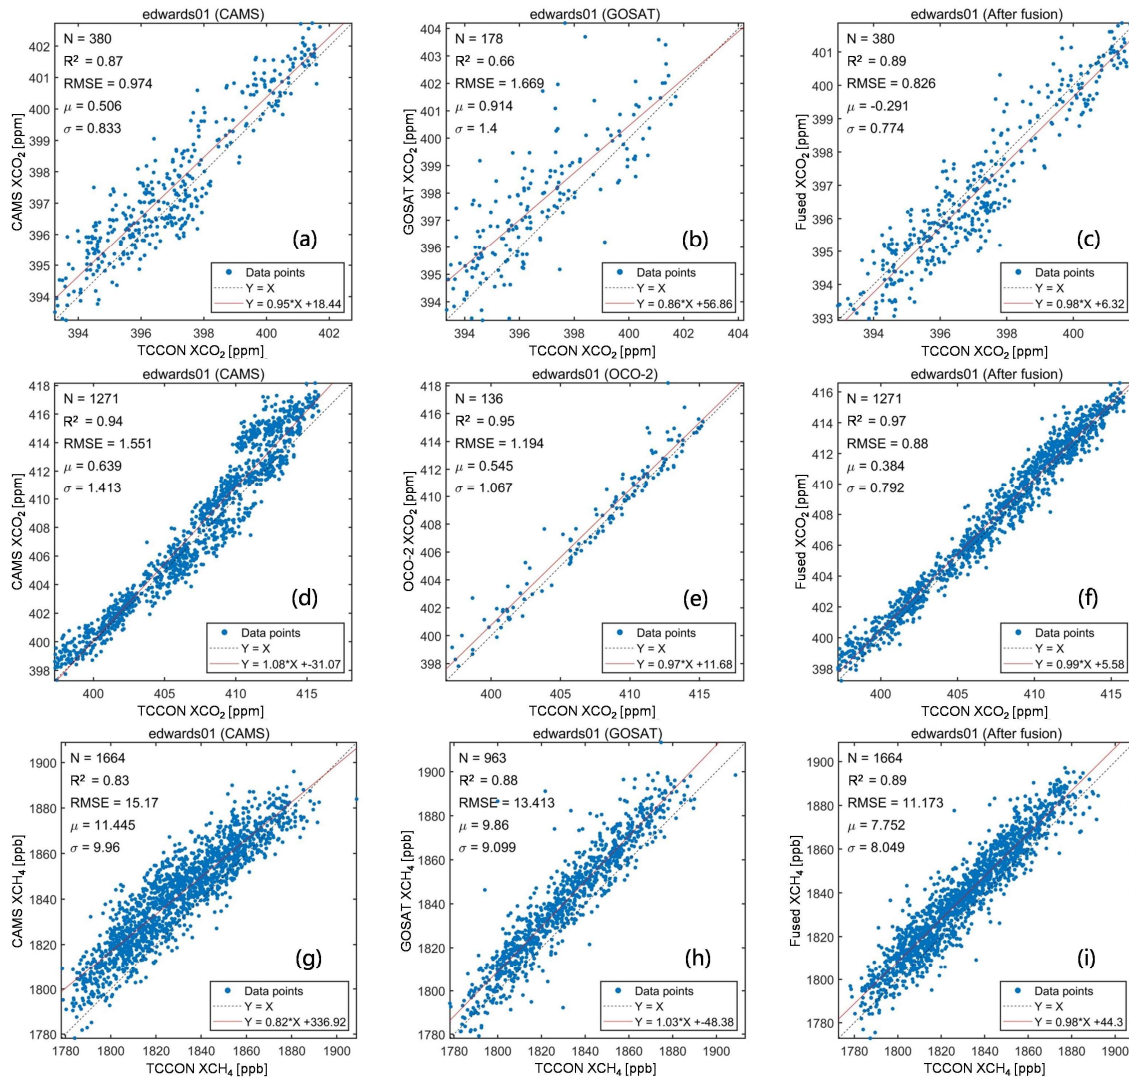

**Figure 3.** Density scatter-plots of the in-situ validation results for (a, d, and g) CAMS-EGG4, (b and h) GOSAT, (e) OCO-2, and (c, f, and i) fused results. Black dotted and red full lines stand for the 1:1 and fitted lines, respectively. Color ramps show the normalized densities of data points. X: TCCON data; Y: CAMS-EGG4/GOSAT/OCO-2/fused data. Unit: ppm/ppb to XCO<sub>2</sub>/XCH<sub>4</sub> for RMSE,  $\mu$ , and  $\sigma$ .

### 217 3.3 Evaluation schemes

218 In our study, the evaluation schemes include in-situ validations and assessments of spatial distribution. To be specific, the  
 219 GOSAT, OCO-2, CAMS-EGG4, and fused XCO<sub>2</sub> and XCH<sub>4</sub> are validated against TCCON measurements, which consists of  
 220 the comparisons for overall and individual in-situ stations. The spatial distribution of the GOSAT, OCO-2, CAMS-EGG4, and  
 221 fused XCO<sub>2</sub> and XCH<sub>4</sub> are assessed on multi-temporal scales, i.e., multi-year mean, seasonal, and annual. A total of four metrics  
 222 are exploited, covering the Determination-Coefficient (R<sup>2</sup>), Root-Mean-Square-Error (RMSE), Mean-Bias ( $\mu$ ), and Standard-  
 223 Deviation of Bias ( $\sigma$ ). The significance levels of  $p < 0.01$  are applied in the computations of all metrics.

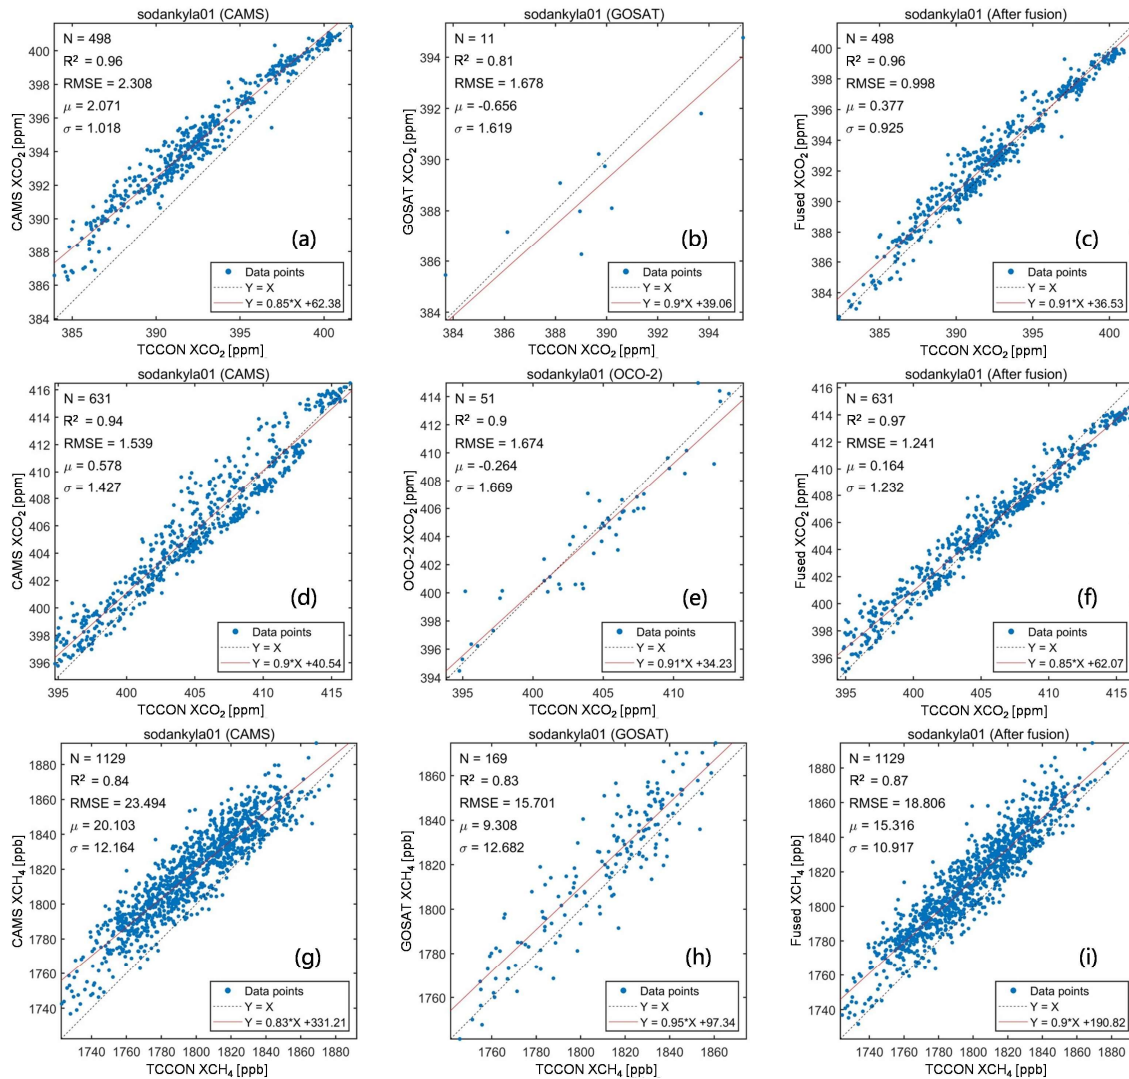

224  
 225 **Figure 4.** Scatter-plots of the in-situ validation results for (a, d, and g) CAMS-EGG4, (b and h) GOSAT, (e) OCO-2, and (c, f, and i) fused  
 226 results on edwards01. Black dotted and red full lines stand for the 1:1 and fitted lines, respectively. X: TCCON data; Y: CAMS-  
 227 EGG4/GOSAT/OCO-2/fused data. Unit: ppm/ppb to XCO<sub>2</sub>/XCH<sub>4</sub> for RMSE,  $\mu$ , and  $\sigma$ .

## 228 4 Experiment results and discussions

### 229 4.1 Overall in-situ validation

230 As displayed in Fig. 2, the XCO<sub>2</sub> and XCH<sub>4</sub> measurements from 29 TCCON in-situ stations are adopted for the validation,  
 231 which evenly distribute over the globe. In this study, TCCON measurements of  $\pm 1$  hour on the satellite overpass times ( $\sim$

232 13:00 and 13:36 local time, see Table 2) are co-matched with the CAMS-EGG4/GOSAT/OCO-2/fused data around each station  
 233 with a diameter of 2°. Figure 3 depicts the overall in-situ validation results for the CAMS-EGG4, GOSAT, OCO-2, and fused  
 234 results. The amounts of data points (N) are sufficient (e.g., 1337 for OCO-2 XCO<sub>2</sub> and 5402 for GOSAT XCH<sub>4</sub>) to support the  
 235 reliability of validation results.

236 **Figure 5.** Scatter-plots of the in-situ validation results for (a, d, and g) CAMS-EGG4, (b and h) GOSAT, (e) OCO-2, and (c, f, and i) fused  
 237 results on sodankyla01. Black dotted and red full lines stand for the 1:1 and fitted lines, respectively. X: TCCON data; Y: CAMS-  
 238 EGG4/GOSAT/OCO-2/fused data. Unit: ppm/ppb to XCO<sub>2</sub>/XCH<sub>4</sub> for RMSE,  $\mu$ , and  $\sigma$ .

240 As shown in Fig. 3, the XCO<sub>2</sub> from OCO-2 and XCH<sub>4</sub> from GOSAT perform better than those from CAMS-EGG4, with larger  
 241 R<sup>2</sup>, smaller RMSE, and smaller  $\sigma$ . After fusion, the XCO<sub>2</sub> (2015-2020) and XCH<sub>4</sub> (2010-2020) present a greatly superior  
 242 accuracy compared to CAMS-EGG4, of which the RMSE ( $\sigma$ ) improvements are 0.443 (0.444) ppm and 3.752 (1.792) ppb for  
 243 XCO<sub>2</sub> and XCH<sub>4</sub>, respectively. Meanwhile, the accuracy of the fused results is higher than and close to those of OCO-2 XCO<sub>2</sub>  
 244 and GOSAT XCH<sub>4</sub>, respectively. These suggest that the proposed fusion method achieves a satisfactory result. Furthermore,  
 245 the performance of XCO<sub>2</sub> from GOSAT is similar to that of CAMS-EGG4. However, the fused XCO<sub>2</sub> (2010-2014) shows  
 246 higher accuracy by comparison with both CAMS-EGG4 and GOSAT, indicating the spatiotemporally local fusion ability of S-  
 247 STDCT. In conclusion, our fusion method can successfully fuse the data from CAMS-EGG4 and satellites, which effectively

248 generates GOSAT-like and OCO-2-like values.

249 **Table 3.** Metrics of the individual in-situ validation results for CAMS-EGG4, GOSAT, and fused XCO<sub>2</sub>. The best and second metrics are  
 250 denoted with bold and underlined fonts. CAMS: CAMS-EGG4; AF: after fusion. Unit: ppm for RMSE and  $\sigma$ .

256 **Figure 6.** Scatter-plots of the time series for daily CAMS-EGG4, GOSAT, OCO-2, fused, and TCCON data on garmisch01. The first and  
 257 second numbers in the bracket represent  $\mu$  and  $\sigma$ , respectively. Unit: ppm/ppb to XCO<sub>2</sub>/XCH<sub>4</sub> for  $\mu$  and  $\sigma$ .  
 258

259 **4.2 Individual in-situ validation and time series**

260 Figure 4, 5, and Table 3-5 show the individual in-situ validation results for the CAMS-EGG4, GOSAT, OCO-2, and fused  
 261 results on each TCCON in-situ station. It is worth noting that only the stations where the individual validation results are  
 262 significant ( $p$ -level  $< 0.01$ ) for all datasets (i.e., CAMS-EGG4, GOSAT, OCO-2, and the fused results) are presented. Since  
 263 the space of text is limited, two stations named edwards01 and sodankyla01 are selected as examples (see Fig. 4 and 5), which  
 264 locate in North America and Europe, respectively. As can be seen, the fused results achieve the best performance compared to  
 265 CAMS-EGG4, GOSAT, and OCO-2 on edwards01 and sodankyla01, with the  $R^2$  ranging from 0.87 to 0.97. Especially, the  
 266 large overestimation of  $XCO_2$  for CAMS-EGG4 on sodankyla01 ( $\mu = 2.071$  ppm) is well mitigated after fusion ( $\mu = 0.377$   
 267 ppm), even for the poor data availability of GOSAT ( $N = 11$ ). This indicates the strong universality of the proposed fusion  
 268 method. The valid individual validation results on all stations are given in Table 3-5. It can be observed that the performance  
 269 of the fused results exceeds those of CAMS-EGG4 and GOSAT/OCO-2 for almost all stations and  $\sim 70\%$  of stations,  
 270 respectively.

271  
 272 **Figure 7.** Scatter-plots of the time series for daily CAMS-EGG4, GOSAT, OCO-2, fused, and TCCON data on lauder02. The first and second  
 273 numbers in the bracket represent  $\mu$  and  $\sigma$ , respectively. Unit: ppm/ppb to  $XCO_2/XCH_4$  for  $\mu$  and  $\sigma$ .

274  
 275 **Figure 8.** Heat maps of the biases between daily (a) CAMS-EGG4/(b) fused/(c) GOSAT and TCCON XCO<sub>2</sub> over time and latitude. Color  
 276 ramps stand for the biases of XCO<sub>2</sub>. Background colors (grey) indicate the missing data.

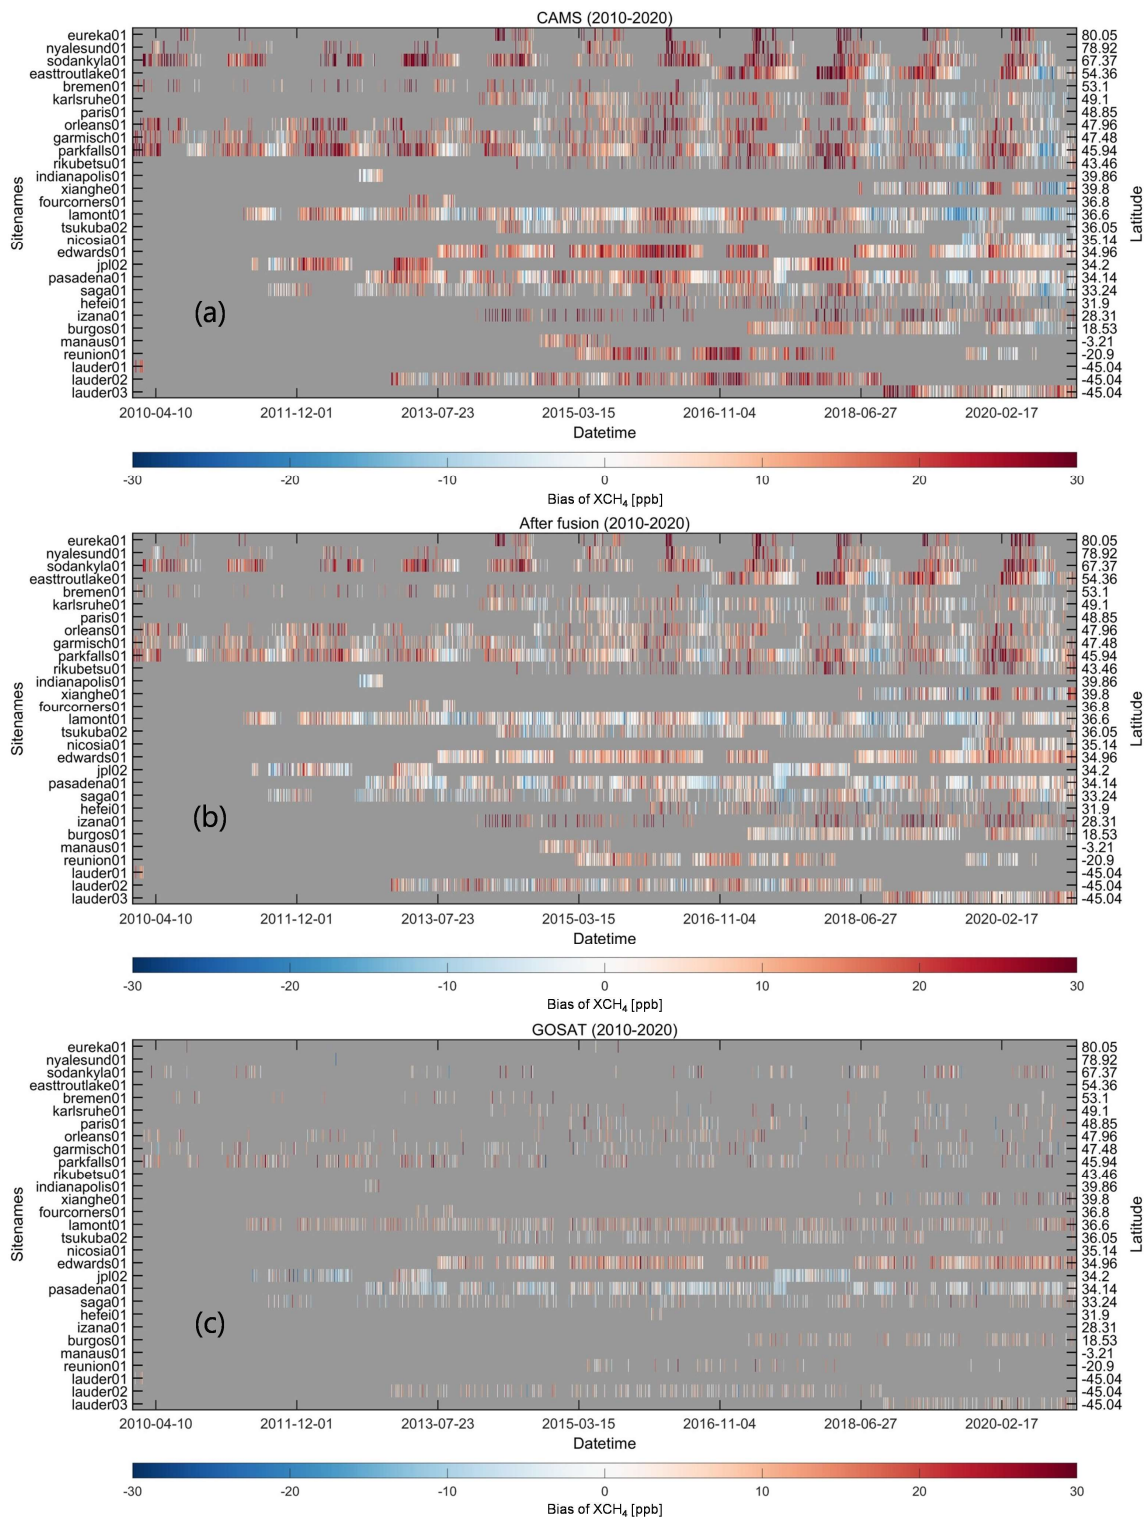

277

278 **Figure 9.** Heat maps of the biases between daily (a) CAMS-EGG4/(b) fused/(c) OCO-2 and TCCON XCO<sub>2</sub> over time and latitude. Color

279 ramps stand for the biases of XCO<sub>2</sub>. Background colors (grey) indicate the missing data.

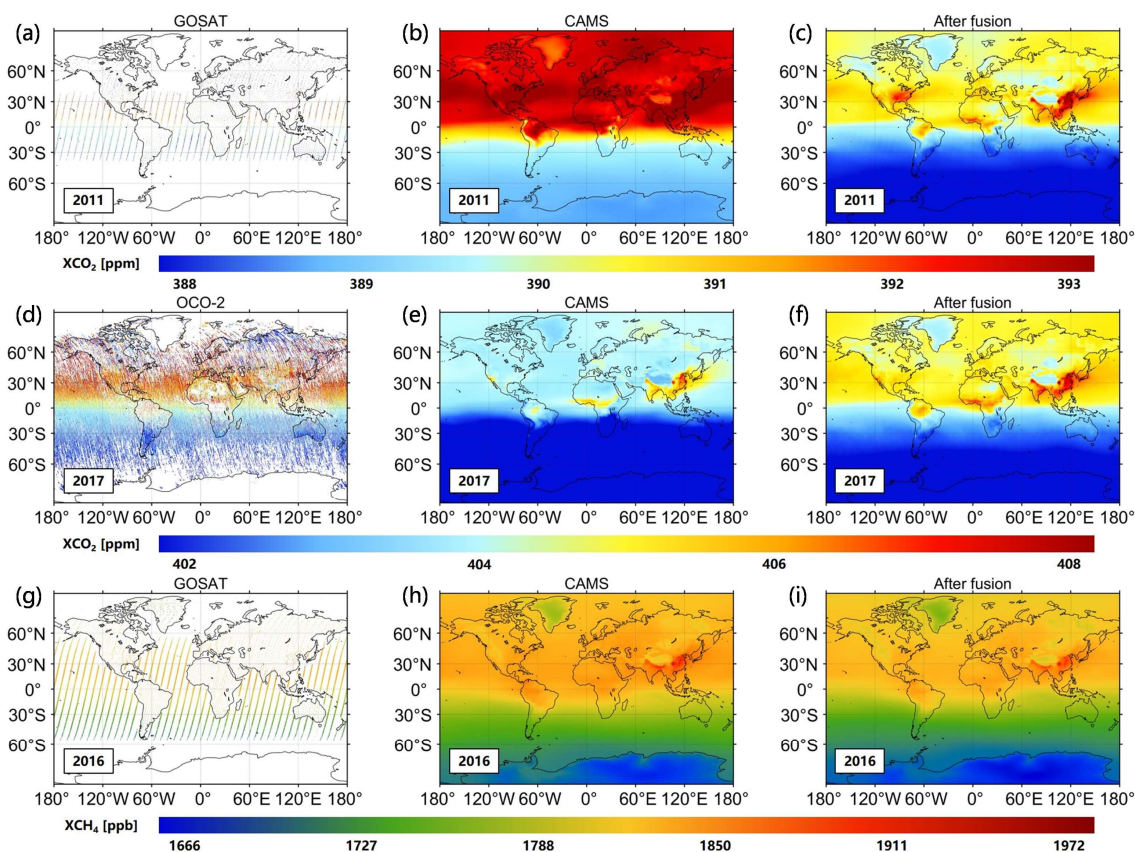

280

281 **Figure 10.** Heat maps of the biases between daily (a) CAMS-EGG4/(b) fused/(c) GOSAT and TCCON XCH<sub>4</sub> over time and latitude. Color  
 282 ramps stand for the biases of XCO<sub>2</sub>. Background colors (grey) indicate the missing data.

283 Figure 6 and 7 demonstrate the time series for daily CAMS-EGG4, GOSAT, OCO-2, fused, and TCCON data on individual  
 284 in-situ stations. Similarly, two stations, i.e., garmisch01 and lauder02, are regarded as examples, which locate in Europe and  
 285 Oceania, respectively. As depicted in Fig. 6, the XCO<sub>2</sub> from CAMS-EGG4 is markedly overestimated on garmisch01 from  
 286 2010 to 2014 and in 2020. After fusion, the XCO<sub>2</sub> presents an equal trend compared to TCCON measurements over time, with  
 287 smaller  $\mu$  (0.096 and 0.139 ppm) and  $\sigma$  (1.067 and 1.01 ppm). In the meantime, the overestimation of CAMS-EGG4 XCH<sub>4</sub>

288 is also mitigated on garmisch01 through our fusion method. Regarding lauder02, Figure 7 shows that CAMS-EGG4 generates  
 289 underestimated  $XCO_2$  (2015-2019) and overestimated  $XCH_4$ . The  $\mu$  and  $\sigma$  of the fused results (e.g., 4.952 and 10.189 ppb  
 290 for  $XCH_4$ ) are significantly improved on lauder02.

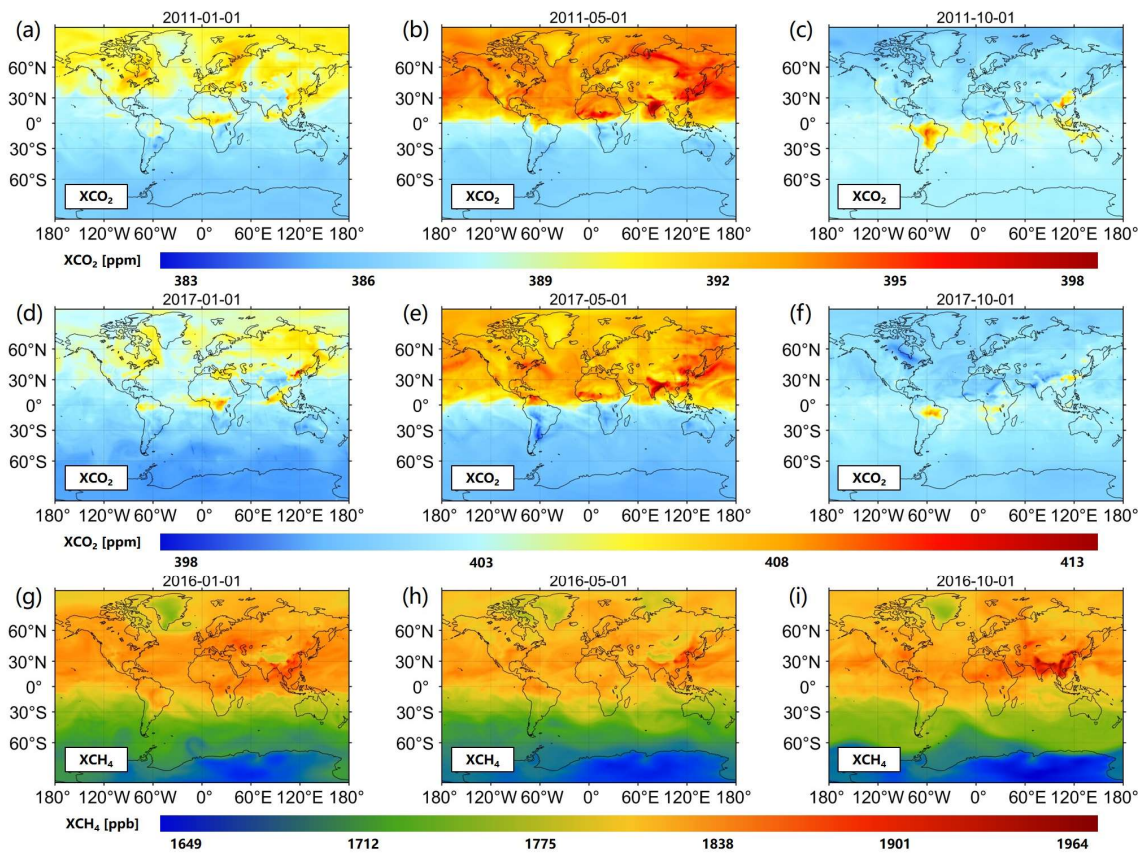

291  
 292 **Figure 11.** Annual (a and g) GOSAT, (d) OCO-2, (b, e, and h) CAMS-EGG4, and (c, f, and i) fused  $XCO_2/XCH_4$  over the globe. Color  
 293 ramps stand for the values of  $XCO_2$  and  $XCH_4$ .

### 294 4.3 Uncertainty analyses

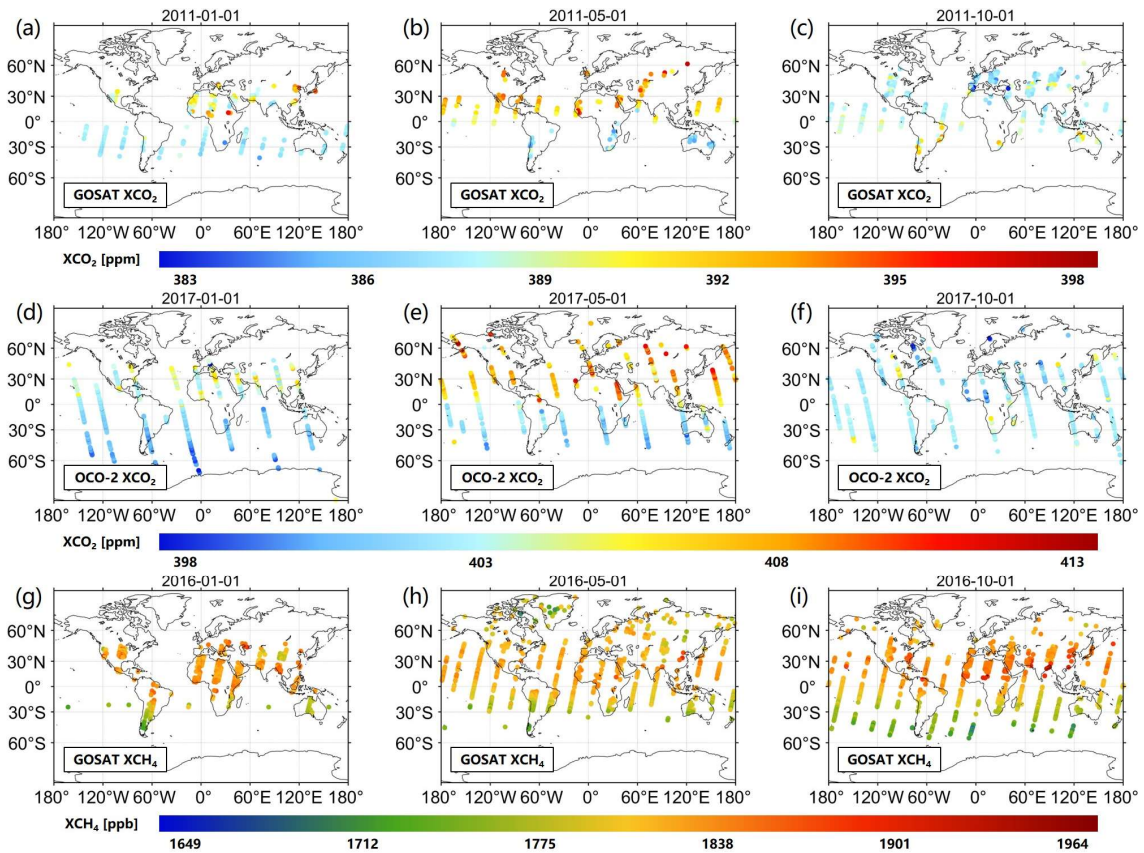

295 Figure 8-10 display the biases between daily CAMS-EGG4/fused/GOSAT/OCO-2 and TCCON data over time and latitude.  
 296 As observed in Fig. 8 and 9, a large overestimation generally exists in the CAMS-EGG4  $XCO_2$  from 2010 to 2014 and in 2020,  
 297 especially before 2013 and in 2020 ( $> 3$  ppm). These are attributed to the considerable errors in the satellite data assimilated  
 298 (2010-2014) and that anthropogenic emissions are not modified for COVID-19 lockdowns in 2020 (Agusti-Panareda et al.,  
 299 2022). After fusion, the biases of  $XCO_2$  are well improved for most TCCON in-situ stations from 2010 to 2014 and in 2020,  
 300 whose patterns are similar to those of GOSAT and OCO-2  $XCO_2$ , respectively. This indicates that the proposed fusion method  
 301 can effectively correct the biases in CAMS-EGG4 due to the issues from assimilation data. Meanwhile, CAMS-EGG4  
 302 generates distinctly underestimated  $XCO_2$  from 2016 to 2019 on the stations of latitude  $< 40^\circ$  N, which is also mitigated via  
 303 the S-STDCT fusion method (see Fig. 10). Moreover, the CAMS-EGG4  $XCH_4$  frequently presents a large positive bias ( $> 30$   
 304 ppb), while the fused  $XCH_4$  only enhances the performance on the stations of latitude  $< 50^\circ$  N. The improvements for other  
 305 stations require our further efforts in the future.

306

307 **Figure 12.** Daily fused (a-f) XCO<sub>2</sub> and (g-i) XCH<sub>4</sub> over the globe. Color ramps stand for the values of XCO<sub>2</sub> and XCH<sub>4</sub>.

308

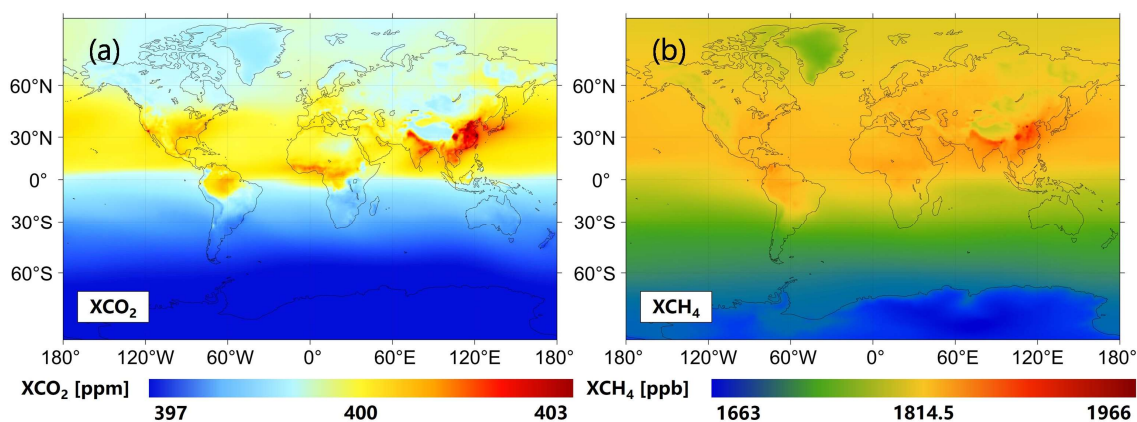

309 **Figure 13.** Daily (a-c) GOSAT, (d-f) OCO-2 XCO<sub>2</sub>, and (g-i) GOSAT XCH<sub>4</sub> over the globe. Color ramps stand for the values of XCO<sub>2</sub> and  
310 XCH<sub>4</sub>.

#### 311 4.4 Assessment of spatial distribution on multi-temporal scales

312 Figure 11 demonstrates the comparisons of annual GOSAT, OCO-2, CAMS-EGG4, and fused XCO<sub>2</sub>/XCH<sub>4</sub> over the globe. A  
313 total of three years are selected, including 2011, 2017, and 2016. As can be seen, the fused results present coincident spatial  
314 patterns with GOSAT and OCO-2, even if the annual GOSAT and OCO-2 data are greatly sparse. Particularly, the large  
315 overestimation and underestimation of CAMS-EGG4 XCO<sub>2</sub> in 2011 and 2017 are significantly modified after fusion,  
316 respectively, which are mutually confirmed with the descriptions in Section 4.3.

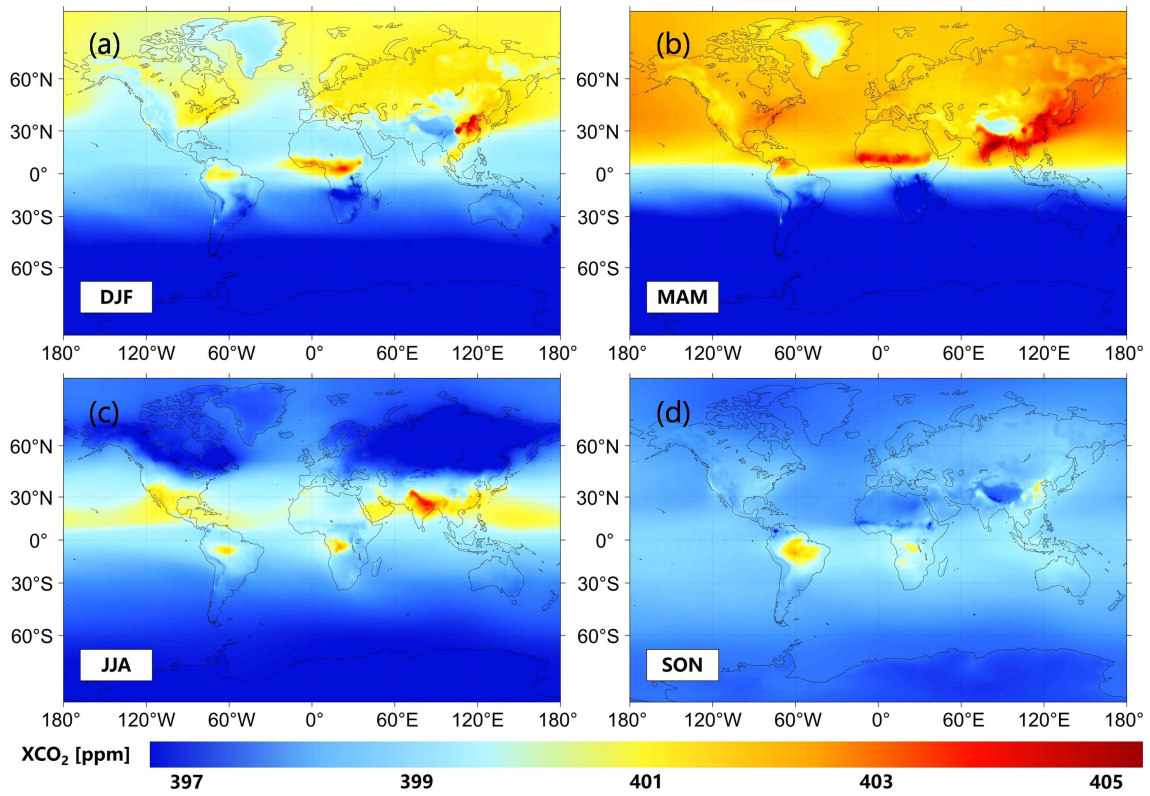

317 Figure 12 illustrates the examples of daily fused XCO<sub>2</sub> and XCH<sub>4</sub> over the globe, consisting of three days in three years. As  
318 shown, the fused results display detailed information on atmospheric CO<sub>2</sub> and CH<sub>4</sub>, which clearly indicate their regional and  
319 global spatial patterns. In addition, incoherent or factitious spatial distribution is not observed in the fused XCO<sub>2</sub> and XCH<sub>4</sub>.  
320 Next, Fig. 13 provides the corresponding daily XCO<sub>2</sub> and XCH<sub>4</sub> from GOSAT and OCO-2 over the globe. It is worth noting  
321 that the daily satellite XCO<sub>2</sub> and XCH<sub>4</sub> are mapped via footprints due to their significant sparse coverage, which are nearly  
322 invisible at grids of 0.25°. As expected, the fused results present identical spatial distribution compared to XCO<sub>2</sub> and XCH<sub>4</sub>  
323 from GOSAT and OCO-2. This suggests the robustness and reliability of the proposed fusion method.

324 Figure 14 depicts the multi-year mean fused global XCO<sub>2</sub> and XCH<sub>4</sub> from 2010 to 2020. Generally, the spatial patterns of  
325 XCO<sub>2</sub> and XCH<sub>4</sub> are divided by the equator. The high values of XCO<sub>2</sub> and XCH<sub>4</sub> mainly distribute over Asia, e.g., China and  
326 India, which is attributed to the large anthropogenic emissions (Kenea et al., 2023; Liu et al., 2020; Turner et al., 2015;  
327 Hotchkiss et al., 2015). In the meantime, considerable natural emissions, e.g., wildfires (Arora and Melton, 2018), also can  
328 obviously increase the XCO<sub>2</sub> values, such as in central Africa and northern South America. Figure 15 and 16 illustrate the  
329 seasonal fused XCO<sub>2</sub> and XCH<sub>4</sub> from 2010 to 2020 over the globe, respectively. As displayed, seasonal changes of global  
330 XCO<sub>2</sub> and XCH<sub>4</sub> spatial patterns are clearly reflected in the fused results. Compared to XCH<sub>4</sub>, the global spatial patterns of  
331 XCO<sub>2</sub> vary more drastically. This is likely driven by the spatiotemporal heterogeneity of meteorological fields (Liu et al., 2011)  
332 and different emission sources of CO<sub>2</sub> and CH<sub>4</sub>.

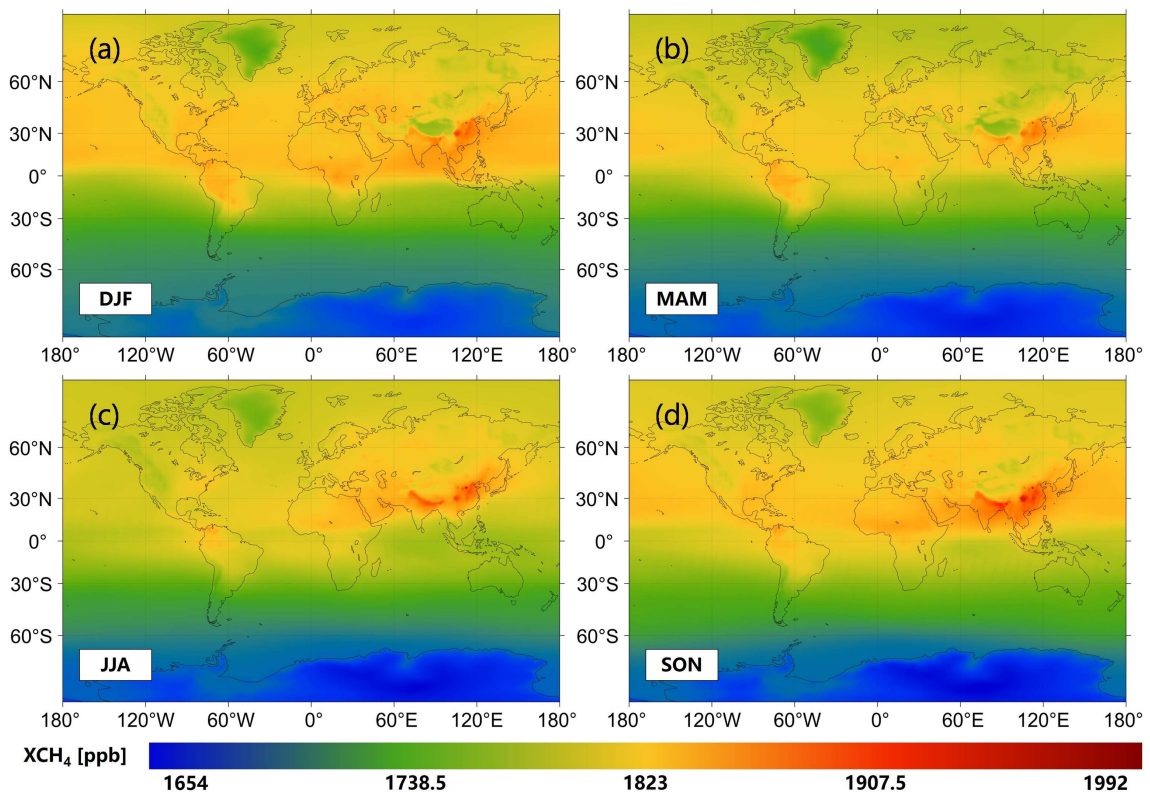

333  
334 **Figure 14.** Multi-year mean fused (a) XCO<sub>2</sub> and (b) XCH<sub>4</sub> from 2010 to 2020 over the globe. Color ramps stand for the values of XCO<sub>2</sub> and  
335 XCH<sub>4</sub>.

336

337 **Figure 15.** Seasonal fused XCO<sub>2</sub> from 2010 to 2020 over the globe. The color ramp stands for the value of XCO<sub>2</sub>. (a) DJF, (b) MAM, (c)  
 338 JJA, and (d) SON denote Dec. to Feb., Mar. to May., Jun. to Aug., and Sep. to Nov., respectively.

339

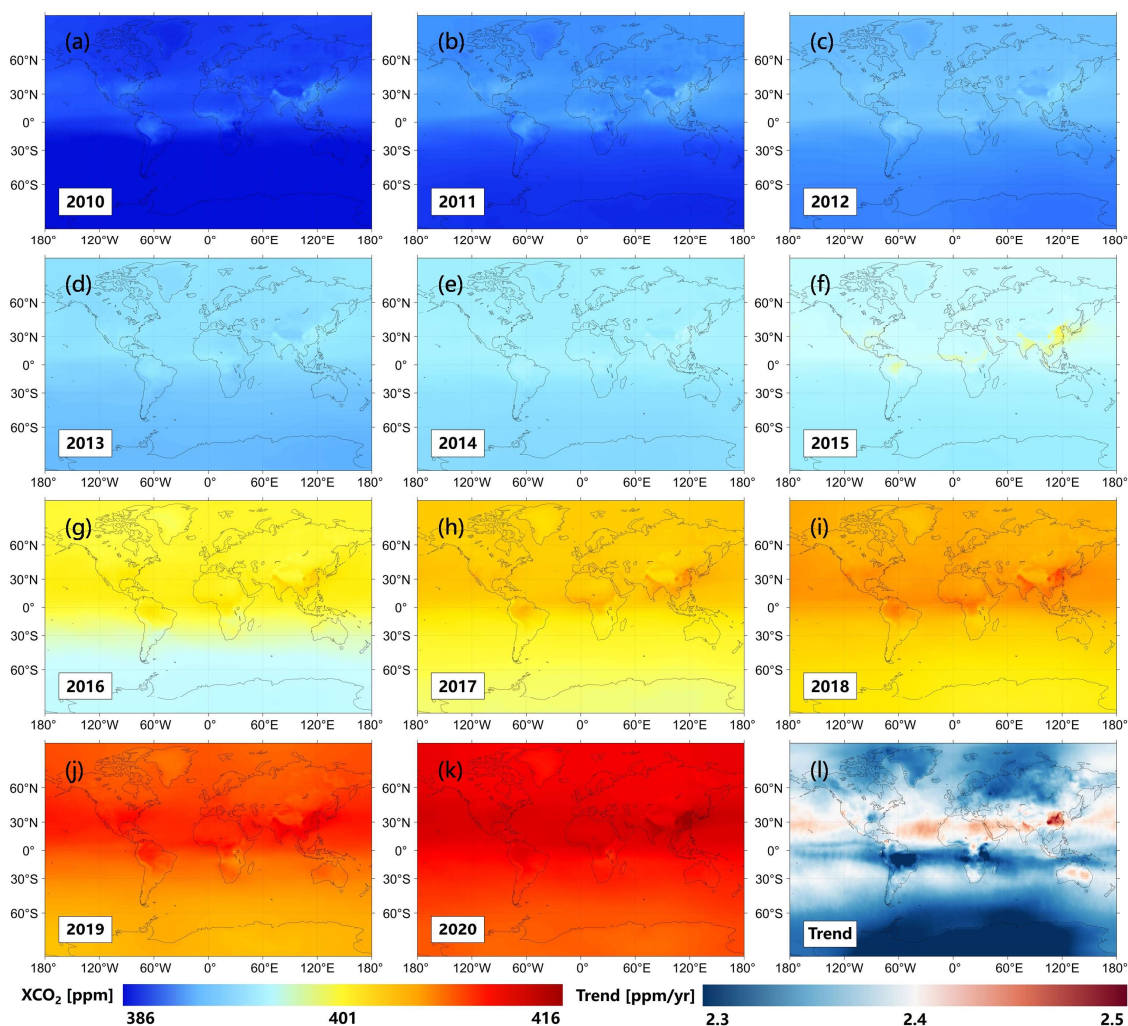

340 **Figure 16.** Seasonal fused XCH<sub>4</sub> from 2010 to 2020 over the globe. The color ramp stands for the value of XCH<sub>4</sub>. (a) DJF, (b) MAM, (c)  
 341 JJA, and (d) SON denote Dec. to Feb., Mar. to May., Jun. to Aug., and Sep. to Nov., respectively.

342 Figure 17 and 18 map the annual fused global XCO<sub>2</sub> and XCH<sub>4</sub> from 2010 to 2020, respectively, including their trends. As

343 observed in Fig. 17, the CO<sub>2</sub> levels continuously increase from 2010 to 2020, with the mean XCO<sub>2</sub> values ranging from ≤  
 344 386 to ≥ 416 ppm. However, the trends of XCO<sub>2</sub> only present small spatial differences (~ 0.2 ppm per year), of which the  
 345 large growth rates primarily distribute along the equator, especially for China (≥ 2.5 ppm per year). It is worth noting that the  
 346 growth rates of XCO<sub>2</sub> are relatively slight (≤ 2.3 ppm per year) in northern South America compared to other regions. This is  
 347 likely caused by the effects from the carbon sequestration of forests (Chazdon et al., 2016). Besides, the XCH<sub>4</sub> values also  
 348 notably rise from 2010 to 2020, of which the maximum is not less than 2008 ppb in 2020 (see Fig. 18). The large growth rates  
 349 of XCH<sub>4</sub> are majorly discovered over southern Asia and northern Europe.

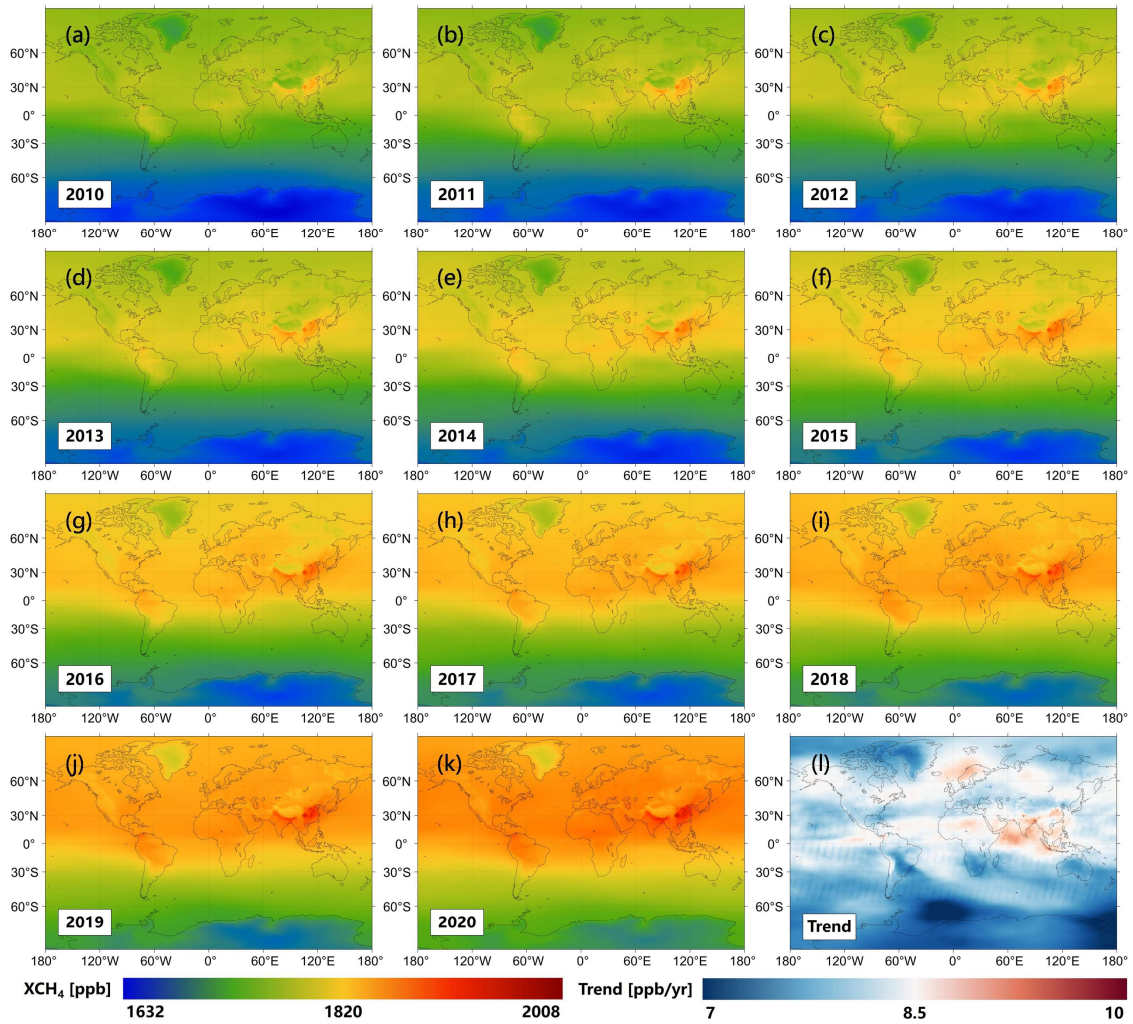

## 350 5 Data availability

351 The fused results can be freely accessed at <http://doi.org/10.5281/zenodo.7388893> (Wang et al., 2022b). The daily global  
 352 seamless gridded (0.25°) XCO<sub>2</sub> and XCH<sub>4</sub> from 2010 to 2020 are stored in the netCDF4 format with a file size of ~ 3.5 MB  
 353 for each day. The units of XCO<sub>2</sub> and XCH<sub>4</sub> are ppm and ppb, respectively.

354  
 355 **Figure 17.** Annual fused (a-k) XCO<sub>2</sub> and (l) its trend from 2010 to 2020 over the globe. Color ramps stand for the values of XCO<sub>2</sub> and its  
 356 trend. ppm/yr: ppm per year.

357  
 358 **Figure 18.** Annual fused (a-k) XCH<sub>4</sub> and (l) its trend from 2010 to 2020 over the globe. Color ramps stand for the values of XCH<sub>4</sub> and its  
 359 trend. ppb/yr: ppb per year.

## 360 6 Conclusions

361 In our study, a novel spatiotemporally self-supervised fusion method, i.e., S-STDCT, is proposed to acquire long-term daily  
 362 seamless globally distributed XCO<sub>2</sub> and XCH<sub>4</sub> products from 2010 to 2020 at the grids of 0.25°. A total of three datasets are  
 363 adopted, which include GOSAT, OCO-2, and CAMS-EGG4. Since the data from GOSAT and OCO-2 is greatly sparse in  
 364 space-time domain, the algorithm for frequency domain (the *STDCT*) is applied in the fusion task. **Validation results show that**  
 365 **the S-STDCT fusion method performs well over the globe, with the  $\sigma$  of ~ 1.18 ppm for XCO<sub>2</sub> and 11.3 ppb for XCH<sub>4</sub> against**  
 366 **TCCON measurements during 2010-2020. Meanwhile, the R<sup>2</sup> of fused XCO<sub>2</sub> and XCH<sub>4</sub> reach 0.91/0.95 (2010-2014/2015-**  
 367 **2020) and 0.9 (2010-2020), respectively.** Generally, the accuracy of fused results is distinctly superior to that of CAMS-EGG4,  
 368 which also exceeds or equals those of GSOAT and OCO-2. Particularly, the proposed fusion method effectively modifies the  
 369 large biases in CAMS-EGG4 caused by the issues from assimilation data, such as the uncorrected anthropogenic emission  
 370 inventories for COVID-19 lockdowns in 2020. Besides, the spatial patterns of fused results remain coincident with GOSAT  
 371 and OCO-2, which can accurately display the long-term and seasonal changes of global XCO<sub>2</sub> and XCH<sub>4</sub> spatial distribution.

372 The long-term (2010-2020) daily global seamless gridded (0.25°) fused results are available at  
373 <http://doi.org/10.5281/zenodo.7388893> (Wang et al., 2022b).

374 Overall, the developed fusion method generates high-quality full-coverage XCO<sub>2</sub> and XCH<sub>4</sub> datasets over the globe from 2010  
375 to 2020. However, it only considers the global spatiotemporal knowledge of self-correlation in GOSAT and OCO-2 products  
376 without attention to local spatiotemporal information. Meanwhile, the spatial resolution and available period of fused results  
377 should be further enhanced, which are devised as 0.1° and more than 20 years (e.g., 2000-2020), respectively. To fix these  
378 issues, we will spare no effort to work on our future works.

#### 379 **Author contributions**

380 YW designed the study, collected and processed the data, analyzed the results, and wrote the paper. QQY and TWL provided  
381 constructive comments on the paper. YJY, SQZ, and LPZ revised the paper. All authors contributed to the study.
