Abstract. DINOSTRAT version 2.1-GTS2020 is now available (Bijl et al., 2024b); <http://dx.doi.org/10.5281/zenodo.10506652>). This version updates DINOSTRAT to the Geologic Time Scale 2020, and new publications are added into the database. The resulting database now contains over 9,450 entries from 209 sites. This update has not led to major and profound changes in the conclusions made previously. DINOSTRAT allows full presentation of first and last stratigraphic occurrences of [dinoflagellate cyst subfamilies and families](#), as well as the evolutionary turnover throughout geologic history, as a reliable representation of dinoflagellate evolution. Although the picture of dinoflagellate evolution from DINOSTRAT is broadly consistent with that in previous publications, the underlying data is with DINOSTRAT openly available, reproducible, and up to date. This release of DINOSTRAT allows calibration of stratigraphic records to the Geologic Time Scale 2020 using dinoflagellate cysts as biostratigraphic tool.

15 1 Introduction

DINOSTRAT version 1.1 (Bijl, 2022) offers a comprehensive open access database of organic-walled dinoflagellate cyst ([dinocysts from hereon](#)) first and last occurrences ([hereafter referred to as 'events'](#)). The dinocyst events in DINOSTRAT were calibrated to the Geologic Time Scale (GTS) 2012 (Gradstein et al., 2012). In 2020, a new geologic time scale was published (Gradstein et al., 2020). I here release DINOSTRAT version 2.1, in which stratigraphic ranges of dinocysts are calibrated to the GTS2020 of (Gradstein et al., 2020).

2 Methods

In the release of version 2.1 of DINOSTRAT, I updated stratigraphic calibrations of [dinocyst](#) first and last occurrences to the GTS2020 (Gradstein et al., 2020). New papers that meet the criteria as laid out in DINOSTRAT version 1.1 (see Bijl, 2022 for more information about the approach) were added (see Table 1 for the new additions). The approach of data entry [remained the same](#) in this new release. [Published](#) dinocyst ranges were included when they could be calibrated to a chrono-, bio-, or magnetostratigraphic zonation, whereby 5 reliability tiers were distinguished: 1) dinocyst events were calibrated against reliable magnetostratigraphy, 2) against compromised magnetostratigraphy, 3) against biostratigraphic zonations (nannofossils, foraminifer zones, ammonites), 4) indirectly against biostratigraphic zones (whereby the origin of those zones

is not exactly clear, or these zones were not derived from the same material), and 5) from unclear chronostratigraphic constraints (Bijl, 2022). [I had the paleolatitude evolution of the “stable” sites \(i.e., away from major plate boundaries or tectonically active regions\) recalculated based on the upgraded paleolatitude.org \(last access 12-1-2024\) calculator, using the framework of Vaes et al. \(2023\). I upgraded the plotting tools](#) with extra features: the stages from the GTS2020 (Gradstein et al., 2020) are added to visually aid the interpretation of the plots.

Deleted: The plotting tools were updated

3 Results: DINOSTRAT version 2.1-GTS2020

The database is released as [version 2.1-GTS2020](#) on Github and Zenodo (Bijl, 2024b); <http://dx.doi.org/10.5281/zenodo.10506652>), on which the new datasets and plotting tools can be found. The supplements (Bijl, 2024a) contain all the new figures for families, genera, species and sites in DINOSTRAT. The calibration of some entries in DINOSTRAT version 1.1 had to be adjusted for DINOSTRAT version 2.1-GTS2020, because of a revision of the Cretaceous ammonite zonations in GTS2020 (see Gradstein et al., 2020; Chapter Cretaceous). An overview of the changes induced by this can be found on Github (Bijl, 2024b). This update has not led to any major changes in the database. For most events, this update caused only minor adjustments in the calculated absolute age. The adjusted ammonite zonation scheme in the Cretaceous that GTS2020 proposed did lead to a lot of recalibrations of dinocyst events. Yet, their absolute age should in principle not have changed much, since the ammonite zonation adjustment was mostly about redefining the index species and zone boundaries. With this update of DINOSTRAT, dinocyst events can now be used as chronostratigraphic indicator on the GTS2020 time scale.

75 4 Discussion

All the conclusions and interpretations made in the release paper of DINOSTRAT still stand with the addition of data and recalibration to the GTS2020. The North Atlantic Ocean is still strongly overrepresented in DINOSTRAT, and the Pacific Ocean underrepresented in the geographical distribution of sites used to calibrate dinocyst assemblages (Fig. 1), and equatorial regions and the Southern Hemisphere remain underexplored, in spite of these being large ocean regions (Fig. 2). Bujak et al. (2022) added crucial calibrated dinocyst events from the Jurassic Arctic Basin. The addition of the new Antarctic-proximal surface sediment data of Thöle et al. (2023) adds geographic distribution information for modern dinocysts in the Southern Hemisphere, but stratigraphic first occurrence of many modern species remains largely unknown (see Supplements). Further exploration of DINOSTRAT has allowed the presentation of the stratigraphic ranges of dinocyst subfamilies and families (Fig. 3). As in Fig. 2b, Fig. 3 presents counts of oldest first occurrences and youngest last occurrences of dinocyst genera and species, but per subfamily or family, which yields the calibrated age of origination and final extinction of dinocyst

sub-families. This is a robust indication of the minimal stratigraphic range of these dincyst subfamilies. It must be noted however that the suprageneric classification will remain in a state of flux for the coming decades, as many uncertainties remain. This may change the ranges of families and subfamilies described herein.

Peridiniphyceidae have their first occurrence in the Ladinian (Middle Triassic), followed by Rhaetogonyaulacaceae,

100 Suessiaceae and several miscellaneous Dinophyceae in the Carnian (Upper Triassic). The Heterocapsaceae, as first representatives of modern Peridinales, the Mancodiniaceae as first representatives of the modern (but now non-cyst-forming) Cladopyxiineae, Nannoceratopsiaceae and Comparodiniaceae first occur in the Sinemurian (Lower Jurassic).

Scrinocassiaceae and Cladopyxiaceae (both part of the suborder of Cladopyxiineae) first occur in the Pliensbachian, which

105 sees the last occurrence of the Shublikodiniaceae, the first of the cyst-forming dinocyst families to go extinct. The Toarcian sees the last occurrence of the Suessiales, as well as the first occurrence of the Pareodiniaceae, and Leptodinioidae of the family Gonyaulacaceae, with many modern representatives. The Aalenian (Middle Jurassic) sees the first occurrence of the Cribroperidinioidae. The Gonyaulacoideae first occur in the Bajocian, during which also many other Gonyaulacaceae taxa

have first occurrences. The Scrinocassaceae have their last occurrence in this stage. The Stephanelytracaceae and Areoligeraceae

110 first occur in the Bathonian, while the Mancodiniaceae have their last occurrence. The Peridiniaceae first occur in the Callovian. The Deflandreoideae first occur in the Oxfordian (Upper Jurassic). The Nannoceratopsiaceae have their last occurrence and the Ceratiaceae their first occurrence in the Kimmeridgian. The Goniodomaceae have their first occurrence in the Tithonian. Palaeoperidinioidae first occur and Dollidiniaceae and Comparodiniaceae have their last occurrence in the Valanginian (Lower Cretaceous). Stephanelytracaceae have their last occurrence in the Aptian. Heterocapsaceae last occur in the

Albian, however, motile cells still live in the modern ocean (Fensome et al., 1993). In the Cenomanian (Upper Cretaceous)

115 Dinogymnioideae first occur, and Pareodiniaceae have their last occurrence. The Santonian sees the first occurrence of the Protoperidinioidae. The Ceratiaceae have their last occurrence at the end of the Maastrichtian. In the Danian (Paleocene), Wetzelielloideae have their first occurrence, the youngest subfamily to appear in the cyst record. Dinogymnioideae have their last occurrence in the Selandian, however motile cells of this subfamily still occur in the modern ocean (Fensome et al., 1993).

The Palaeoperidinioidae, Cladoxyxiaceae and Wetzelielloideae have their last occurrence in the Chattian (Oligocene). The

120 Areoligeraceae have their last occurrence in the Burdigalian (Miocene). The Tortonian sees the last occurrence of the Leptodinioidae, and the Messinian the last occurrence of the Deflandreoideae.

The counts of oldest first occurrences and youngest last occurrences through time (Fig. 3) provide a rough indication of the amount of turnover in subfamilies. Yet, for several reasons I dictate, caution not to overinterpret Fig. 3, particularly the implications of cyst species turnover for biological diversity and evolution. The first practical reason is that many entries in

125 DINOSTRAT have only a first occurrence or last occurrence logged, not both (because of their long range or because of calibration limitations), which prevents assessing the full stratigraphic range of many species, and therefore, prevents the assessment of total diversity through time. The second reason for this caution is the chance of absence bias or false negatives in the fossil cyst record, for instance the absence of 4inocysts species because the corresponding dinoflagellate ceased to make cysts and not because it went extinct. Only about 10% of modern dinoflagellates include a cyst-phase in their life cycle (Bravo

Deleted: This has several reasons. First of all, dinocyst diversity does

Deleted: necessarily reflect biological diversity of dinoflagellates, as only

145 and Figueroa, 2014). It is impossible to assess whether this fraction of cyst-producing dinoflagellates has changed through
time. Yet, the representation of many dinoflagellate families in the fossil record of dinocysts (Fig. 3) does suggest that a cyst-
phase was more common in a more diverse group of dinoflagellate taxa in the past. Interpreting what 5inocysts turnover would
mean for the paleobiology of dinoflagellates remains complex due to the apparent ability for a few 5inocysts families to switch
cyst formation on and off: the Cladopyxiaceae and Ceratiaceae are known as modern motile cells (Fensome et al., 1993) yet
150 their stratigraphic occurrence as cysts in the fossil record ended long before modern times (Fig. 3). This demonstrates that
dinocysts diversity likely underestimates past dinoflagellate diversity, by an unknown amount that is likely not stable through
time. Finally, dinocyst taxonomy is a morphological taxonomy, and not defined on genetic grounds. On a cyst genus level and
higher, the defining morphological differences focus on plate tabulation (Fensome et al., 1993), a feature so fundamental to
cell structure that it probably does reflect biological diversity. The defining features of many cyst species, however, are focused
155 on ornament rather than tabulation, and for some of those features it remains a question to what extent it reflects biological
diversity, eco-phenotypical variability or effects of bio-provincialism. Examples of this complexity was a study whereby one
strain of Gonyaulax spinifera produced cysts of Spiniferites and Nematosphaeropsis spp., with a full suite of morphological
intermediates (Rochon et al., 2009). Such examples call into question the biological significance of cyst species, also in the
fossil record. Although surely there is a signal of biological diversity captured in fossil dinocyst species assemblages, the total
160 species diversity needs to be treated with some caution.

The stratigraphic ranges of dinocyst subfamilies or families (Fig. 3) from DINOSTRAT match closely those in the dinocyst
diversity plot of (Fensome et al., 1996). This was expected, as both syntheses probably use overlapping literature resources as
basis for the inferred dinoflagellate evolution. DINOSTRAT delivers a verifiable, reproducible database, that underpins
dinoflagellate evolution, and that is updated to the most recent Geologic Time Scale. It provides a platform that allows iterative
improvement of the communities' collective knowledge of dinocyst biostratigraphy. The similarity to other overviews of
165 evolution (Fensome et al., 1996) demonstrates the completeness of the DINOSTRAT database.

5 Data and code availability

DINOSTRAT Version 2.1-GTS2020, including R-code to make the figures, is available on Github and Zenodo (Bijl, 2024b);
<http://dx.doi.org/10.5281/zenodo.10506652>.

170 6 Supplements

Supplementary figures are available (Bijl, 2024a) for those not familiar with R programming:

- Paleolatitude distributions of dinocyst subfamilies and species (2066 plots)
- Paleolatitude distributions, stratigraphic ranges and distribution maps of dinocyst genera (471 plots)
- Paleolatitude distributions, stratigraphic ranges and distribution maps of dinocyst families (27 plots)

Deleted: 3) does suggest that a cyst-phase was ubiquitous among a wider scope of dinoflagellate taxa in the past. Second, and on top of the above, many entries in DINOSTRAT have only a first occurrence or last occurrence logged, not both (because of their long range or because of calibration limitations), which prevents assessing the full stratigraphic range of many species, and therefore, prevents the assessment of total diversity through time. Incorporating more publications, e.g., those with perhaps poorer independent age control, could in the future result in a more complete database of full ranges of cyst taxa but would compromise the reliability of entries. Thirdly, interpreting what dinoflagellate cyst

Deleted: dinocyst (sub)

Deleted: Cladopyxiaceae, Nannoceratopsiae

Deleted: Dinogymniae

Deleted: Finally, and most importantly, dinoflagellate cyst taxonomy is not a biological but a morphological taxonomy, whereby it remains a question to what extent morphological species of cysts are produced by genetically distinctly different dinoflagellate species. On genus level, defining morphological differences comprise more fundamental characteristics related to plate tabulation (Fensome et al., 1993), and that gives more confidence that it reflects biological diversity. What the overview presented here does reflect at minimum is how important certain dinoflagellate cyst subfamilies are for chronostratigraphy in any particular time interval.
