16 **Abstract.** A high-resolution, spatially explicit forest age map is essential for quantifying forest carbon stocks and carbon
17 sequestration potential. Prior attempts to estimate forest age on a national scale in China have been limited by sparse resolution
18 and incomplete coverage of forest ecosystems, attributed to complex species composition, extensive forest areas, insufficient
19 field measurements, and inadequate methods. To address these challenges, we developed a framework that combines machine
20 learning algorithms (MLAs) and remote sensing time series analysis for estimating the age of China's forests. Initially, we
21 identify and develop the optimal MLAs for forest age estimation across various vegetation divisions based on forest height,
22 climate, terrain, soil, and forest-age field measurements, utilizing these MLAs to ascertain forest age information. Subsequently,
23 we apply the LandTrendr time series analysis to detect forest disturbances from 1985 to 2020, with the time since the last
24 disturbance serving as a proxy for forest age. Ultimately, the forest age data derived from LandTrendr is integrated with the
25 result of MLAs to produce the 2020 forest age map of China. Validation against independent field plots yielded an R^2 ranging
26 from 0.51 to 0.63. On a national scale, the average forest age is 56.1 years (standard deviation of 32.7 years). The Qinghai-
27 Tibet Plateau alpine vegetation zone possesses the oldest forest with an average of 138.0 years, whereas the forest in the warm
28 temperate deciduous-broadleaf forest vegetation zone averages only 28.5 years. This 30-m-resolution forest age map offers
29 crucial insights for comprehensively understanding the ecological benefits of China's forests and to sustainably manage
30 China's forest resources. The map is available at <http://dx.doi.org/10.5281/zenodo.8354262> (Cheng et al., 2023b).

31 1 Introduction

32 Forest age is crucial for gaining insights into forest ecosystem succession and condition, thereby playing a pivotal role in
33 comprehending the ecological benefits of forests (Lin et al., 2023). China's forests have undergone significant disruptions due

34 to natural disasters and human activities over the past few decades, leading to notable changes in the forest age structure (Niu
35 et al., 2023). Consequently, this scenario presents considerable challenges in accurately assessing forest ecosystem carbon
36 storage (Pan et al., 2011; Tong et al., 2020). The complexity of species composition, extensive forest areas, limited field
37 measurements, and ineffective methods have led to existing national-scale estimates of China's forest age focusing on either
38 sparse resolution (Zhang et al., 2017) or partial forest ecosystem coverage (Xiao et al., 2023). This has resulted in significant
39 uncertainties in evaluating the carbon sources and sinks within China's forest ecosystem (Piao et al., 2022; Wang et al., 2022).
40 Therefore, there is an urgent requirement for time-efficient, high-resolution mapping of forest age across China.

41 At present, China's forest age data is primarily obtained through the national forest inventory with its high accuracy (Xiao et
42 al., 2023), but this method requires extensive labour and material resources, making it time-consuming and costly (Liu et al.,
43 2022). Additionally, most of China's forests are rugged mountainous areas that are difficult to access (Cheng et al., 2023a),
44 which limits the survey range and uneven distribution of field samples, making it difficult to estimate the age of China's forests
45 on a national scale. Thus, the traditional forest inventory method struggles to accurately and timely capture the complete age
46 distribution and spatial characteristics of China's forests.

47 Remote sensing technology has demonstrated effectiveness in estimating forest cover (Su et al., 2020; Tubiello et al., 2023)
48 and forest structure (Yu et al., 2020; Maltman et al., 2023) across various scales. The availability and sharing of Landsat time
49 series data, along with the development of Google Earth Engine (GEE) cloud-processing platform have significantly facilitated
50 the application of remote sensing in forest age estimation. Several studies have been conducted to map China's forest age.
51 Xiao et al. (2023) mapped the age of China's young forests at 30 m resolution using time series Landsat imagery. Yu et al.
52 (2020) produced a 1-km resolution map of the age for planted forests in China. Zhang et al. (2017) developed a 1km stand age
53 map using climate and forest height data. Zhang et al. (2014) mapped a national forest age map with 1 km resolution by using
54 remote-sensing forest height and forest type data. However, the existing China's forest age maps are typically undertaken at
55 coarser spatial resolutions (e.g., 1 km), with finer resolutions (e.g., 30 m) being limited to young forests. There remains a lack
56 of high-resolution forest age spatial dataset covering the entire forest region of China.

57 Statistical models and disturbance detection approaches are two common methods utilized in remote sensing-based forest age
58 estimations. Statistical models deduce forest age by establishing a coherent relationship between remote sensing features and
59 field-collected empirical samples, including parametric regression approaches (Maltamo et al., 2020; Schumacher et al., 2020)
60 and nonparametric machine learning algorithms (MLAs). Growth models represent one of the most widely used parametric
61 models for estimating forest age (Zhang et al., 2014; Zhang et al., 2017; Yu et al., 2020). However, this type of model relies
62 on tree species information, posing challenges in forest age derivation when such data is lacking, particularly at large scales.
63 MLAs has been employed for forest age estimation, owing to their flexibility in addressing complex problems (Alerskans et
64 al., 2022). For examples, Huang et al (2023) integrated random forest (RF) to derived forest age. Chen et al (2016) mapped
65 forest stand age dynamics using RF and Landsat imagery. Nevertheless, the application of MLAs to estimate national forest
66 age has not been deeply explored. Most previous studies used a single MLA, such as RF (Besnard et al., 2021b), to estimate
67 forest age. The extensive distribution of forests, diverse forest types, and varying terrain and climate conditions in China make

68 it difficult in using a single model for accurately forest age determination on national scale. Therefore, exploring the
69 applicability of MLAs for forest age estimation in various regions of China is essential.

70 Disturbance detection approaches, capable of identifying the time of the most recent stand-replacing disturbance, have proven
71 accurate in forest age estimation (Li et al. 2024). These approaches mainly include Landsat-based Detection of Trends in
72 Disturbance and Recovery (LandTrendr) (Kennedy et al. 2010), Continuous Change Detection and Classification (CCDC)
73 (Zhu and Woodcock 2014), the Vegetation Change Tracker (VCT) (Huang et al. 2010), Breaks for Additive Season and Trend
74 (BFAST) (Verbesselt et al. 2010a; Verbesselt et al. 2010b). Among these algorithms, LandTrendr has been recognized for its
75 efficiency in detecting forest disturbances such as fire, deforestation, and urban expansion (de Jong et al. 2021; Rodman et al.
76 2021). For instance, Li et al (2024) mapped planted forest age using LandTrendr algorithm, demonstrating its efficiency and
77 reliable for forest age mapping. However, these approaches are limited to obtaining forest age in areas with disturbance
78 recorded by remote sensing, thus restricting a comprehensive understanding of forest age structures. Consequently, it is
79 necessary to develop a framework that can provide comprehensive forest age information on a large scale.

80 The objective of the present study is to generate the first China's forest age dataset at 30 m resolution using multi-source
81 datasets through combining remote sensing time series analysis and MLAs. This involves: 1) identifying the most optimal
82 MLAs for age estimation across various vegetation zones in China and estimating the age of China's forests. 2) Utilizing
83 LandTrendr disturbance detection algorithm to identify the most recent forest disturbances from 1985 to 2020, and estimating
84 the forest of these disturbed areas. 3) Using the forest age derived by LandTrendr algorithm to update the result of MLAs to
85 generate China's forest age map, which is then subjected to validation. The generated 30 m resolution forest age map provides
86 critical information to quantify forest carbon storage and to sustainably manage China's forests.

87 **2 Materials and methods**

88 **2.1 Dataset and pre-processing**

89 **2.1.1 Forest inventory data**

90 The data from China's seventh national forest inventory survey from 2004 to 2008 (<http://www.forestry.gov.cn/>) were
91 collected to develop models to estimate forest age. The inventory involves systematically and accurately monitoring the
92 national forest resources based on 667 m² sample plots covering the whole country (Ren et al., 2011). The main information
93 collected from the sample plots are tree species, stand age, average tree height, and geographic location. The stand age is
94 determined based on the planting time or is estimated using tree diameter at breast height (Zhang et al., 2017). We totally
95 collected 58,033 field plots ranging in age from 1 to 480 years (Figures 1b and 1c). The mean age of the samples is 34.0 years,
96 with a standard deviation of 29.6 years. The sample plots were distributed across eight vegetation divisions (Liu et al. 2022)
97 (Figure 1b), each containing at least 436 sample plots for building MLAs to estimate forest age (Figure 1d).

98
 99 **Figure 1: Forest mask and field sample distribution.** (a) Planted forest and natural forest mask generated by Cheng et al. (2023a).
 100 (b) Distribution of field samples over eight vegetation divisions. (c) Frequency distribution of field sample ages. (d) Frequency
 101 distribution of field samples for eight vegetation divisions. PF: planted forest, NF: natural forest, CT: Cold Temperate needleleaf
 102 forest, WT: Warm Temperate deciduous-broadleaf forest, QT: Qinghai-Tibet Plateau alpine vegetation, TM: Tropical Monsoon
 103 forest-rainforest, TS: Temperate Steppe, TD: Temperate Desert, TN: Temperate Needleleaf-broadleaf mixed forest, SE: Subtropical
 104 Evergreen broadleaf forest. N: the number of plots, Std: standard deviation, Mean: mean age.

105 2.1.2 Landsat time-series data

106 From the GEE platform, we collected Landsat TM, ETM+, OLI Tier 1 surface reflectance images dating from 1985 to 2020
 107 to estimate forest age for disturbed forest regions. All data were atmospherically corrected and processed by the Land Surface
 108 Reflectance Code and the Landsat Ecosystem Disturbance Adaptive Processing System algorithms. We removed the clouds
 109 or cloud shadows using the C function of the mask algorithm (Du et al., 2023), then we created composited images using a
 110 median compositing method for forest regions. Finally, we calculated the normalized burn ratio (NBR) to detect forest
 111 disturbance. NBR has been proved effective in numerous studies detecting forest disturbance (Du et al., 2023; Tian et al.,
 112 2023). It is calculated as follows by using the near-infrared (NIR) and short-wave infrared (SWIR) bands:

$$NBR = \frac{NIR - SWIR}{NIR + SWIR} \quad (1)$$

113 **2.1.3 Forest mask**

114 This study uses the 2020 dataset of planted and natural forests at 30 m resolution in China (Figure 1a) as a mask for forest age
115 mapping. This dataset is produced by integrating multisource remote-sensing data and a large number of crowdsourced samples,
116 with an overall accuracy of over 80% (Cheng et al., 2023a). In this study, we employ this dataset as a forest mask and utilize
117 a combination of time series change detection algorithms and MLAs to trace the age of these planted and natural forests.

118 **2.1.4 Forest height data**

119 The canopy height data for China was downloaded from the website (<https://3decology.org/>), which was generated based on
120 deep learning by integrating Global Ecosystem Dynamics Investigation and Ice, Cloud and land Elevation Satellite -2 data.
121 This dataset has a spatial resolution of 30 m and corresponds to 2019. The accuracy of this national forest canopy height data
122 was assessed by comparing three independent validation datasets, indicating high accuracy for the canopy height product by
123 neural network guided interpolation ($R^2 \geq 0.55$, $RMSE \leq 5.5$ m) (Liu et al., 2022). Notably, the forest extent used in this dataset
124 is consistent with the forest extent mentioned earlier for planted and natural forests, ensuring spatial consistency when
125 estimating forest age.

126 **2.1.5 Climate data**

127 Climate data were acquired from WorldClim 2.1 (<https://worldclim.org/>), which offers 19 bioclimatic variables, including
128 temperature and precipitation, with 30 arc-second resolution. The 19 bioclimatic variables include annual trends, seasonality,
129 and extreme environmental factors in temperature and precipitation. We resampled the 19 GeoTiff (.tif) files to 30 m resolution
130 using a nearest-resampling method for spatial resolution consistency. To reduce the dimension of bioclimatic variables, we
131 applied a principal component analysis to map the 19 bioclimatic variables into a new principal component (PC) space. We
132 use the first three components PC1, PC2, PC3 to represent the climate factors. According to the results of the analysis, PC1
133 gives annual trends in temperature and precipitation, PC2 gives seasonal variations in temperature and precipitation, and PC3
134 gives precipitation and temperature extremes (Supplementary Table 1).

135 **2.1.6 Soil data**

136 Soil data were extracted from the harmonized world soil database, V1.2, developed jointly by the Food and Agriculture
137 Organization of the United Nations, the International Institute for Applied Systems, the ISRIC-World Soil Information, the
138 Institute of Soil Science, Chinese Academy of Sciences, and the Joint Research Centre of the European Commission with a
139 resolution of 30 arc-seconds. As per previous studies, soil type and texture were selected from the soil dataset in this study to

140 construct the model to estimate forest age (Besnard et al., 2021). We also resampled the soil data to 30 m using a nearest-
141 resampling method.

142 2.1.7 Topographic data

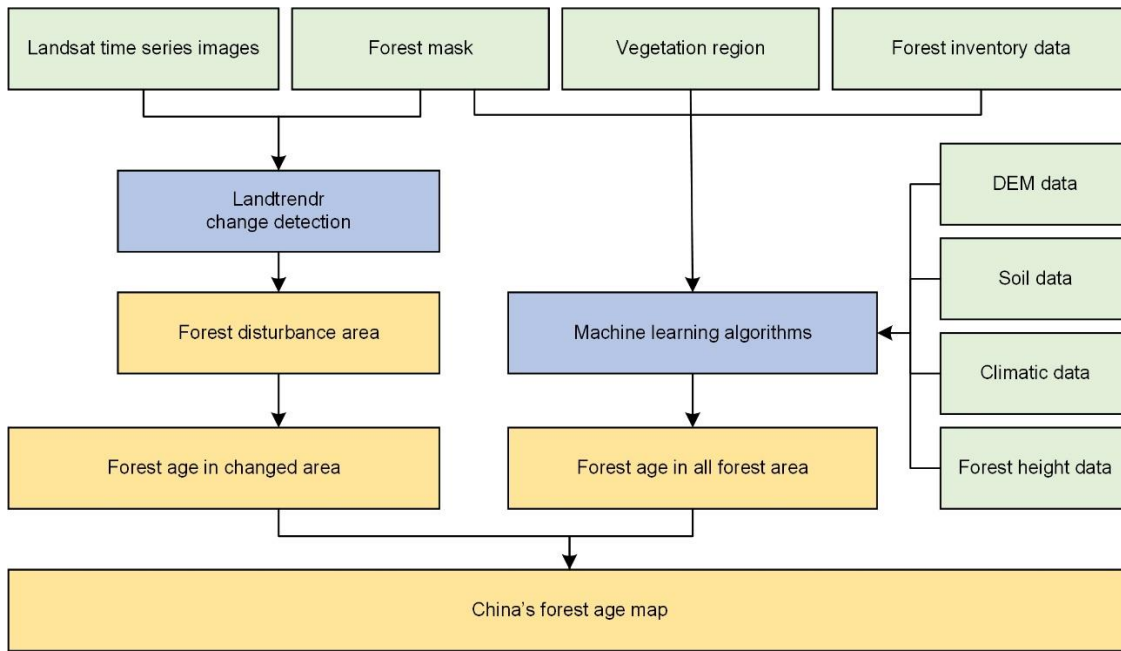

143 The Shuttle Radar Topography Mission (SRTM) V3 provides global digital elevation data at 30 m resolution and was used in
144 this study to extract topographic variables (Su et al., 2020). Three topographic features, elevation, slope, and aspect, were
145 calculated to estimate forest ages.

146 **Table 1.** Descriptions of variables used to estimate the forest age of China.

| Data type | Data source | Resolution | Time | Variables |
|---------------------------|--|---------------|-----------|------------------------------|
| Remote sensing images | Landsat TM/ETM+/OLI | 30 m | 1985–2020 | NBR |
| Forest mask | Planted and natural forest map (Cheng et al., 2023a) | 30 m | 2020 | Planted and natural forest |
| Forest canopy height data | NNGI-Forest Canopy Height | 30 m | 2019 | Forest height |
| Climate data | WorldClim version 2.1 (Fick and Hijmans 2017) | 30 arc-second | 1970–2000 | PC1, PC2, PC3 |
| Soil data | Harmonized World Soil Database V1.2(https://www.fao.org/soils-portal/data-hub/soil-maps-and-databases/harmonized-world-soil-database-v12/en/) | 30 arc-second | 1971–1981 | Soil type, soil texture |
| Topographic data | SRTM DEM | 30 m | 2000 | Elevation, slope, and aspect |

147 2.2 Forest age estimation

148 To generate China’s forest age map and explore the performance of MLAs to retrieve forest age, we applied two approaches
149 to estimate forest age in China: The MLAs approach and the LandTrendr disturbance detection approach. First, the MLAs
150 approach estimates ages for forest regions using forest inventory and multi-source remote sensing data. Second, the
151 LandTrendr algorithm is applied to detect stand-replacing disturbances based on the Landsat time series images. Third, we use
152 the forest age map detected by LandTrendr to update the forest age map derived using MLAs approach, and generate the
153 China’s forest age map with 30 m resolution. Figure 2 shows a detailed framework for forest age estimation proposed in this
154 study.

155

156 **Figure 2: Framework of China's forest age estimation.**

157 **2.2.1 Machine learning approach**

158 **(1) MLAs selection**

159 This study used the following model-screening procedure to explore which model works best for each vegetation division.
 160 First, we used the automated machine learning (Auto-ML) open-source Python library LazyPredict to filter for alternative
 161 models. LazyRegressor (including 40 MLAs) was used to build stand-age estimation models based on all data, which helps to
 162 understand which MLA works well without tuning parameters. The performing models with R^2 greater than 0.60 in each
 163 vegetation division were concentrated in thirteen MLAs (Supplementary Table 2). Second, by splitting training data and testing
 164 data, the top three MLAs for each vegetation division were determined (Supplementary Table 2). It can be found that the
 165 potential optimal models of eight vegetation divisions were concentrated in RF, Gradient Boosting Decision Tree (GBDT),
 166 Histogram Gradient Boosting (HistGradientBoost), Light Gradient Boosting Machine (LightGBM), and Categorical Boosting
 167 (CatBoost).

168 RF is an ensemble learning method that combines multiple decision trees (Breiman 2001; Dutta et al., 2020). It leverages the
 169 wisdom of crowds to make accurate predictions. RF mitigates overfitting and provides robust results by training each tree on
 170 a random subset of the data and features (Lavanya et al., 2017; Guo et al., 2019). GBDT is an ensemble technique that builds
 171 a strong predictive model by sequentially training decision trees (Jerome 2001). Each tree corrects the errors of its predecessor
 172 (Wei et al., 2019), resulting in a highly accurate and robust model. HistGradientBoost is a variant of GBDT that employs
 173 histogram-based techniques. It efficiently approximates data distributions and reduces memory consumption during training.
 174 This algorithm is particularly beneficial when dealing with large datasets and complex features (Teshfagerish et al., 2022).

175 LightGBM is a gradient-boosting framework that prioritizes speed and efficiency. It employs a histogram-based approach and
176 parallel computing, making it suitable for large datasets. CatBoost, as a new modification gradient boosting algorithm, is
177 designed specifically for handling categorical features. It automatically encodes categorical variables, simplifying the data pre-
178 processing stage. CatBoost is known for its robustness and efficiency, can achieve high accuracy on a small-scale dataset.
179 We implemented RF, GBDT, and HistGradientBoost by using the Scikit-learn package, while the LightGBM and CatBoost
180 algorithms were constructed by using the lightgbm and catboost packages in Python 3.9.11.

181 **(2) Hyperparameter tuning**

182 Hyperparameter tuning of MLAs is critical in the ML model training process because it significantly enhances the model's
183 performance, generalization capability, and adaptability (Sandha et al., 2020). Bayesian optimization has been selected for
184 hyperparameter tuning due to its complicated derivative evaluation, and nonconvex-function-related features (Mekruksavanich
185 et al., 2022). It is implemented by using Optuna, an open source hyperparameter optimization framework to automate
186 hyperparameter searches (Akiba et al., 2019). The hyperparameters and their searching range in MLAs are listed in
187 Supplementary Table 3.

188 **(3) Model interpretation**

189 Furthermore, we used Shapley Additive explanations (SHAP) values (Lundberg and Lee, 2017; Lundberg et al., 2019), a
190 model-agnostic technique for interpreting ML models, to explore functional correlations between the variables and forest age
191 (Besnard et al. 2021). SHAP derives the Shapely additive contribution values from coalitional game theory (Kim et al. 2023).
192 By examining the contribution of each input variable to the model's output, SHAP can identify the primary drivers of the
193 model's predictions and provide insights into the underlying causes that influence forest age (Sun et al. 2023). The higher the
194 SHAP value, the larger the contribution of the variable. Here SHAP value was calculated through *shap* package in Python
195 3.9.11.

196 **2.2.2 LandTrendr disturbance detection approach**

197 LandTrendr was designed to detect and analyse changes in surface features, particularly disturbances and recovery processes,
198 and is commonly applied to multispectral remote sensing imagery from the Landsat satellite series to capture long-term forest
199 disturbances (Du et al., 2022). Using LandTrendr to detect forest age involves the following steps:

200 **(1) Time series data transformation**

201 LandTrendr transforms multiple temporal remote-sensing image datasets into a series of indices, such as the NBR.

202 **(2) Breakpoint detection**

203 Using the generated time series indices, LandTrendr retraces from the 2020 state to search breakpoints in the time series. These
204 breakpoints represent transition points in the time series, indicating instances of surface disturbance or recovery.

205 **(3) Age estimation**

206 By pinpointing breakpoints, the time of occurrence for each breakpoint is established. Forest age estimates for the current
207 location are accomplished by subtracting the breakpoint time from the latest time.

208 LandTrendr was implemented on the GEE platform by using the function of *runLT()* provided by the LT_GEE API (Kennedy
 209 et al., 2018). Table 2 lists the main input parameters.

210 **Table 2.** Parameters of LandTrendr used in this study.

| Parameters | Definition | Value |
|------------------------|---|-------|
| maxSegments | Maximum number of segments to be fitted on the time series | 10 |
| spikeThreshold | Threshold for dampening the spikes (1.0 means no dampening) | 0.9 |
| vertexCountOvershoot | The initial model can overshoot the maxSegments + 1 vertices by this amount. Later, it will be pruned down to maxSegments + 1 | 3 |
| preventOneYearRecovery | Prevent segments that represent one-year recoveries | False |
| recoveryThreshold | If a segment has a recovery rate faster than 1/recovery threshold (in years), then the segment is disallowed | 0.25 |
| pvalThreshold | If the <i>p</i> -value of the fitted model exceeds this threshold, then the current model is discarded and another one is fit by using the Levenberg–Marquardt optimizer | 0.05 |
| bestModelProportion | Takes the model with most vertices that has a <i>p</i> -value that is at most this fraction away from the model with the lowest <i>p</i> -value | 0.75 |
| minObservationsNeeded | Minimum observations required to perform output fitting | 6 |

211 2.2.3 Mapping China’s forest age

212 Given the extensive forest coverage in China, it is challenging to handle such large forest area for ML and the LandTrendr
 213 algorithm to estimate forest age, even with our vegetation zoning efforts. To enhance the efficiency of forest age estimation
 214 and conserve computational resources, we have divided China into $1^{\circ} \times 1^{\circ}$ grids (see Supplementary Figure 2), limiting ML
 215 and LandTrendr algorithms to estimate forest age within each grid. Subsequently, we merge the predictive results from each
 216 grid using the Mosaic New Raster tool in ArcGIS Pro 3.0 to obtain nationwide forest age map. Finally, the forest age map
 217 estimated through LandTrendr algorithm is applied to update the ML-based results to produce China's forest age data.

218 2.3 Accuracy assessment

219 2.3.1 Comparison with field samples

220 We collected field samples through two sources to validate the generated final forest age map. The first is the forest inventory
 221 samples independent of training data. The second source involves validation samples obtained from the literatures. To ensure
 222 the samples collected were representative, we excluded samples dated before 2010. As validation metrics, we used the
 223 coefficient of determination (R^2), the root mean square error (RMSE), the mean absolute error (MAE), and the mean error
 224 (ME). These are given mathematically as

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y}_i)^2}, \quad (2)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2}, \quad (3)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i|, \quad (5)$$

$$ME = \frac{\sum_{i=1}^n (y_i - \bar{y}_i)}{n}, \quad (6)$$

225 where y_i is the observed value for the i th analytic tree, \hat{y}_i is the predicted value of the i th observed value, n is the number of
 226 trees, and \bar{y}_i is the mean of the observed value.

227 2.3.2 Comparison with existing forest age data

228 To make our forest age map more reliable and comparable, we also downloaded global forest age data product produced by
 229 Besnard et al. (2021a), which is the only forest age map that can be publicly accessible covering entire China's forests. Then,
 230 we resampled our result to the same resolution as this global map, and compared our resultant forest age map with it by
 231 assessing their differences in each cell. Additionally, we also collected estimated average forest ages of China by previous
 232 studies, and using these statistical numbers to further validate our estimation.

233 3 Results

234 3.1 MLAs performance for China's forest age estimation

235 Through a rigorous hyperparameter-optimization process and independent validation, four distinct MLAs (RF, GBDT,
 236 LightGBM, and CatBoost) were selected across eight different vegetation divisions (Table 3). GBDT performed exceptionally
 237 well for estimating the forest age of cold temperate needleleaf forest (CT) vegetation zone, producing R^2 of 0.47 and RMSE
 238 of 4.95 years (MAE=17.99, ME=-1.86). RF excelled at estimating the forest age of warm temperate deciduous-broadleaf forest
 239 (WT) vegetation zone, producing an independent validation R^2 of 0.61 and RMSE of 3.47 years (MAE=9.13, ME=-0.01).
 240 CatBoost consistently demonstrated strong performance for the Qinghai-Tibet Plateau alpine vegetation (QT), tropical
 241 monsoon forest-rainforest (TM), temperate steppe (TS), temperate desert (TD), and subtropical evergreen broadleaf forest (SE)
 242 zones, with R^2 values ranging from 0.57 to 0.85 and RMSE values from 2.04 to 7.65 years. LGBMRegressor was the preferred
 243 choice in the temperate needleleaf-broadleaf mixed forest (TN) vegetation division, yielding an R^2 of 0.63 and an RMSE of
 244 4.14 years.

245 **Table 3.** MLAs for eight vegetation divisions and their validation metrics.

| Vegetation division | Algorithm | R^2 | RMSE | MAE | ME |
|---------------------|-----------|-------|------|-----|----|
|---------------------|-----------|-------|------|-----|----|

| | | | | | |
|----|---------------|------|------|-------|-------|
| CT | GradientBoost | 0.47 | 4.95 | 17.99 | -1.86 |
| WT | RF | 0.61 | 3.47 | 9.13 | -0.01 |
| QT | CatBoost | 0.57 | 7.65 | 42.58 | 10.43 |
| TM | CatBoost | 0.85 | 2.04 | 1.34 | -0.08 |
| TS | CatBoost | 0.78 | 4.16 | 11.85 | -0.87 |
| TD | CatBoost | 0.80 | 5.33 | 21.02 | 1.84 |
| TN | LGBM | 0.63 | 4.14 | 12.78 | 0.36 |
| SE | CatBoost | 0.70 | 3.49 | 7.97 | 0.00 |

246 Note: CT: cold temperate needleleaf forest, WT: warm temperate deciduous-broadleaf forest, TM: tropical monsoon forest-rainforest, QT:
247 Qinghai-Tibet Plateau alpine vegetation, TN: temperate needleleaf-broadleaf mixed forest, TS: temperate steppe, TD: temperate desert, SE:
248 subtropical evergreen broadleaf forest.

249 We further analysed the factors influencing the forest age estimation in each vegetation division, and the findings are illustrated
250 in Figure 3. While the prioritization of factors affecting forest age estimation varies across different vegetation divisions,
251 canopy height is unquestionably the predominant factor influencing this estimation. Its absolute value is the highest of the CT,
252 WT, TN, TS, and TM vegetation zones (Figure 3). Moreover, it is among the top three most influential factors in all the
253 remaining vegetation zones. Subsequently, topographical conditions assume prominence, with elevation consistently featuring
254 among the top three factors in the SHAP value across all vegetation divisions. In the TD vegetation division, elevation becomes
255 the most influential factor. Climate factors earn third-tier consideration, particularly in the SE vegetation zone, where the
256 impact of PC2 of the climate factors surpasses that of both canopy height and topographical conditions. In the other vegetation
257 divisions, the influence of climate factors generally falls to the mid-range. In contrast, across all eight vegetation divisions,
258 factors related to soil, such as soil type and soil texture, do not exert a pronounced influence on forest age estimation.

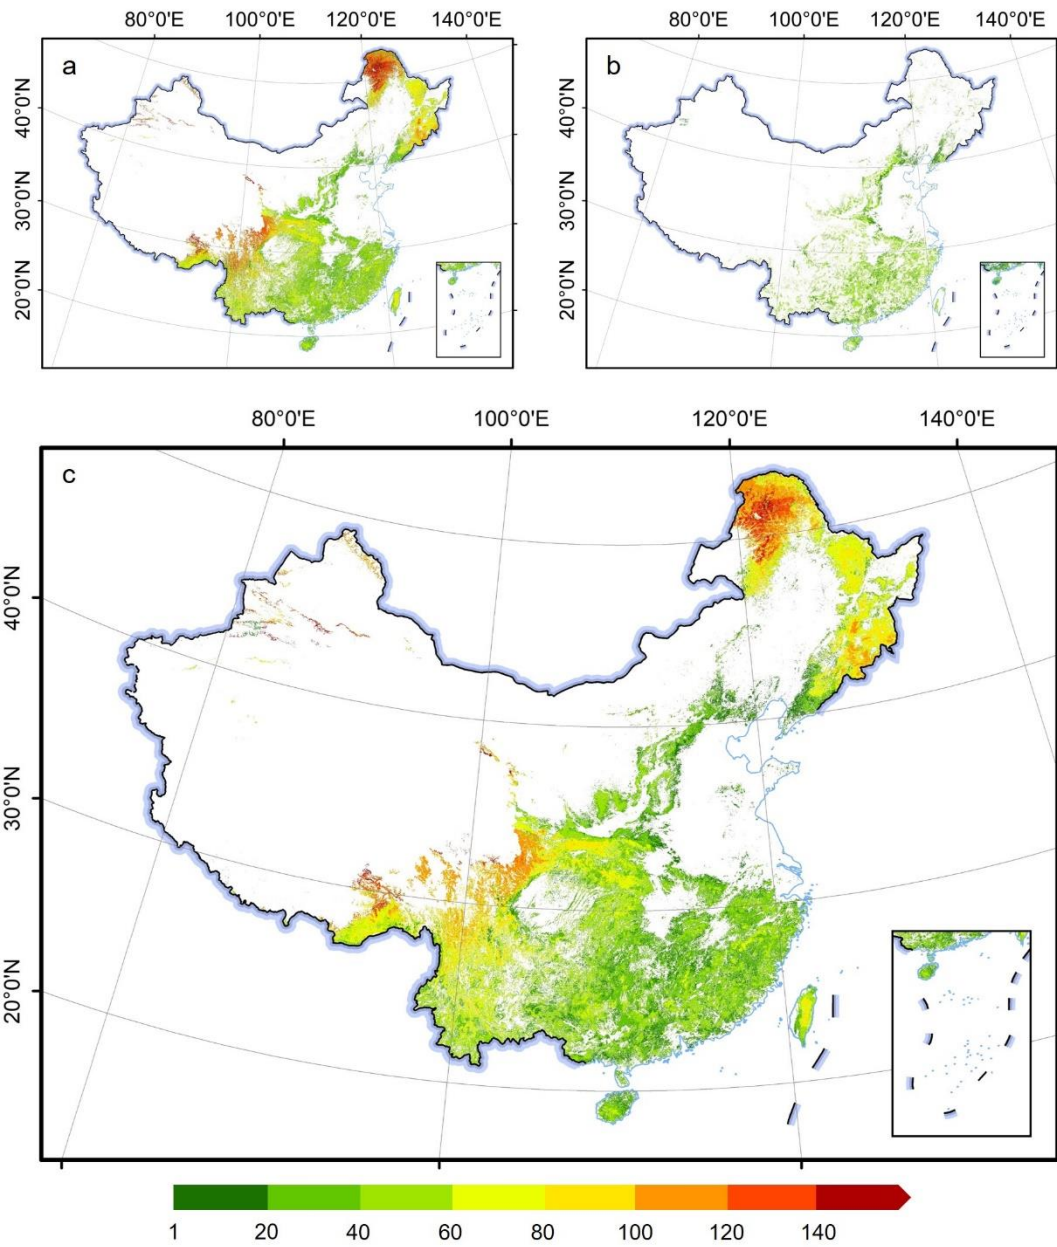

259

260 **Figure 3: Order of shape values of factors affecting the estimation of forest age in different vegetation zones**

261 3.2 China's forest age map

262 Based on the optimal MLAs and the LandTrendr change detection algorithm, we have obtained forest age data for China as
263 shown in Figure 4. Figure 4a presents the nationwide distribution of forest age as estimated by MLAs, whereas Figure 4b
264 displays the age distribution from 1985 and 2020 as determined through change detection. The results reveal that reforestation
265 activities from 1985 and 2020 are primarily situated in the southern, southeastern, and northern China, aligning with the
266 findings from Xiao et al (2023). Furthermore, estimates derived from MLAs indicate that old-growth forests are primarily
267 located in the northeast and southwest regions of China.

268 The final forest age map for China obtained in this study is depicted in Figure 4c. Statistically, the mean of the estimated
269 China's forest age is 56.11 years with a standard deviation of 32.67 years. Geographically, forests in northeast and southwest
270 China are relatively older than those in other regions (Figure 4c). At the provincial scale, the average forest age ranges from
271 3.9 to 116.8 years (Figure 5a, Supplementary Table 6), whereas Qinghai province has the highest mean forest age, and Hong
272 Kong has the lowest mean forest age. Forest ages in Sichuan province are more varied than in other provinces (Figure 5a). On
273 the regional scale, the QT vegetation zones have the oldest forests with an average of 138.0 years, followed by CT (107.6
274 years), TS (107.0 years), TN (68.3 years), TD (60.3 years), TM (53.0 years), and SE (49.2 years) (Figure 5b, Supplementary
275 Table 7). The WT vegetation zones have the youngest forests (28.5 years).

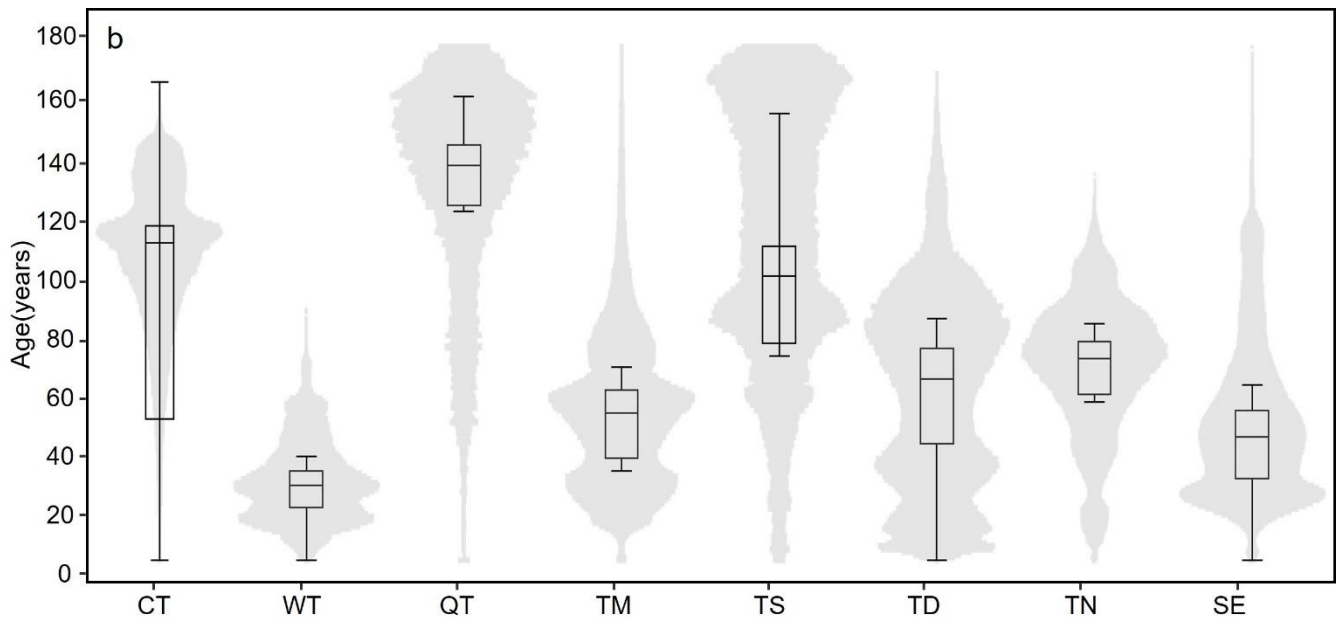

276

277 **Figure 4: Forest age estimated from LandTrendr (a), MLAs (b), and final China's forest age distribution (c) with 30 m resolution.**

278

279

280 **Figure 5: (a) Boxplot of China's forest age grouped by provinces (b) Violin plot of the forest age grouped by vegetation divisions.**

281 3.3 Evaluation

282 3.3.1 Comparison with field samples

283 We initially validated the forest age estimations by using forest inventory data. The forest inventory samples were acquired
284 from 2004 to 2008. To align with the time frame of the forest age data obtained in this study, we shifted the predicted values
285 corresponding to each sample forward by ~16 years. This strategy allows us to compare them with the inventory-measured
286 forest ages. Figure 6a shows the comparison, which suggests that they have a significant linear relationship with $R^2 = 0.51$
287 (Figure 6a). We collected 99 field measurements of mean forest stand age after 2010 from published papers (Supplementary
288 Table 8) and compared them with our estimated results. Figure 6b shows that the predicted forest ages also present a significant
289 linear relationship with field measurements, with $R^2 = 0.62$.

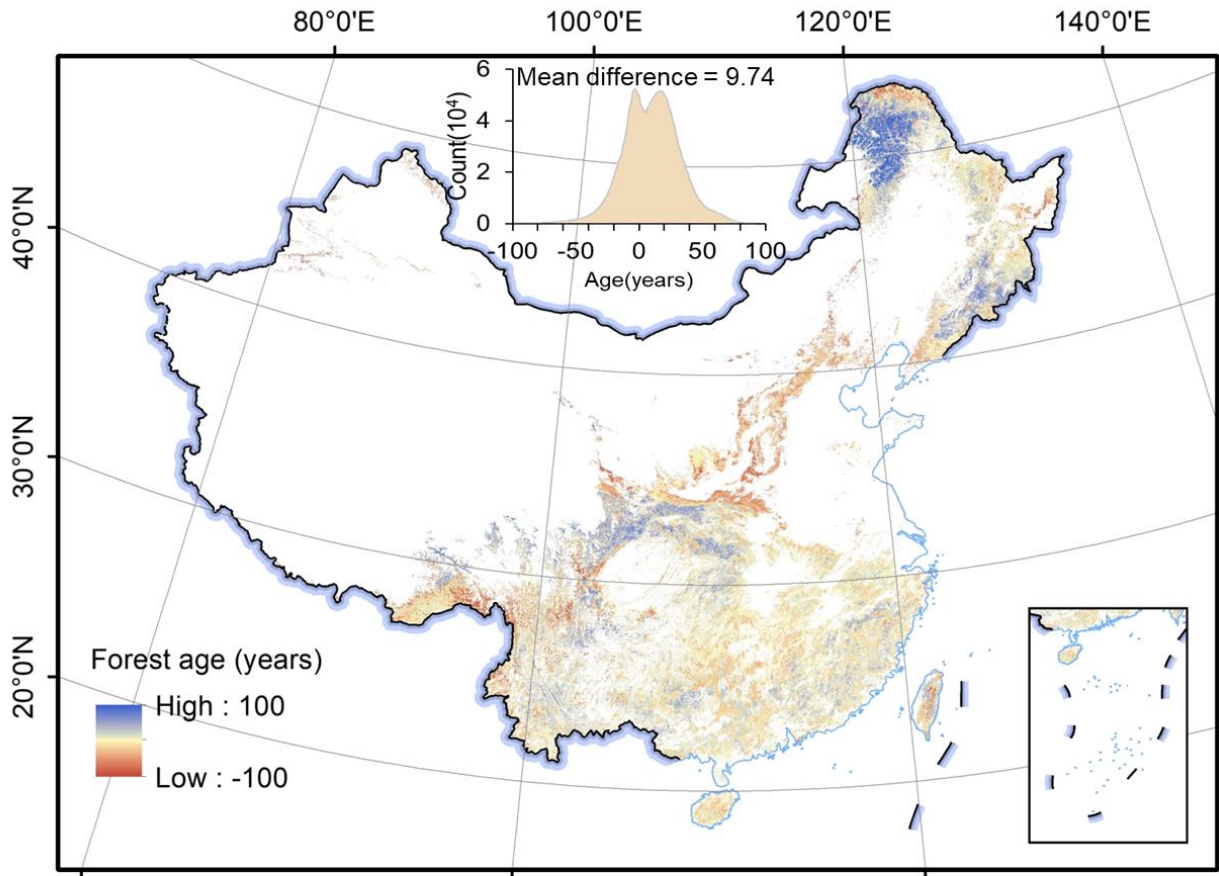

291

292 **Figure 6: Scatter plots of (a) forest inventory age vs. predicted forest age for this study and (b) field measurements of forest stand**
293 **age collected from published papers vs predicted forest.**

294 3.3.2 Comparison with existing forest age map

295 Figure 7 shows the difference between our estimation and existing global forest age map, which suggests an average difference
296 of 9.7 years. Our mapped forest age shows older forests in the northeast regions but younger forests in the central regions
297 compared to the dataset from Besnard et al. (2021a) dataset. In addition, we gathered the existing forest age maps over China
298 from published datasets and compared their average forest age with our results (Table 4). According to the available data, the
299 average forest age in China ranged from 40 to 43 years between 2000 and 2013, corresponding to approximately 50 to 53 years

300 in 2020. This aligns with the average forest age of 56.1 years obtained in this study for the year of 2020, further underscoring
 301 the reliability of the forest age mapped in this study.

302
 303 **Figure 7: Comparison with global forest age product. The inset at the top left shows the frequency distribution of differences between**
 304 **the global forest age map and our estimated forest age map.**

305 **Table 4.** China's mean forest age collected from published papers.

| Source | Mean forest age (years) | Resolution | Mapping year |
|---------------------|-------------------------|------------|--------------|
| Zhang et al. (2017) | 42.6 | 1 km | 2013 |
| Zhang et al. (2014) | 43 | 1 km | 2005 |
| Dai Ming (2011) | 40.6 | 8 km | 1998 |
| Wang et al. (2007) | <40 | 1 km | 2001 |
| Xia et al. (2023) | 44.0 | 1 km | 2015 |
| This study | 56.1 | 30 m | 2020 |

306 4 Discussion

307 A high-spatial resolution forest age map is an important input for accurately quantifying forest carbon storage and its potential.
308 Despite the generation of several forest age maps for China in recent decades, their spatial resolution is relatively coarse,
309 typically ranging from 1 km to 8 km (e.g., Zhang et al., 2014; Zhang et al., 2017). This resolution does not meet the application
310 requirements for local-to-regional scales (Xiao et al., 2023). Therefore, we generated a 30 m resolution forest age map of China
311 using remote sensing and inventory data for 2020. Validation against independent forest inventory samples, field
312 measurements collected from published papers, and existing forest age products indicate that the estimated forest age map has
313 R^2 of 0.51 to 0.62, and presented high spatial agreement with the existing forest age products. Such a high-resolution and
314 timely forest age dataset is vital to assess ecological benefits of China's forests and to manage forest resources for sustainable
315 development.

316 The generated forest age map indicates that 40.08% of forests are younger than 40 years, 38.11% are 41–80 years old, and
317 21.81% are over 80 years old. Consistent with the findings of Zhang et al. (2017) and Zhang et al. (2014), our result shows
318 that the majority of China's forests are young, while the specific proportions exhibit some variance due to the variations in
319 produced time. Furthermore, similar to Zhang et al. (2017) and Zhang et al. (2014), forests younger than 40 years are primarily
320 in southern and eastern China, whereas forests older than 80 years are predominantly in northeastern and southwestern China
321 (Figure 4). We further analyse the forest age by using China's planted and natural forest mask generated by Cheng et al. (2023a)
322 for 2020. The results reveal that the average forest age for planted forests in China is 29.1 years with a standard deviation of
323 18.2 years, whereas natural forests have an average age of 69.7 years with a standard deviation of 30.6 years. This result aligns
324 with the reported 16.5 years for China's planted forests in 2005 (which equates to approximately 31 years in 2020) by Yu et
325 al. (2020).

326 This study combines two methods to estimate forest age across China. We first investigate in-depth the suitability of current
327 mainstream MLAs for estimating forest age. For each vegetation division, we establish the optimal MLAs and its optimal
328 parameters (Table 3, Supplementary Table 4). Of the established MLAs, the ensemble learning approaches perform best for
329 both training and evaluation compared with individual-based learners. Several previous studies support the idea that ensemble
330 techniques have achieved better performance than that of its base learners (e. g. Rodriguez et al., 2006; Banfield et al., 2007;
331 Canul-Reich et al., 2007; Rokach, 2009; De Stefano et al., 2011; Matloob et al., 2021). Bagging and boosting are two
332 mainstream ensemble techniques in ensemble learning that combine multiple base models to improve predictive performance.
333 Bagging reduces variance, whereas boosting reduces bias and improves overall model performance (Abbasi et al., 2022).
334 However, most previous studies focused on bagging-based RF models to derive forest structure parameters in remote sensing
335 fields (Simard et al., 2011; Cartus et al., 2012; Montesano et al., 2013; Matasci et al., 2018; Luther et al., 2019; Bolton et al.,
336 2020). The present study highlights that ensemble learning algorithms based on boosting, including GBDT, LightGBM, and
337 CatBoost, demonstrate higher accuracy in estimating China's forest age compared to the bagging-based RF algorithm.
338 Furthermore, within the current ensemble learning framework, the CatBoost algorithm based on boosting has a clear advantage

339 for estimating forest age in China (Table 3). It produces optimal results in five vegetation zones and is as accurate as the best-
340 performing algorithms in the remaining vegetation zones (Supplementary Table 5). Therefore, we recommend giving priority
341 to the utilization of the CatBoost algorithm in deriving the forest structural parameters in China.

342 In the process of machine learning modelling for forest age estimation, we selected a total of 10 features, including canopy
343 height, meteorological factors, soil factors, terrain factors, and human activities. Factor analysis indicates that canopy height
344 has significantly influence forest age modelling, which is consistent with previous research, such as Zhang et al. (2017), who
345 estimated forest age in China based on the relationship between canopy height and forest age. The main reason is that canopy
346 height is typically correlated with the growth period (Sharma and Parton, 2007; Schumacher et al., 2020; Lin et al., 2023).
347 Young trees usually have lower canopy height and, as trees age, canopy height gradually increases (Yu et al., 2020).
348 Therefore, canopy height gives clues about tree age, and many age-estimation models are based on forest height (Lin et al.,
349 2023). Terrain conditions also play important roles in all vegetation zones, especially the elevation and slope features (Figure
350 2). This is mainly because terrain factors are closely related to vegetation distribution, growth conditions, and hydrological
351 processes (Fernández-Martínez et al., 2014) and affecting forest age estimation (Lin et al., 2008). Climate factors, including
352 temperature and precipitation, also play a significant role in estimating forest age and have been applied to estimate global
353 forest age (Besnard et al., 2021). Climate elements are most pronounced in the SE and QT vegetation zones because these two
354 zones belong to areas with extreme climates and pronounced seasonal variations (Zhang et al., 2018). The SE region has a
355 warm and humid climate with abundant rainfall (Zhang et al., 2018), which aligns with seasonal growth, making it influential
356 in forest age estimation. The QT region experiences extreme temperature fluctuations, with extremely cold winters and short
357 and cool summers, significantly affecting tree growth rates and cycles (Zhang et al., 2021). Although soil and human activities
358 seem to have a relatively smaller impact in this study, the high accuracy achieved in this study is attributed to the combined
359 contributions of all factors.

360 The second method uses time-series remote sensing imagery and the LandTrendr algorithm to detect pixels that changed within
361 the forest extent from 1985 to 2020. The forest age was estimated according the time since the last disturbance serving as a
362 proxy for forest age. This approach has been extensively used to estimate forest age and is generally acknowledged to be
363 accurate and reliable for detecting disturbance (Hermosilla et al., 2016). For instance, Du et al. (2022) used the LandTrendr
364 algorithm to detect planting times of global planted forests, and Xiao et al. (2023) estimated the forest age of young forests in
365 China since 1984 by using the CCDC time-series algorithm. These successful cases validate the feasibility of using time-series
366 change-detection algorithms to estimate the age of disturbed forests. In this study, we compared our change-detection derived
367 forest age with the age of young forests provided by Xiao et al. (2023) (Figure 8). These two outcomes have a mean difference
368 of -3.79 years (Figure 8a) and have a significant linear relationship with $R^2 = 0.53$ (Figure 8b).

369

370 **Figure 8.** (a) Age difference and (b) linear relationship between estimated forest age and China’s Young Forest Age dataset generated by
 371 Xiao et al. (2023).

372 Overall, we produce a reliable forest age map for China. This forest age product has been validated by independent field
 373 samples and compared with existing datasets with a R^2 ranging from 0.51 to 0.62 (Figure 6). However, there is still a slight
 374 overestimation of younger forest and an underestimation of older forest compared with validation samples, which is mainly
 375 related to dataset and methods used in this study. In terms of dataset, primarily, the utilization of forest mask that delineate
 376 planted and natural forests introduces an inescapable source of uncertainty, which is particularly high (approximately 10%) in
 377 the southern regions of China (Cheng et al., 2023a). Furthermore, the dependence on canopy-height data generated by Liu et
 378 al. (2022) as the crucial determinant in forest age estimation (Figure 2) necessitates meticulous consideration (Zhang et al.,
 379 2017), giving the uncertainties in the canopy-height data ($R^2=0.55$) could strongly affect the accuracy in forest age modelling.
 380 Finally, when benchmarked against extant products, conspicuous disparities in forest age estimates appear within the
 381 northeastern and southwestern regions (Figure 7). These disparities, coupled with insights from forest inventory data, highlight
 382 the prevalence of older forests (exceeding 100 years) within these regions (Figure 4). The unique challenge posed by
 383 estimating the age of such older forests, characterized by sluggish growth rates (Maltman et al., 2023), accentuates the
 384 sensitivity to crown height data. Consequently, the uncertainty associated with canopy height data was conspicuously
 385 accentuated in these regions. Regarding to methods, we combined MLAs and disturbance detection approach to derive forest
 386 age. For MLAs, overfitting is a common challenge, where a model learns the training data too accurately but fails to generalize
 387 to unseen data (Belgiu and Drăguț 2016). The results (Supplementary Table 5) suggest that the constructed forest age models
 388 exhibit a certain degree of overfitting, which can cause some errors for forest age estimation. Addressing the issue of overfitting,
 389 data augmentation and exploring new deep learning algorithms may be a direction for further investigation. For LandTrendr

390 approach, it is affected by different parameters such as input bands, vegetation parameters (NBR index), climates, vegetation,
391 terrain and atmospheric conditions (Banskota et al. 2014; Hermosilla et al, 2015; Hua et al, 2021; Huang et al, 2023; Yang et
392 al, 2018). China's unprecedented development has led to extensive land cover changes, making it one of the most intensively
393 managed forest regions globally (Tong et al., 2020). This has resulted in significant forest fragmentation, posing challenges in
394 using NBR and other indices for change detection (Li et al 2024), and creating uncertainty in forest age identification.
395 Furthermore, while the LandTrendr algorithm effectively captures sharp disturbances like fires, clearcutting, and reforestation,
396 it falls short in detecting subtle changes such as silviculture and thinning (Huang et al. 2023; Zhu 2017), This limitation may
397 lead to the omission of young trees and an overestimation of forest age.

398 **5 Data availability**

399 The 30 m resolution forest age map of China generated by this study is openly available at
400 <https://doi.org/10.5281/zenodo.8354262> (Cheng et al., 2023b). Please contact the authors for more detailed information

401 **6 Conclusion**

402 High-resolution and spatially explicit forest age mapping for China play a crucial role in accurately quantifying the current
403 carbon sequestration of forest ecosystems and its future potential. Currently, available China's forest age data suffer from low
404 resolution and incomplete coverage of age ranges, making it difficult to meet the requirements of studies at various spatial
405 scales. Therefore, this study combines time-series analysis of remote sensing imagery with MLAs to create the first 30 m
406 resolution China's forest age map for the year of 2020. Validation against forest inventory data, field measurements, and
407 existing products demonstrates the R^2 values between 0.51 and 0.62. The estimated forest age data reveal an average forest
408 age of 56.1 years for China, with a standard deviation of 32.7 years. This dataset holds significant importance for understanding
409 the carbon source and sink dynamics in China's forest ecosystem.

410 **Author contributions**

411 KC, YC and QG designed the research. KC, YC, TX performed the analysis, KC and YC wrote the paper. QG, HY, and QM
412 supervised and reviewed the paper. HG and YR reviewed the manuscript. QG, KC, YC, WL collected the field measurements
413 and existing remote sensing products. KC and YC contributed equally to this work.

414 **Competing interests**

415 The contact author has declared that none of the authors has any competing interests.
