19

20 **Abstract:**

21 Climate warming and anthropogenic disturbances result in permafrost degradation
22 in cold regions, including in the Qilian Mountains. These changes lead to extensive
23 hillslope thermokarst (HT) formation, such as retrogressive thaw slumps, active-layer
24 detachment slides, and thermal erosion gullies. These in turn cause, e.g., degradation
25 of local vegetation, economic losses, infrastructure damages, and threats to human
26 safety. However, despite its importance, there is currently no thermokarst inventory
27 for the Qilian Mountains. Through manual visual interpretation and field validation,
28 we therefore produce the first quantification of HT features. We count a total of 1064
29 HT features, with 67% located in the upper reaches of the Heihe River Basin, which
30 encompasses ~13% of the Qilian Mountains region. We furthermore document that
31 82% of the HT was initiated in the last 10 years. The thermokarst terrain is observed
32 primarily in areas with shallow active layer depth, on northern shaded slopes of 3–25°,
33 with low solar radiation and moderate elevations ranging from 3200 to 4000 m. This
34 first inventory of HT features is an important and missing piece in documenting
35 changes on the Qinghai-Tibetan Plateau, and this new dataset also provides an
36 important basis for further studies on, e.g., quantitative assessment losses caused by
37 HT. The datasets are available from the National Tibetan Plateau/Third Pole
38 Environment Data Center and can be downloaded from
39 <https://doi.org/10.11888/Cryos.tpd.300805> (Peng and Yang, 2023).

40 1 Introduction

41 The Qilian Mountains are located in the northeastern part of the Qinghai-Tibetan
42 Plateau, at the confluence of three major geographical regions that include the eastern
43 monsoon zone, the northwestern arid zone, and the alpine zone of the Qinghai-Tibetan
44 Plateau. The Qilian Mountains play an important role in maintaining the ecological
45 balance of the Tibetan Plateau, stopping the southward progression of deserts, and
46 maintaining the stability of the oases in the Hexi Corridor. Due to its unique
47 geographical and environmental characteristics, permafrost is widespread and
48 underlies about 50% of the area (Ran et al., 2021a). Permafrost has an important role
49 instoring frozen water, thereby contributing to water conservation (Wang et al., 2022).
50 These roles can aid in inland river runoff recharge, which is crucial to regional
51 ecology, production, and life. Due to climate warming and human activities,
52 significant permafrost degradation results in the frequent occurrence of thermokarst,
53 representing a serious threat to ecological security and adversely impacts the
54 environment and human beings

55 Despite the importance of thermokarst processes and their potential geohazards,
56 the distribution of thermokarst landscapes is currently mostly undocumented. The
57 available distribution of thermokarst in the Northern Hemisphere, including
58 retrogressive thaw slumps (RTSs), thermokarst lakes, and other terrain features,
59 represents mainly probabilistic estimates (Olefeldt et al., 2016). Muster et al. (2017)
60 determined the distribution of circumpolar Arctic permafrost lakes and ponds from
61 2002-2013 at a resolution of 5 m using optical remote sensing, satellite (Geo-Eye,
62 QuickBird, WorldView-1 and -2, KOMPSAT-2), and radar imagery (TerraSAR-X),
63 but temporal inconsistencies make comparisons in time and space difficult. At the
64 regional scale, the techniques and spatial resolution of remote sensing imagery
65 currently used at different study areas are inconsistent, e.g., estimating the distribution
66 and development of RTSs on Banks Island, Canada, based on the interpretation of
67 Google Earth satellite images (Lewkowicz & Way, 2019). Satellite imagery at 30-m
68 resolution from Landsat has been used to analyze RTSs and thermokarst lakes in
69 circumpolar Alaska, eastern Canada, and Siberia (Nitze et al., 2018). The permafrost
70 zone of the Qinghai-Tibetan Plateau (QTP) has been a site of thermokarst
71 geomorphology research in recent years. For example, combining field surveys and
72 SPOT-5 satellite data for August 2010, a total of 2,163 thermokarst lakes and ponds
73 were recorded within 10 km on either side of the Chumar River to Fenghuo Mountain
74 of the Qinghai-Tibet Railway, with a total surface area of 1.09×10^7 m² and ranging in
75 size from 100 m² to 4.49×10^5 m² (Luo et al., 2015; Niu et al., 2014). In the Beiluhe
76 region of the central QTP, the number of RTSs increased from 124 to 438 between
77 2008 and 2017, with an approximate 9-fold increase in area (Huang et al., 2020; Luo
78 et al., 2019). The latest results show that the number of RTSs on the QTP is 2669, but
79 for the Qilian Mountains in the northeastern part of the region, only 6 (Luo et al.,
80 2022) or as many as 15 are documented (Mu et al., 2020). A lack of a thermokarst
81 inventory in this region is therefore evident, representing a crucial gap in the RTSs
82 inventory on the QTP.

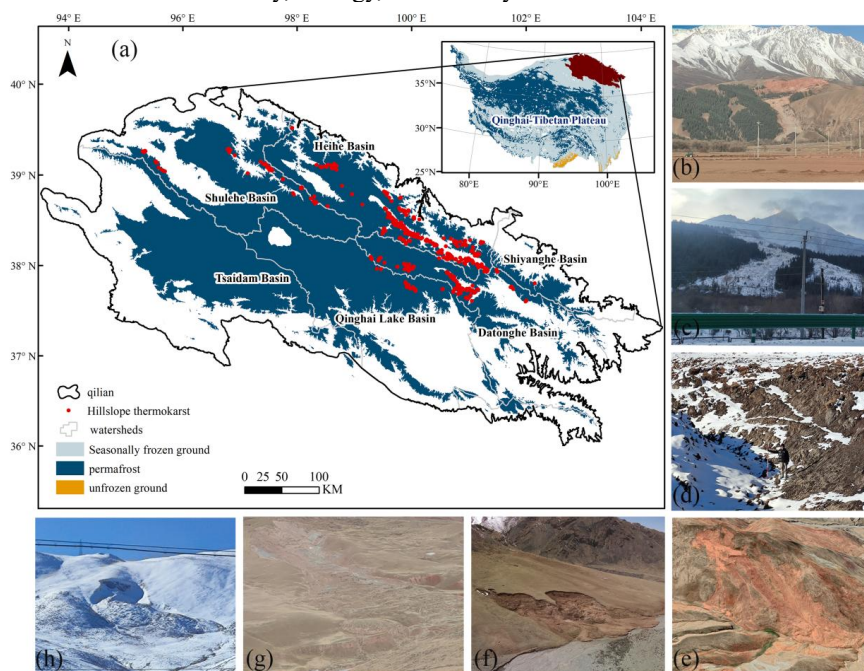

83 The Qilian Mountains impact the ecology of the QTP where permafrost
84 degradation causes frequent freeze/thaw-induced hazards. The ecological environment
85 of the permafrost areas has a significant impact, and there is a direct correlation
86 between human activities and major permafrost engineering problems, including
87 uneven subsidence of infrastructure, slumps, and cracks. Meanwhile, there is little to
88 no information regarding hillslope thermokarst (HT) features such as RTSs,
89 active-layer detachment slides, and thermal erosion gullies in the region (Gooseff et

90 al., 2009). Thus, the urgent need to survey and quantify these undocumented terrain
91 features in the Qilian Mountains motivates and represents the goal of this study.

93 2 Study Area

94 The Qilian Mountains are located at the northern edge of the QTP, with an
95 average elevation of 3855 m. The region is underlain by permafrost and seasonally
96 frozen ground (36-40°N and 94-104°E, Figure 1a), with a permafrost area of 94,235
97 km² that accounts for 49% of the study domain. Characterized by both an alpine
98 mountain climate and a temperate continental monsoon climate, the mean annual air
99 temperature is 0.30°C (Jin et al., 2022) with high precipitation variability and higher
100 amounts in the southeast during the thawing season of June to September (Chen et al.,
101 2013). Due to human activities, climate change, and earthquakes, permafrost
102 instability in Qilian Mountains has gradually increased, resulting in HT formation
103 including RTSS, thermokarst lakes, and thermal erosion gullies, which pose a direct
104 threat to the local economy, ecology, and security.

105 Figure 1. The location of the study area and a) its HT distribution (QTP permafrost
106 extent data are from (Zou et al., 2017) and the Qilian Mountains delineation from
107 Sheng et al., 2020), and b)–h) HT features obtained from different watersheds during
108 our field surveys with the exception of e) a © Google Earth image, as this site is too
109 difficult to access.

112 3 Data Sources

113 We collected and collated validated satellite imagery available starting in 1999 for
114 temporal detection of the onset of the HT formation. These data include unmanned
115 aerial vehicle imagery (e.g., Figure 1b–h) and 30 m resolution digital elevation model
116 data from the Shuttle Radar Topography Mission (Farr et al., 2007). A combination of
117 Omap and Google Earth software was used to detect the location of HT occurrence,

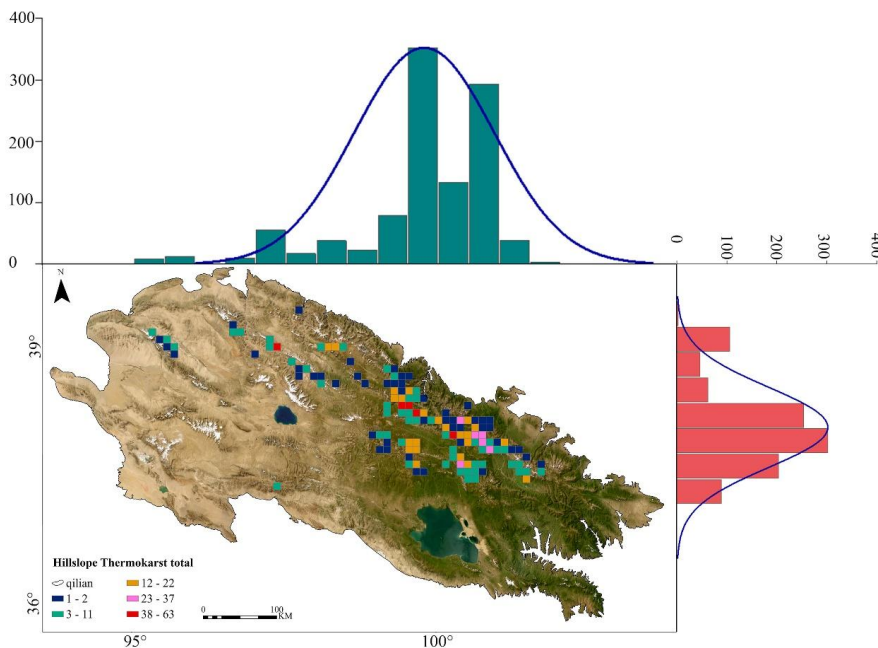

118 and Wayback imagery provided by ESRI was used to access high-resolution (<1 m)
 119 satellite imagery to aid in the identification (Table 1). In addition, we used digital
 120 elevation model data to tabulate variables such as slope and topographic position
 121 index (TPI) of the HT. The TPI is calculated as follows:

$$122 \quad TPI = \log_{10} \left(\frac{E}{Mean E} + 1 \right) \times \left(\frac{S}{Mean S} + 1 \right) \quad (1)$$

123 where E is the elevation (m), S is the slope ($^{\circ}$), and $Mean$ indicates that the mean
 124 value for the region of interest.

125 To further analyze the distribution of HT and the analogous environmental
 126 variables, we apply mean annual ground temperature (MAGT) and permafrost types
 127 from Ran et al. (2018). Permafrost types are divided into six MAGT categories: very
 128 stable ($MAGT < -5.0^{\circ}C$), stable ($-5.0^{\circ}C < MAGT < -3.0^{\circ}C$), semi-stable
 129 ($-3.0^{\circ}C < MAGT < -1.5^{\circ}C$), transitional ($-1.5^{\circ}C < MAGT < -0.5^{\circ}C$), unstable
 130 ($-0.5^{\circ}C < MAGT < 0^{\circ}C$), and very unstable ($MAGT > 0^{\circ}C$) (Ran et al., 2021b). We also
 131 obtain seismic data from the U.S. Geological Survey
 132 (<https://earthquake.usgs.gov/earthquakes/search/>) describing earthquakes, including
 133 their timing, epicenter location, and magnitude. To categorize vegetation types into
 134 deciduous-coniferous forests (DCF), undergrowth (U), alpine scrub meadow (ASM),
 135 alpine meadow (AM), alpine grassland (AG), alpine vegetation (AV), and
 136 non-vegetated area (NA), based on data from the Resource and Environment Science
 137 and Data Center (<https://www.resdc.cn/data.aspx?DATAID=122>). To assess the
 138 relationship of air temperature and precipitation with HT, we download monthly 2 m
 139 mean air temperature and precipitation from the fifth generation of the European
 140 Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis (ERA5;
 141 <https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-land-monthly-mean>
 142 [s?tab=overview](https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-land-monthly-mean)).

143

144
 145

146 Figure 2. Frequency distribution of HT on the Qilian Mountains. The concentration of
147 HTs is shown per 100 km² grid cell, with the histograms denoting the latitudinal (red)
148 and longitudinal (green) distributions of HT and their curve fits (blue).
149

150 4 Methods

151 4.1 Manual Mapping

152 We first quantified and mapped HT via remote sensing observations. Most
153 occurrences of HT in the permafrost region of the Qilian Mountains since 2000 were
154 compiled by visual interpretation in Google Earth Pro and Omap. They were also
155 aided by high resolution (<1 m) observations from Esri Wayback Imagery, which
156 archives all published versions of world imagery (Table 1). We used a fishnet with a
157 mesh size of 1×1 km to segment the latest satellite imagery for the entire Qilian
158 Mountains to quantify HT mesh by mesh. RTSs are often horseshoe shaped, tongue
159 shaped, elongated, branched, and circle chair-shaped (Lantuit & Pollard, 2008; Yin et
160 al., 2021), characterized by a headwall, collapsed layer, and accumulation area (Lantz
161 & Kokelj, 2008). These features are tonally and morphologically different from
162 thermokarst landslides and their surroundings in color satellite images during the
163 thawing season. Landslides also produce folded textures due to accumulation, which
164 appear as laterally folded stripes on imagery. Active-layer detachment slides are a
165 common shallow landslide in permafrost areas. Their destabilization characteristics
166 vary depending on vegetation cover, slope, and permafrost conditions, but common
167 features are highly disturbed slopes and lateral shear zones, as well as fracture zones
168 formed after active layer slippage (Lewkowicz, 2007). We detected and sketched these
169 features based on morphological, tonal, textural, shading, and other characteristics on
170 remote sensing images, and then digitized their morphological features into polygonal
171 data. Although the accuracy of this type of visual interpretation is relatively high,
172 some HT features can be missed via this manual interpretation. To reduce such errors,
173 satellite images of the similar period from different sources were evaluated four times
174 using the same methods to ensure accurate results. The date of the satellite image
175 when perturbations caused by HT can be first observed was defined as the initiation
176 year of a particular HT feature. Depending on the initiation year, HT is categorized as
177 occurring before 2010, 2010–2015, or after 2015. To observe the temporal evolution
178 of HT features, we used the initiation year and retraced historical images covering the
179 Qilian Mountains, a process that also helped us distinguish between HT features and
180 one-time transient landslides.

181 4.2 Field Verification

182 Similar HT can have different morphological characteristics due to different
183 triggers. It is thus difficult to identify the type of HT simply through imagery. In
184 addition, after an initial trigger and HT formation, thermokarst can evolve into
185 different types. For example, active layer detachment slides may transition into RTS
186 due to the exposure of subsurface ice at the trailing edge and water erosion due to
187 meltwater, which can cause the RTS to further progress into mudflows. Therefore, with
188 visual interpretation based on imagery only providing individual snapshots, it is
189 essential to also conduct field surveys as a validation exercise. We conducted a total
190 of three field surveys in winter 2022, and spring and summer of 2023. Field work
191 covered the Shiyanghe basin, Heihe basin, Datonghe-Huangshui basin, Qinghai Lake
192 basin, and Shulehe basin. Due to the harsh climatic conditions and accessibility issues
193 in the Qilian Mountains, unmanned aerial vehicles were used to survey and verify
194 hard-to-reach areas.
195

198

199 *4.3 Morphological and Spatial Statistical Analysis*

200 A landscape shape index (LSI) can be quantified to characterize shape complexity
 201 by calculating the degree of deviation of a given patch from a circle or square of the
 202 same area. To quantify the shape characteristics of HT features, two LSIs are
 203 calculated as follows:

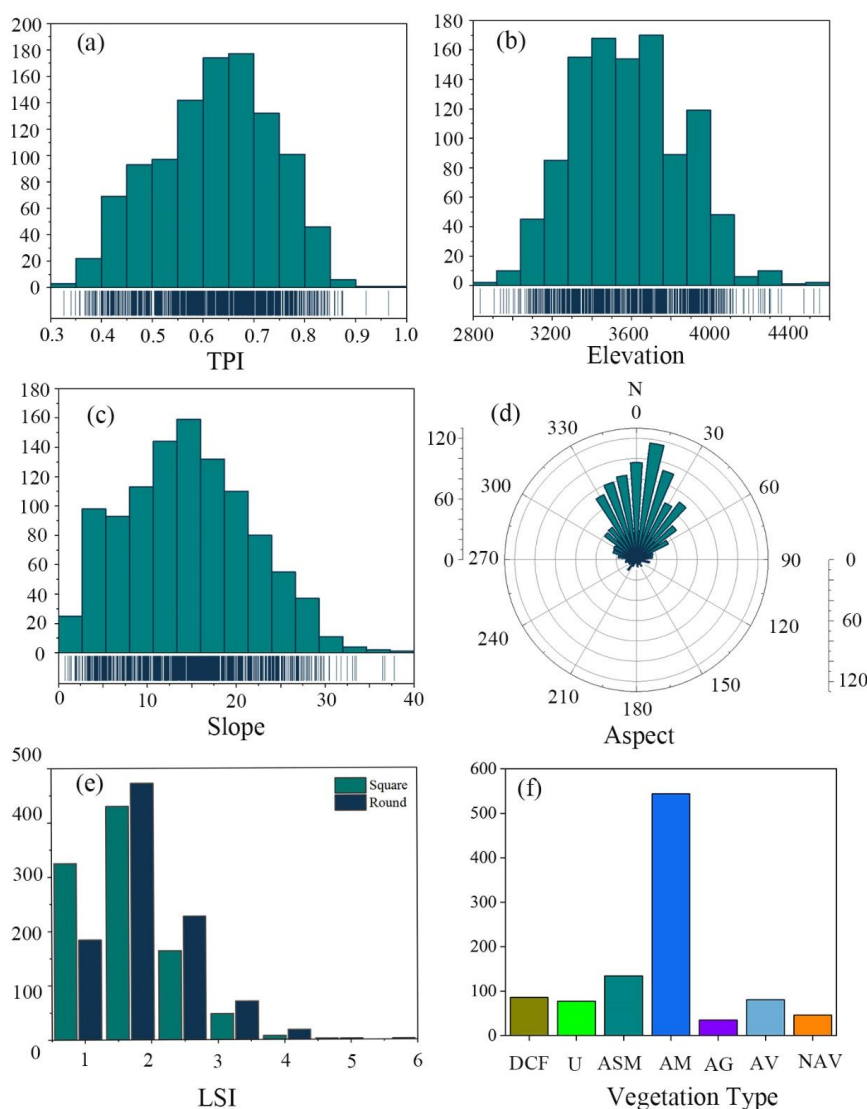

204
$$LSI_{square} = \frac{0.25P}{\sqrt{A}} \quad (2)$$

205
$$LSI_{round} = \frac{P}{2\sqrt{\pi A}} \quad (3)$$

206 where P is the perimeter (m) and A is the area (m²). The closer the values of LSI_{square}
 207 or LSI_{round} are to 1, the more square or round the shape of the HT feature is,
 208 respectively.

209 To further investigate the spatial distribution of HT, we computed a global
 210 Moran's index, z-score and p-value to determine whether there is autocorrelation in
 211 the spatial distribution of HT. Where p-value and z-score are used to measure
 212 statistical significance, when p-value < 0.01 and z-score > 2.58, it means that there is
 213 a 99% probability that the elements are clustered within the study area, and the
 214 smaller the p-value and the larger the z-score, the greater the probability that such
 215 spatial patterns are clustered. Moran's index ranges from -1 to 1, with negative values
 216 meaning negative correlation, positive values meaning positive correlation, and 0
 217 denotes that the spatial objects in the study area are independent of each other.
 218 Additionally, the closer the index is to 1, the more clustered the HT features are, and
 219 the closer of the index is to -1, the more dispersed the HT features are. To delineate
 220 the regions that may have spatial autocorrelation (Bivand & Wong, 2018), we further
 221 process local autocorrelation on this basis. The local autocorrelation regions are
 222 divided into four types: high-high (HH) clustering, high-low (HL) clustering,
 223 low-high (LH) clustering, and low-low (LL) clustering, based on the local Moran's
 224 index. HH represents a higher amount of HT and a higher amount of HT in the
 225 neighboring region; HL represents a higher amount of HT and a lower amount of HT
 226 in the neighboring region; LH represents a lower amount of HT and a higher amount
 227 of HT in the neighboring region; and LL represents a lower amount of HT and a lower
 228 amount of HT in the neighboring region. Although the methods described above can
 229 identify global and local spatial autocorrelation, respectively, they are unable to
 230 identify clusters of concentrated HT features. We therefore also apply hot spot
 231 analysis, which is another effective way of exploring the characteristics of local
 232 spatial distributions. All the above techniques are based on spatial statistical analysis
 233 functions of ArcGIS.

234 To determine the effects of climate on HT, we average 2-m air temperature and
 235 precipitation from ERA5 over the period 2000–2020 and calculate their standard
 236 deviations (Figure 6).

237
 238 **Figure 3.** The number of HT terrain features (y-axes) of HT as categorized by (a)
 239 topographic position index (TPI), (b) elevation, (c) slope, (d) aspect, (e) landscape
 240 shape index (LSI), and (f) vegetation type including deciduous coniferous forests
 241 (DCF), undergrowth (U), alpine scrub meadow (ASM), alpine meadow (AM), alpine
 242 grassland (AG), alpine vegetation (AV), and non-vegetated area (NA); the blue
 243 vertical lines at the bottom of panels a–c represent the number of HT features in each
 244 x-axis bin.

245
 246 **5 Results**

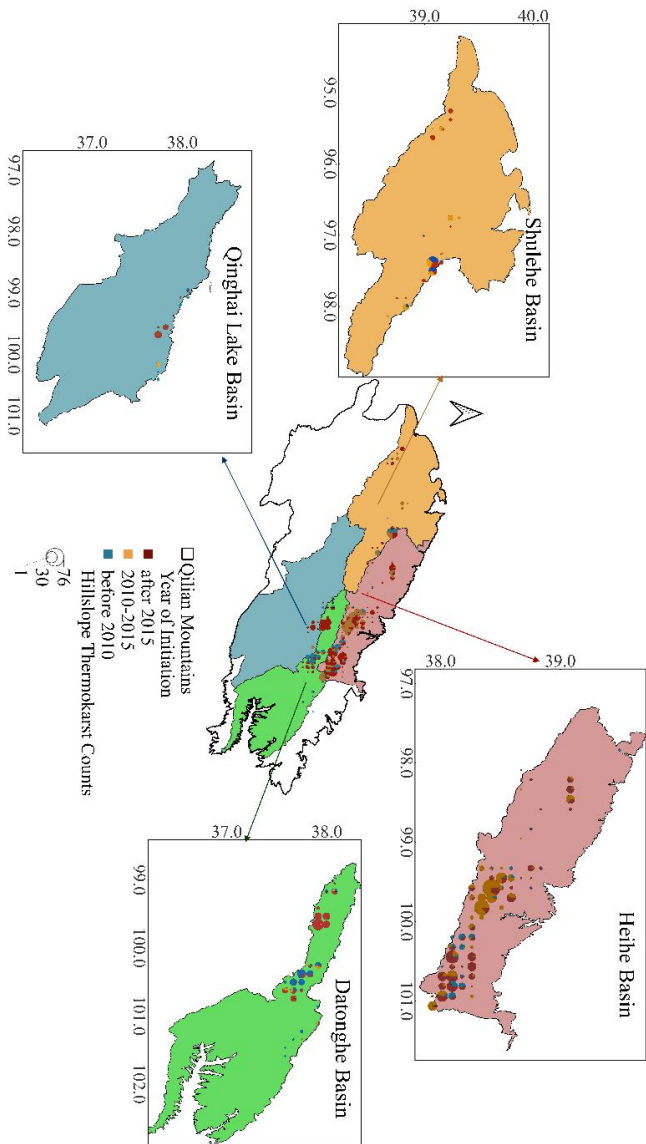

247 Our inventory of HT includes the Heihe Basin, Shulehe Basin, Datonghe Basin,
248 Shiyanghe Basin, Qinghai Lake Basin, and Tsaidam Basin within the Qilian
249 Mountains, with a total of 1064 HT features. In any 100 km² grid cell, the maximum
250 density of HT is 63 (Figure 2). This density is lower than the 68 per 25 km² in the
251 central Tibetan Plateau reported by Luo et al. (2022) and 88 per 25 square km² on
252 Banks Island, Canada from Lewkowicz & Way (2019). 67% of these HT features
253 were identified in the Heihe River basin, followed by the Datong River Basin,
254 accounting for 19%. The HT distribution in these river basins is irregular,
255 corroborated by a positive statistically significant Moran's index value of 0.3, p-value
256 of 0.00001 and z-score of 32.5. Of all the HT features, the largest is 58 ha, the
257 smallest area is 0.01 ha, with most being smaller than 10 ha. The average area is 1.75
258 ha, with a total area of 1708 ha.

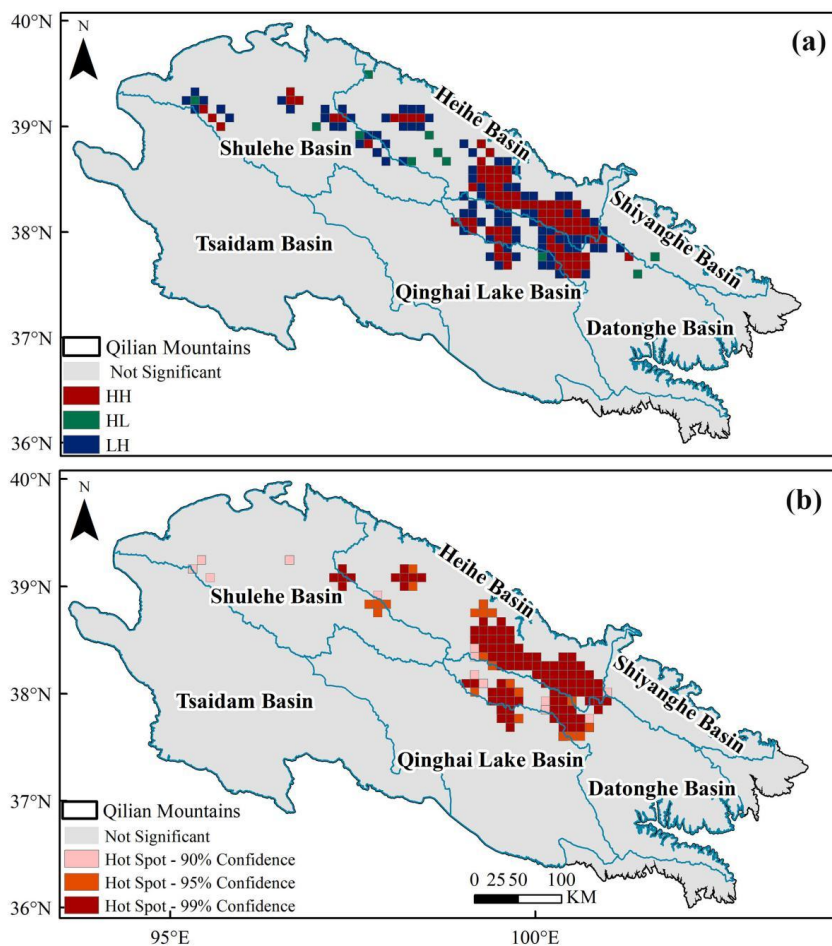

259 The spatial distribution of HT on the QTP is strongly controlled by terrain factors
260 such as the elevation, slope, TPI, and aspect (Luo et al., 2022). The statistical results
261 indicate that HT is observed at elevations ranging from 2,835 to 4,550 m. However,
262 90% of RTSs are more likely to occur at elevations ranging from 3,200 to 4,000 m in
263 the middle/high elevation area of the Qilian Mountains. HT tends to occur on
264 north-facing slopes (Figure 3b and 3d), with slopes ranging from 3° to 25° (Figure 3c).
265 In addition, the TPI shows that ~85% of the HTs occur mainly between 0.5 and 0.8
266 (Figure 3a), suggesting that they commonly occur in locations that are lower than their
267 surroundings. Both LSI indices suggest that 75% of HT has values close to 1.0
268 (Figure 3e), indicating that most HT is simple in shape and compact in morphology,
269 rather than elongated (Niu et al., 2016), implying it has a relatively low probability of
270 being reactivated (Yang et al., 2023). Alpine meadow areas contain ~53% of HT,
271 followed by alpine scrub meadows, which contain 13% (Figure 3f).

272 The initiation years of HT features are variable across the study area. 187 HT
273 features (18%) were identified before 2010, and the remaining 82% in the last 10
274 years. 392 sites (37%) were initiated in 2010-2015 and 482 (45%) after 2015. Much
275 of the newly initiated HT occurred in the middle and upper reaches of the Datonghe
276 basin bordering the Heihe basin (Figure 4), which is also a HT hotspot region. The
277 recent increase in HT can be attributed to the anomalous weather conditions in the
278 corresponding years. The association between newly observed HT and meteorological
279 data indicates a sudden HT increase in years with unusually high temperatures during
280 the thawing season (Figure 6).

281
 282 **Figure 4. The timing of HT initiation within 100 km² grid cells.**

285 low-high (LH) clustering, and (b) hotspot analysis where the different colors represent
286 the confidence levels.
287

288 6 Discussion

289 6.1 Drivers of HT in the Qilian Mountainous

290 6.1.1 Permafrost Conditions

291 Formation of HT is facilitated by thick subsurface ice and various internal and
292 external environmental conditions (Stephani et al., 2023). Permafrost stability in
293 ~80% of the permafrost area of the Qilian Mountains is predominantly transitional,
294 and higher permafrost temperatures (Ran et al., 2021a) will exacerbate the climate
295 sensitivity of this area (Lewkowicz & Way, 2019; Patton et al., 2021) leading to
296 melting of the subsurface ice and an increase in active layer thickness, thus decreasing
297 the stability of the slope (Behnia & Blais-Stevens, 2018). This is also supported by
298 our finding that ~90% of HT occurs in the transition zone between permafrost and
299 seasonally frozen soil where mean annual ground temperature is greater than -1°C .
300

301 *6.1.2 Environmental Factors*

302 Topographic conditions facilitate the formation of subsurface ice and the
303 continuous development of HT. At elevations below 5100 m on the QTP, aspect
304 dominates the distribution of permafrost. More permafrost underlies regions of shaded,
305 north-facing slopes than sunny south-facing slopes (Ran et al., 2021a). Indeed, we
306 find that ~95% of Qilian Mountain HT is found on north-facing slopes where it also
307 enhances vegetation growth and soil moisture storage (Jin et al., 2009). Lower solar
308 radiation, higher permafrost ice content, and shallow active layer thickness (Lacelle et
309 al., 2015; Ward Jones et al., 2019) also enables HT formation (Luo et al., 2022; Niu et
310 al., 2016; Xia et al., 2022). We find more than half of the HT occurs in alpine
311 meadows, which require more water content than alpine steppes (Yin et al., 2017) and
312 consequently also results in more ground ice development under this vegetation type.
313 We determined that ~90% of HT in the Qilian Mountains occurs on 3° to 25° slopes.
314 Low and gentle slopes are favorable for groundwater pooling (Luo et al., 2022),
315 whereas slopes greater than 16° are relatively steep and therefore not conducive to
316 groundwater enrichment for ice formation, but such slopes also provide dynamic
317 conditions for active layer detachments and collapsing ground (Wang, 1990). We also
318 observe more HT initiation at locations that are lower compared to their surroundings,
319 as such depressions favor the accumulation of snow and rainwater (Stieglitz et al.,
320 2003) and prevent heat loss from the soil. This encourages melting of subsurface ice
321 (Zhang, 2005) at the base of the active layer and, after an unstable layer is formed
322 between the permafrost and the active layer, the overlying soil can slide along the
323 slope (Patton et al., 2021).

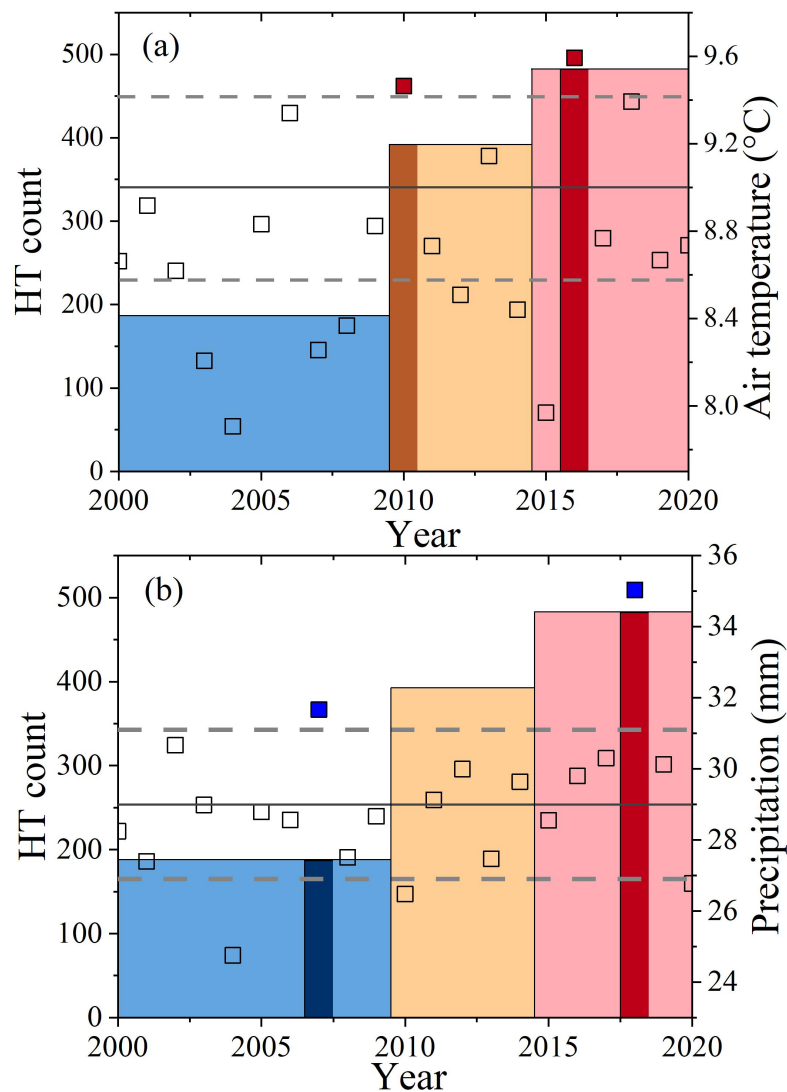

324 The Qilian Mountains were and are still formed by the ongoing collision of the
325 Indian Ocean Plate and the Eurasian Plate, resulting in the Qilian Mountains-Hexi
326 Corridor active fault system (Xiong et al., 2017) that has seen nearly 400 earthquakes
327 of magnitude 2 or greater over the past two decades. In particular, the high seismic
328 activity of the Heihe, Shiyanghe, and Datonghe Basins (Figure 7a) represents a
329 potential threat to the safety and integrity of current and future infrastructure in the
330 region. During our field investigations we found a nearly 3 km long and 2 m deep
331 slope fracture caused by a 6.9-magnitude earthquake in 2022, resulting in a massive
332 exposure of subsurface ice and the collapse of the Lanzhou-Xinjiang High Speed Rail
333 Tunnel (Figure 7b and c). The occurrence of an earthquake can result in an
334 instantaneous increase in pore water pressure and slope sliding forces that reduce
335 slope stability and potentially leads to a massive exposure of subsurface ice (Niu et al.,
336 2016), sediment liquefaction (Dadfar et al., 2017), and permafrost warming (Che et al.,
337 2014), creating the ideal setting for active-layer detachment slides.

339 *6.1.3 Climate Factors*

340 Extreme summer temperatures and precipitation have been identified as triggers
341 for the initiation of RTSs in many Arctic permafrost zones (Balsler et al., 2014; Kokelj
342 et al., 2015; Lewkowicz & Way, 2019; Segal et al., 2016). Given our finding that 82%
343 of HT was initiated in the last decade (Figure 4), mostly during 2010-2015 and after
344 2015, we used ERA5 to determine the temperature and precipitation characteristics
345 for the Qilian Mountains over the last 20 years (Li et al., 2022) (Figure 6, the square
346 symbols). The mean thawing season air temperatures in 2010 and 2016 were higher
347 than in other years (Figure 6a, red square symbols). A warming thaw season could
348 lead to thaw consolidation at the base of the active layer or to higher porewater
349 pressure in the transient thaw layer, reducing the effective shear strength, and causing
350 slope failure (Lewkowicz & Way, 2019). The anomalous air temperatures during the

351 thawing season could accelerate permafrost thaw and expose ice-rich permafrost, thus
352 leading to new HT (Figure 6a, dark brown and dark red bars, respectively). Rainfall
353 infiltration may transfer heat to the top layer of permafrost and induce melting of
354 ground ice in ice-rich transient layers, which would increase the porewater pressure at
355 the active layer-permafrost interface and thereby trigger formation of HT (Luo et al.,
356 2022). However, precipitation variability during the thawing season does not match
357 HT formation (Figure 6b). Despite high precipitation in both 2007 and 2018 (Figure
358 6b, blue square symbols), no initiation of HT was found to subsequently coincide with
359 these peaks, and precipitation also does not explain the significant initiation of HTs
360 between 2010-2015, nor after 2015 (Figure 6b, yellow and red bars, respectively). The
361 same conclusion also applies to the other three sub-regions—Hoh Xil Mountain,
362 Maqu country, and Honglianghe—and it could be speculated that the nature of the
363 soils on the QTP may instead play a role (Luo et al., 2022).
364

365
 366 Figure 6. The relationship between HT numbers (unequal width bars, the darker colors
 367 represent years with extreme weather events.) and (a) temperature and (b)
 368 precipitation in the thawing season from 2000 to 2020 (square symbols, the red
 369 squares and the blue squares represent the extreme weather events.). The solid
 370 horizontal line represents the mean, and the dashed line represents ± 1 standard
 371 deviation.

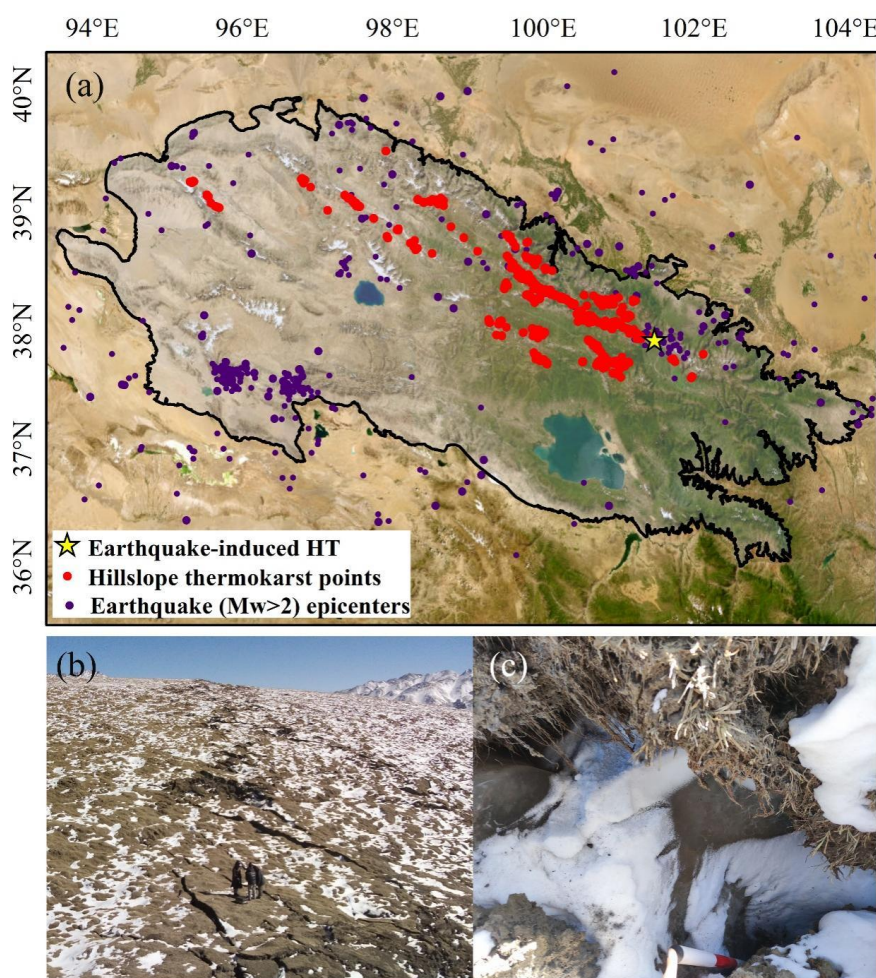

372

373 6.1.4 Human Activities

374 Extensive and increasing human activities have been shown to significantly
 375 accelerate permafrost degradation (Cheng & Jin, 2013; IPCC, 2019). The total
 376 population of the Qilian Mountains is about 60,000, there are approximately 1,000
 377 metal, energy, and other types of mineral deposits (National Mineral Properties

378 Database 2021 Edition, <http://data.ngac.org.cn/mineralresource/index.html>), and there
379 are ~8,000 km of railroads and highways. The core of this human activity is
380 concentrated on the eastern side of the Qilian Mountains, which generally coincides
381 with the spatial distribution of the HT hotspots we documented. This qualitatively
382 suggests a role of human activities on HT from, e.g., engineering disturbances,
383 vegetation degradation due to overgrazing, etc. (Sharkhuu et al., 2007). Establishing
384 the impact of human activities on HT quantitatively is still a difficult challenge, but
385 our identification of the location and timing of HT formation is a first, important step
386 for further future studies, especially on the socioeconomic development in the region.

387

7 Data Availability

395 DEM data can be accessed through NASA
396 (<https://www.earthdata.nasa.gov/sensors/srtm>). Landsat5-8 data are available from
397 USGS (<https://www.usgs.gov/>) and Sentinel-2 from ESA (<https://www.esa.int/>), and
398 can be downloaded through Google Earth Engine. Esri World Imagery can be
399 accessed through Esri Wayback Imagery at: <https://livingalas.arcgis.com>. Some GF-2
400 imagery is also available online through Omap software, and high resolution 3D
401 satellite imagery of the Qilian Mountain region can be viewed in Google Earth
402 software. High-resolution satellite images captured by the Jilin-1 satellite in China can
403 be viewed by accessing <https://www.jl1mall.com/rskit/>. The HT inventory for the
404 Qilian Mountains can be freely downloaded from the National Tibetan Plateau/Third
405 Pole Environment Data Center (<https://doi.org/10.11888/Cryos.tpcd.300805>, Peng and
406 Yang, 2023).

407

408 8 Conclusion

409 This study used visual interpretation and field investigations for repeated verification
410 to investigate HT in the permafrost zone of the Qilian Mountains. We successfully
411 produced the first HT inventory for this area, and found it contains a total of 1064 HT
412 features. The area of these features ranged from 0.01 to 58 ha, with an average of 1.75
413 ha. Thermokarst is primarily concentrated at the junction between the upstream
414 portion of the Heihe River Basin and the mid- and upstream portion of the Datonghe
415 Basin. Within a 10×10 km area, thermokarst has a maximum density of 63 features,
416 affecting an area of ~20 km². HT in the Qilian Mountains is more likely to occur on
417 north-facing shaded slopes, at elevations between 3200–4000 m, slopes of 3–25°,
418 0.5<TPI<0.8, and in alpine meadow vegetation. Based on long-term satellite imagery,
419 874 new HT features were initiated after 2010, accounting for 82% of the total HT.
420 Recent higher air temperatures during the thawing season are likely important reasons
421 for the intensification of HT formation in the Qilian Mountains, while precipitation
422 does not seem to play a role. This first HT inventory for the Qilian Mountains will be
423 fundamental for quantitative assessments that explore the exact causes and underlying
424 thermokarst processes, and ultimately allow for better identification prediction of
425 areas prone to thermokarst formation in the future.

426

427 **Author contributions.** XP and GY designed the research and obtained funding. GY
428 analyzed the data and prepared the data files. GY, WT, XL and XP conducted the field
429 work. GY, XP, OWF, JL, CM, FN wrote the paper with input from the coauthors and
430 coordinated the analysis and contributions from all coauthors. XP and GY contributed
431 to the work equally and should be regarded as co-first authors.

432

433 **Competing interests.** The contact author has declared that neither they nor their
434 coauthors have any competing interests.

435

436 **Disclaimer.** Publisher's note: Copernicus Publications remains neutral with regard to
437 jurisdictional claims in published maps and institutional affiliations.
