Abstract. The ATL2MED demonstration experiment involved two autonomous surface vehicles from Saildrone Inc. (SD) which travelled a route from the eastern tropical North Atlantic to the Adriatic Sea between October 2019 and July 2020. This nine-month experiment in a transition zone between the temperate and tropical belts represents a major challenge for SD's operations. The sensors on board were exposed to varying degrees of degradation and biofouling depending on the geographical area and season, which led to a deterioration of the measurements. As a result, some maintenance measures were required during the mission.

We address the difficulty of correcting the data during a period of COVID-19 restrictions, which significantly reduced the number of discrete samples planned for SD salinity and dissolved oxygen validation. This article details alternative correction methods for salinity and dissolved oxygen. Due to the lack of *in situ* data, model products have been used to correct the salinity data acquired by the SDs, and then the resulting corrected salinity was validated with data from fixed ocean stations, gliders, and Argo floats. In addition, dissolved oxygen data acquired from SDs after correction using air oxygen measurements were tested and found to be coherent with the variation of oxygen concentrations expected from change in temperature and phytoplankton abundance (from chlorophyll-a). The correction methods are relevant and useful in situations where validation capabilities are lacking, which was the case during the ATL2MED demonstration experiment. For future experiments, a more frequent sample collection would improve the data qualification and validation.

1 Introduction

Automated observations contribute to a steadily increasing knowledge of the ocean and its role in the global climate system. For a long time, fixed ocean stations and research vessels formed the backbone of the monitoring network. In recent years, efforts have been made to improve the frequency of acquisition through technological developments (e.g., EU infrastructures ICOS, <https://www.icos-cp.eu/>; EMSO, <https://emso.eu/>; EuroArgo,

41 <https://www.euro-argo.eu>). Among other improvements, fixed ocean stations and ships of opportunity (Lüger et
42 al., 2004) were equipped with autonomous and accurate sensors for partial pressure of CO₂ ($p\text{CO}_2$) measurements
43 in addition to sensors for complementary measurements (*e.g.*, water temperature, salinity, dissolved oxygen, pH,
44 nutrients, fluorescence) needed to understand the dynamics and the effects of CO₂ fluxes on the carbon budget.
45 Despite efforts to do so, it remains difficult to obtain a comprehensive overview of CO₂ fluxes at regional and
46 larger scales because of very sparse coverage by fixed observatories, low measurement frequency and limited
47 systematic reference measurements.

48 One way to address such observational gaps (Tanhua et al., 2019) is to develop and deploy Autonomous Surface
49 Vehicles (ASV) equipped with a suite of sensors, and capable of measuring CO₂ fluxes at the air-sea interface with
50 gas reference, high sampling frequency and real-time data transmission. ASV monitoring systems have the
51 potential to collect data from large ocean areas and at a frequency that resolves processes at multiple time scales.
52 Nevertheless, there are challenges with those surface monitoring systems, and one of the most important is
53 biofouling, which can interfere with measurements of *e.g.*, conductivity, dissolved oxygen and especially
54 chlorophyll-a (Chl-a), and could ultimately render the sensors inoperable (*e.g.*, Delauney et al., 2010). Regular
55 maintenance counteracts biofouling or at least reduces the impact on measurements, but this is not always possible
56 due to long distance from shore or from the maintenance vessel. Therefore, the value of ASV data depends heavily
57 on quality control and quality assurance.

58 During the 9-month-long demonstration experiment ATL2MED, two wind-driven Saildrone ASV (SD;
59 Gentemann et al., 2020) manufactured by Saildrone Inc. (Alameda, CA, USA) were used to improve data coverage
60 and link CO₂ surface observations at fixed ocean stations on a larger scale from the eastern tropical North Atlantic
61 (ETNA) to the central Mediterranean Sea. SDs are prone to errors primarily due to sensor drift, which can be
62 caused by either biofouling or malfunctioning sensor parts. During the ATL2MED demonstration experiment,
63 problems were found with the data collected by several SD sensors, and severe biofouling occurred, as expected
64 in such a long-duration experiment.

65 Still, the use of SDs provided the opportunity to expand and link fixed CO₂ observations at the surface on a
66 larger scale, particularly during the COVID-19 pandemic when access to ocean platforms and ship visits were
67 restricted or even prohibited. Furthermore, the demonstration experiment allowed us to focus SD measurements
68 on different marine environments, the Atlantic Ocean and the Mediterranean Sea, which made it possible to assess
69 the quality of measurements across a wide range of values. The experiment additionally evaluated the ability of
70 such ASV to provide data with sufficient quality to be relevant for the scientific community.

71 The objective of the present work is to evaluate and correct the data collected by the SDs in order to provide
72 a homogenised and comparable data set useful for the study of processes such as air-sea gas exchange in the
73 Atlantic Ocean and Mediterranean Sea. While this paper focuses on the methods, a follow up paper will focus on
74 biogeochemical processes occurring in the area.

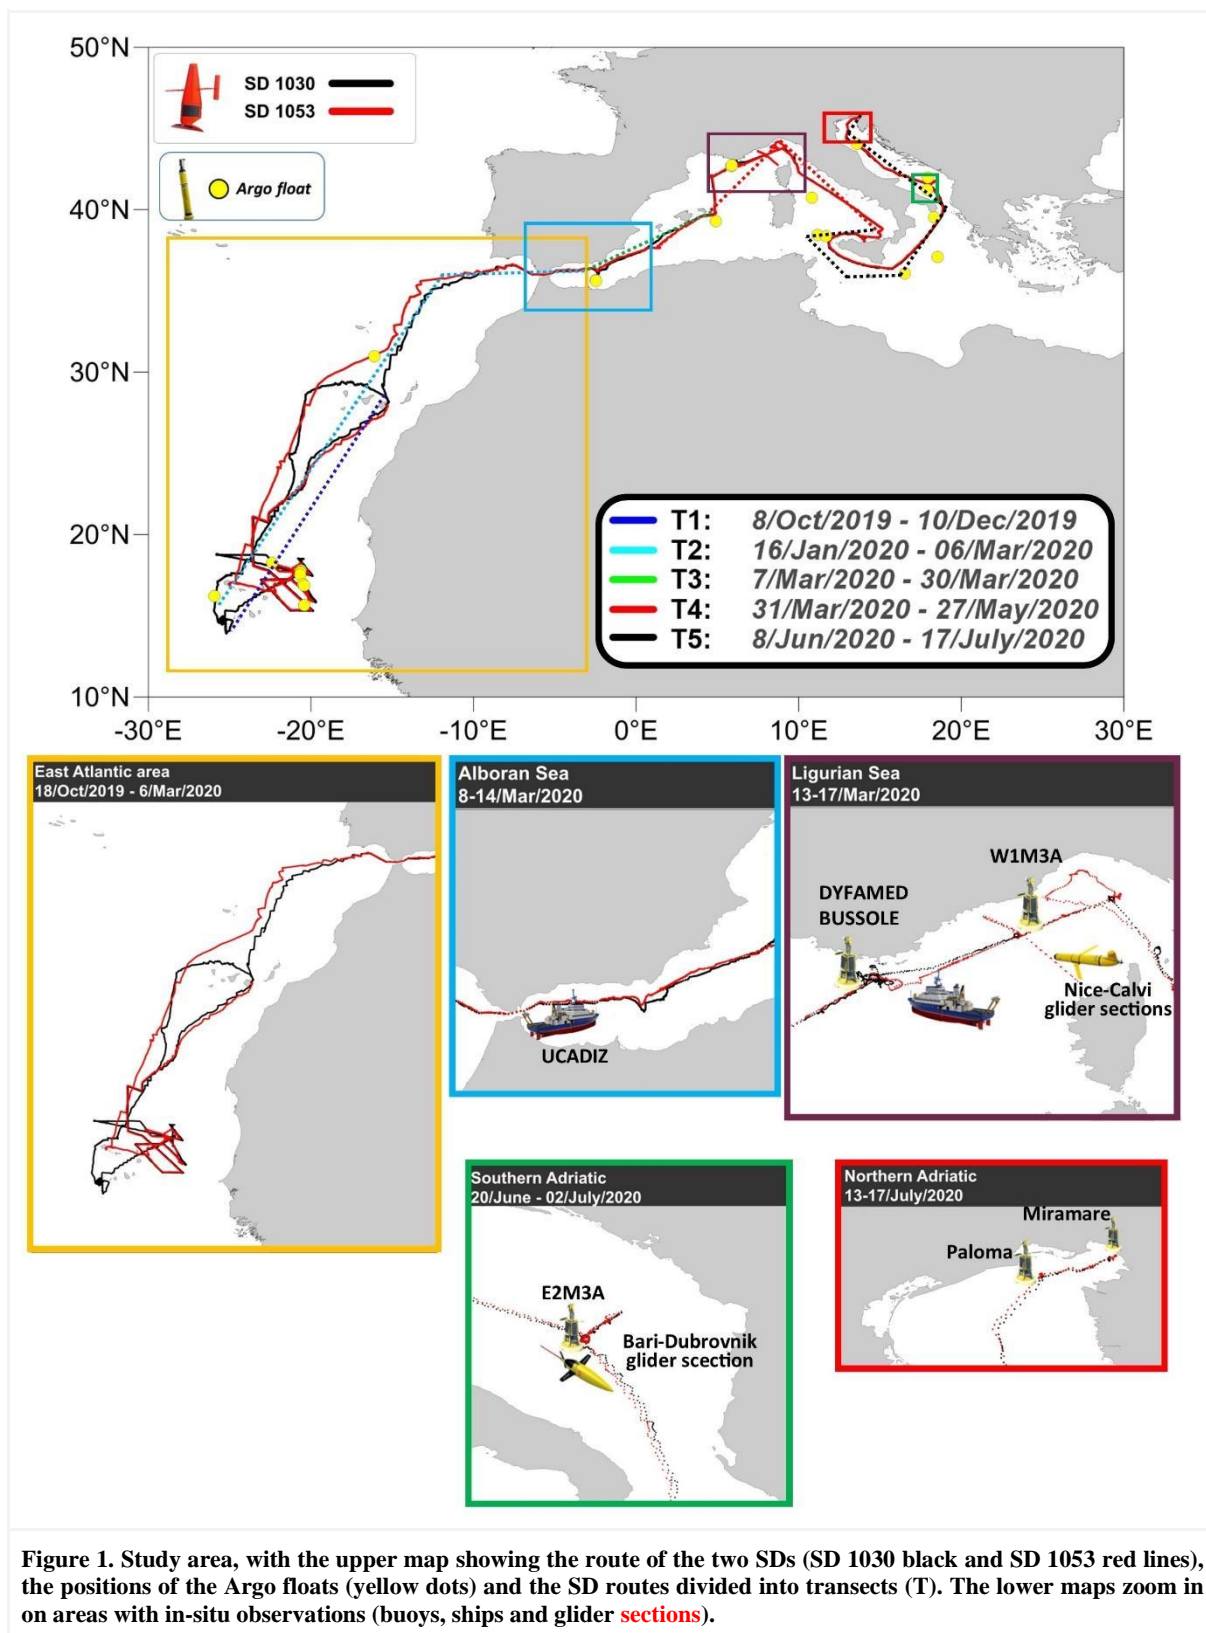

75

76 **2 Material**

77 **2.1 Data collection and experiment**

78 The ATL2MED demonstration experiment took place between 18 October 2019 and 17 July 2020 as a joint effort
79 among a number of European academic institutions and SD piloting team. A detailed description of the ATL2MED
80 demonstration experiment can be found in Skjelvan et al. (2021). During the experiment, the SDs crossed the
81 ETNA region, the Strait of Gibraltar, and the northern part of the western and central Mediterranean Sea including
82 the Ligurian Sea, the Strait of Sicily, the Strait of Otranto, and the Adriatic Sea (Fig. 1).

83 The aim of the ATL2MED demonstration experiment was to (1) study eddies in the Canary Current upwelling
84 system off West Africa jointly with a vessel-based research expedition (RV Meteor M160) and (2) to validate the
85 CO₂ measurements acquired at 5 fixed ocean stations (DYFAMED, W1M3A, E2M3A, PALOMA, and
86 MIRAMARE). This monitoring experiment was achieved with sensors and instruments installed on the SDs, but
87 also equipment deployed at a number of facilities that were used to correct data from the SDs (see Section 3).
88 Table 1 provides an overview of the various facilities and the times at which the SD visits were carried out. A
89 detailed description of the instruments and sensors installed on the different platforms as well as their
90 characteristics can be found in Tables S1, S2 and S3 of the Supplementary Material.

91

92 Maintenance operations ensured the reliability and accuracy of the data collected by the SDs. Throughout the
 93 expedition, the data collected by the SDs were categorised into different transects, designated as T1, T2, T3, T4,
 94 and T5. These transects corresponded to specific sections of the expedition timeline in terms of maintenance events
 95 (see Table S1 in Supplementary Material), which facilitates data correction.

96 The SDs were equipped with a number of autonomous sensors (CTD: conductivity, temperature, depth;
97 dissolved oxygen; fluorescence; pH; $p\text{CO}_2$; meteorological sensors). This study focuses primarily on sensors
98 acquiring temperature, salinity, dissolved oxygen, and $p\text{CO}_2$ data. This selection is based on the available options
99 for correcting the SD datasets: some of the sensors (*e.g.*, fluorescence) were so severely affected by biofouling
100 that it could not be accounted for, while others only worked for a short period of time (*e.g.*, Durafet Honeywell
101 pH sensor). One of the SDs (SD 1030) was equipped with an ASVCO₂ system developed by PMEL (NOAA's
102 Pacific Marine Environmental Laboratory). The ASVCO₂ system is a compressed version of the more voluminous
103 system described in detail in Sutton et al. (2014) and Sabine et al. (2020). Water from a depth of approximately
104 0.5 m is fed into a bubble equilibrator (Friederich et al., 1995) and the partially dried $x\text{CO}_2$ is measured with an
105 infrared detector (LI-COR 820 CO₂ gas analyser). A two points calibration was used where the first is a reference
106 gas from NOAA/ERSL, while the second is air purged for CO₂. An air inlet was mounted approximately 1 m
107 above sea level and atmospheric $x\text{CO}_2$ was measured between measurements of the sea surface. See Table S2 in
108 the Supplementary Material for the measurement frequency and initial accuracy of the SD sensors during the
109 ATL2MED experiment.

110

111 2.2 Comparative datasets

112 2.2.1 Liguro-Provencal basin facilities

113 In the French EEZ, the open-ocean station DYFAMED is located in the Ligurian Sea in the northwestern
114 Mediterranean Sea. The CNRS (French National Centre for Scientific Research) is in charge of the station as part
115 of the national MOOSE program (Coppola et al., 2019). At the DYFAMED site, a CARIOCA $p\text{CO}_2$ sensor ensures
116 autonomous measurements and detailed description can be found in Merlivat et al. (2018). In addition, gliders are
117 regularly operating the Nice-Calvi section where the DYFAMED site is located (MOOSE program; Coppola et
118 al., 2019; Bosse et al., 2015; Testor et al., 2019). During the demonstration experiment, a deployment of the
119 Slocum glider was used along the endurance line (MOOSE T00-43 mission) performed from 12 March to 20 June
120 2020. Table S2 includes information about which sensors the glider was equipped with. Discrete samples were
121 collected from the DYFAMED site in February and March 2020 for comparison with the $p\text{CO}_2$ sensor
122 measurements (Table S4).

123 The open-ocean station W1M3A is located in the Italian EEZ of the Liguro-Provencal basin. Operated by
124 CNR-IAS, the W1M3A consists of a large spar buoy and a subsurface mooring positioned in the immediate
125 vicinity. A detailed description of the observatory can be found in Canepa et al. (2015) and some of this information
126 is found in Table S2. Discrete samples were collected from W1M3A in October 2020 (Table S4).

127

128 2.2.2 Adriatic Sea facilities

129 The fixed station E2M3A is situated in the open sea of the southern Adriatic Sea and is operated by **Italian National**
130 **Institute of Oceanography and Applied Geophysics - OGS**. Information on this site is found in Bozzano et al.
131 (2013) and Ravaioli et al. (2016). In the southern Adriatic, OGS also regularly operates an ocean glider at the Bari-
132 Dubrovnik section (Mauri et al., 2016; Pirro et al., 2022; Kokkini et al., 2019). During the ATL2MED
133 demonstration experiment, the glider transect was extended to include the area of the E2M3A fixed station from
134 12 June to 2 July 2020. During the 20-day campaign 250 dives between 20 to 950 m profiles separated by 3-5 km
135 and 4-6 hours were collected. Table S2 contains information about the specific sensors mounted at the glider.

136 In the Gulf of Trieste in the northern Adriatic, the coastal stations PALOMA (operated by CNR-ISMAR) and
137 MIRAMARE (operated by OGS) are situated. Description of the PALOMA station is found in Ravaioli et al.
138 (2016) and Cantoni et al. (2012), while the MIRAMARE site is described in Ravaioli et al. (2016). See Table S2
139 for information about which sensors are used at the sites. By means of comparing the $p\text{CO}_2$ sensor measurements
140 performed at the sites, discrete carbon samples were collected near PALOMA on 15 July 2020 and in the vicinity
141 of MIRAMARE on 17 July 2020 (Table S4).

142

143 2.3 Shipboard data

144 Discrete samples for Dissolved Inorganic Carbon (DIC) and TA were collected onboard the RV Meteor (M160)
 145 during fall 2019 and analysed by GEOMAR. Discrete samples for DIC, TA, pH, and dissolved oxygen are
 146 regularly collected next to the fixed ocean stations, however, this was not always possible during the ATL2MED
 147 demonstration experiment due to COVID-19 pandemic restrictions. Table S4 gives an overview of the discrete
 148 samples collected during the ATL2MED demonstration experiment and their sampling depth and analysing
 149 methods.

150 In addition, salinity was measured continuously on board of the RV Ucadiz at a depth of 2.3 m between 5 and
 151 6 March 2020, when the SD crossed the Gibraltar Strait. Table S2 contains information about the sensor used.

152
 153 **Table 1. Research vessels and fixed ocean stations from which temperature, salinity and/or carbon measurements were**
 154 **compared with those of the SDs.**

Research vessel/ fixed station	Position	Institution	SD 1030	SD 1053
RV Meteor	17.80°N 20.60°W	GEOMAR (DE)	30 November 2019	12 December 2019
RV Ucadiz	36.55°N 6.31°W - 36.09°N 5.36°W	UCA (ES)	5-6 March 2020	5-6 March 2020
DYFAMED	43.42°N 7.87°E	CNRS (FR)	28 April 2020	23 April 2020
W1M3A*	43.83°N 9.12°E	CNR-IAS (IT)	29 April-2 May 2020	28 April-2 May 2020
E2M3A*	41.57°N 18.08°E	OGS (IT)	29 June-2 July 2020	29 June-23 July 2020
PALOMA*	45.62°N 13.57°E	CNR-ISMAR (IT)	15 July 2020	15 July 2020
MIRAMARE*	45.70°N 13.71°E	OGS (IT)	17 July 2020	17 July 2020

155 * These stations are part of the ICOS station network (Steinhoff et al., 2019).

156

157 2.4 Argo Float

158 Float data were retrieved from the Argo Coriolis Global Data Assembly Center in France (GDAC;
 159 <ftp://ftp.ifremer.fr/argo>, Wong et al., 2020). For each Argo float the variable SALINITY ADJUSTED was
 160 extracted, and then used for comparison with SD salinity data. Every profile close in space and time (1 day and 30
 161 km) was chosen and then salinity was averaged in the upper 5 m of the water column.

162

163 2.5 Model output

164 The Copernicus Marine Service (CMEMS) model product, specifically the Global Ocean 1/12° Physics Analysis
 165 and Forecast (<https://doi.org/10.48670/moi-00016>) and the Mediterranean Sea Physics Analysis and Forecast
 166 (Escudier et al., 2020, Clementi et al., 2021) were used. Daily data were developed for the global ocean and
 167 Mediterranean Sea.

168

169 2.6 Satellite product

170 To evaluate the ocean response, sea surface Chl-a (OCEANCOLOUR_MED_BGC_L3_NRT_009_141), sea
 171 surface temperature (Merchant et al., 2019, Buongiorno Nardelli et al., 2022) and the vertical structure of ocean

172 temperature (MEDSEA_MULTIYEAR_PHY_006_004) were downloaded from the CMEMS data portal and
 173 analysed (Table S6 in the Supplementary Material).

174

175 3 Methods

176 3.1 Salinity

177 Here, the salinity is measured using the PSS-78 scale. During the first transect, T1 (Fig. 2), the two salinity sensors
 178 on board the SDs showed high consistency (Fig. 2a, b). After the first maintenance in T2, the SD 1053 showed a
 179 reduction in salinity of about 1 compared to the salinity measured by the SD 1030. In T3, the difference in salinity
 180 decreased on average to 0.15. During this period, the SDs crossed the Alboran Sea characterised by high
 181 thermohaline variability due to the presence of Atlantic and Mediterranean waters (Poulain et al., 2021), and the
 182 high spatial and temporal variability in salinity distribution in the area (Capó et al., 2021) complicates the
 183 understanding of the observed differences (i.e., sensor error or natural variability). In T4 and T5, salinity shifts of
 184 1 were observed until the end of the experiment.

185 Given the large variability found in the salinity data of the SDs, a comparison with *in situ* data along the
 186 trajectory of the experiment was necessary. We first identified the observing systems (fixed buoy, Argo float)
 187 temporally and spatially close to the positions of the SDs. Salinity data, with a temporal and spatial interval lower
 188 than 1 day and 30 km, respectively, were used for the comparison and/or correlation, however they were extremely
 189 scarce.

190 To further evaluate the salinity data of the two SDs, a comparison was made with climatological data,
 191 considering the closest point in the climatology dataset to the SDs measurements (Fig. 2). SD 1030 exhibited
 192 consistent salinity data in periods T1, T2, and T4 ($\Delta S < 0.1$), with deviations observed in periods T3 and T5 (Fig.
 193 2a). Conversely, SD 1053 displayed consistent salinity data only in period T1 ($\Delta S < 0.1$), with higher deviations in
 194 periods T2, T3, T4, and T5. Subsequent evaluation of the data distribution characteristics revealed variances
 195 between the two SDs (Fig. 2b).

196 In T5, the climatology failed to represent salinity in Ionian and Adriatic Sea, characterised by a continuous
 197 increase in salinity since 2017 (Mauri et al., 2021; Mihanović et al., 2021; Menna et al., 2022; Neri et al., 2023;
 198 Pranic et al., 2023). This was due to the bipolar behaviour of the Ionian Sea, subject to an alternation between the
 199 highly saline waters of the Levantine Basin and the less saline waters of Atlantic origin (Pinardi et al., 2019; Gačić
 200 et al., 2021; Menna et al., 2022; Civitarese et al., 2023).

201 To overcome the problem of lack of data, we decided to compare the data acquired by the SDs with the
 202 reanalysis model products along the entire route (Fig. 2a, b). The model, while not deviating much from the *in situ*
 203 and climatological data (Fig. 2), can provide salinity products along the SD's trajectory **allowing for the correction**
 204 **of** the salinity recorded by the SD. Moreover, comparative works between the physical model and experimental
 205 observations have shown a satisfactory correlation both in the open ocean (Escudier et al., 2021; Menna et al.,
 206 2023) and in the coastal environment (Martellucci et al., 2021). Despite all the limitations a model may have in
 207 such cases, the use of model products allows a minimum spatial and temporal distance in the comparison of the
 208 along track SD measurements. The nearest nodes (in km) with respect to the model data grid to the SD trajectory
 209 were chosen. The salinity provided by the model along the two SD trajectories shows very similar values to that
 210 measured by SD 1030 (Fig. 3). Salinity differences between the CMEMS model and the SD 1030 observations
 211 show a difference less than 0.1 in T1, T2, T4 and T5. During the Alboran Sea crossing (T3), the observed salinity
 212 deviated strongly from the model (about 0.6) over only 20 days. In contrast, SD 1053 showed deviating values
 213 compared to the model and SD 1030, which cannot be explained by space-time variability. With the exception of
 214 T1, the remaining transects (Fig. 3i-j) showed large deviations between model and observed salinities (T2: 0.8,
 215 T3: 0.7, T4: 0.9, and T5: 1). This could be related to the long time between the SD 1053 maintenance (early January
 216 and early May 2020), but it is more likely that a sensor error occurred in mid-January which even maintenance
 217 could not correct.

218 The salinity correction was performed using a linear regression method in which the salinity data recorded by
 219 the autonomous vehicles averaged over the day, were calibrated with the corresponding data from numerical
 220 models. A strict criterion, with a significance level of $p < 0.05$ (Table 2), was applied to the correction process.

221

222

223 Table 2. Statistics for the salinity correction. T1, to T5 refer to the different transects, *pval* is the significance level,
 224 distribution refers to normal or non normal data distribution, R^2 is the correlation coefficient, RMSE is the root mean
 225 square error, and NaN refers to lack of data.

		Direct comparison				
		<i>T1</i>	<i>T2</i>	<i>T3</i>	<i>T4</i>	<i>T5</i>
SD 1030	<i>pval</i>	0.0007	0.04	<0.001	0.04	0.025
	<i>distribution</i>	non normal	non normal	normal	non normal	normal
	<i>R2</i>	0.59	0.61	0.19	0.71	0.85
	<i>RMSE</i>	-	-	0.9058	-	0.2789

SD 1053	<i>pval</i>	0.026	0.003	0.004	<0.001	<0.001
	<i>distribution</i>	non normal	normal	normal	normal	normal
	<i>R2</i>	0.08	0.44	0.25	0.789	0.919
	<i>RMSE</i>	-	0.826	0.7072	0.8444	1.1275

226

227

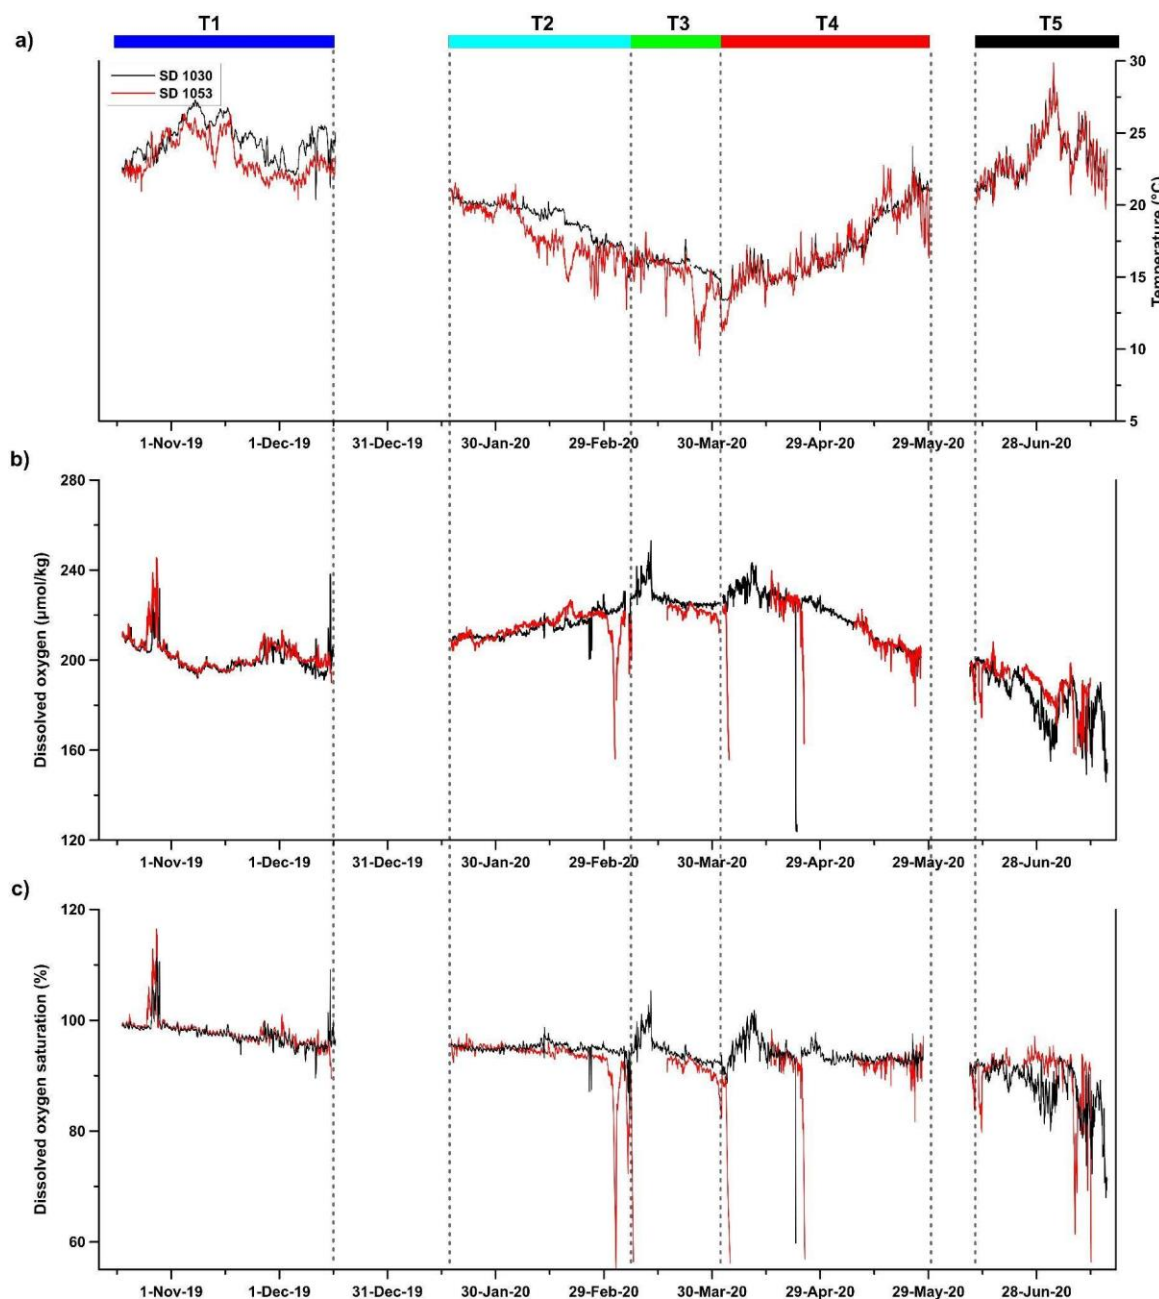

228

229 3.2 Dissolved Oxygen

230 Due to the strong dependence of dissolved oxygen on temperature, we first analyse the temperature along the track
 231 of the SDs. During the demonstration experiment, sea temperature (Fig. 4a) showed a seasonal signal similar to
 232 those observed at these latitudes (Pastor et al., 2019). The high observed temperature variability also includes the
 233 wide geographical coverage of the SDs. The highest temperatures were measured in November 2019 and July
 234 2020 in the tropical Atlantic and the southern Adriatic, respectively. The lowest temperatures were measured in
 235 the Gulf of Lion in April 2020. Along the SD tracks, the salinity (Fig. 2b) showed a gradual increase from the
 236 Atlantic Ocean to the eastern Mediterranean Sea. Given the correct temperature measurement, any dissolved
 237 oxygen drift can be assessed through comparison with dissolved oxygen saturation values. This procedure was

238 also used to correct Argo float data with climatological observations (Takeshita et al., 2013). The dissolved oxygen
 239 saturation showed a gradual decrease from 100% at the start of the demonstration experiment to 80% at the end
 240 (Fig. 4c). This behaviour is also reflected in the dissolved oxygen concentration, which decreases by about 40
 241 $\mu\text{mol/kg}$ for SD 1030 and 60 $\mu\text{mol/kg}$ for SD 1053 (Fig. 4b) over the course of nine months with standard deviation
 242 of the uncorrected oxygen record of 16 $\mu\text{mol/kg}$ and 72 $\mu\text{mol/kg}$ for SDs 1030 and 1053, respectively.
 243

244
 245
 246 **Figure 4. (a) Temperature, (b) dissolved oxygen concentration, and (c) dissolved oxygen saturation for the SD raw data**
 247 **(SD 1030 black line and SD 1053 red line).**
 248

249 Prior to applying correction all the outliers were excluded. After the first analysis we proceeded to correct the
 250 dissolved oxygen data, using the same oxygen correction method as used in the Argo program (Bittig et al., 2018).
 251 The principle of this method is to compare the dissolved oxygen measurements performed while the Argo oxygen
 252 sensor is in air with the oxygen partial pressure ($p\text{O}_2$) in air (Johnson et al., 2015). The latter variable is easily
 253 calculated from air temperature, air pressure, and relative humidity acquired by the SDs. Considering that the SD
 254 oxygen sensor is installed on the hull about 0.5 m below sea surface and that the SDs sailing cause mixing of the

255 water surface while sailing, we assume that the SDs oxygen sensors were in equilibrium with the atmosphere
 256 above, and furthermore, we can correct for the oxygen sensor drift using the in air calibration method (Bittig et al.,
 257 2018; Johnson et al., 2015). Specifically, we computed vapour pressure (V_p , in hPa) from the empirical equation
 258 reported in the operating manual of Aanderaa oxygen optode (model 4330) using the air temperature (T_{sd}) recorded
 259 from SDs:

$$260 \quad V_p = e^{(52.57 - \frac{6690.90}{T_{sd} + 273.15}) - 4.681 \cdot \ln T_{sd} + 273.15} \quad (1)$$

261 and expected partial pressure (E_{PP} , in hPa) from volume fraction of oxygen ($V_{fO_2}=0.20946$; Glueckauf, 1951),
 262 atmospheric pressure (AP_{sd}), vapour pressure (V_p) and relative humidity (RH_{sd}), as follows:

$$263 \quad E_{PP} = V_{fO_2} * (AP_{sd} - (V_p * \frac{RH_{sd}}{100})) \quad (2)$$

264 The E_{PP} was then compared to the pO_2 from the SDs to compute the gain factor (G) for daily correction.

$$265 \quad G = \frac{E_{PP}}{pO_{2sd}} \quad (3)$$

266 The corrected oxygen concentration (O_{2csd}) from the SDs was calculated from adjusting the oxygen data from SDs
 267 (O_{2sd}) with the gain factor.

$$268 \quad O_{2csd} = G * O_{2sd} \quad (4)$$

269 For each transect the mean gain was calculated and then, the gain factor was multiplied by the hourly oxygen
 270 data allowing to correct the time series.

271

272 **3.3 Correction and adjustment of pCO_2 data**

273 **3.3.1 Fixed-sites pCO_2 data acquisition and qualification**

274 The pCO_2 measurements from the different fixed ocean stations were regularly compared to the pCO_2 calculated
 275 from discrete water samples collected by the fixed stations and analysed for TA, pH, and DIC. During the last half
 276 of the ATL2MED demonstration experiment, this routine was hampered due to COVID-19 restrictions, thus,
 277 between March and July 2020, there were **fewer** discrete carbon samples for comparison with fixed station pCO_2 .
 278 Furthermore, there was minor variability in sampling frequency with regards to the fixed station pCO_2
 279 measurements and in the pair of measured variables used for pCO_2 calculation (TA-pH or DIC-TA) between the
 280 different fixed ocean stations (see Table S2 and S4). During the ATL2MED demonstration experiment, DIC, TA,
 281 and pH were analysed according to SOP 2, 3b, and 6b, respectively (Dickson et al., 2007) with some minor local
 282 variations (Table S4). Certified Reference Material (CRM) and TRIS provided by Prof. A. Dickson (Scripps,
 283 USDC, USA) were used to determine the accuracy. pCO_2 was calculated using the speciation software CO2SYS
 284 (Pelletier et al., 2007), with the discrete carbon pairs TA-pH or DIC-TA as input variables. In the computation, the
 285 carbonate system constants from Lueker et al. (2000), the HSO_4^- constant from Dickson (1990), the total borate-
 286 salinity relationship of Lee et al. (2010), and the hydrogen fluoride constant K_F from Perez and Fraga (1987) were
 287 used. The uncertainties connected to this calculation ranged from 1.82% when using TA-pH as input variables to
 288 2.65% when DIC-TA were the input variables (Orr et al., 2018). Based on this, no adjustments were performed
 289 for the fixed station pCO_2 data when the deviation from pCO_2 calculated from discrete carbon data were less than
 290 7.5 μatm and 10 μatm for the discrete carbon pairs TA-pH and DIC-TA, respectively. Uncertainty thresholds were
 291 set based on measurement uncertainties at each facility and temperature and pCO_2 in the vicinity of the fixed
 292 stations.

293

294 3.3.2 Correction of SD CO₂ data

295 The general accuracy of the ASVCO₂ system attached to the SD 1030 was checked by PMEL prior to deployment
 296 by comparing the results with ESRL CO₂ standards traceable to WMO standards (Sutton et al., 2014). For this
 297 test, typically 6 standard gases were used. On the return of the ASVCO₂ system to PMEL, it was discovered that
 298 the span gas was adjusted too low to completely flush the detector and that this had been so during the whole
 299 ATL2MED demonstration experiment. Thus, the LI-COR had to be recalibrated at the PMEL lab and this implied
 300 that the onboard gas spanning was bypassed, and new calibration coefficients were developed. Furthermore, the
 301 pre-mission test data from the PMEL lab were reprocessed using the new calibration coefficients. Based on the
 302 reported issues with the ASVCO₂ instrument, the accuracy of the CO₂ measurements is estimated to be < 5 µatm.
 303 Laboratory tests of the ASVCO₂ system on SD platforms highlighted an uncertainty of less than 2 µatm (Table 3
 304 in Sutton et al., 2014).

305

306 4 Results and discussion

307 4.1 Salinity

308

309

310 The salinity correction was based on the significant linear correlation (Fig. 3) observed across the different
 311 periods (Table 2). The periods characterised by small differences in salinity (<0.1) were not corrected. In general,
 312 the corrected salinity for both SDs showed similar values (Fig. 5), and the major differences between the two SDs
 313 were mainly due to their temporal and spatial distance. Overall, the correction was largest for SD 1053 (see RMSE
 314 values in Table 2). To validate the salinity corrected data a comparison with different observing systems was done.

315 For SD1030, the corrected salinity data showed a slight overestimation of salinity, while the raw salinity data
 316 showed an underestimation. The SD 1030 salinity highlights good agreement in T1 with respect to the SD 1053
 317 (Fig. 5), the average difference was less than 0.05, the highest difference between Argo float data and corrected
 318 salinity data observed on 17 November 2019 was ~0.15. In T2, the comparison can only be made for SD 1030
 319 with only one Argo float profile.

320 Between T2 and T3 a drop in salinity was observed when the SDs crossed the ETNA area, where the salinity
 321 exhibits a strong variability (Reverdin et al., 2007), triggered by freshwater flux and eddy transport (Gordon and
 322 Giulivi, 2014). This salinity drop was also observed in the climatological data (Fig. 2).

323 The salinity in T2 (SD 1030) only slightly differed ($\Delta S \sim 0.05$) with respect to the model and values were in
 324 agreement with the observations of the Argo floats during the crossing of the Gibraltar strait. In T3 a significant

325 difference was observed between model and observation (RMSE = 0.906; Table 2), while T4 was in line with the
326 climatology as well as the fixed stations. In T5, the RMSE was 0.279 (Table 2), in the southern Adriatic, the SDs
327 spent four days sampling the area, which allowed a robust comparison between data from the E2M3A fixed ocean
328 station and the glider measurements. The comparison showed a very good agreement between the observations,
329 which had almost the same salinity. In the northern Adriatic (T5), the comparison with *in situ* data showed the
330 highest differences with respect to the other *in situ* platforms comparison. However, the comparison with the fixed
331 stations (MIRAMARE and PALOMA) showed the same temporal changes with an average difference between
332 the SDs and the MIRAMARE fixed ocean station of ~0.3.

333 Regarding SD 1053, the comparison with the different fixed ocean stations shows that the corrected salinity
334 in T2, T3, T4 and T5 are consistent with the values measured at the stations (Argo float, glider, buoy, and RV
335 Ucadiz), the differences being mainly due to the distance between the different observatories and to the natural
336 variability of the areas. Also, the corrected data fit well with climatological values and *in situ* platforms.
337 Considering that during T1 the SDs raw data showed a smaller deviation from the Argo float data, the salinity
338 correction was applied after this transect (*i.e.*, from the start of T2).

339 4.2 Dissolved oxygen

340 For dissolved oxygen concentration, it would have been preferable to be able to compare the SD data to discrete
341 data. However, over the period of the ATL2MED demonstration experiment, no discrete dissolved oxygen
342 measurements were available due to COVID-19 restrictions. The corrected oxygen measurements (Fig. 6a)
343 spanned from 170 $\mu\text{mol/kg}$ to 270 $\mu\text{mol/kg}$ highlighting the highest concentrations during spring 2020. Time series
344 of percent dissolved oxygen saturation did not show any significant trend (Fig. 6b). Oversaturation was observed
345 at the end of October 2019 (~115%) and at the beginning of March 2020 (~105%), while strong undersaturation
346 was observed at 1-2 of April 2020 (~95%) and 8-11 July 2020 (~92%).

347 Furthermore, we evaluated the change in dissolved oxygen measured by the two SDs in two different
348 geographical areas (the Canary Islands area and the Balearic basin), where dissolved oxygen showed
349 oversaturation (Fig. 7) and undersaturation (Fig. 8). In the first region, we made use of Chl-a data and temperature,
350 while in the second region, temperature was used to evaluate the representativeness of the correction with respect
351 to ecosystem dynamics. The optical sensors on the SDs and thus, the Chl-a measurements, were strongly affected
352 by biofouling for most of the demonstration experiment, which is why we do not use these measurements in this
353 work. However, during the 10 first days in October 2019, the Chl-a data acquired by the SDs seemed to produce
354 reasonable values in accordance with Delory et al. (2018), who found that for new sensors the increase in
355 biofouling needs weeks to become significant. We refer to these Chl-a data, collected by the SDs in the transect
356 T1, when explaining the dissolved oxygen oversaturation episode off the Canary Islands.

357 The oxygen saturation concentration can be expressed as a function of salinity and temperature, in terms of
358 solubility (Garcia and Gordon, 1992). The gas concentration in seawater depends on thermohaline characteristics
359 and biological activity. The solubility of oxygen decreases with increasing temperature and salinity, showing a
360 strong correlation. In the ocean, dissolved oxygen saturation lower than 100% can be observed during the cold
361 seasons while in the warm season oxygen saturation is higher than 100%, inversely to the dissolved oxygen
362 concentrations (*i.e.*, high concentrations during cold season and low in the warm season). This is because heating
363 and cooling are generally faster than outgassing, except for episodes of high wind speeds which intensifies the air-
364 sea gas exchange (Ulses et al., 2021). Furthermore, dissolved oxygen concentration is affected by primary
365 production and respiration.

366

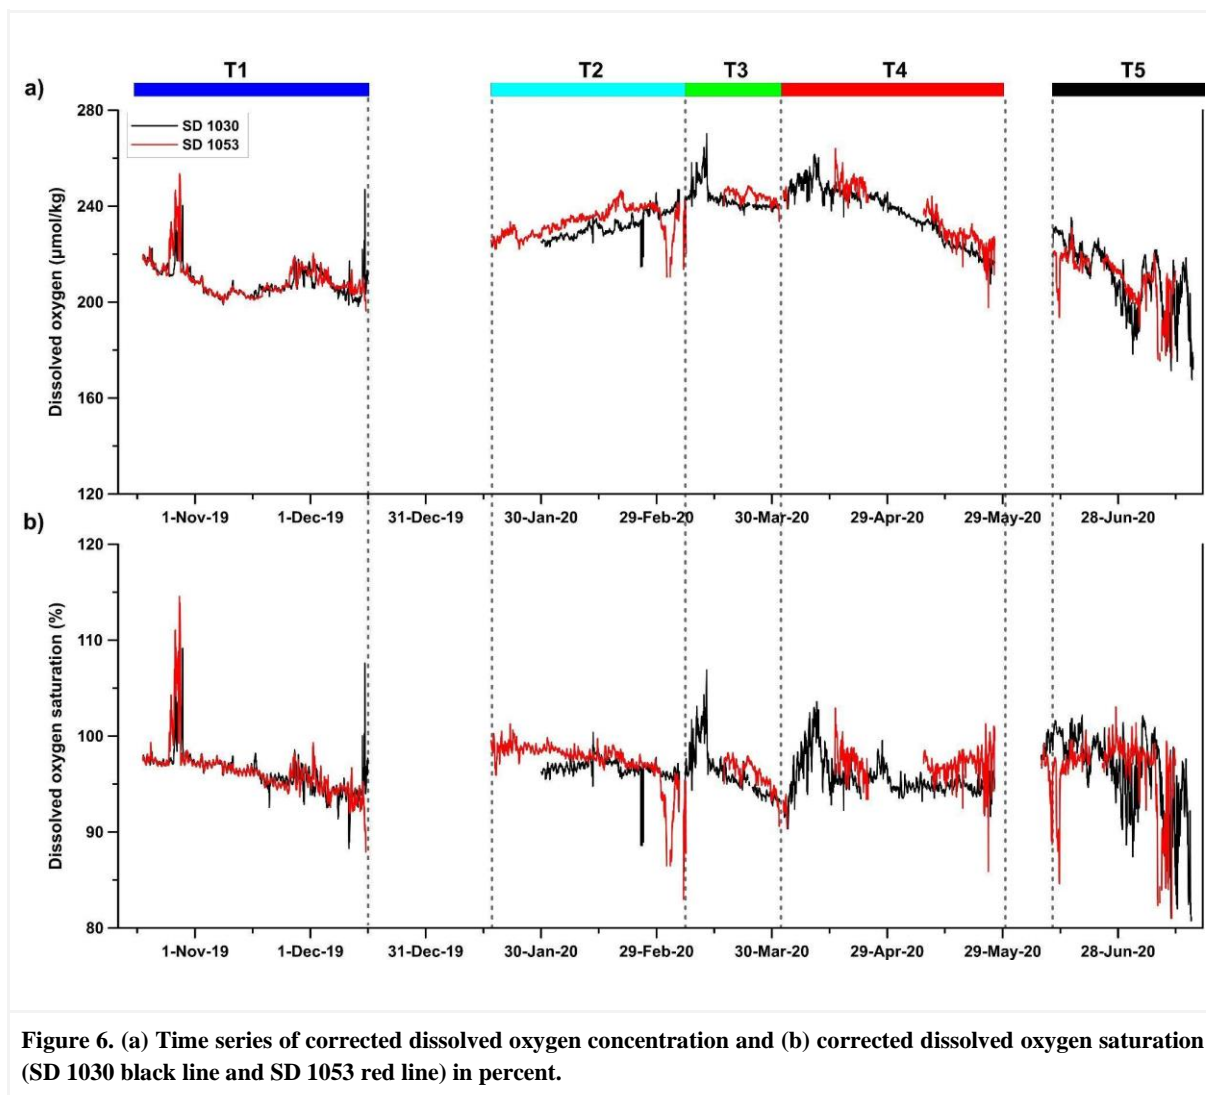

Figure 6. (a) Time series of corrected dissolved oxygen concentration and (b) corrected dissolved oxygen saturation (SD 1030 black line and SD 1053 red line) in percent.

367

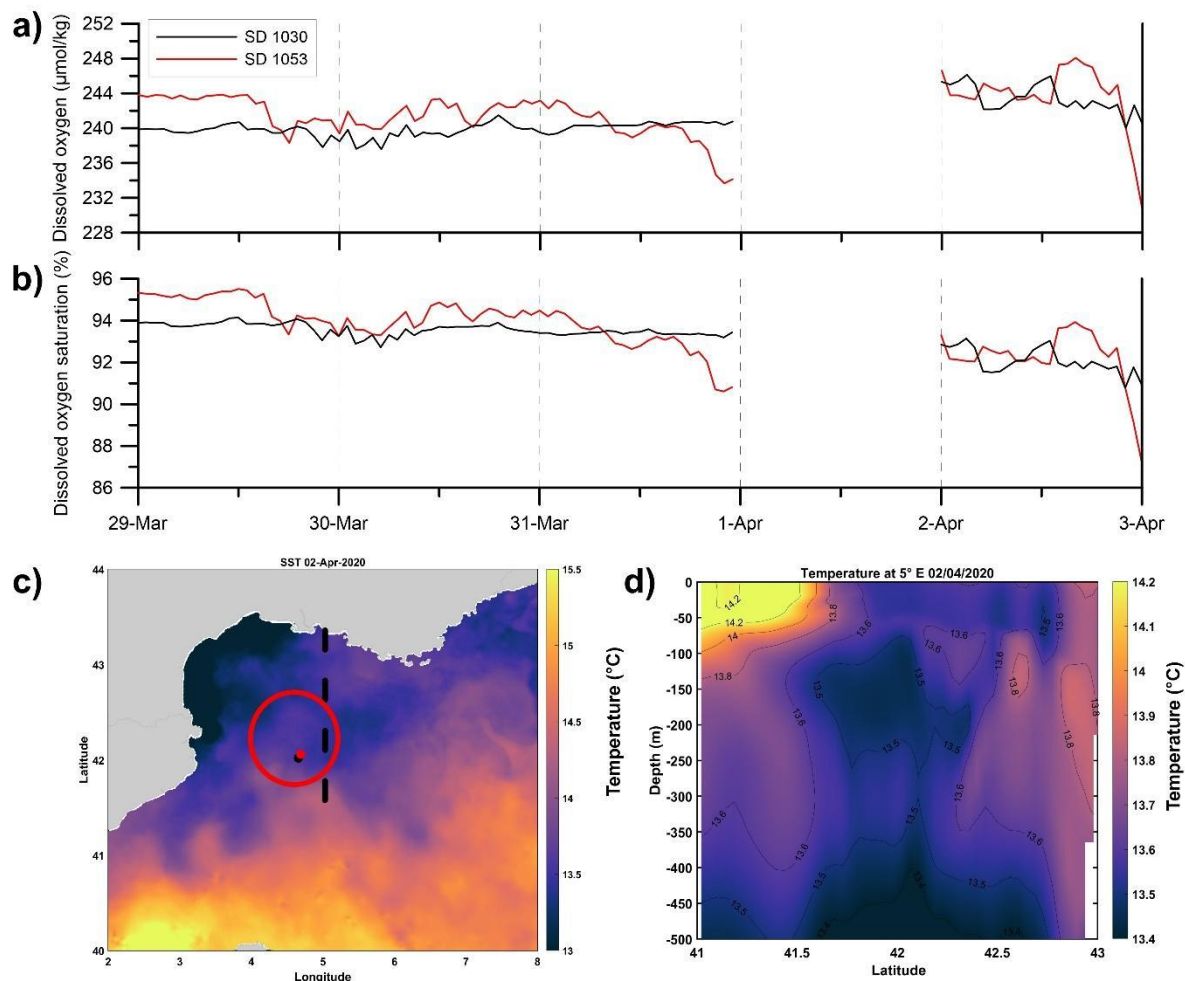

368 Between 25 and 29 October, the dissolved oxygen concentration and saturation were high around the Canary
 369 Islands ($>240 \mu\text{mol/kg}$ and $>110\%$; Fig. 7a and b). During the same period high concentrations of Chl-a were
 370 measured by SDs ($\sim 2 \mu\text{g/l}$, Fig. 7b, blue and orange line). The area with high Chl-a concentrations off the Canary
 371 Islands was visible on the satellite images of sea surface Chl-a concentration (Fig. 7c) and at the same time low
 372 sea surface temperature was observed (Fig. 7d). High Chl-a concentrations and low temperatures identify a
 373 mesoscale structure that has moved away from the African shelf. Considering that the latter is a very productive
 374 area due to the permanent upwelling off NW Africa coast (Cropper et al., 2014; Fischer et al., 2016), this justifies
 375 the high Chl-a concentration observed by the SDs at that time.

Sea surface Chl-a concentration (c), and (d) sea surface temperature on 28 October 2019. The red circle highlights the position of SDs (black dot = SD1030 and red dot=SD1053).

383

384

385

Figure 8. Time series of (a) dissolved oxygen concentration and (b) percent dissolved oxygen saturation in the Balearic basin. (c) Sea surface temperature evolution between 31 March and 2 April 2020. The black dotted line highlights the vertical section in (d). The red circle highlights the position of SDs (black dot = SD1030 and red dot = SD1053).

388

Between 29 March and 3 April 2020, the SDs crossed the Balearic basin reaching the Gulf of Lion on 1 April 2020, the SD 1053 measured a decrease in dissolved oxygen concentrations of about $10 \mu\text{mol/kg}$ (Fig. 8a). This behaviour was also observed in the dissolved oxygen saturation (Fig. 8b) which reached values lower than 95%. The northern part of the basin was characterised by lower surface temperatures (Fig. 8c) than the southern part. The vertical temperature section (Fig. 8d) highlighted the presence of upwelling of cold water to the surface justifying the lower surface temperature observed in Fig. 8c. The presence of this upwelled water caused the decrease in dissolved oxygen saturation (Fig. 8b) observed by the SDs, as the upwelled water is commonly characterised by low dissolved oxygen concentrations due to biological respiration (Chan et al., 2019).

397

398 4.3 $p\text{CO}_2$

399 $p\text{CO}_2$ (in μatm) from the ASVCO2 instrument attached to the SD 1030 were calculated according to Sutton et al.
 400 (2014) using T and S from the SBE37-SMP-ODO at the SD. Fig. 9a shows the uncorrected and corrected $p\text{CO}_2$
 401 acquired from the SD 1030. In Fig. 9b, the difference between corrected and uncorrected $p\text{CO}_2$ is shown and the
 402 offset increases from approximately $1 \mu\text{atm}$ at the start of the experiment to approximately $12 \mu\text{atm}$ at the end.

403

404

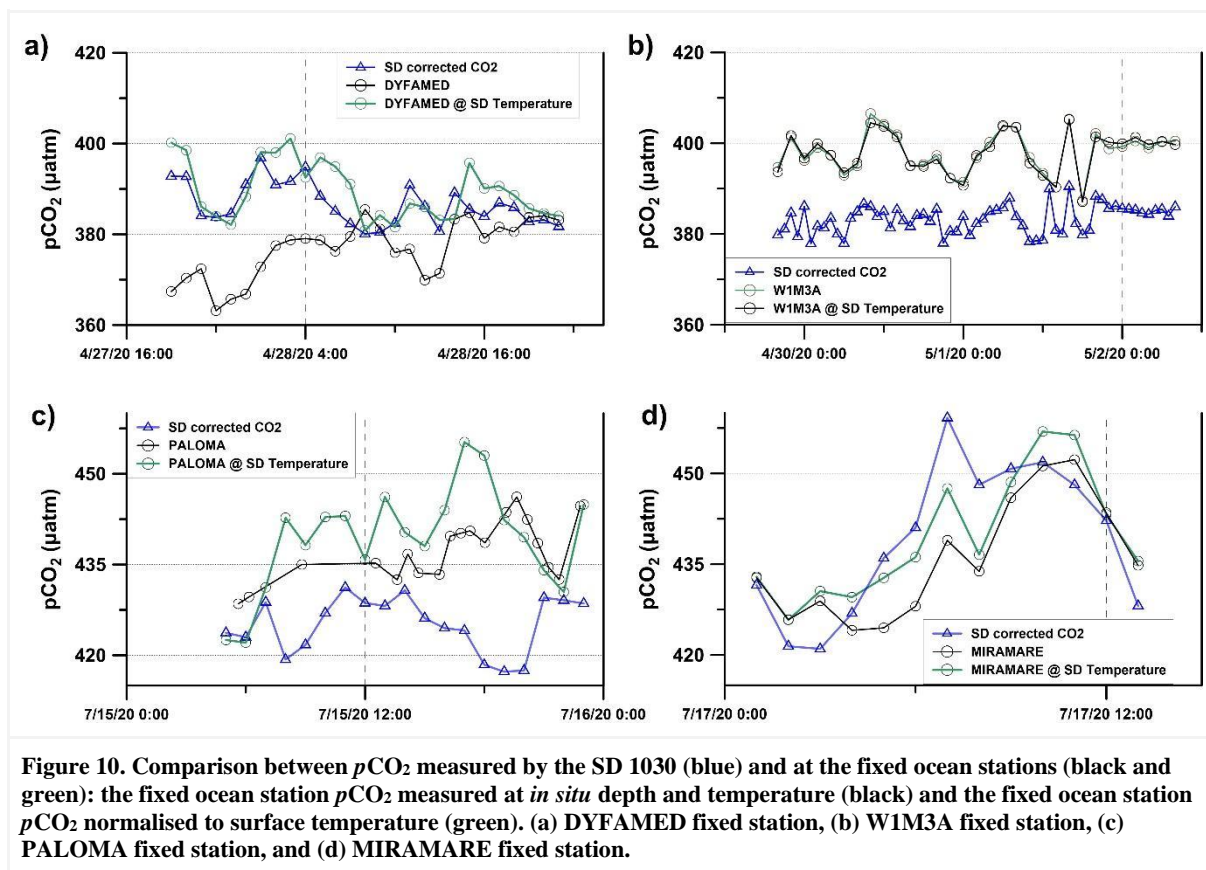

Figure 9. (a) Raw (red crosses) and corrected (black circles) $p\text{CO}_2$ data acquired by the SD 1030 as functions of time. (b) Difference between raw and corrected $p\text{CO}_2$ ($\Delta p\text{CO}_2 = \text{corrected } p\text{CO}_2 - \text{raw } p\text{CO}_2$).

405

406 The $p\text{CO}_2$ sensors at the different fixed stations were deployed at depths between 2 to 10 m while the SD measured
 407 at 0.5 m depth. To be able to compare $p\text{CO}_2$ measurements from the different depths, the station $p\text{CO}_2$ data were
 408 normalised to surface temperature by using the relationship of Takahashi et al. (1993): $p\text{CO}_2(1) =$
 409 $p\text{CO}_2(2) \exp^{0.0423(T_1 - T_2)}$ (5)

410 where T is temperature and 1 and 2 refer to the measurements at 0.5 m depth of the SD and at the measurement
 411 depth of each local station, respectively. Furthermore, the $p\text{CO}_2$ measurements acquired by the SD 1030 were
 412 compared to the corrected $p\text{CO}_2$, surface temperature normalised, from the fixed ocean stations (Fig. 10 and Table
 413 3). The difference varied between -0.5 and -16.9 μatm. The largest difference occurred in the eastern Atlantic,
 414 where calculated $p\text{CO}_2$ from discrete DIC and TA were compared to the SD 1030 $p\text{CO}_2$ data. Part of this deviation
 415 is likely attributed to calculation errors which is estimated to about 10 μatm when errors in both DIC, TA, and the
 416 carbon constants are included (Orr et al., 2018). The smallest difference between the SD 1030 $p\text{CO}_2$ and the $p\text{CO}_2$
 417 acquired from the fixed stations and normalised to surface temperature are seen at DYFAMED toward the end of
 418 April 2020 (-2.9 μatm) and at MIRAMARE in mid July 2020 (-0.5 μatm). The larger discrepancy at W1M3A and
 419 PALOMA might be attributed to processes which are not taken into account by temperature normalising, e.g.,
 420 spatial gradients due to primary production/remineralisation, which would decrease/increase the $p\text{CO}_2$. However,
 421 it is difficult to estimate the impact of these processes.

422

423

424

425 To assess the representativeness of the $p\text{CO}_2$ correction in terms of ecosystem dynamics, a comparison was made
 426 between the corrected $p\text{CO}_2$, temperature, and Chl-a concentrations from satellites. The $p\text{CO}_2$ in seawater is
 427 influenced by primary production, respiration, air-sea gas exchange, formation and dissolution of calcium
 428 carbonates, water mixing, riverine discharges and advection (Zeebe and Wolf- Gladrow, 2007; Bauer et al., 2013;
 429 Millero 2007), which leads to significant variations in different regions. The temperature affects the $p\text{CO}_2$ through
 430 the thermodynamic dissociation constants of the carbonic acids, which directly affects the CO_2 equilibria (eg.
 431 Millero, 2007) and to a lesser extent also the gas solubility.

432 Throughout the ATL2MED demonstration experiment, the $p\text{CO}_2$ value (Fig. 11a) showed almost the same
 433 pattern as the surface temperature (Fig. 11b), and furthermore, the $p\text{CO}_2$ values in the ETNA were lower than those
 434 of the Mediterranean at the same sea surface temperature. The main reason for this difference is attributed to the
 435 lower DIC in the Atlantic waters with respect to the Mediterranean (Alvarez et al., 2014).

436 We observed the highest $p\text{CO}_2$ variability in the Mediterranean Sea , as the temperature increased by more
 437 than 15°C from winter to summer leading to an increase in $p\text{CO}_2$. A reduction in $p\text{CO}_2$ due to phytoplankton
 438 photosynthesis is present at the end of the mission in the northern Adriatic where the fertilisation by nutrients
 439 carried by the Po river induced an increase in Chl-a concentrations (green line in Fig. 11b).

440

441

Table 3. Comparison between $p\text{CO}_2$ measurements at SD 1030 and the fixed ocean stations.

Station/ platform	Measurements	Date	Deviation between $p\text{CO}_2$ at SD 1030 and $p\text{CO}_2$ at fixed station normalised to SST (µatm)
RV Meteor	Discrete DIC and TA samples @ 5 m	30 Nov 2019	-16.9 µatm
DYFAMED	$p\text{CO}_2$ sensor @ 10 m	27-28 Apr 2020	-2.9 µatm
WIM3A	$p\text{CO}_2$ sensor @ 6 m	28 Apr - 2 May 2020	-14.2 µatm
PALOMA	$p\text{CO}_2$ sensor @ 3 m	15 July 2020	-14.7 µatm
MIRAMARE	$p\text{CO}_2$ sensor @ 2 m	17 July 2020	-0.5 µatm

447 SST= sea surface temperature

448

449 5 Summary

450 The ATL2MED demonstration experiment, which lasted for 273 days, represented the first monitoring
451 experiments of SDs covering both the ETNA region and the Mediterranean Sea, evaluating dynamics between
452 fixed ocean stations within the same basin as well as comparing characteristics between basins. The experiment
453 covered all seasons with varying meteorological and oceanographic conditions, primary productivity, and maritime

454 traffic. The ATL2MED lasted longer than planned primarily due to challenges with heavy biofouling of the two
455 SDs, COVID-19 pandemic restrictions, low winds, and strong contrary winds.

456 A huge amount of data has been produced during the ATL2MED demonstration experiment, and the data
457 required quality control and assurance to a varying degree, primarily depending on how sensitive the sensors were
458 to biofouling. Due to the COVID-19 pandemic restrictions, there was a lack of validation samples collected from
459 cruise transects, Argo floats, and fixed stations, and this has enforced a new way of thinking regarding drift
460 correction. The SBE salinity data acquired by the SDs have been corrected, when necessary, using model products
461 and the method was validated by comparing the data corrected with available *in situ* measurements. This resulted
462 in remarkable **consistency in the corrected salinity values between both SDs**. Data from the Aanderaa dissolved
463 oxygen sensors mounted on the SDs were corrected making use of in air oxygen measurements **to correct for the**
464 **erroneous trend in O₂ saturation (%)**. **The pCO₂ data from SD 1030 were corrected at PMEL and compared with**
465 **pCO₂ data acquired from fixed ocean stations**. The corrected SD datasets fit well with the data from fixed stations
466 and gliders, which means that the correction methods used are valid. The output is datasets that are available for
467 process interpretations in future research.

468 Other SD sensors were affected by biofouling to such a degree that the datasets were unable to be corrected
469 given the limited samples available for validation, like *e.g.* the optical sensors for fluorescence measurements.
470 Some recommendations related to this issue are presented in the next section.

471 The ATL2MED demonstration experiment is an example of how ASV can be used to perform multi-variable
472 and high-resolution sampling from areas which are not easily accessible, *e.g.* due to remote location, limited
473 shiptime availability, or COVID-19 restrictions. The SDs are environmentally friendly platforms, and they,
474 together with other ASV, are useful as a complement in the validation of fixed ocean stations. However, the
475 experiment clearly shows some of the challenges faced when this type of surface vehicle is part of long-term
476 missions.

477

478 **6 Experiences and recommendations**

479 **Our experiences and recommendations from the ATL2MED demonstration experiment can be summarised in the**
480 **following bullet points, which are explained in more detail at the end of this paragraph:**

481 **We experienced that**

- 482 - **the SD sensors were exposed to severe biofouling**
- 483 - **a substantial amount of effort was required to correct the SD datasets**
- 484 - **some of the SD sensors were mounted in an unfavourable way**
- 485 - **the COVID-19 pandemic limited the access to ship time and thus impacts on the collection of discrete**
486 **validation samples**

487 **We recommend to**

- 488 - **ensure a maintenance and cleaning frequency of the SD sensors and the hull that is adapted to the local**
489 **environment**
- 490 - **use of biolimiting equipment at the SDs**
- 491 - **implement an automatic in air calibration procedure for SD oxygen measurements**
- 492 - **ensure that the SD sensors are mounted in such a way that they are exposed to open water**
- 493 - **ensure that a sufficient amount of independent measurements (*e.g.*, salinity, dissolved oxygen, carbonate**
494 **system, Chl-a) are collected in the vicinity of the SD trajectories in order to validate the SD sensors**

495 **In general, the use of SDs requires considerable effort to ensure that the data are of scientifically usable quality, as**
496 **these vehicles operate on the surface and are more exposed to biofouling. For future trials, a frequency of sensor**
497 **cleaning and hull maintenance cleaning should be introduced depending on the monitoring area. In situations**
498 **where this is not possible, bio-limiting devices should be used, such as UV systems and wipers powered by the**
499 **solar panels that regularly clean the optical sensors. Experience from the ATL2MED demonstration experiment**
500 **has shown that the SBE37 sensors appear to be reliable and robust with respect to biofouling. Regarding the**
501 **dissolved oxygen correction, it is recommended to perform an in-air calibration as used for Argo floats to be able**
502 **to correct the drift of the oxygen sensor more easily.**

503 The ATL2MED demonstration experiment suffered from a lack of discrete samples for validation. Therefore,
504 future experiments should be organised to collect discrete samples for acquired parameters at appropriate
505 frequencies, which will greatly facilitate validation of the quality of the SD dataset. Finally, the suitability of SDs
506 as a tool to validate other types of measuring platforms (e.g. fixed ocean stations, mobile devices or ships) strongly
507 depends on various conditions, such as the distance to the platforms, the depth of measurements at fixed stations
508 and the environmental conditions. All these factors need to be carefully considered to ensure the best possible data
509 set for such a validation.

510

511 **Data availability.** Data described in this work is available from different sources, see Table S6 in the
512 Supplementary Material.

513

514 **Supplement.** The supplementary material is available at the end of this manuscript.

530 Acknowledgement

531 The ATL2MED experiment has received generous funding from the US company PEAK 6 Invest and invaluable
532 support regarding coordination, operation, and data deliverance from Saildrone Inc.. Furthermore, funding has
533 been provided by GEOMAR Helmholtz Centre for Ocean Research (GEOMAR), Integrated Carbon Observation
534 System - Ocean Thematic Centre (ICOS-OTC), the French National Centre for Scientific Research (CNRS),
535 Oceanography Laboratory of Villefranche (LOV), the Oceanic Platform of the Canary Islands (PLOCAN), Ocean
536 Science Centre Mindelo (OSCM), the Hydrographic Institute of Portugal (IH), Balearic Islands Coastal Observing
537 and Forecasting System (SOCIB), Italian National Institute of Oceanography and Applied Geophysics (OGS),
538 Helmholtz Zentrum Geesthacht (HZG), Centre Scientifique de Monaco (CSM), National Research Council-
539 Institute of Marine Sciences (CNR-ISMAR), and National Research Council - Institute for the study of Anthropic
540 Impact and Sustainability in the Marine Environment (CNR-IAS). We thank OGS engineers Paolo Mansutti and
541 Giuseppe Siena for the assistance during the final recovery of the SDs, and Piero Zuppelli, Riccardo Gerin, Antonio
542 Bussani and Massimo Pacciaroni for piloting the OGS glider. Furthermore, we thank Björn Fiedeler and Benjamin
543 Pfeil for initialising the demonstration experiment and for executing the first phase of the experiment. Finally, we
544 thank Adrienne Sutton and Stacy Manner (PMEL) for invaluable help with correcting the ASVCO₂ pCO₂ data.
