Abstract. The Land Use/Cover Area frame Survey (LUCAS) of the European Union (EU) presents a rich resource for detailed understanding of land cover and use, making it invaluable for Earth Observation (EO) applications. This manuscript discusses the recent advancements and improvements in the LUCAS Copernicus module, particularly the data collection process of 2022, its protocol simplifications, and geometry definitions compared to the 2018 survey and data. With approximately 5 150,000 polygons collected in 2022, an increase from 60,000 in 2018, the LUCAS Copernicus 2022 data provides a unique and comprehensive in-situ dataset for EO applications. The protocol simplification also facilitates a faster and more efficient data collection process. In 2022, there are 137,966 polygons generated, out of the original 149,408 LUCAS Copernicus points, which means 92.3% of the points were actually surveyed. The data holds 82 land cover classes for the Copernicus module which map to 88 classes for up to LUCAS level 3 legend. For land use the data holds 40 classes, along with 18 classes of land use 10 types. The dataset is available here for download (PID: <http://data.europa.eu/89h/e3fe3cd0-44db-470e-8769-172a8b9e8874>). The paper further elaborates on the implications of these enhancements and the need for continuous harmonisation to ensure semantic consistency and temporal usability of data across different periods. Moreover, it calls for additional studies exploring the potential of the collected data, especially in the context of remote sensing and computer vision. The manuscript ends with a discussion on future data usage and dissemination strategies.

15 1 Introduction

The importance of in-situ data for Earth Observation (EO) applications cannot be overstated. In-situ observations provide ground-based reference data, crucial for the production, validation and calibration of remote sensing products derived from satellite or airborne observations. The two largest constraints to satellite-based model performance are training data and imagery (Burke et al., 2021). While imagery has become abundant, the scarcity and frequent unreliability of ground-based reference

20 observations data make both training and validation of satellite-based models difficult. Particularly, they are pivotal in the assimilation practices to better inform Earth surface modeling and other EO endeavors (Balsamo et al., 2018). The Copernicus component of the EU's space program, known for its Earth Observation capabilities, heavily relies on a vast array of in-situ data. The Cross cutting coordination of Copernicus access to in-situ data¹ provides support to Entrusted Entities in accessing such data for both the production and validation of Copernicus products.

25 Despite the significant value, the collection of low-uncertainty in-situ data presents a myriad of challenges. The systematic collection of such data by humans is very resource-intensive, and ensuring the necessary quality and representativity for effective use in Earth Observation applications further exacerbates the challenge (Teucher et al., 2022; Andries et al., 2022).

In the EU, a regular surveyed sample of land cover and land use has been collected since 2006 under the Land Use/Cover Area frame Survey (LUCAS) (d'Andrimont et al., 2020). The data collected under this survey, especially the new LUCAS Copernicus module introduced in 2018, offers a remarkable resource of in-situ data. In 2018, this new LUCAS module (the Copernicus module) specifically tailored to EO was introduced, see d'Andrimont et al. (2021). A specific protocol was designed to collect *in-situ* information with specific characteristics fitting EO processing requirements. As a result, a total of 58,428 polygons are provided with a level-3 land cover (66 specific classes including crop types) and land use (38 classes) information. This represent a unique set of in-situ data, opening the possibility for applications with higher thematic detail as compared to
35 previous LUCAS surveys, such as crop type mapping. This dataset has been used to generate continental mapping of crop with sentinel-1 (d'Andrimont et al., 2021), with Sentinel-2 (Ghassemi et al., 2022a; Luo et al., 2022) but also for Land cover (Venter and Sydenham, 2021; Ghassemi et al., 2022b; Witjes et al., 2022), forest mapping (Bonannella et al., 2022), and land cover dynamics in watersheds (Beselly et al., 2021).

In 2022, a new survey and protocol was carried out. The advancements in the LUCAS Copernicus module, particularly
40 the data collection process of 2022, its protocol simplifications, and geometry definitions compared to the 2018 survey and data, provide a substantial enhancement in the in-situ dataset available for EO applications. This manuscript delves into these improvements and the implications thereof, alongside discussing the future data usage and dissemination strategies.

2 LUCAS Survey

LUCAS is a two phase sample survey. The LUCAS first phase sample is a systematic selection of points on a grid with a 2 km
45 spacing in Eastings and Northings covering the whole of the EU's territory Gallego and Bamps (2008). Currently, it includes around 1.1 million points (Figure 1) and is referred to as the master sample. Each point of the first phase sample is classified in one of ten land-cover classes via visual interpretation of ortho-photos or satellite images ESTAT (2018).

2.1 LUCAS 2018 survey

The LUCAS 2018 survey collected 97 variables at 337,854 points. Most of the points surveyed fall in a homogeneous area for
50 which the minimum mapping unit is about 7 m²(a circle of 1.5 m radius). This homogeneity is ascertained by way of orto-photo

¹<https://insitu.copernicus.eu/>

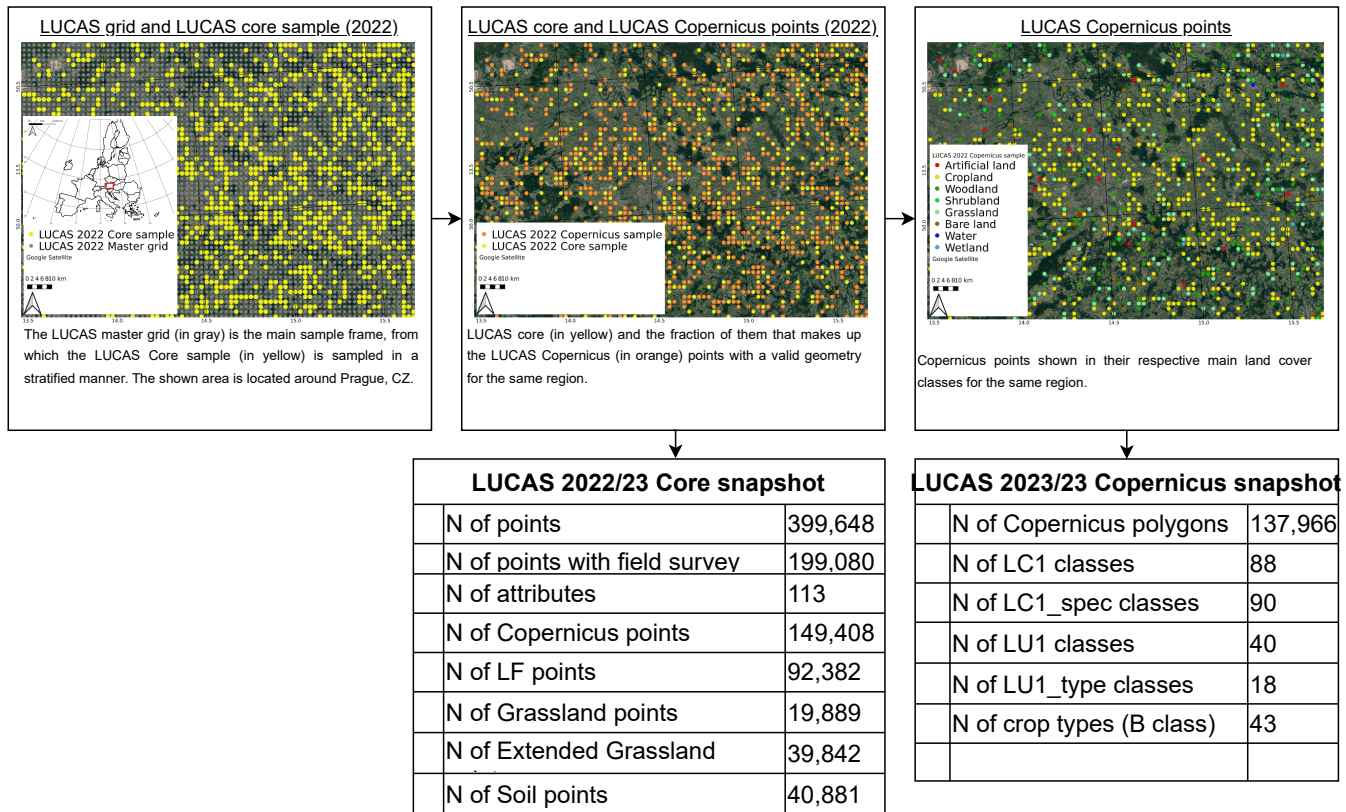

Figure 1. Schematic overview of the LUCAS and harmonisation methodologies. This illustrates the sampling at the basis of the production of the LUCAS primary data. (The background map is obtained from © GoogleSatellite contributors 2023. Distributed under the Open Data Commons Open Database License (ODbL) v1.0).

first and affirmed or switched by field survey after. When the land cover is not homogeneous, for example when it is composed of trees or shrubs interspersed with grass, the scale of observation is extended to classify it. In these cases, a systematic observation of the “environment” in the vicinity of the point, which in LUCAS is called the extended window of observation, has to be adopted. The extended window of observation expands to a radius of 20 meters from the point (representing an area of 0.13 ha) for forest and shrublands. Detailed information about the survey can be found in Eurostat (2018a). The land cover surveyed is classified according to a harmonized 3-level legend system Eurostat (2018b). Additionally to the *core* variables collected, other specific modules were carried out on demand on a subset of points, such as (i) the topsoil module and (ii) the grassland module. The LUCAS 2018 *core* data are available in an harmonised open database in d’Andrimont et al. (2020).

2.2 LUCAS Copernicus module

The LUCAS 2018 Copernicus module was applied to a subset of points from the 2018 survey to collect homogeneous land cover information up to an extent of 51 meters until the land cover changes in four cardinal directions around a point of

observation. The exercise aims at collecting the area and shape of a pure and uninterrupted land cover, specifically aimed at acquiring multi-pixel *in-situ* data compatible with the spatial resolution of high-resolution sensors (specifically Sentinel 1 and 2; see d’Andrimont et al. (2021) for the open ready-to-use dataset). The LUCAS Copernicus dataset contains 63,287 polygons that are supposed to represent the pure land cover at level-2 (genus). When filtering the data for which a level-3 (species) legend is available, 58,426 polygons with a level-3 land cover are available. Although the survey was designed with the idea of capturing pure land cover, every data collection exercise is prone to errors, such as wrong polygon labels, general geo-location error, or errors with extent in the cardinal direction. In order to arrive to a measure for homogeneity a Copernicus polygon, one can weigh the pixel value by the fraction of the pixel that intersects the polygon Meroni et al. (2021).

70 3 LUCAS Copernicus 2022

In 2022, the Copernicus module was simplified as illustrated by the field form (Figure A4). By removing some variables that were sampled in the 2018 protocol but that did not prove to be useful, the survey cost at each point could be reduced. Therefore, the total number of points could be increased to 150k. The protocol requires the surveyor to register the LUCAS LC level 3 at the position they have reached. In contrast to the 2018 Copernicus module, this means that detailed information on e.g. permanent tree crops is also collected. The position reached can coincide with the LUCAS point or not due to physical, legal, or privacy barriers. Even when a surveyor cannot reach the LUCAS point and is even too far away to physically see it, they normally are able to collect Copernicus-relevant information via photo-interpretation, except when on a linear feature narrower than 3 m (e.g. tracks, grass margins or similar), because this introduces excessive complexity. For most cases when doing Photo-Interpretation (PI) in the field it was generally possible to find a suitable location to carry out the survey.

80 An example of the data can be seen on Figure 2, where the coverage of the polygons is visible over a recent Google basemap. The shape of the polygons adequately capture the extent of the land cover. The small offsets between the positions of the theoretical and survey points can be explained by either GPS precision, or the slight adjustments of the surveyors in the landscape. Of specific interest is Figure 2b, which shows a point, unreachable by the surveyor, as it is on private property. The surveyor in this case followed the Copernicus module protocol and completed the survey, as pertaining to the physical location reached. We can see the Copernicus land cover registered at this point ID (36782992) is A22 (Non built-up linear features), while the land cover of the theoretical point, as registered by the LC1 variable shows, is A11 (Buildings with 1 to 3 floors), which corresponds to the physical reality.

All LUCAS points	Copernicus point = YES	CANDO = YES	With geometry
399,648	149,408	138,024	137,966

Table 1. The number of LUCAS points at each step. Column one shows all LUCAS 2022 points to be surveyed. The second, whether the point was originally selected as a LUCAS Copernicus point. The third, whether the Copernicus sample was actually taken (CANDO is the suffix of the column name). The final column shows the number of points, for which it was possible to generate the radial geometry.

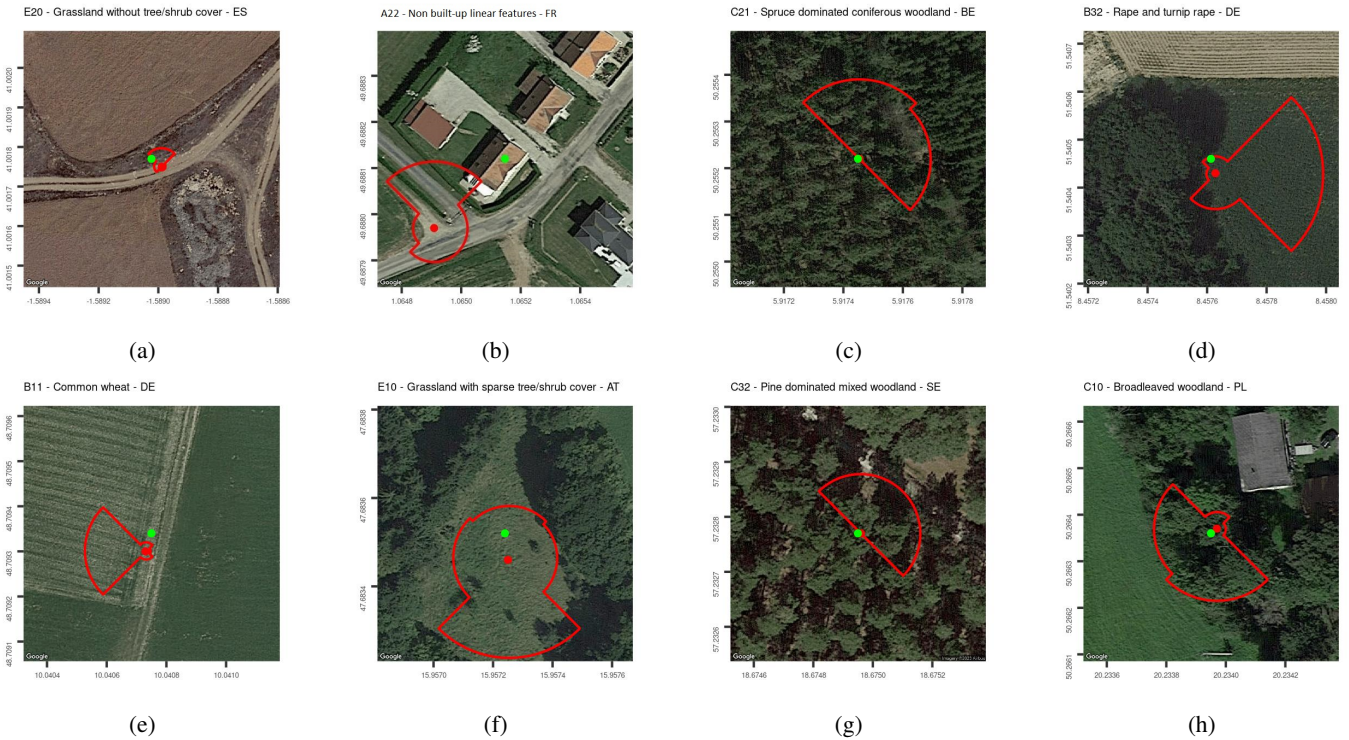

Figure 2. Examples of LUCAS Copernicus built polygons. The green point is the theoretical LUCAS point. The red point is the GPS location of the Copernicus surveyor. Polygons are built using distances in the N, E, S, and W directions collected on the ground. The background RGB imagery is obtained from map data ©2023 Google Maps.

4 Public data and usage note

In the 2022 survey, 137,966 polygons were generated from validly collected survey data over EU-27 as shown in the map
 90 Figure 3. They were produced in varying amounts for 88 LC classes up to LUCAS legend level 3 as illustrated on Figure 4. The clean version of these classes can be found in column *lc1_code*, whereas column *survey_lc1* hosts the original data, which we thought might also be interesting for users.

The mean size of the LUCAS Copernicus polygons is 0.35 Ha with the full distribution visible on Figure 5. There are two
 95 tails at either end of the distribution - before the first quantile, and after the third. There is no obvious reason behind the tails, meaning no LCLU class or NUTS0 is overly represented within them, although many of the polygons larger than 0.8 Ha are in the Arable land class, meaning used for agriculture. The parcels at the small ranges, specifically the 21,207 which are under 100 square meters, are distributed throughout all classes and member states. These should be used with caution and bearing in mind the ground-range resolution of the sensor, used to extract remote sensing data.

The crop samples of the survey are mapped on Figure A2 and their distribution is on Figure A3.

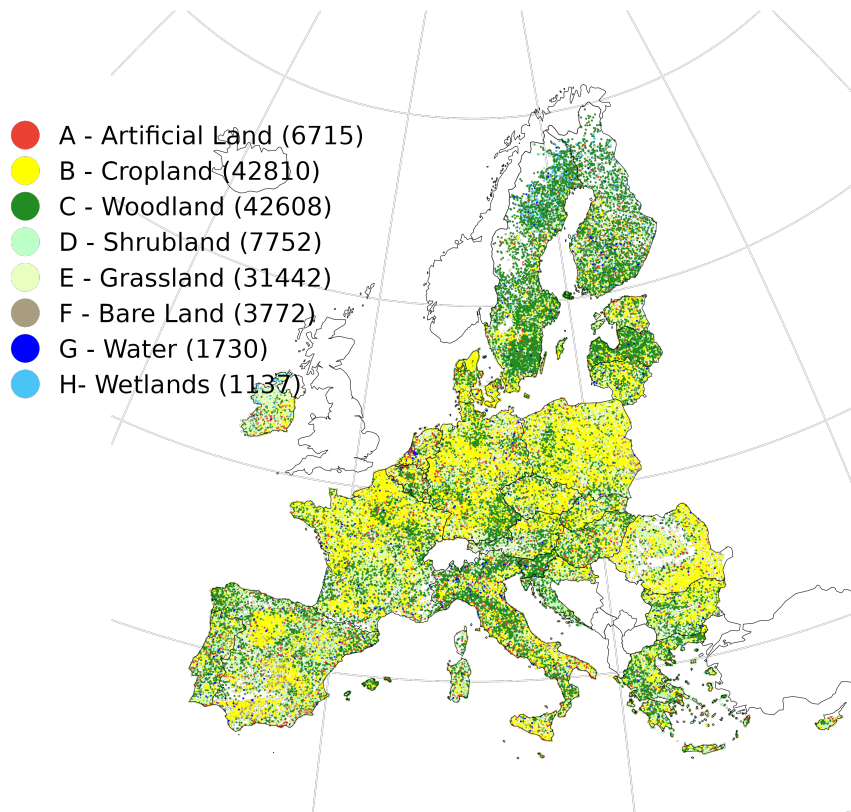

Figure 3. Map of the LUCAS Copernicus polygon collected in 2022 as per their respective main Land Cover class. The number in brackets represents the number of Copernicus polygons for that LC class.

Figure 4. Land cover class distribution of the LUCAS Copernicus polygon collected in 2022.

Figure 5. Area of polygons collected in 2022.

5.1 Comparison 2018-2022

Evolution between the LUCAS Copernicus 2018 and 2022 by Land cover (Figure 6a) and by country (Figure 6b). From Figure 6a we see that for every LUCAS LC1 the number of samples has at least doubled. For some classes, like Artificial land (A) and Water (G), the samples are much more - 91.6% and 98.6% respectively.

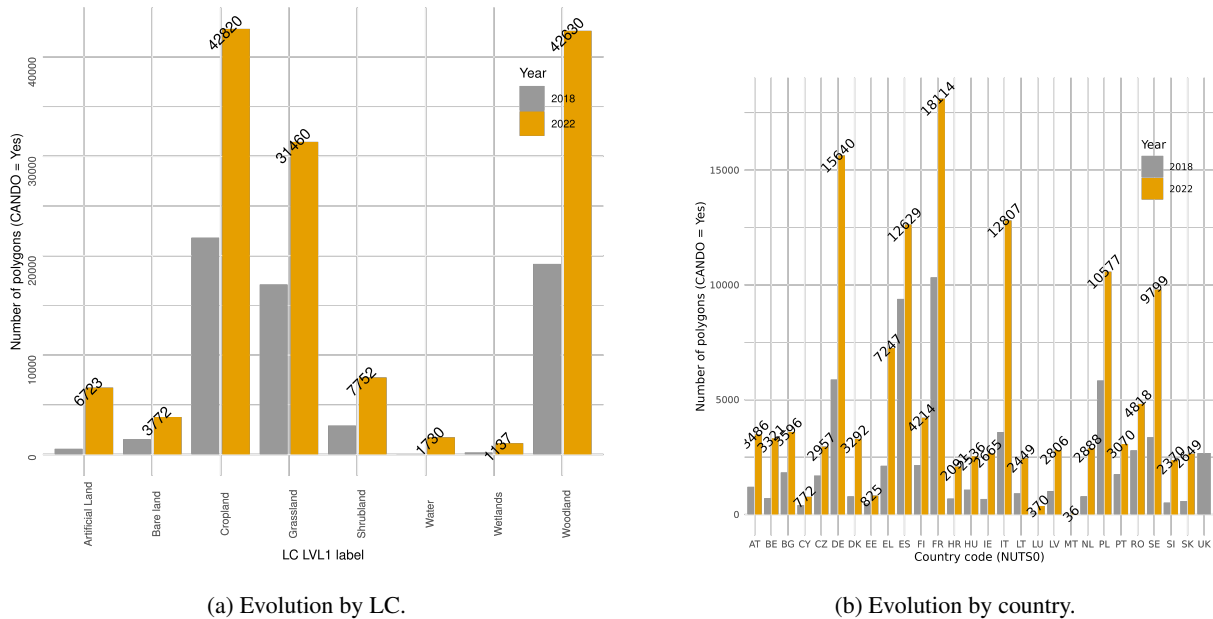

Figure 6. Change between the two LUCAS Copernicus surveys 2018 - 2022/23 in terms of representativeness in general LUCAS Land Cover classes and by NUTS0. The number at the top of the bar shows the value for the 2022 survey.

105 A similar trend is observed for each country (NUTS0), where the number of samples has at least doubled, in some cases tripled (Belgium, Germany, Denmark, Greece, Ireland, Italy, Netherlands, Slovenia, Slovakia), safe for the UK, which is no longer part of the survey. In essence, because of BREXIT, the quota of points available to the UK have now been re-distributed to the other Member States.

5.2 Quadrilateral vs radial polygon geometry

110 As shown in Figure A1, in 2018 the polygons were erroneously generated by using the distances noted by surveyors as the lengths of the line segments that make up the shape of the irregular quadrilateral Copernicus polygons. In essence, this was a simplification of the actual survey design, which required the generation of radial quarter-arc slices in each cardinal direction, which are to be merged together to form another irregular quasi-circular polygon shape. The difference between the two shapes obviously has an impact on the area of the polygon and hence - on the amount of Sentinel pixels that fall within it.

115 The difference in area between the two types of polygon definition (quadrilateral and radial) is shown on Figure 7. The total area of quadrilateral LUCAS Copernicus 2022 polygons is 274.6 km², while for the radial definition the area is 489.4 km², or an increase of 78.2% for the entire EU-27. The maximum increase in area is registered in Malta (95.5%) and the minimum in Latvia (68.5%).

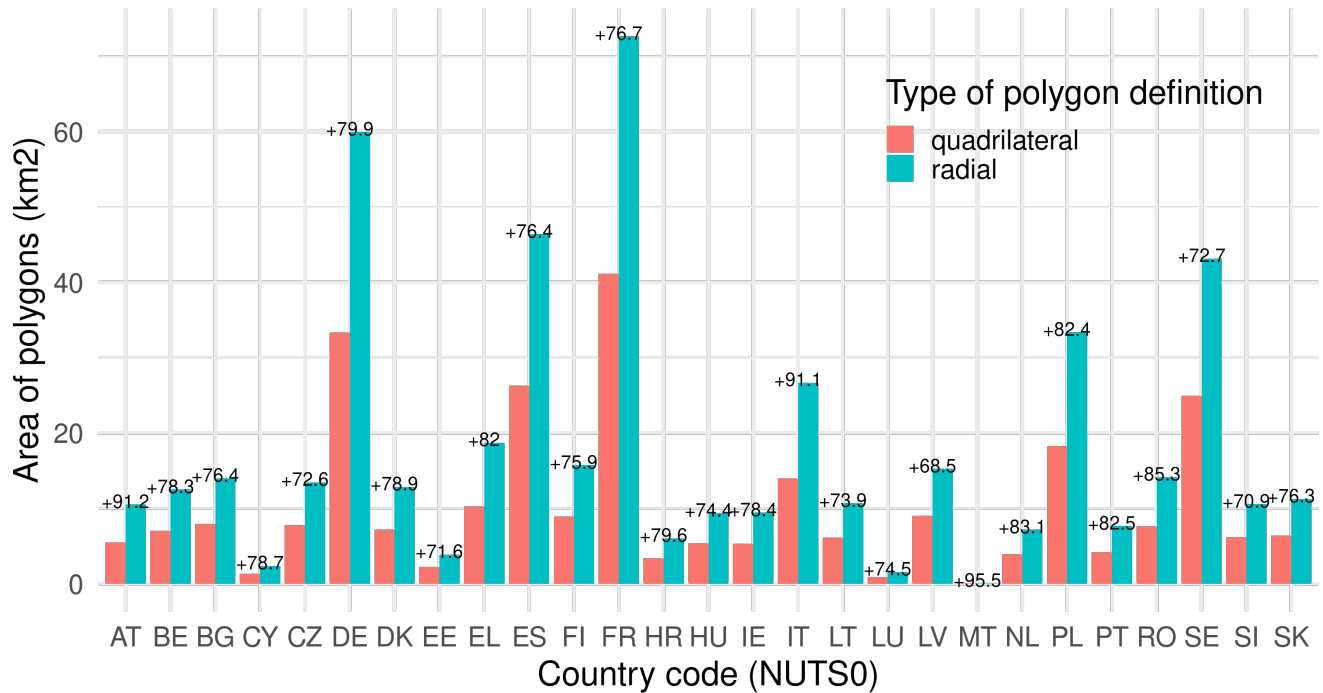

Figure 7. Area of LUCAS Copernicus polygons, aggregated to NUTS0 region, as derived based on the two types of polygon definition. The number at the top of each bar group represents the increase (in percent) between the two.

5.3 Assessment

120 A preliminary assessment of the dataset highlights the following key insights:

- LUCAS 2018 Copernicus data proved itself as a valuable source for training and/or validation data for various operational programs, such as the Copernicus Land Monitoring Service (CLMS), Horizon 2020, Horizon Europe, and other associated activities. The improvements of the 2022 survey will further enhance this value by maximising pure land cover area, irrespective of its size, having a more precise legend upon data collection, and sharing the data in a clear and open manner.
- LUCAS point data can be used as a sampling and/or stratification scheme for selecting training/validation data that originates from elsewhere.

125

– Sampling grid density, spatio-temporal coverage, temporal asynchrony from other CLMS products, geo-location precision issues during data collection, and legend-matching issues still prevent the easy and straightforward use of LUCAS data for many applications (Schweitzer et al., 2023).

6 Conclusions

A new simplified Copernicus protocol has been defined. Some notable improvements have been made such as collecting the land cover Level 3 data directly in the Copernicus polygon and increasing the area covered by pure land cover. With 150K polygons collected in 2022, compared to 60K in 2018, the dataset provides unique in-situ data for Earth Observation applications. Because of some inherent differences between the survey years, be in the form of the sampling design (Ballin et al., 2022), or due to differences in classification of land cover or land use (Eurostat, 2022), further harmonisation is needed in order to guarantee the semantic consistency of the coding and legend, as well as the temporal inter-usability of both the 2018 and 2022 data. In the event of such a harmonisation by the authors, they commit to a publishing a new version of the data in a similar format and with all relevant documentation. In terms of analysis there is much to be done with the polygons themselves in the remote sensing context, as well as, the collection of ground photos that can be leveraged for further computer vision work. From a data collection point of view, most issues with the surveys (FAQ from surveyor) have been solved. Further discussion about the data use and diffusion still needed.

7 Code and data availability

To produce the processing pipeline the authors used both the R programming language, version 4.2.1, and PostgreSQL (13.0) with the PostGIS plugin (3.0.2). The code for producing the dataset from the raw LUCAS data and all the figures shown in the manuscript consists of four commented scripts - pre-processing, generating quadrilateral LUCAS polygons, generating radial LUCAS polygons, and producing figures and tables. The order in which these are executed is important and they are numbered accordingly. The pre-processing includes the download of the micro data from Eurostat website². These, alongside a ReadMe file can be accessed here: https://jeodpp.jrc.ec.europa.eu/ftp/jrc-opendata/LUCAS/LUCAS_2022_Copernicus/.

The produced dataset is provided in geopackage format and hosts 121 relevant LUCAS attribute columns, plus the radial geometry of the Copernicus polygons. The dataset is available here for download (PID: <http://data.europa.eu/89h/e3fe3cd0-44db-470e-8769-172a8b9e8874>, European Commission (2022)). The data will also be available on Google Earth Engine after official publication. The link between this dataset and previous LUCAS surveys, or with the harmonised product d'Andrimont et al. (2020), is accomplished via the pointid column. Although all columns come from the data, the authors have added two additional columns - "survey_year" and "poly_area_sqm"; the first one in order to track which records come from which year of survey; the second is the calculated area in square meters.

²The micro data were obtained from https://ec.europa.eu/eurostat/documents/205002/17561401/EU_LUCAS_2022.zip accessed on 1/11/2023. For the latest version of the data, please refer to Eurostat website.

Appendix A

A1

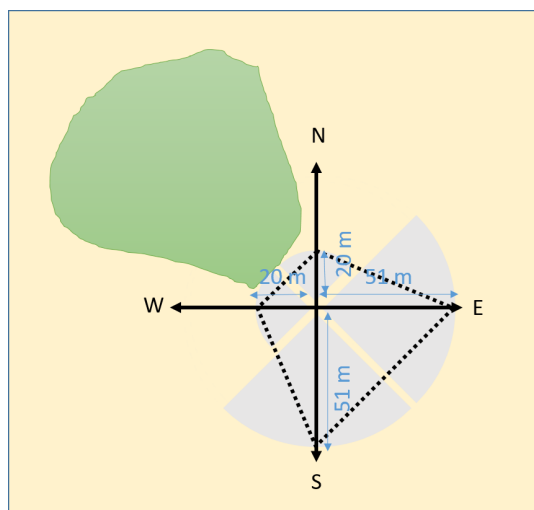

Figure A1. Overview of how polygons were built based on the radial distance collected on the ground. A distinction can be made between constructing a polygon based on quadrilateral distance, shown in a dotted line (as was done for the 2018 survey), and by generating the radial quarter arcs, shown as gray polygons, corresponding to the field of view the observation should represent (as was done for the 2022 survey).

160 *Competing interests.* The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper. The authors also declare that the information and views set out in this article are those of the authors and do not necessarily reflect the official opinion of the Institution that produced the data - EUROSTAT.

Acknowledgements. The authors would like to acknowledge the invaluable efforts of the LUCAS field surveyors and the teams involved in the LUCAS database management at Eurostat. Their dedication and hard work have made the LUCAS Copernicus 2022 dataset possible. We would also like to thank the various project partners for their continuous support and feedback.
