31 **Abstract**

32 Atmospheric aerosol in the Tibetan Plateau (TP) and its surroundings has ~~received~~
33 ~~widely attracted significant~~ scientific ~~concern~~ interest in recent decades ~~owing due~~ to its
34 ~~significant~~ notable impacts on ~~regional~~ regionally climatic and cryospheric changes,
35 ecological and environmental securities, and the hydrological cycle. However, our
36 understanding on the atmospheric aerosol in this remote region is highly limited by the
37 ~~severe~~ scarcity of available dataset ~~due, owing~~ to the extremely harsh natural
38 conditions. This ~~condition~~ challenge has been ~~improved~~ mitigated in recent decades by
39 ~~constructing a few stable~~ establishing field observatories at typical sites ~~on~~ within the TP
40 and its surroundings. A continuous project ~~was carried out since~~ initiated in 2015 aims
41 to ~~investigate~~ explore the properties and sources of atmospheric aerosols, as well as their
42 regional differences ~~in the vast TP regions by performing, through~~ multiple short-term
43 intensive ~~field~~ observations ~~using across this vast region utilizing~~ a suite of high-time-
44 resolution online instruments. This paper presents a systematic hourly scaled dataset of
45 ~~the high time resolution (hourly scales)~~ aerosol physicochemical and optical properties
46 at eight ~~different~~ sites ~~over~~ across the TP and its surroundings derived from the
47 ~~observation~~ project, ~~including the. It includes~~ size-resolved chemical compositions of
48 submicron aerosols, ~~standard~~ high-resolution mass spectra and sources of organic
49 aerosols, size distributions of particle number concentrations, particle light scattering
50 and absorption coefficients, particle light absorptions ~~from~~ attributed to different
51 carbonaceous substances ~~of~~ including black carbon and brown carbon, and number
52 concentrations of cloud condensation nuclei. In brief, atmospheric aerosols in these
53 remote sites were all well-mixed and highly aged ~~due to, reflecting~~ their dominated
54 regional transport sources. However, the southern TP region exhibited high
55 contributions of carbonaceous organic aerosols, neutralized bulk submicron aerosols,
56 and a relatively higher light absorption ~~capability were observed in the southern TP~~
57 ~~region~~ capacity, whereas in the northern TP region, secondary inorganic species
58 ~~contributed dominantly~~ were the main contributors to the overall acidic submicron
59 aerosols ~~in the northern TP region. In addition to the. Beyond providing~~ insights into
60 the regional differences ~~on~~ in aerosol sources and properties ~~in~~ across the ~~vast~~ TP
61 ~~regions and its surroundings,~~ the datasets ~~are~~ will also ~~useful for the simulation~~ benefit
62 simulations of aerosol radiative forcing and ~~the evaluation~~ evaluations of interactions
63 among different ~~components of the~~ Earth system components in numerical models. in

64 this region. The datasets are ~~available from~~accessible through the National Cryosphere
65 Desert Data Center, Chinese Academy of Sciences
66 (<https://doi.org/10.12072/ncdc.NIEER.db2200.2022>; Xu, 2022).

67 1 Introduction

68 Tibetan Plateau (TP), with ~~a mean altitude of over 4000~~ an average elevation exceeding
69 4,000 m above sea level (a.s.l.) and ~~spanning a huge~~ surface area of approximately
70 ~~2.5×10⁶ km², is the~~ million square kilometers, stands as the highest plateau on the
71 Earth. ~~The~~ Its high-altitude mountain ranges ~~on the TP and its surroundings are,~~ integral
72 to one of the world's most ~~important~~ crucial cryospheric regions ~~in,~~ have earned the TP
73 the world. Therefore, the TP has been widely known as the monikers “roof of the world”,
74 ~~the~~ “Third Pole”, ~~or the~~ and “Asian Water Tower” (Qiu, 2008; Yao et al., 2019). The TP
75 and its surroundings ~~have significant impacts in~~ play a pivotal role in influencing the
76 global and regional climate systems, hydrological cycles, and cryospheric changes
77 through its ~~huge~~ vast and complex topography and its function as a significant heat
78 source (Duan and Wu, 2005; Yao et al., 2012; Chen et al., 2021). ~~Over the past few~~ In
79 recent decades, ~~one of the most concerns on the TP and its surroundings~~ a major concern
80 has ~~been~~ focusing on the significant climatic warming and the rapid cryospheric
81 changes in the cryosphere of this region (Kang et al., 2010), which ~~show~~ exhibits a
82 higher warming ~~rate than~~ trend that exceeding that of the Northern Hemisphere (0.34 vs.
83 0.29 °C/decade) (You et al., 2021; Zhou and Zhang, 2021).

84 ~~As~~ Atmospheric aerosols, as one of the most complex and ~~important~~ component critical
85 components in the atmosphere, ~~atmospheric aerosols play significant roles in~~
86 ~~the~~ significantly influence climatic warming and cryospheric changes in the TP regions
87 ~~through their.~~ They exert crucial direct and indirect effects on solar
88 ~~radiation~~ atmospheric energy budget and the albedos of snow and ice surfaces,
89 impacting Earth's climate system (Xu et al., 2009; Kang et al., 2019b). Atmospheric
90 aerosols, particularly the two important Notably, light-absorbing carbonaceous aerosols
91 (CAs) ~~of~~ such as black carbon (BC) and brown carbon (BrC), ~~can~~ directly absorb ~~the~~
92 solar radiation ~~directly, warm,~~ warming the atmosphere, and ~~finally lead~~ contributing to
93 a positive forcing on Earth's energy budget (Ramanathan et al., 2007; Kopacz et al.,
94 2011). For ~~example~~ instance, Li et al. (2018) ~~has simulated~~ demonstrated that BC causes
95 significantly ~~higher~~ average greater albedo reduction (~46%) and instantaneous
96 radiative forcing (7–64 W m⁻²) ~~caused by BC than mineral dust that deposited~~ on aged
97 snow ~~in the surfaces~~ surfaces of a TP glacier. ~~In addition~~ than mineral dust. Moreover,
98 aerosol particles over the TP ~~also exert significant impacts on~~ significantly affect ice
99 cloud properties and cloud development through their semi-direct effects (Liu et al.,

100 2019). ~~Since the direct observation of atmospheric aerosols over~~Given the vast and
101 remote ~~nature of the TP regions is remarkably difficult due to the,~~ coupled with its
102 complex topography ~~and,~~ meteorology, and harsh environment, ~~the~~in-situ observation
103 ~~of atmospheric aerosols poses substantial challenges. Consequently,~~ numerical model
104 ~~simulations~~simulations based on reanalysis data ~~has become one of the most popular and~~
105 ~~critical ways over the past~~have emerged as a predominant and crucial method in recent
106 decades. ~~For example,~~Notable studies include Lau et al. (2006) ~~evaluated,~~ who assessed
107 the ~~significant~~ impact of atmospheric aerosols ~~over the TP~~ on the ~~intensification of the~~
108 Asian summer monsoon ~~by~~intensification using the NASA finite-volume general
109 circulation model, ~~of which inputs were driven by the realistic global wind analyses and~~
110 ~~humidity;~~ Kopacz et al. (2011) ~~investigated,~~ who explored the origin and radiative
111 forcing of BC ~~transported to~~in the TP and Himalayas ~~by using~~with the GEOS-Chem
112 global chemical transport model ~~based on the global BC emissions inventory data;; and~~
113 Liu et al. (2015) ~~investigated,~~ who examined the transport of summer dust and
114 anthropogenic aerosols ~~over the TP by~~ using a three-dimensional aerosol transport–
115 radiation model with ~~the~~satellite data inputs. ~~Despite the significant insights gained~~
116 ~~from diverse satellite remoting products. Although important findings have been~~
117 ~~reported from those numerical model these~~ simulations, ~~the~~ in-situ
118 ~~observation~~observations of atmospheric aerosols ~~over the TP regions has become more~~
119 ~~erucial and urgent due to their key roles in~~ the TP are increasingly recognized as critical
120 ~~for~~ evaluating and ~~improving the~~enhancing model ~~performanees over the~~accuracy in
121 ~~this~~ remote region. ~~Lacking~~area. The absence of in-situ ~~observational~~ aerosol
122 ~~parameters for constraining the model would lead to high~~ data to refine models
123 ~~introduces considerable~~ uncertainty ~~in~~into the results. ~~In addition,~~Furthermore, while
124 model simulations ~~in the TP mostly focused~~primarily focus on ~~the~~ spatial distribution
125 ~~over a large range, but rarely on the~~across broad regions, they often overlook temporal
126 variations or ~~the~~ inherent evolution ~~meehanism with~~mechanisms at high ~~time~~temporal
127 resolution ~~as those from, which~~ in-situ observations could illuminate.

128 ~~With great improvements~~Recent advancements in observational ~~condition~~techniques
129 and ~~instruments,~~instrumentation have enabled numerous in-situ ~~measurements have~~
130 ~~been conducted in~~measurement within the TP and its surroundings ~~during,~~ aiming to
131 delincate the ~~past few years to characterize the aerosol~~ physical, chemical, and optical
132 properties, of aerosols, along with their potential sources, transport pathways, and

133 regional distributions. ~~A comprehensive summary~~ A detailed compilation of direct
134 ~~measurements on ambient aerosols~~ aerosol measurements in the TP ~~using various,~~
135 employing a variety of observational methods and instruments ~~has been listed, is~~
136 presented in Table S1 in the supplementary. ~~Among them, the material.~~ Notably, off-
137 line atmospheric filter sampling ~~was one of the most important and popular~~ has emerged
138 as a key in-situ aerosol collection ~~approach~~ method in the TP ~~because it was relatively,~~
139 favored for its low-cost and ~~easy to carry out~~ feasibility under the ~~extremely~~ region's
140 harsh ~~natural~~ conditions and ~~limit~~ logistical supports constraints. This ~~approach~~ method
141 ~~has been successfully conducted to characterize the compositions, sizes~~ effectively
142 captured the composition, size, light ~~absorptions~~ absorption properties, sources, and
143 variations of ambient aerosols, ~~especially those different CAs constituents~~ including
144 diverse CAs components such as BC, BrC, organic carbon (OC), water-soluble OC
145 (WSOC), humic-like substances (HULS), and polycyclic aromatic hydrocarbons
146 (PAHs); ~~in the remote TP region~~ (Cao et al., 2009; Zhao et al., 2013; Xu et al., 2014a;
147 Zhang et al., 2014; Cong et al., 2015; Wan et al., 2015; Xu et al., 2015; Kang et al.,
148 2016; Li et al., 2016b; Xu et al., 2020). ~~In addition, characterizing~~ Furthermore, off-line
149 filter sampling has been instrumental in mapping the regional aerosol distribution ~~of~~
150 ~~atmospheric aerosols over a large area of~~ across the TP ~~was another important advantage~~
151 ~~of, facilitated by its simplicity and~~ the ~~off-line filter sampling through their~~ ability to
152 conduct simultaneous observations at multiple ~~sites due to the relatively easy~~
153 ~~instrumental operations~~ locations (Li et al., 2016a; Chen et al., 2019; Kang et al., 2022).
154 ~~However, studies on the atmospheric aerosols over the remote TP regions through~~
155 ~~Despite these advancements,~~ off-line filter ~~samplings are still scarce and far meeting~~
156 ~~the demand at present. These observational sampling studies in the TP's remote regions~~
157 ~~remain insufficient for current needs. The gathered data was~~ generally
158 ~~scattered~~ fragmented and unsystematic ~~with relatively,~~ characterized by low
159 ~~time~~ temporal resolution, ~~few~~ limited aerosol property parameters, and ~~less~~ sparse
160 ~~points because most of them were carried out at certain site using. Typically, these~~
161 ~~studies have been localized to specific sites, utilizing~~ single instruments with
162 ~~time~~ temporal resolutions ranging from days to weeks ~~during a short term period. The~~
163 ~~over brief periods. Such~~ low ~~time~~ temporal resolution ~~measurement would limit~~ limits
164 the accurate understanding of aerosols' temporal evolution ~~processes~~ and underlying
165 ~~mechanisms of aerosol properties, especially~~ during ~~a fast and rapid,~~ short-term ~~event.~~
166 ~~Meantime, these observational~~ events. Additionally, integrating and comparing data

167 ~~from across~~ different research groups ~~was also difficult to compare and integrate~~
168 ~~because most of them had different~~ is challenging due to variations in research ~~concerns,~~
169 ~~measurement focuses,~~ measured parameters, sampling ~~flows~~ methodologies, laboratory
170 filter ~~treatment procedures, processing, and~~ data analysis ~~methods, etc.~~ ~~Besides,~~
171 ~~although the~~ techniques. Moreover, despite the relative ease of off-line sampling ~~is~~
172 ~~relatively easy to carry out,~~ there are still large TP regions where similar observations
173 ~~have not yet been conducted or only conducted in a short term period.~~ Up to now,
174 extensive areas of the TP still lack such observational efforts. To date, comprehensive
175 research focusing on multiple aerosol ~~physicochemical and optical~~
176 ~~properties~~ parameters through ~~the~~ real-time online consecutive measurements (with
177 high temporal resolutions from minute to hour scales) at multiple sites ~~are still~~
178 ~~rare~~ remains a rarity in the TP.

179 Studies Research on atmospheric aerosols ~~have in~~ China has achieved great progress
180 ~~during~~ significant advancements over the ~~last past~~ decade ~~in China~~. The Aerodyne high-
181 resolution time-of-flight aerosol mass spectrometer (HR-ToF-AMS) ~~was one of the~~
182 ~~most popular~~ has become a widely used online instrument ~~that successfully~~
183 ~~implemented in,~~ enabling numerous ~~aerosol chemistry observations~~ studies to
184 characterize the real-time, size-resolved chemical compositions and sources of
185 submicron aerosols (Li et al., 2017; Zhou et al., 2020). However, ~~the utilization of HR-~~
186 ~~ToF AMS on its application in~~ the TP ~~was still very scarce due~~ has been limited, a
187 situation attributed to the ~~high instrumental~~ instrument's demanding operational
188 requirements ~~but extremely harsh~~ and the area's challenging observation conditions.
189 Since 2015, our research group has initiated a continuous and systematic observation
190 project, aiming to investigate the regional differences on aerosol sources and properties
191 ~~in across~~ the ~~different~~ TP ~~regions,~~ has been launched by our research team by performing.
192 This effort involves annual deployments of the HR-ToF-AMS measurement
193 ~~and alongside~~ other high-resolution, real-time online instruments at ~~different~~ various
194 sites ~~during almost every year.~~ Indeed. Remarkably, our dataset ~~was~~ represents the first
195 and only set of dataset focusing on abundant collection that extensively covers a wide
196 range of aerosol parameters (including ~~the~~ physical, chemical, and optical properties
197 and their diverse sources) ~~at across~~ multiple ~~different types of site~~ geographic
198 environments (e.g., ~~the~~ urban, remote, high-altitude mountain, grassland, and
199 subtropical forest ~~sites that basically represented the different TP regions) based on the~~)

200 within the TP and its surroundings. This is achieved through real-time and high-time-
201 resolution online observations ~~in the TP and its surroundings. These datasets provide~~
202 ~~not only, providing a~~ comprehensive data resource for ~~the~~ understanding ~~of~~ regional
203 ~~differences in aerosol sources and properties in different TP regions, but also potential~~
204 ~~basic inputs~~ aerosol variations and serving as essential input for ~~the simulation of future~~
205 aerosol radiative forcing ~~and the assessments of interactions among different~~
206 ~~components of the simulations and~~ Earth system ~~in future models.~~ interaction
207 assessments. The ~~contents~~ structure of this paper ~~are organized~~ is as: Sects. follows:
208 Sections 2 and 3 describe the observation sites, instrumental deployments, and data
209 processing ~~methods, Sect.~~ Section 4 ~~introduces~~ presents the high-time-resolution data
210 ~~of aerosol~~ data, encompassing physical, chemical, and optical properties as well as
211 ~~sources, while the~~ source information. The limitations and the uniqueness of our dataset
212 are discussed in ~~Sect.~~ Section 5.

213 **2 Observation site descriptions**

214 ~~Continuous~~ Between 2015 and 2022, intensive observations of atmospheric aerosol
215 chemistry were ~~conducted~~ carried out at eight sites ~~in~~ across the ~~different regions of~~ TP
216 and its surroundings ~~from 2015 to 2022. The.~~ These sites ~~include~~ comprise seven remote
217 sites (QOMS, Motuo, NamCo, Ngari, Waliguan, LHG, and Bayanbulak) and one urban
218 site (Lhasa) ~~which is used~~, the latter serving as a contrast for ~~comparison-comparative~~
219 analysis. Figure 1 illustrates the geographical locations of these sites ~~and the picture~~
220 ~~of~~ along with photographs during each observation. Table 1 ~~provides~~ detailed
221 ~~information~~ details the specifics of each site ~~as well as~~ including the sampling
222 ~~period~~ periods and ~~available~~ the instruments deployed during each field campaign. The
223 ~~following text gives~~ subsequent sections provide brief ~~description of each~~
224 ~~site~~ descriptions these sites, arranged geographically from the ~~south~~ southern to ~~north~~ the
225 northern parts of the TP.

226 **2.1 QOMS**

227 The Qomolangma Station for Atmospheric and Environmental Observation and
228 Research, Chinese Academy of Sciences (86.56°E, 28.21°N; 4276 m a.s.l.; abbreviated
229 as QOMS for short in this study ~~and similarly hereinafter, with similar abbreviations~~
230 ~~for other sites; 86.56°E, 28.21°N; 4276 m a.s.l.) hereafter), is situated in the ~~basin of~~
231 Rongbuk valley in basin on the northern slope of Mt. Everest. The climate in the~~

232 northern slope of Mt. Everest has obvious seasonal variation ~~under~~, heavily influenced
233 by the ~~influence of~~ Indian monsoon system (Bonasoni et al., 2010; Cong et al., 2015).
234 During the pre-monsoon season (~~generally typically~~ March ~~=~~ to May), ~~the~~
235 ~~dominated dominant~~ westerlies ~~play important roles in~~ facilitates the long-range
236 transport of atmospheric pollutants from ~~those polluted regions in~~ South Asia, ~~which~~
237 ~~makes making~~ QOMS an ideal high-altitude observatory ~~at on~~ the south edge of the TP
238 for ~~studying the examining~~ transboundary pollutant transport ~~of atmospheric pollutants~~
239 ~~from South Asia to into~~ the ~~inner TP. During~~ plateau's interior. In the summer monsoon
240 season ~~in summer~~ (June–August), ~~the prevailing~~ southerly winds ~~prevail and~~ bring
241 warm and wet airflow from the Indian Ocean, leading to ~~this region with~~
242 ~~increasing increased~~ humidity and precipitation in the plateau.

243 2.2 Motuo

244 Motuo ~~county is~~ County, located in the lower reaches of the Yarlung Tsangpo River
245 ~~and on~~ the southern ~~slopes slopes~~ of the eastern Himalayas and Gangrigab Mountains in
246 the southeast edge of the TP. The county ~~sits at a, sited~~ halfway up a mountain ~~and has,~~
247 enjoys a subtropical humid climate ~~with~~ characterized by relatively high
248 ~~temperature temperatures~~ and abundant rainfall. ~~Due to the minor~~ With a small
249 population (~~of ~15,000~~), ~~Motuo county is also a relatively~~ County remains one of the
250 TP's most pristine ~~region in the TP. regions.~~ The sampling site in Motuo (29.30°N,
251 95.32°E; 1305 m a.s.l.) was ~~at the summit of~~ located atop a hill ~~that towards~~
252 ~~to overlooking~~ the Yarlung Tsangpo Grand Canyon, ~~which.~~ This vantage point makes it
253 ~~a very an~~ ideal site in the southeast edge of the TP to location for directly
254 ~~monitor monitoring~~ the transboundary transport of atmospheric pollutants and moisture
255 from Southeast Asia and the Indian Ocean ~~to into~~ the TP.

256 2.3 NamCo

257 The Nam Co Station for Multisphere Observation and Research, Chinese Academy of
258 Sciences (NamCo; 90.95°E, 30.77°N; 4730 m a.s.l.) is a high-altitude observatory at in
259 the south-central part of the TP. ~~This station is situated~~ Situated at the southeast shore of
260 Nam Co Lake. ~~The surrounding of this, the~~ station is surrounded by a pristine region in
261 the TP and isolated ~~from major populated areas. area.~~ The region ~~is generally affected~~
262 ~~by the~~ experiences a typical semi-arid plateau monsoon climate ~~with more,~~
263 characterized by increased precipitation during the summer monsoon season. ~~The~~

264 NamCo is ~~the most important site in a pivotal~~ inland ~~of site within~~ the TP ~~and dominated,~~
265 ~~predominantly influenced~~ by air ~~mass masses~~ from ~~the~~ south and west.

266 **2.4 Ngari**

267 The Ngari Station for Desert Environment Observation and Research, Chinese
268 Academy of Science (Ngari; 79.70°E, 33.39°N; 4270 m a.s.l.) ~~locates is located~~ in the
269 Rutog County, ~~within the~~ Ngari Prefecture, ~~of the~~ Tibet Autonomous Region, China.
270 This ~~region area~~ is ~~at~~ the southwestern edge of the TP and ~~belongs to is characterized by~~
271 ~~its~~ semi-arid ~~areas with barren land surface climate, sparse vegetation,~~ and ~~strong intense~~
272 solar radiation. As ~~the major a key~~ member of ~~the~~ “high-cold region observation and
273 research network for land surface processes & environment of China”, ~~the~~ Ngari station
274 ~~is one of the most important filed stations for~~ ~~plays a crucial role in~~ monitoring ~~the~~
275 ~~changes in~~ climate, ~~hydrology, atmosphere hydrological, atmospheric,~~ and ecological
276 ~~environment environmental changes~~ in the TP’s western ~~region of the TP and further~~
277 ~~revealing the interaction territories.~~ Additionally, it contributes to understanding the
278 ~~interactions~~ between the Indian monsoon ~~system~~ and the ~~westerly belt westerlies.~~

279 **2.5 Waliguan**

280 The Waliguan Baseline Observatory (Waliguan; 100.9°E, 36.28°N; 3816 m a.s.l.) is one
281 of the twenty-nine baseline stations of Global Atmosphere Watch (GAW) ~~of under~~ the
282 World Meteorological Organization (WMO). ~~The observatory is situated~~ ~~Situated~~ at the
283 top of ~~the~~ Mt. Waliguan ~~(mountain height of ~600 m),~~ which ~~is also a relatively rises~~
284 ~~approximately 600 m, the observatory is located in a~~ pristine region with ~~little influence~~
285 ~~from~~ ~~minimal~~ human ~~activities.~~ ~~The activity impact.~~ Waliguan is ~~an~~
286 ~~important~~ ~~represented as a key~~ observatory ~~in on~~ the ~~northeast northeastern~~ edge of the
287 TP ~~and dominated, predominantly influenced~~ by air ~~mass masses~~ from ~~the~~ northeast
288 during the summer ~~season, which makes it an ideal site to study the influence.~~ ~~This~~
289 ~~location is strategic for studying the transport and impact~~ of air pollutants from ~~the~~
290 industrial ~~areas regions~~ in ~~the~~ northwestern China to the TP ~~in this study.~~

291 **2.6 LHG**

292 The Qilian Observation and Research Station of Cryosphere and Ecologic Environment,
293 Chinese Academy of Sciences (LHG; 39.50°N, 96.51°E; 4180 m a.s.l.) ~~locates near~~
294 ~~the~~ ~~), is located approximately 1 km from the~~ terminus ~~(~1 km)~~ of ~~the~~ Laohugou Glacier
295 No.12, ~~which.~~ ~~This glacier~~ is ~~one among~~ the largest mountain glacier in the northern

296 slope of the western Qilian Mountains. LHG ~~is serves as~~ another ~~representative~~ notable
297 station in the northeastern TP ~~and significantly isolated, distinctly remote~~ from the
298 human ~~living areas~~ settlements. The climate in this region is ~~a typically~~ predominantly
299 arid and continental ~~climate and dominated, influenced~~ by the East-Asian monsoon in
300 ~~the~~ summer and ~~the~~ Westerlies in ~~the~~ winter. ~~Strongly~~ A pronounced mountain-valley
301 breeze ~~is formed~~ during summer ~~which can bring air mass~~ facilitates the upward
302 ~~transport of air masses~~ from lower ~~altitude zones to mountain regions~~. Therefore, it is
303 ~~also well suited~~ altitudes, making LHG an ideal site for ~~sampling the~~ background air
304 mass ~~sampling~~ and ~~studying for investigating~~ the transport ~~mechanisms~~ and potential
305 impacts of air pollutants from ~~its~~ surrounding ~~regions~~ areas.

306 2.7 Bayanbulak

307 The Bayanbulak National Basic Meteorological Station (Bayanbulak; 84.35° N, 42.83°
308 E; 2454 m a.s.l.) ~~locates is~~ located in the Bayanbulak grassland ~~at the~~, northwest of
309 Hejing ~~county~~, County in the Xinjiang Uygur Autonomous Region, China. ~~The~~
310 Bayanbulak ~~is situated in~~ lies within an intermontane basin in the central Tianshan
311 Mountains ~~and~~, surrounded by numerous snow mountains with altitudes more than
312 3000 m. The climate in Bayanbulak grassland ~~belongs to the~~ is characterized by a typical
313 temperate continental mountain climate, with an annual average precipitation ~~of~~
314 ~~about~~ ranging between 200 ~~to~~ 300 mm. ~~The~~ Bayanbulak town ~~has limited~~ experiences
315 ~~minimal~~ human activities and traffic ~~transportation, maintaining its pristine~~
316 ~~environment~~.

317 2.8 Lhasa

318 Lhasa (29.65°N, 91.03°E; 3650 m a.s.l.) is the capital ~~city~~ of the Tibet Autonomous
319 Region, China ~~that, and~~ located in the south-central part of the TP. The city lies in a
320 ~~flat~~ broad river valley ~~with the surrounding, surrounded by~~ mountains ~~reaching that~~
321 ~~reach up to~~ 5500 m ~~and, with~~ the Lhasa River passing through the city from west to
322 east. ~~The~~ Our observation site ~~is located in~~ Lhasa ~~is in the~~ Binhe Park ~~near, adjacent to~~
323 the Lhasa River. ~~The~~ Notably, the Norbulingka scenic area, one of the main activity
324 centers for local Tibetans ~~to celebrate~~ celebrating their religious festivals (~~e.g., such as~~
325 the Sho Dun festival),₂ is located ~1 km to the northwest of the sampling site, ~~while,~~
326 ~~Moreover,~~ the Potala Palace, the center of Tibetan Buddhism, is ~1.8 km to the northeast.
327 ~~Since the Given~~ Lhasa's unique energy structure and ~~different residential habit in~~ Lhasa

328 ~~comparing with those remote sites, at~~ the distinct living habits of the residents,
329 comparative ~~observation is conducted in~~ observations are carried out at this urban site
330 ~~for studying. These studies aim to investigate~~ the primary aerosol properties and sources,
331 ~~particularly~~ from various residential combustion activities.

322 **3 Online sampling, instrumental setup, and data processing**

323 **3.1 Online real-time aerosol sampling over the TP**

324 ~~The online based Atmospheric aerosol~~ observations ~~of atmospheric aerosols~~ were
325 ~~carried out~~ conducted at each site using a ~~suit~~ suite of real-time, high-resolution
326 instruments, ~~usually including. This instruments typically included~~ a HR-ToF-AMS
327 (Aerodyne Research Inc., Billerica, MA, USA) ~~for acquiring to determine~~ the chemical
328 ~~compositions~~ composition (organic aerosol (OA), nitrate, sulfate, ammonium, and
329 chloride) of non-refractory submicron aerosol (PM₁); ~~a~~; A scanning mobility particle
330 sizer (SMPS, model 3936, TSI Inc., Shoreview, MN, USA) ~~for acquiring was used to~~
331 ~~measure~~ the size distribution ~~of and~~ number concentration of submicron particles; ~~a~~; A
332 photoacoustic extinctions (PAX, DMT Inc., Boulder, CO, USA) ~~was used for~~
333 ~~acquiring the~~ obtaining particle light absorption, scattering, and extinction coefficients
334 (Babs, Bscat, and Bext) ~~and along with~~ single scattering albedo (SSA) at 405 nm, as
335 well as ~~the~~ BC mass concentration ~~of BC, an~~; An Aethalometer (model AE33/AE31,
336 Magee Scientific Corp., Berkeley, CA, USA) ~~was used for~~ acquiring the B_{abs} ~~at across~~
337 seven ~~fixed~~ wavelengths (370–950 nm), ~~and a~~; A cloud condensation nuclei (CCN)
338 counter (model CCN-100, DMT Inc., Boulder, CO, USA) ~~for acquiring the measured~~
339 CCN number ~~concentration at different supersaturation (SS) of concentrations at various~~
340 water vapor; ~~supersaturations (SS). The measurement uncertainties for each instrument~~
341 ~~are difficult to quantify based on data from a single instrument. The uncertainty~~
342 ~~showing below are referred from other studies: <30% for HR-ToF-AMS (Jimenez et al.,~~
343 ~~2016) and SMPS, <40% for Aethalometer (Backman et al., 2017), <10% for PAX~~
344 ~~(Selimovic et al., 2018), and <25% for CCNC (Rose et al., 2008). Details on the specific~~
345 ~~instrumental deployment instruments deployed and the sampling period during periods~~
346 ~~for~~ each observation campaign ~~is~~ are summarized in Table 1.

347 The HR-ToF-AMS, ~~serving as was~~ the ~~primary~~ cornerstone instrument for ~~observing~~
348 atmospheric aerosol chemistry, ~~was deployed throughout observations across~~ all field
349 campaigns. The SMPS was ~~utilized~~ deployed at QOMS, Motuo, LHG, and Lhasa,
350 ~~while whereas~~ the PAX was employed at QOMS, Motuo, Ngari, Waliguan, and Lhasa.

361 ~~Additionally, the~~The Aethalometer was utilized at QOMS, NamCo, and Waliguan,
362 ~~and with~~ the CCN-100 operational at Motuo, Waliguan, and LHG. Field observations in
363 the southern, western, ~~or and~~ central TP ~~regions~~ of the TP were predominantly
364 conducted during the pre-monsoon ~~periods~~ season, aimed to study the transboundary
365 transport of pollutants from South Asia into the TP, under the influence of Westerlies
366 and the Indian monsoon. For instance, observations took place from 12 April to 12 May
367 at QOMS, Motuo from 26 March to 22 May ~~at Motuo~~, NamCo from 31 May to 1 July
368 ~~at NamCo~~, and Ngari from 1 Jun to 5 July ~~at Ngari, which were to investigate the~~
369 ~~transboundary transport of atmospheric pollutants from polluted regions in South Asia~~
370 ~~to the inland areas of the TP, considering the influences of Westerlies and the Indian~~
371 ~~monsoon~~. On the other hand, measurements in the remote regions of the northern TP
372 and its surroundings were carried out during the summer ~~to track aerosol transport~~
373 ~~from surrounding polluted areas, considering the effects of the Westerlies or the~~
374 intensified East Asian monsoon. Specifically, observations occurred from 1 to 31 July
375 at Waliguan, from 4 to 29 August at LHG, and from 29 August to 26 September at
376 Bayanbulak. ~~These measurements were undertaken to monitor the aerosols transported~~
377 ~~from surrounding polluted regions, considering the influences of Westerlies or the~~
378 ~~intensified East Asian monsoon~~. The observation ~~in~~at Lhasa was conducted
379 ~~between~~from 31 August ~~and to~~ 26 September, focusing on capturing the strongest peak
380 atmospheric oxidation ~~capability~~capacity during the summer ~~season~~.

381 3.2 Instrumental setup

382 Despite the variations in ~~the instruments used during instrumentation across~~ different
383 observation campaigns, the core setup for sampling ~~settings remain generally was~~
384 largely consistent. Figure 1b illustrates the fundamental standard sampling setup
385 ~~employed configuration~~ for each campaign. ~~All instruments are~~ typically housed
386 involved housing all instruments within an air-conditioned trailer or room. The inlets
387 ~~are were~~ induced to the instruments from the roof with a fine particle cyclone (model
388 URG-2000-30EH, URG Corp., Chapel Hill, NC, USA) in the front of the inlet to
389 eliminate particles with an aerodynamic diameter (D_{va}) exceeding 2.5 μm . ~~Subsequently,~~
390 ~~the~~ These fine particles ~~are directed into~~ were then passed through a Nafion dryer via
391 1/2-inch stainless steel ~~tube~~tubing to ~~remove moisture from~~ dehumidify the airflows.
392 ~~Lastly, the particles are sampled into a series of online~~ before being directed into the
393 instruments for real-time measurements analysis. For ~~a more comprehensive~~

394 ~~understanding~~detailed information on the setup and methodology of the ~~instrumental~~
395 ~~setups, please refer to~~instruments, it can be found in our previous publications (Xu et
396 al., 2018; Zhang et al., 2018; Zhang et al., 2019; Zhao et al., 2022).

397 **3.3 Instrumental operation and data processing**

398 The measurement principles, operation procedures, calibration methods, and data
399 analysis for these instruments ~~are extensively described~~used in detail~~this study are~~
400 thoroughly detailed in Text~~Texts S1–4 in the~~S4 of supplementary ~~materials of this study.~~
401 ~~Only a few essential~~material. Here, we highlight only key descriptions and ~~important~~
402 ~~settings are emphasized here~~critical setting as follows: (1) The HR-ToF-AMS
403 ~~instruments were~~was operated at ~~the~~-V-mode during ~~almost all~~most of the eight field
404 campaigns, ~~considering to accommodate~~ the relatively low ~~aerosol mass levels and~~
405 signal-to-noise ratios ~~over~~due to low aerosol mass loading in the TP regions. (2) ~~Due to~~
406 ~~chopper malfunction in the HR-ToF-AMS, particle~~Particle size observations were not
407 conducted during the NamCo and LHG campaigns: ~~due to a chopper malfunction in the~~
408 HR-ToF-AMS. (3) Different relative ionization efficiency (RIE) values were used for
409 ammonium and sulfate according to the ionization efficiency calibrations of HR-ToF-
410 AMS in different campaigns, ~~while default values were used to rest species.~~ (4)
411 Different size parameters were achieved according to the particle sizing calibrations in
412 different campaigns, ~~which ultimately resulted in the distinct size ranges of non-~~
413 ~~refractory PM₁.~~ (5) Elemental ratios of OA, ~~i.e.,~~ such as oxygen-to-carbon (O/C),
414 hydrogen-to-carbon (H/C), organic matter-to-organic carbon (OM/OC), and nitrogen-
415 to-carbon (N/C), were determined using the improved method (Canagaratna et al.,
416 2015). (6) ~~Default~~A default collection efficiency (CE) ~~values~~value of 0.5 were
417 employed to the HR-ToF-AMS measurements during the QOMS, NamCo, Ngari,
418 Waliguan, and Lhasa campaigns in consideration of their overall neutralized bulk
419 submicron aerosols, whereas ~~the~~a composition-dependent CE (Middlebrook et al., 2012)
420 ~~values are~~value was adopted at Motuo, LHG, and Bayanbulak, where ~~bulk submicron~~
421 aerosols were slightly acidic. (7) Source ~~apportionments~~apportionment of OA during
422 all observations were performed by the positive matrix factorization (PMF) analysis
423 ~~method.~~ The details of the PMF solution determination for each site are not presented
424 here but can be referenced in our previous publication for select campaigns (Xu et al.,
425 2018; Zhang et al., 2018; 2019). (8) Only the chemical compositions of non-refractory
426 PM₁ are reported ~~during~~for the Bayanbulak campaign due to the absence of BC

427 observations. (9) The sample and sheath flow rates of SMPS were set at 0.3 and 3.0 L
428 min^{-1} , respectively, at both QOMS and Lhasa, ~~measuring particles covering a particle~~
429 ~~size range~~ between 14.6 and 661.2 nm in mobility diameter (D_m), whereas 0.5 and 5.0
430 L min^{-1} at LHG and Motuo sites with a ~~particle size~~ range of 10.9–495.8 nm in D_m . (10)
431 Aethalometer ~~measurement~~ measurements were corrected for ~~both the~~ filter-based
432 loading ~~effect~~ and multiple scattering ~~effect~~ effects. A traditional absorption Ångström
433 exponents (AAE) method (Zhang et al., 2021) was adopted to ~~quantitatively~~ apportion
434 ~~the~~ total B_{abs} into two parts ~~from of~~ BC and BrC ($B_{abs,BC}$ and $B_{abs,BrC}$). (11) ~~During the~~
435 ~~Motuo, Waliguan, and LHG campaigns, the CCN~~ number concentrations ~~of CCN~~ were
436 ~~conducted consecutively measured~~ at five different SS values of 0.2%, 0.4%, 0.6%,
437 0.8%, and 1.0% ~~every 5 minutes at a 30-min cycle during the Motuo, Waliguan, and~~
438 ~~LHG campaigns.~~

439 **4 Aerosol properties, sources, and radiative forcing over the TP**

440 **4.1 Mass loading and chemical composition of submicron aerosols**

441 Figure S1 ~~provides an overview of the high-time-resolution~~ presents the temporal
442 variations of PM_{10} chemical species (OA, nitrate, sulfate, ammonium, chloride, and BC)
443 ~~during observed across~~ the eight observations in the TP and its surroundings. ~~Generally,~~
444 ~~the~~ The mass concentrations of PM_{10} and its ~~chemical species varied~~
445 ~~dynamically~~ components exhibited distinct variations, with ~~alternating a few~~ periods of
446 high ~~and low~~ mass loading observed throughout ~~the~~ each campaign's sampling period
447 ~~of each campaign.~~ Despite ~~differences~~ variations in sampling years (2015–2022),
448 seasons (March–September), and altitudes (1350–4730 m a.s.l.) ~~at across~~ these sites, the
449 ~~significantly~~ distinct PM_{10} mass concentrations and chemical compositions ~~can~~
450 ~~effectively reflect~~ clearly illustrate the regional difference ~~in aerosol mass levels,~~
451 ~~properties, and sources at different regions among these sites.~~ On average, ~~the mass~~
452 ~~concentration of~~ total PM_{10} mass concentrations across the eight campaigns ranged from
453 1.9 to 9.1 $\mu\text{g m}^{-3}$ (Fig. 2 and Table 2). The highest ~~PM_{10}~~ mass concentration was
454 observed at Waliguan ~~due to, driven by~~ the ~~rapid~~ transport of anthropogenic aerosols
455 and gaseous pollutants from urban ~~areas~~ centers in northwestern China. ~~Conversely~~ In
456 contrast, the lowest values were ~~measured~~ observed at NamCo and Bayanbulak,
457 ~~attributed to reflecting~~ their background and pristine environmental conditions. The
458 average PM_{10} mass level ~~in across~~ the TP and its surroundings was comparable to
459 ~~values~~ those observed at other high-altitude, coastal, forest, and remote background sites

460 ~~worldwide globally~~ (0.46–15.1 $\mu\text{g m}^{-3}$; Table 3), ~~but yet remains~~ significantly lower than
461 those observed at densely urban (34.4–71.5 $\mu\text{g m}^{-3}$) and suburban (21.4–44.9 $\mu\text{g m}^{-3}$)
462 ~~sites areas~~ in other ~~regions parts~~ of China (Li et al., 2017), ~~suggesting. This suggests~~ the
463 predominantly clean ~~nature of atmosphere condition atmospheric conditions~~ in the
464 remote ~~and~~ high-altitude regions of the TP.

465 The chemical compositions of PM_{10} also exhibited significant regional ~~difference~~
466 ~~differences across the TP~~ (Fig. 2), ~~indicating distinct highlighting varied~~ aerosol sources
467 ~~across in~~ different TP regions. ~~OA and BC together contributed as high as~~
468 ~~64.9–85.7% areas~~ of the ~~total PM_{10} mass at the TP. At~~ five sites ~~of~~ (QOMS, Motuo,
469 NamCo, Ngari, and Lhasa ~~that are~~) located in the southern, western, or central TP, ~~OA~~
470 ~~and BC together accounted for as high as 64.9–85.7% of the total PM_{10} mass.~~ (Table 2).
471 ~~These This~~ high ~~contributions were mainly contribution was largely~~ attributed to the
472 frequent transport of biomass-burning ~~related~~ emissions from ~~polluted regions in~~ South
473 and Southeast Asia to the ~~remote sites of~~ TP during the pre-monsoon season (Bonasoni
474 et al., 2010; Cong et al., 2015; Zhang et al., 2018) ~~as well as the intense, along with~~
475 ~~significant~~ local biomass burning ~~emissions~~ from religious activities in ~~the urban area~~
476 ~~of~~ Lhasa (Cui et al., 2018; Zhao et al., 2022). In ~~contrary, contrast, at~~ the three ~~northern~~
477 ~~sites (Waliguan, LHG, and Bayanbulak),~~ inorganic species (sulfate, nitrate, and
478 ammonium; referred to as SNA) accounted for more than 60% of the total PM_{10} ~~at three~~
479 ~~northern sites (Waliguan, LHG, and Bayanbulak). Among these, sulfate had. Sulfate~~
480 ~~was~~ the most ~~dominant contributions significant component~~ of SNA (38.1–46.0%),
481 ~~consistent aligning with the results observed at observations from~~ another high-altitude
482 site in the northeastern TP (Menyuan; 28%) and ~~other various~~ rural and remote sites
483 (19–64%) in East Asia, ~~indicating the regional transported sources~~ (Du et al., 2015).
484 The ~~high pronounced SNA~~ contributions ~~of SNA~~, particularly ~~the~~ sulfate, in the northern
485 TP and its surroundings, were mainly related to the regional transport of anthropogenic
486 aerosols and gaseous precursor ~~emissions~~ from ~~surrounding nearby~~ urban areas as well
487 as important in-cloud aqueous reactions during the transportation to the mountains
488 (Zhang et al., 2019).

489 **4.2 Bulk acidity, size distribution, and diurnal variation of submicron aerosols**

490 Particle phase acidity ~~is an important parameter affecting the significantly influences~~
491 ~~aerosol~~ physicochemical properties ~~of aerosol, with significant impacts on hygroscopic~~
492 ~~growth, affecting hygroscopicity,~~ toxicity, and heterogeneous reactions ~~of aerosol~~

493 ~~particles~~. The bulk acidity of submicron aerosols was evaluated at each site following
494 the method in Zhang et al. (2007b) and Schueneman et al. (2021) ~~based on using~~ AMS
495 measurements. A detailed description of this method can be found in Text S5 of the
496 supplementary material or our previous publications (Zhang et al., 2018; Zhang et al.,
497 2019) ~~or in Text S5 in the supplementary materials of this study. It is interesting to find~~
498 ~~that the bulk acidity of submicron aerosols exhibited distinct~~. Notably, we observed
499 clear regional difference variations between the southern and northern TP ~~(Fig. 3),~~
500 ~~primarily attributed to variations, largely due to differences~~ in aerosol sources and
501 ~~compositions.composition (Fig. 3)~~. Linear regression slopes ~~were fitted to be 1.2, 1.11,~~
502 ~~0.98, and 1.18 at the four sites of at~~ QOMS, NamCo, Ngari, and Lhasa ~~that~~
503 ~~locates (located~~ in the southern, western, or central TP) ~~were fitted to be 1.2, 1.11, 0.98,~~
504 ~~and 1.18, respectively~~, indicating the submicron ~~aerosol particles aerosols~~ at these sites
505 were generally neutralized, ~~and in some cases, showed occasionally showing~~ an excess
506 of ammonium. The ~~finding result~~ is consistent with previous ~~observations offindings on~~
507 high ammonia availability ~~resulted~~ from agriculture emissions in the South Asia (Van
508 Damme et al., 2015). ~~In addition Moreover~~, as reported in our previous publications,
509 atmospheric aerosols at QOMS and NamCo were significantly influenced by ~~the~~
510 ~~transport of biomass-burning related~~ emissions from South and Southeast Asia during
511 the pre-monsoon season (Xu et al., 2018; Zhang et al., 2018), ~~while various~~
512 ~~residential and Lhasa experienced intense~~ biomass ~~fuels were burned intensely fuel~~
513 ~~burning~~ during ~~these~~ frequent religious festivals ~~in urban areas of Lhasa~~ (Zhao et al.,
514 2022). In contrast, ~~the~~ submicron particles at the remaining four sites, particularly LHG
515 and Bayanbulak in the north, were overall acidic, with regression slopes ranging from
516 0.73 to 0.86 ~~at the remaining four sites, especially in the two northern sites (LHG and~~
517 ~~Bayanbulak),~~ where sulfate ~~significantly contributed to the total was a major~~ PM₁
518 component (46.0% and 41.6%). Similar ~~observations findings~~ of acidic submicron
519 aerosol particles have also been observed at Menyuan and LHG in the northern TP in
520 previous studies (Du et al., 2015; Xu et al., 2015), mainly related to the transport of ~~the~~
521 enriched SNA species or their gaseous precursors from the industrial areas in
522 northwestern China ~~to the remote regions in the northern TP~~.

523 The size distributions of non-refractory PM₁ chemical species, obtained from HR-ToF-
524 AMS measurement, provide valuable insights into aerosol sources, oxidation degrees,
525 mixing states, formation, transformation, and growth mechanisms as well as their

526 impacts on CCN activity. Typically, ~~the~~ size distributions for SNA species and oxidized
527 OA peaked at in the accumulation mode (~400–600 nm in D_{va}) ~~for those SNA species~~
528 ~~and oxidized OA components~~, as a result of ~~their~~ secondary formation processes. In
529 contrast, fresh organics from primary emission sources ~~had exhibit~~ smaller ~~sizesize~~
530 (Zhang et al., 2005b; Aiken et al., 2009). In this study, ~~bothwe focus on~~ organics and
531 ~~the sum of combined~~ three SNA species ~~were selected to illustrate the highlight~~ regional
532 ~~differencevariations~~ in size distributions across the ~~different TP regions~~. As shown in
533 Figs. 4a and S2 and Table 2, the peak diameters ~~in the size distribution~~ of OA and SNA
534 size distributions varied significantly, ~~ranging~~ from 584.4 and 634.5 nm at Ngari to a
535 smaller size of 228.1 and 250.0 nm at Lhasa, respectively. This variation suggests the
536 distinctly different sources and aging processes of atmospheric aerosols ~~in~~
537 ~~different across the~~ TP ~~regions~~, particularly between those high-altitude remote sites and
538 urban sites. For ~~exampleinstance~~, bulk PM_1 at QOMS was reported to be internally
539 well-mixed and aged ~~at QOMS due, attributed~~ to long-range transport ~~aerosol sources~~
540 ~~of from~~ biomass-burning-related emissions ~~from in~~ South Asia (Zhang et al., 2018),
541 whereas local primary sources, including cooking, traffic exhausts, and biomass
542 burning ~~together contributed, totally accounted for~~ more than 60% of the total OA ~~at~~
543 ~~the in~~ urban ~~site in~~ Lhasa (Zhao et al., 2022). The crucial influence of aerosol sources
544 on size distributions is further supported ~~in Fig. 4a~~ by the quantitative
545 relationshipcorrelation between the mode size and O/C ratios of OA ($R^2 = 0.74$) (Fig.
546 4a).

547 The diurnal variations of PM_1 chemical compositions are typically influenced by
548 multiple factors, including ~~the~~ meteorological conditions (~~such as e.g.~~, planetary
549 boundary layer (PBL) height, wind direction and speed, temperature, relative humidity),
550 ~~different various~~ primary emission sources (~~such as intense e.g.~~, vehicle exhausts during
551 traffic rush hours, cooking emissions, and coal combustion emissions ~~from for~~ heating
552 ~~activities~~), and distinct formation mechanisms (~~such as e.g.~~, daytime photochemical
553 oxidation ~~processes~~, nighttime heterogeneous reactions, and gas-particle partitioning of
554 secondary species). ~~Therefore, a~~ comprehensive understanding of ~~the these~~ diurnal
555 ~~variation characteristics of different aerosol chemical compositions variations~~ is ~~not~~
556 ~~only beneficial crucial~~ for ~~investigating their exploring the~~ dynamic evolution ~~processes~~
557 ~~but also helpful in understanding of aerosol compositions and identifying~~ the key
558 factorsprimary drivers (source, meteorology, or secondary formation) ~~that drive behind~~

559 the variations ~~of~~in different chemical species. ~~Clearly, different~~
560 Distinct diurnal ~~variation~~patterns ~~of~~in the total PM₁ mass concentrations were observed
561 ~~during the~~across different field campaigns (Fig. 4b). ~~The diurnal variations at those~~At
562 remote sites ~~(such as of~~QOMS, LHG, NamCo, and Waliguan), located ~~either in the~~
563 ~~valley~~valleys or ~~at the top of the~~atop mountains, variations were ~~mostly~~
564 ~~controlled~~largely governed by ~~the circulation of~~mountain-valley wind circulation and
565 ~~the variation of~~change in PBL height ~~during the day~~. For instance, QOMS exhibited a
566 distinct diurnal pattern with continuously decreasing concentrations during the daytime,
567 but relatively higher concentrations at night. The minimum ~~mass~~ occurred at around
568 ~15:00 in this valley site, mainlylikely due to ~~the~~strong ~~down-slope~~afternoon glacier
569 winds ~~with high wind speed and enhanced a~~higher PBL height ~~in the afternoon~~ (Zhang
570 et al., 2018). Conversely, LHG and NamCo experienced lower PM₁ ~~mass~~
571 ~~concentration~~concentrations from night to early morning ~~and continuously increasing~~
572 ~~concentrations during the afternoon were observed at LHG and NamCo sites. The high~~
573 ~~mass concentrations, with increase~~ in the afternoon, attributed at LHG ~~were tightly~~
574 ~~associated with the~~to up-slope wind transport ~~of~~and at NamCo to aerosols ~~advected by~~
575 ~~the prevailing up-slope winds during that time. However, the high concentration in the~~
576 ~~afternoon at NamCo might be influenced by the downward transmission of~~
577 ~~aerosols~~descending from higher layer ~~to the ground surface, as well as~~layers and
578 enhanced ~~aerosol plume~~afternoon transport from ~~those relatively polluted western~~
579 ~~regions during the afternoon~~the west (Xu et al., 2018). A ~~relatively~~ complex diurnal
580 ~~variation~~pattern of total PM₁ was observed at ~~the top of Mt. Waliguan, which could be~~
581 ~~attributed to the combined effects of variabilities in~~influenced by diffusion conditions
582 ~~(such as PBL height)~~, wind directions ~~(such as mountain valley wind circulation)~~, and
583 air mass sources ~~(such as enhanced, including afternoon air~~massmasses from the
584 northeast ~~during the afternoon, favoring the transport of polluted aerosols from, which~~
585 likely carried industrial ~~areas~~pollutants (Zhang et al., 2019). At Motuo, the diurnal
586 ~~variation~~pattern of PM₁ ~~mass concentration~~ was relatively stable, ~~except for~~with two
587 weak peaks linked to local combustion activities in the late morning and evening, ~~which~~
588 ~~were possibly related to combustion emissions from local residents in the county~~. Ngari
589 exhibited relatively highmasshigher nighttime loadings ~~at night, whereas low values~~
590 ~~were observed during the~~and lower daytime loadings, mainly due to the variations of
591 PBL height. Bayanbulak, on the other hand, had relatively low and stable PM₁ mass

throughout the entire day, ~~primarily~~ due to its background ~~feature~~ location. In contrast ~~to the remote sites, the~~ urban site in Lhasa showed a clear diurnal variation pattern with ~~displayed~~ two ~~pronounced~~ peaks around 8:00–9:00 and 20:00–21:00. This pattern could ~~be attributed to strong~~ correlating with primary aerosol emissions ~~from vehicle exhausts, cooking, and biomass burning activities~~ during the morning and evening ~~times~~ rush hours (Zhao et al., 2022). Although the diurnal ~~variations~~ pattern of total PM₁ were mainly ~~affected~~ shaped by ~~the variabilities in~~ mountain-valley ~~wind circulation~~ winds and PBL height in those remote sites, and primary emissions in the urban site in this study, ~~the~~ secondary formation processes, including photochemical oxidation and aqueous-phase reactions were also ~~two important~~ played a key role in the formation pathways of ~~secondary~~ inorganic and organic aerosol species. This could be ~~observed~~ clearly evidenced by ~~those identified~~ the afternoon peaks of oxygenated OA (OOA) components ~~at~~ observed across almost all the sites, which ~~were~~ commonly ~~showed~~ peaks during the afternoon formed by photo-chemical processes (Xu et al., 2018; Zhang et al., 2018; Zhang et al., 2019; Zhao et al., 2022).

607 **4.3 High-resolution mass spectrum and elemental ratios of organic aerosol**

608 The high-resolution mass spectrum (HRMS) and elemental ratios of OA were
609 determined to identify the possible sources, formation and evolution mechanisms, ~~as~~
610 ~~well as the~~ and oxidation states ~~of these complex OA components~~ at each site. ~~The~~ A
611 direct comparison of the average O/C ratios ~~of the OAs~~ from the eight field campaigns
612 ~~were compared directly (was presented in Fig. 5a).~~ It is ~~evident~~ apparent that the
613 ~~average~~ O/C ratios ~~of OAs were generally close to or larger than 1.0~~ at the remote sites
614 of QOMS, Motuo, NamCo, Ngari, Waliguan, and LHG, ~~whereas typically reached or~~
615 ~~exceeded 1.0, indicating highly oxidized OA. In contrast, Bayanbulak exhibited~~ a lower
616 O/C ratio of 0.69 ~~was observed at Bayanbulak and, and the urban site of Lhasa showed~~
617 an even lower ~~O/C~~ ratio of 0.44 ~~was observed at the urban site in Lhasa.~~ These
618 ~~variations in O/C ratios across sites primarily reflect~~ differences in ~~O/C ratios were~~
619 ~~mainly attributed to the variations in~~ OA sources and aging processes ~~across different~~
620 ~~sites. As mentioned earlier, atmospheric aerosols in the remote. Remote~~ sites in the TP
621 were generally ~~associated with~~ received well-mixed and aged OA due to long-range
622 transport ~~from surrounding areas, hence the OAs were generally well mixed and highly~~
623 ~~aged during the transport from source region to the remote sites in the TP~~ (Xu et al.,
624 2018; Zhang et al., 2018; Zhang et al., 2019). ~~However~~ Meanwhile, local ~~fresh~~ OAs

625 ~~emitted emissions~~ from ~~various residential~~ activities ~~such as like~~ cooking, traffic
626 ~~exhausts~~, and biomass burning ~~predominated significantly contribute to the total OA at in~~
627 urban Lhasa, ~~resulting in a comparatively low O/C ratio~~ (Zhao et al., 2022), ~~which~~
628 ~~ultimately led to a relatively low O/C ratio. Similar differences in O/C ratios have been.~~
629 ~~This pattern of higher O/C ratios at remote sites and lower ratios at urban sites were~~
630 observed in previous ~~studies in findings across~~ China. ~~For instance, higher, such as~~ O/C
631 ratios of 0.98, 1.11, and 1.16 ~~were measured at remote sites in observed at~~ Mt. Wuzhi
632 (Zhu et al., 2016), Mt. Yulong (Zheng et al., 2017), and LHG (Xu et al., 2015),
633 ~~while respectively, versus urban sites where~~ O/C ratios ~~of OAs were generally lower~~
634 ~~than typically fell below~~ 0.5 at most urban sites (Zhou et al., 2020). The Van Krevelen
635 diagram ~~(, which plots H/C versus O/C), a widely used approach ratios to depict~~
636 ~~the illustrate~~ changes in ~~the OA~~ elemental composition ~~of OA resulting from due to~~
637 atmospheric aging ~~processing, is displayed in Fig. 5b. An, shows an~~ overall slope of
638 ~~-0.66 was observed~~ for the bulk ~~OAs OA~~ across ~~the eight field measurement all~~
639 campaigns ~~in our study, which.~~ ~~This result~~ is comparable to ~~those slopes~~ of -0.58 and
640 -0.47 obtained ~~from different synthesized datasets from diverse field observations in~~
641 previous studies, ~~further illustrating common pathways in OA aging~~ (Chen et al., 2015;
642 Zhou et al., 2020).

643 The average HRMSs of OA between the remote site (Waliguan) and the urban site
644 (Lhasa) were directly compared to investigate the ~~inherent~~ difference in ~~ionionic~~
645 compositions (Fig. 5c). Waliguan was ~~chosen as an example because the selected for~~
646 ~~comparison due to its representation of~~ overall highly- aged OA ~~nature, a characteristic~~
647 ~~shared~~ with ~~very similar HRMSs among the seven other~~ remote sites, ~~as shown in-~~ (Fig.
648 S3 ~~in the supplementary materials. It is evident that the-). The HRMS of OA HRMSs~~
649 ~~exhibited distinct variations between these two types of sites. At the at~~ Waliguan site,
650 ~~and Lhasa displayed significant differences. At Waliguan, the m/z 44, which~~
651 ~~is predominantly~~ composed ~~totally by of~~ CO₂⁺ and ~~one of the most reliable markers a~~
652 ~~key marker~~ for OOA, was the ~~base most prominent~~ peak (18%) in the OA HRMS. The
653 CO₂⁺ and its related ~~four~~ ions (CO⁺, H₂O⁺, HO⁺ and O⁺) together contributed ~~more~~
654 ~~than over~~ 41% of the total OA signals. Additionally, ~~the~~ two oxygenated ion fragments
655 (C_xH_yO₁⁺ and C_xH_yO₂⁺) accounted for as much as 66% of the total OA signals (Fig.
656 5c). ~~All these features demonstrated), suggesting~~ the ~~overall~~ highly oxygenated nature
657 of OA at ~~the this~~ remote ~~background sites in the TP site.~~ In contrast, the OA HRMS at

Lhasa was remarkably similar to those observed at ~~most in~~ urban ~~cities~~. ~~The environments, with significant contributions from~~ four ~~m/z values~~ at 43, 55, 57, and 60, ~~which~~. ~~These ions~~ are recognized as ~~important mass spectral tracers/markers~~ for less oxidized OA ~~compounds~~ or primary emissions related to traffic, cooking, and biomass burning ~~activities~~ (Zhang et al., 2005a; Alfarra et al., 2007; He et al., 2010), ~~showed making up a significant contributions/contribution~~ to the total-OA signals in ~~this urban site-Lhasa~~. Specifically, ~~the non-oxygenated ion fragment of C_x fragments (C_xH_y⁺)~~ contributed as ~~higher/much~~ as 64.5% of the total OA ~~signal~~ in Lhasa, whereas the ~~two~~ oxygenated ~~ion~~ fragments ~~contributed/accounted for~~ only 33.6%. ~~The high contribution~~ ~~This pattern~~ of fresh ion fragments in the OA HRMS in Lhasa is comparable to those measured at other urban cities, such as 56% and 59% in Lanzhou (Xu et al., 2014b; Xu et al., 2016), 51.2% in Nanjing (Wang et al., 2016), and 51.2% in New York (Sun et al., 2011).

671 **4.4 OA components from PMF source apportionment**

672 Source apportionments of OA were performed using PMF analysis on OA HRMS data
673 for each field campaign. Figure 6 presents the average mass contributions of ~~different~~
674 OA components from the selected 2–4 factor solutions ~~among the across~~ eight ~~different~~
675 field campaigns, while ~~Figure S4 details~~ the specific HRMS ~~of signatures for~~ each OA
676 component ~~is displayed in Fig. S4. Due to the~~. ~~In regions with~~ limited local
677 ~~source emissions~~ but ~~dominated source significant influence~~ from regional transport,
678 ~~only such as NamCo, LHG, and Bayanbulak~~, two secondary ~~OOA/OA~~ factors with
679 different oxidation degrees, namely a less oxidized OOA (LO-OOA) and a more
680 oxidized OOA (MO-OOA), were identified ~~during the NamCo, LHG, and Bayanbulak~~
681 ~~campaigns. On average. For instance~~, during the NamCo campaign, ~~the~~ MO-OOA and
682 LO-OOA ~~accounted for 59.0% and 41.0% of the total OA mass~~, with average O/C ratios
683 of 0.96 and 0.49, respectively, ~~accounted for 59.0% and 41.0% of the total OA mass~~.
684 ~~Similarly, the~~. ~~The~~ Bayanbulak campaign exhibited ~~contributions of a similar result~~,
685 ~~with~~ MO-OOA (average O/C of 1.12) and LO-OOA (average O/C of 0.55) ~~to total OA~~
686 ~~mass accounting for 66.3% and 33.7%,% of the OA mass~~, respectively.
687 ~~However~~ ~~Contrastingly~~, the LHG campaign ~~showed only revealed a different pattern~~,
688 ~~with~~ 24.9% ~~of~~ MO-OOA and 75.1% ~~of~~ LO-OOA, ~~albeit~~ with ~~relatively high/higher~~ O/C
689 ratios of 1.29 and 1.08, respectively. ~~Besides~~ ~~Note that the two properties of each~~ OOA
690 ~~factors~~ factor could be different across the locations in the TP despite the same name.

691 Additionally, biomass-burning-related OA (BBOA) was also ~~widely identified a~~
692 ~~prevalent component~~ in the TP ~~regions~~. At QOMS, the ~~total OA mass~~ was composed by
693 42.4% ~~of~~ MO-OOA, 43.9% ~~of~~ BBOA, and 13.9% ~~of~~ nitrogen-containing OA (NOA),
694 with average O/C ratios of 1.34, 0.85, and 1.10, respectively. The high O/C ratio and
695 significant contributions ~~from of~~ BBOA and NOA at QOMS were ~~associated with the~~
696 ~~transport of linked to~~ biomass burning emissions ~~transported~~ from ~~polluted regions in~~
697 South Asia ~~to the Himalaya and inland TP regions~~ during the pre-monsoon season
698 (Cong et al., 2015; Zhang et al., 2018; Kang et al., 2019a). At Waliguan, the ~~total OA~~
699 ~~mass~~ was composed by 34.4% ~~of~~ MO-OOA, 40.4% ~~of~~ relatively aged BBOA
700 (agBBOA), 18.3% ~~of~~ BBOA, and 6.9% ~~of~~ hydrocarbon-like OA (HOA), with average
701 O/C ratios of 1.42, 1.02, 0.69, and 0.33, respectively. The ~~two BBOA components,~~
702 ~~particularly agBBOA,~~ exhibited an enhanced contribution to ~~total OA~~ as the OA mass
703 concentration increased, ranging from ~~only~~ ~10% to ~~as high as~~ 70% when OA mass
704 varied from $<1.0 \mu\text{g m}^{-3}$ to $7 \mu\text{g m}^{-3}$ (Zhang et al., 2019). ~~In addition, source analysis~~
705 ~~indicated that the high~~ High contributions of ~~the two BBOA components~~ at Waliguan
706 were associated with ~~the~~ regional transport of biomass burning emissions from ~~the~~
707 ~~residential areas in northeastern Waliguan~~ the northeast (Zhang et al., 2019). At Ngari,
708 the ~~total OA mass~~ was composed by 43.7% ~~of~~ MO-OOA, 28.5% ~~of~~ LO-OOA, and 27.8%
709 ~~of~~ BBOA, with average O/C ratios of 1.43, 1.00, and 0.56, respectively. In
710 ~~comparison contrast,~~ the ~~contributions of the three Motuo exhibited~~ OA components at
711 ~~Motuo site were of~~ 36.9%, % MO-OOA, 46.9%, % LO-OOA, and 16.2%, % BBOA, with
712 O/C ratios of 1.30, 1.11, and 0.25, respectively. ~~The BBOA factor at Motuo exhibited~~
713 ~~relatively~~ The lower ~~mass BBOA~~ contribution and O/C ratio ~~compared to those observed~~
714 ~~at QOMS, Ngari, and Waliguan, suggesting weak~~ at Motuo suggest a weaker local
715 ~~source from~~ biomass burning. ~~Four~~ emissions. At urban Lhasa, four OA factors ~~were~~
716 ~~identified~~ including an OOA ~~component~~ with O/C ratio of 0.54 and three primary OA
717 components, i.e., ~~a BBOA with (O/C of 0.13, a),~~ cooking-related OA (COA) ~~with,~~ O/C
718 ~~of 0.12,)~~, and ~~a HOA with (O/C of 0.11, were identified at the urban site in Lhasa, which~~
719 ~~were distinctly).~~ These components were markedly different ~~with from~~ those ~~observed~~
720 at ~~the~~ above remote sites. ~~The with the~~ three primary OA components ~~together~~
721 ~~contributed accounting for~~ more than 60% of the total OA ~~mass at Lhasa,~~ suggesting the
722 abundant primary aerosol sources from the residential activities. In addition, the BBOA
723 contribution increased ~~obviously significantly~~ (up to 36%) during a ~~grand major~~ local
724 festival ~~at in~~ Lhasa, suggesting the crucial aerosol source from biomass burning during

725 religious activities in the city (Zhao et al., 2022). ~~In summary, distinct types of OA~~
726 ~~components with different O/C ratios were identified at different sites, indicating the~~
727 ~~different sources and oxidation states of OA in the different TP regions.~~

728 In summary, our study identified diverse OA components with varying O/C ratios at
729 different sites, indicating the heterogeneity of sources and oxidation states of OA across
730 the TP regions.

731 **4.5 Number concentrations of submicron aerosols and cloud condensation nuclei**

732 ~~Real time online measurements of the size distribution of number concentration of fine~~
733 ~~particles were also conducted simultaneously using SMPS instruments during four field~~
734 ~~campaigns (QOMS, Motuo, LHG, and Lhasa). The measurement of particle number~~
735 ~~size distribution (PNSD) was not only an important auxiliary data for calibrating and~~
736 ~~verifying the accuracy of HR-ToF-AMS data, but also very useful for studying the~~
737 ~~formation and growth mechanisms of aerosol particles in the atmosphere. Figure 7a~~
738 ~~shows the high-resolution temporal variations of the PNSDs during the four field~~
739 ~~campaigns. The PNSDs varied dynamically throughout the measurement period at each~~
740 ~~site and showed distinct variations in (QOMS, Motuo, LHG, and Lhasa), revealing~~
741 ~~significant variability in number concentrations and size distribution pattern~~
742 ~~among patterns across the four different campaign sites. On average, the total number~~
743 ~~concentrations were concentration was 709.3 and 3994.4 cm⁻³ at QOMS and Lhasa,~~
744 ~~respectively, while they were it was 1639.2 and 1462.0 cm⁻³ at Motuo and LHG.~~
745 ~~Interestingly~~ Notably, the ~~difference~~ variations in particle number concentrations were
746 not consistent with ~~those in~~ mass concentrations measured from the HR-ToF-AMS
747 ~~among at~~ the four ~~campaign sites~~ (Table 2). For ~~example~~ instance, although the PM₁
748 mass concentration at Lhasa was comparable to that at QOMS (4.7 versus 4.4 μg m⁻³),
749 the number concentration at Lhasa was more than five times higher than that at QOMS.
750 This inconsistency ~~may be was mainly~~ related to the ~~distinctly different~~ difference on
751 size distribution at different sites. As discussed mentioned above, submicron aerosols at
752 QOMS were ~~overall highly aged~~ predominantly secondary due to ~~the~~ long-range
753 ~~transported source~~ transport from South Asia and ~~dominated~~ characterized by aerosols
754 ~~at accumulation mode size mode, whereas more fresh. In contrast, Lhasa exhibited~~
755 fresher aerosols, emitted from local residential activities and ~~dominated~~ characterized
756 by aerosols of Aitken size mode ~~were observed at Lhasa size.~~ The ~~different sizes of~~
757 variation in submicron aerosols ~~among aerosol sizes across~~ the ~~different~~ TP regions

758 ~~could be~~ further ~~confirmed~~ ~~evidenced~~ by the peak diameters in the average mass and
759 number size distributions ~~of mass and number concentrations~~ (Figs. 4a and 7b). For
760 ~~example~~ ~~instance~~, the average OA mass size ~~distributions exhibited peak diameters of~~
761 distribution peaked at 510.2 and 430.5 nm in D_{va} ~~at~~ for QOMS and Motuo, respectively,
762 ~~while~~. Meanwhile, the average number size distributions at these two sites had peak
763 ~~diameters of~~ at 109.4 and 131.0 nm in D_m ~~at the same sites~~. In contrast, Lhasa displayed
764 significantly smaller peak diameters of only 228.1 nm in D_{va} and 28.9 nm in D_m .

765 New particle formation (NPF) events were ~~also~~ observed at ~~a few~~ several sites in our
766 study. Typically, an NPF event is characterized by a rapid burst in nucleation mode
767 followed by the subsequent growth into larger particles, as defined as banana-shaped
768 temporal developments in the PNSD (Dal Maso et al., 2005). ~~As shown in Fig.~~ Figure
769 7a, ~~frequent~~ displays the cases of banana-shaped ~~variation~~ patterns in the PNSD,
770 which were frequently observed at ~~Lhasa~~, suggesting the frequent occurrence of NPF
771 at this urban region. ~~During~~ Lhasa. ~~Throughout~~ the 27-day Lhasa campaign (~~27 days~~),
772 a total of 10 NPF events were observed (Zhao et al., 2022). In contrast, ~~this~~ such banana-
773 shaped pattern in the PNSD was relatively rare at the other three remote sites, (QOMS,
774 Motuo, and LHG), which might be related to their predominated
775 transport predominance of long-range transported aerosol sources, with overall highly-
776 aged states, and limited gaseous precursors.

777 Cloud condensation nuclei (CCN) is a distinct class of atmospheric aerosol particles
778 which could be activated as cloud droplets at a certain supersaturated water vapor
779 condition and played important roles in cloud formation, ~~atmospheric~~ precipitation,
780 ~~the climate change, and~~ regional ~~climate, as well as the~~ hydrological cycle (Andreae and
781 Rosenfeld, 2008). ~~During~~ Across the TP field campaigns, ~~real time online~~ CCN
782 measurements of CCN number concentrations were conducted at three sites, i.e.,
783 Motuo in the southeastern TP while, Waliguan, and LHG in the northeastern TP.
784 Generally, ~~the~~. The temporal variation variations of CCN number
785 ~~concentration~~ concentrations at each SS exhibited a ~~consistent~~ similar trend with the total
786 number concentration from the SMPS measurement ~~or total~~ and the PM_{10} mass
787 concentration from the HR-ToF-AMS measurement during each campaign. On average,
788 at Motuo, the CCN number concentrations at Motuo were 974.0, 1142.6, 1240.1, 1296.5,
789 and 1337.9 cm^{-3} at ~~different~~ SS values level of 0.2%, 0.4%, 0.6%, 0.8%, and 1.0%,
790 respectively. At Waliguan, relatively comparable average values of ~~507.0, 805~~ 233.7,

857.8, 1138.7, 1313.1, ~~1073.3, 1230.6, and 1336.6~~1407.0 cm^{-3} were observed at ~~the~~
859 same SS steps, respectively. However, ~~at~~corresponding SS levels. In contrast, LHG,
861 these average values exhibited significantly ~~decreased to~~ 83.9, 344.3, 429.9, 480.8,
863 lower average CCN concentration of 120.5, 340.1, 417.8, 468.0, and ~~516.1~~504.5 cm^{-3}
865 at the same SS levels, respectively (Table 2). The lower CCN number concentrations at
867 LHG compared to Waliguan and Motuo were consistent with ~~the relatively its~~ lower
869 PM_{10} mass loading ~~at the LHG site. The~~. Comparing with other regions, the CCN
871 number concentrations at the three TP sites were almost an order of magnitude lower
873 than those observed in polluted urban atmospheres environments or emissions off from
875 specific combustion sources, such as emissions. For instance, CCN concentrations
877 reached 12963 cm^{-3} ($SS = 0.70\%$) in Wuqing, 9890 cm^{-3} ($SS = 0.86\%$) in Beijing (Deng
879 et al., 2011; Gunthe et al., 2011), 7913 cm^{-3} ($SS = 0.70\%$) at Panyu in the Pearl River
881 Delta, as well as 11565 cm^{-3} ($SS = 0.87\%$) and 10000 cm^{-3} ($SS = 0.80\%$) during unique
883 biomass burning plumes (Rose et al., 2010; Zhang et al., 2020). However, ~~our~~the CCN
885 values from our study were comparable to those (~~228–2150 cm^{-3} with SS of 0.87%~~)
887 measured at eight remote marine sites in the South China Sea (~~228–2150 cm^{-3} at SS =~~
889 ~~0.87%~~) and 941 cm^{-3} (~~SS = 0.74%~~) in the amazon rain forest (~~941 cm^{-3} at SS = 0.74%~~)
891 (Pöhlker et al., 2016; Atwood et al., 2017). These comparisons again highlight the
893 overall clean atmospheric condition in the TP.

810 4.6 Aerosol optical properties and light absorptions from BC and BrC

811 ~~The optical properties of aerosol particles are crucial input parameters for accurately~~
812 ~~estimating aerosol radiative forcing in climate models. However, significant~~
813 ~~uncertainties persist due to the limited dataset in~~ In this remote region. In our
814 ~~project study~~, the parameters of B_{scat} , B_{abs} , and SSA of fine particles at 405 nm were
815 observed ~~during five at the~~ field campaigns, ~~i.e., of~~ QOMS, Motuo, Waliguan, Ngari,
817 and Lhasa, to explore the differences variations in aerosol optical properties at
819 different across the TP regions. On average, the B_{scat} and B_{abs} at 405 nm during the five
821 campaigns were 121.9, 44.9, 36.3, 8.9, and 2.1 Mm^{-1} and 10.8, 7.0, 4.1, 3.6, and 1.9
823 Mm^{-1} , respectively, ~~which finally resulted in~~. These values yielded average SSA values
825 of 0.89, 0.83, 0.86, 0.67, and 0.52, correspondingly (Fig. 8a and Table 2). ~~These~~The
827 B_{scat} and B_{abs} values at the ~~five~~ TP sites were ~~both~~ significantly lower than those reported
829 at in various urban sites areas in China, such as 459.5 and 47.2 Mm^{-1} , ~~respectively~~, at
831 630 nm in Beijing (Xie et al., 2019), 272 and 31 Mm^{-1} , ~~respectively~~, at 532 nm in Xi'an

(Zhu et al., 2015), and 418 and 91 Mm^{-1} , respectively, at 540 nm in Guangzhou (Andreae et al., 2008), ~~once~~ again suggesting the overall clean atmospheric condition in the TP. Although the PM_{10} mass concentrations at QOMS was comparable to or even lower than those at the other four sites, QOMS exhibited the highest B_{scat} , B_{abs} , and SSA values ~~were observed at QOMS. These results. This discrepancy~~ may be attributed ~~due~~ to ~~the differences~~ variations in aerosol chemical compositions and ~~their~~ mass scattering and absorbing efficiencies. In contrast, Lhasa exhibited a significantly lower SSA compared to the other four remote sites, suggesting a prevalence of fresh aerosols in the urban ~~area~~ environment. On the other hand, aerosols at the four remote sites were highly aged, ~~which resulted in leading to~~ significant photobleaching ~~in of~~ BrC chromophores and an obvious decrease in their light absorptivity ~~at these sites~~.

~~In this study, real~~ Real-time online measurements of particle B_{abs} at seven ~~fixed~~ wavelengths (~~ranging from 370= to 950 nm~~) were also conducted using an aethalometer at QOMS, NamCo, and Waliguan, respectively, to explore ~~the~~ regional ~~difference~~ variations in aerosol absorption properties ~~in across~~ the ~~different~~ TP regions. Overall, the multi-wavelength B_{abs} decreased significantly with the increasing wavelength during ~~all~~ the three measurement campaigns, with ~~fitting~~ fitted AAE values ~~to be of~~ 1.73, 1.28, and 1.12, respectively (Fig. 8b). The average B_{abs} at the shortest wavelength of 370 nm was 13.40, 3.25, and 2.66 Mm^{-1} at the three sites, respectively (Table 2). ~~Although~~ Despite a relatively low PM_{10} mass ~~was observed~~ concentrations at QOMS, the B_{abs} at 370 nm was five times higher than that at Waliguan, mainly ~~as due~~ to a ~~result of the~~ higher contribution of light-absorbing aerosol components in the southern TP ~~regions. For example. Specifically,~~ OA and BC together ~~contributed~~ accounted for nearly 80% of the total PM_{10} at QOMS, whereas this contribution decreased to only 37.5% at Waliguan. The obviously higher AAE at QOMS also suggested a dominant light-absorbing contribution from BrC or the significant lensing effect of ~~non-BC materials~~ coated ~~on BC at this southern site~~ BC (Zhang et al., 2021). ~~As shown in the~~ The inserted plots in Fig. 8b, ~~both BC and BrC components showed~~ illustrate significant ~~decrease of~~ decreases in particle B_{abs} (~~BC and $B_{\text{abs},\text{BC}}$ and $B_{\text{abs},\text{BrC}}$ to total $B_{\text{abs},\text{BrC}}$~~) with increasing wavelength, ~~but yet~~ their contributions to total B_{abs} ($f_{B_{\text{abs},\text{BC}}}$ and $f_{B_{\text{abs},\text{BrC}}}$) varied inversely. BC was the primary light-absorbing component ~~at across~~ all the three sites, contributing 66.9%, 78.7%, and 77.6% to the total B_{abs} at 370 nm at QOMS, NamCo, and Waliguan sites, respectively, ~~and;~~ its

857 contribution increased apparently with longer wavelengths (Table 2). Conversely, BrC
858 showed more significant contributions to total B_{abs} at shorter wavelengths. For
859 exampleinstance, the average $B_{abs,BrC}$ at 370 nm were 4.42, 0.69, and 0.60 Mm^{-1} at the
860 three sites, respectively, ~~which finally contributed~~ ultimately contributing 33.1%, 21.3%,
861 and 22.4% ~~of~~ to the total B_{abs} . The significantly higher values of total B_{abs} , $B_{abs,BC}$,
862 $B_{abs,BrC}$, and $fB_{abs,BrC}$ in the southern TP region could be related to the important
863 contributions of light-absorbing CAs from transported biomass burning emissions (Xu
864 et al., 2020, 2022).

865 4.7 Estimation of aerosol radiative forcing in the different TP regions

866 Atmospheric aerosols ~~have been found to significantly impact the~~ play a significant role
867 in impacting Earth's climate systems through affecting solar radiation and exerting a
868 positive forcing on the energy budget (Bond and Bergstrom, 2006). In this study,
869 aerosol direct radiative forcings (DRF) caused by BC, organic carbon (OC), and water-
870 soluble ions (WSIs) are estimated, respectively, ~~by the widely used~~ using Santa Barbara
871 DISORT (Discrete Ordinate Radiative Transfer) Atmospheric Radiative Transfer
872 (SBDART) model (Ricchiazzi et al., 1998). A detailed introduction and operation
873 ~~process~~ of this model are described in Text S6 in the supplementary material. Since the
874 model's performance is evaluated and calibrated by comparing the values with
875 measurements from ~~the~~ Aethalometer and PAX ~~instruments~~ results, the aerosol DRF
876 estimations are limited to ~~the three sites of~~ QOMS, NamCo, and Waliguan, ~~which have~~
877 ~~both online measurements from the aforementioned instruments~~. Furthermore, these
878 three sites are located in the southern, central, and northern regions of the TP,
879 respectively, which ~~enables us to explore the~~ allows for an exploration of regional
880 variations in aerosol DRF across ~~different~~ the TP ~~regions~~.

881 Figure 9 presents the ~~modelled results of~~ DRFs ~~caused by~~ attributed to BC, OC, and
882 WSIs ~~during~~ across the three campaigns. BC ~~exhibited~~ demonstrated a
883 ~~significant~~ pronounced warming effect at the top of the atmosphere, with average DRF
884 values of $+2.5 \pm 0.5$, $+2.1 \pm 0.1$, and $+1.9 \pm 0.1$ $W m^{-2}$ during the QOMS, Waliguan,
885 and NamCo ~~campaign~~ campaigns, respectively. In contrast, BC exhibited a noticeable
886 cooling effect ~~caused by BC was observed~~ at the earth's surface, with average DRF
887 values of -4.7 ± 0.8 , -4.1 ± 0.2 , and -3.7 ± 0.1 $W m^{-2}$ across the three campaigns. The
888 combination of ~~warming effect at the top of the atmosphere and cooling effect at the~~
889 ~~earth's surface~~ these two effects resulted in significantly high net atmospheric

890 ~~forcings~~forcing by BC, amounting to $+7.3 \pm 1.2$, $+6.2 \pm 0.3$, and $+5.6 \pm 0.2$ W m⁻²
891 ~~during~~for the QOMS, Waliguan, and NamCo ~~three~~ campaigns, ~~respectively~~. These
892 ~~findings~~results suggest the important radiative effect ~~caused by~~of BC in the TP,
893 especially in the southern TP-region, ~~which was significantly~~ influenced by ~~the~~ long-
894 range transported biomass burning emission from South Asia. ~~For~~In contrast, OC and
895 WSIs, ~~exhibited~~cooling effects ~~were observed~~ at both the top of the atmosphere and
896 the ~~earth's~~Earth's surface, characterized by negative and relatively low average DRFs.
897 Consequently, the net atmospheric forcings for OC and WSIs were ~~significantly~~notably
898 lower compared to BC across the three campaigns, with values of $+2.0 \pm 1.2$, $+0.7 \pm$
899 0.2 , and $+0.9 \pm 0.7$ W m⁻² for OC, and $+1.9 \pm 0.8$, $+1.4 \pm 0.6$, and $+1.2 \pm 0.2$ W m⁻² for
900 WSIs at QOMS, Waliguan and NamCo, respectively. Interestingly, at QOMS, the
901 average atmospheric DRF of OC accounted for 27.3% of that of BC, whereas at
902 Waliguan and NamCo, the fractions were only 11.1% and 15.7%, respectively. The
903 higher atmospheric DRF observed at QOMS suggests a dominant contribution from
904 light-absorbing BC and BrC aerosols, compared to Waliguan and NamCo.

905 It was worth noting that the simulations of DRF effects in this study were only
906 conducted at three specific sites ~~during~~over limited periods. ~~Therefore,~~Future research
907 should focus on long-term comprehensive measurements and DRF simulations
908 ~~over~~across the entire TP ~~regions under different seasons are needed in the future to~~
909 enhance our understanding of aerosol impacts on regional climate.

910 **4.8 Long-range transport of aerosols from surrounding areas**

911 To further understand the potential sources and specific transport pathways of ~~air~~
912 ~~masses~~aerosols at each site, particularly for those remote sites ~~where regional transport~~
913 ~~dominated~~, three- or five-days air mass back trajectories were calculated during each
914 measurement period at an ending height of 500 m above ground level every 6h using
915 the Hybrid Single Particle Lagrangian Integrated Trajectory (HYSPLIT) model
916 (Draxler and Rolph, 2003). The cluster analysis on the trajectories was based on the
917 total spatial minimum variance method. Figure 10 ~~display~~displays the average
918 backward trajectory clusters ~~during~~across all ~~the~~ eight field campaigns ~~and the major~~
919 ~~trajectory clusters at each site are marked with large solid circles in different colors~~.

920 In general, distinct air mass sources were identified ~~among~~across the ~~different~~ TP
921 ~~regions~~. The five sites (QOMS, Motuo, Lhasa, NamCo, and Ngari) located in the

922 southern or south-central part of the TP generally showed ~~dominant~~ air mass
923 ~~sources~~ masses from ~~the~~ south or southwest with different transport distances and
924 pathways during their measurement periods ~~in pre-monsoon season~~. For
925 ~~example~~ instance, during the QOMS campaign, 38% of the air masses originated from
926 the west, covering a ~~considerably~~ long ~~transport~~ distance, while another 40% ~~was~~
927 originated from the southwest, covering a ~~relatively~~ shorter distance. In the Motuo
928 campaign, two major clusters ~~were~~ both originated from the southwest, ~~but their~~
929 transport with different distances ~~were distinctly different~~ (77% at shorter distance
930 compared to only 13% at a longer distance). Similarly, during the NamCo campaign,
931 two ~~different~~ major clusters with comparable contributions (37% and 34%) and
932 transport distances, but different ~~transport~~ pathways, were ~~found~~ identified from the
933 south. ~~The~~ In the Ngari campaign ~~also observed~~, air masses showed similar transport
934 distances, with 56% ~~of the air masses~~ originating from southwest and 26% from the
935 ~~south of the site~~. These air mass clusters originating from the south of the TP generally
936 traverse ~~heavy~~ polluted regions in South Asia, such as the Indo-Gangetic Plain, Nepal,
937 and Bangladesh, carrying significant amounts of ~~polluted aerosols~~ pollutants,
938 particularly ~~the~~ biomass-burning ~~related~~ emissions ~~from the source origins to~~ into the
939 inland of the TP. In contrast, air masses at ~~the~~ northern sites were primarily influenced
940 by ~~the prevailing~~ Westerlies ~~wind~~ and East Asian monsoon during ~~the~~ summer season
941 ~~measurement periods~~. In the campaigns of Bayanbulak ~~campaign, the major~~, air masses
942 ~~were all~~ originated from the west ~~of the site~~ with ~~varying transport~~ different distances (~~,~~
943 i.e., 69% in relatively shorter distance versus 18% in a longer distance). During the
944 LHG campaign, the air masses originated from the northwest of the site with 63% in
945 longer ~~transport~~ distance but 27% in shorter distance. For the Waliguan campaign, the
946 air mass ~~clusters~~ originated from two ~~distinctly different~~ distinct directions. ~~The~~
947 majority ~~Most~~ of ~~the~~ air masses (57%) came from the northeast of the site ~~covering with~~
948 a ~~relatively~~ shorter distance ~~and faster transport speed~~, while the remaining ~~clusters~~ air
949 masses originated from the west and northwest ~~of the site covering significantly with~~
950 longer distances.

951 In summary, significant ~~differences~~ variations in air mass sources and transport
952 pathways were ~~identified among~~ observed across the ~~different~~ TP ~~regions~~, particularly
953 between ~~the~~ southern and ~~the~~ northern TP ~~regions~~. These differences ~~are the primary~~
954 ~~factors contributing to the~~ significantly play a crucial role in shaping the different

955 physiochemical and optical properties of aerosols ~~in~~across the ~~different~~ TP regions.

956 **5 Dataset limitations and applications**

957 Our dataset was ~~achieved~~compiled from ~~multiple~~eight short-term intensive field
958 observations ~~conducted at eight different sites of~~across the TP ~~during their high mass-~~
959 ~~loading periods~~ utilizing a suite of high-resolution online instruments. However, it is
960 important to ~~acknowledge~~note that our dataset ~~has~~does have certain limitations ~~due to~~
961 ~~objective restrictions~~ that ~~were~~proved to be quite challenging to ~~overcome~~address in
962 these remote regions.

963 The primary limitation ~~revolves around~~stems from the short and inconsistent
964 measurement periods across different observational years and seasons at different sites.
965 ~~This limitation hinders the ability to make a,~~ impeding robust ~~comparison~~comparisons
966 of aerosol properties across the ~~vast TP region,~~ TP. This limitation also hampers the
967 ability to ascertain long-term and seasonal ~~variation~~ characteristics, ~~and apply the~~
968 ~~current data and findings to other different seasons.~~ The harsh natural environments,
969 challenging weather conditions, limited logistical support, ~~sole availability of our high-~~
970 ~~resolution~~ and instruments, and ~~the~~ stringent instrumental requirements (e.g., ~~such as~~
971 the ~~need~~necessity for comprehensive field stations with ~~uninterrupted and~~ stable power
972 supply) ~~were the most~~presented significant challenges ~~we faced~~ during our field
973 observations in these remote TP regions. It is worth noting that online HR-ToF-AMS
974 observations, such as the ~~ones~~one we conducted, are predominantly short-term and
975 ~~intense~~intensive observations carried out worldwide due to the ~~stability~~instability issues
976 and its challenging maintenance ~~during~~required for long-term
977 ~~measurement~~measurements. The short-term intensive measurement ~~can well~~is enough
978 to capture and characterize the dynamic evolution of aerosol properties at a high-time-
979 resolution (Jimenez et al., 2009; Li et al., 2017). ~~Until now, long~~Long-term high-time-
980 resolution observation utilizing HR-ToF-AMS have ~~been~~ rarely ~~been~~ conducted thus
981 far, even ~~at~~in urban ~~sites~~environment with relatively favorable observational
982 ~~environments~~conditions and logistic support compared to our remote TP sites.
983 Consequently, performing continuous long-term observations or simultaneous
984 comparison at multiple sites in these high-altitude remote ~~and challenging~~ TP regions,
985 ~~without stable power supply, is nearly impossible~~ TP regions, without stable power
986 supply, is exceedingly challenging. Furthermore, assessing the representativeness of
987 each observation for the spatial scale is particularly challenging due to the limited

988 number of observatories across the TP. Actually, these observatories have been
989 strategically established based on the representation of specific geographic and climatic
990 features.

991 ~~However~~In addition to the limitations above, our team has made significant efforts to
992 conduct ~~the~~this comprehensive observation project over the past ~~ten years~~decade,
993 aiming to study the regional differences in aerosol sources and properties across the
994 ~~different~~ TP ~~regions~~. The dataset generated from our project represents the first and
995 ~~sole~~exclusive high-time-resolution dataset focusing on atmospheric aerosol
996 physicochemical and optical properties, ~~covering the~~covering most ~~part~~region of the TP.
997 The applications of this dataset in atmospheric science ~~can be summarized as follows:~~
998 ~~firstly are multifaceted.~~ Firstly, the high-time-resolution observations offer crucial
999 advantages in understanding the rapid evolution and diurnal variations of aerosol
1000 properties during a short period or special event. ~~Additionally~~Furthermore, these
1001 observations are ~~valuable~~invaluable for model simulation and verification, ~~as they~~
1002 ~~provide sufficient~~providing a wealth of data points ~~that can be utilized for assessing~~
1003 aerosol loading, chemical composition, size distribution, and other parameters essential
1004 for model accuracy and validation. Such advantages are not achievable with traditional
1005 off-line samplings, which ~~have~~typically exhibit low time resolutions ranging from days
1006 to weeks. Secondly, the eight sites ~~included~~encompassed in our project effectively
1007 represent a wide range of the TP. This is particularly noteworthy considering the limited
1008 availability of ~~observational stations~~observatories on the ~~plateau.~~ ~~Furthermore, these~~ TP.
1009 ~~These~~ sites ~~provide excellent opportunities for comparing~~facilitate comparisons of
1010 aerosol sources and properties among different ~~types of sites with varying altitudes,~~
1011 ~~land covers, surrounding environments, human activities, and influences from large-~~
1012 ~~scale atmospheric circulations~~regions. Thirdly, our observations encompass a wide
1013 range of aerosol physical, chemical, and optical parameters, including aerosol mass
1014 loadings, chemical compositions, size distribution, diurnal variations, number
1015 concentrations, light scattering and absorption coefficients, and so on. This
1016 comprehensive dataset isplays a crucial ~~for a thorough~~role in fostering a profound
1017 understanding of aerosol properties in the TP ~~regions.~~ ~~Overall, it is worth noting that~~
1018 ~~until now, similar online observational aerosol datasets focusing on multiple parameters~~
1019 ~~with at least hourly scale resolution at various sites in the diverse TP regions had been~~
1020 ~~rarely reported.~~ .

1021 Overall, it is noteworthy that our online observational aerosol datasets, focusing on
1022 multiple parameters with at least hourly-scale resolution at various sites across the TP,
1023 are the only ones reported to date.

1024 **6 Data availability**

1025 The high-resolution online measurement datasets, encompassing aerosol physical,
1026 chemical, and optical properties over the Tibetan Plateau and its surroundings in our
1027 observation project have been released and are now available for download from the
1028 National Cryosphere Desert Data Center
1029 (<https://doi.org/10.12072/ncdc.NIEER.db2200.2022>). These datasets are provided in an
1030 Excel file comprising eight worksheets. The first sheet of the Excel file contains a
1031 concise description of the dataset, including the dataset name, observation stations,
1032 sampling periods, online instruments used, and corresponding references. The
1033 remaining seven sheets present the high-resolution measurement data obtained from the
1034 online instruments employed during the eight campaigns. These instruments include
1035 HR-ToF-AMS, SMPS, PAX, aethalometer, and CCN-100.

1036 **7 Conclusions**

1037 ~~A This study presents a comprehensive dataset includingencompassing aerosol~~
1038 ~~physicochemical and optical properties, especially thewith a particular focus on high-~~
1039 ~~resolution size-resolved chemical characteristics and sources of submicron aerosols,~~
1040 ~~conducted through real-time online measurements at at eight different sites of the TP~~
1041 ~~and its surroundings is presented in this study. The objective of this study is to elucidate~~
1042 ~~the mass concentration level of atmospheric aerosols in this isolated background region~~
1043 ~~and identify regional variations in aerosol sources, as well as physicochemical and~~
1044 ~~optical properties among different TP regions. Ultimately, these valuable data will~~
1045 ~~significantly contribute to accurately simulating the radiative forcing and other~~
1046 ~~potential impacts of atmospheric aerosols in this remote region in future climatic~~
1047 ~~models.~~

1048 ~~A total of eight aerosol field measurements were conducted at QOMS, Motuo, NamCo,~~
1049 ~~Ngari, Waliguan, LHG, Bayanbulak, and Lhasa in the different regions of TP and its~~
1050 ~~surroundings by deploying multiple online instruments, including HR ToF AMS,~~
1051 ~~SMPS, PAX, Aethalometer, and CCN-100. The datasets collected datasets provide the~~
1052 ~~offer insights into temporal and diurnal variations as well as the, size distribution~~

1053 ~~patterns~~ of PM₁ chemical compositions, ~~the standard high-resolution mass spectra and~~
1054 ~~temporal variations of OA~~HRMS and chemical components, ~~the temporal variations of~~
1055 ~~particle number size distribution of OA~~, particle light scattering and absorption
1056 coefficients, ~~particle light absorptions from different CAs of BC and BrC~~, and CCN
1057 number concentrations at different ~~supersaturation in each campaign~~supersaturations in
1058 different campaigns.

1059 The datasets ~~provide~~offer valuable insights into ~~the~~ regional variations in aerosol
1060 properties and sources. In the southern TP region, atmospheric aerosols were ~~found to~~
1061 ~~be~~ primarily influenced by biomass burning emissions transported from ~~polluted~~
1062 ~~regions in~~ South Asia, ~~which~~ resulted in high mass contributions (>70%) of CAs and
1063 overall neutralized PM₁, as well as an enhanced light absorption capability of ~~the light-~~
1064 ~~absorbing BC and BrC aerosols~~. In contrast, in the northern TP, secondary inorganic
1065 species, particularly sulfate, contributed significantly to total PM₁ due to the regional
1066 transport of anthropogenic aerosol and gaseous precursor emissions from urban areas
1067 in northwestern China. Furthermore, in contrast to the well-mixed, highly-aged, and
1068 regionally transported aerosols observed in the remote sites, atmospheric aerosols in
1069 the urban Lhasa were mainly originated from local primary sources such as cooking,
1070 traffic vehicle exhausts, and biofuel combustion during the residential activities.
1071 Consequently, these aerosol particles were relatively fresh, characterized by small size
1072 and low oxidation degree, but exhibited a high frequency of NPF origins.

1073 **Appendix A: Main Abbreviations**

TP	Tibetan Plateau
HR-ToF-AMS	high-resolution time-of-flight aerosol mass spectrometer
SMPS	scanning mobility particle sizer
PAX	photo-acoustic extinctions
CCN	cloud condensation nuclei
SS	supersaturation
PM ₁	submicron aerosol
BC	black carbon
BrC	brown carbon
OA	organic aerosol
SNA	sulfate, nitrate, and ammonium
D_m	mobility diameter
D_{va}	aerodynamic diameter
CE	collection efficiency
HRMS	high-resolution mass spectrum
PBL	planetary boundary layer
O/C	oxygen-to-carbon ratio

H/C	hydrogen-to-carbon ratio
N/C	nitrogen-to-carbon ratio
OM/OC	organic matter-to-organic carbon ratio
PMF	positive matrix factorization
OOA	oxygenated organic aerosol
LO-OOA	less oxidized oxygenated organic aerosol
MO-OOA	more oxidized oxygenated organic aerosol
BBOA	biomass-burning-related organic aerosol
agBBOA	aged biomass-burning-related organic aerosol
NOA	nitrogen-containing organic aerosol
HOA	traffic-related hydrocarbon-like organic aerosol
COA	cooking-related organic aerosol
PNSD	particle number size distribution
NPF	new particle formation
B_{scat}	light scattering coefficient
B_{abs}	light absorption coefficient
B_{ext}	light extinction coefficient
SSA	single scattering albedo
AAE	absorption Ångström exponents
$B_{abs,BC}$	light absorption coefficient from BC
$B_{abs,BrC}$	light absorption coefficient from BrC
OC	organic carbon
WSIs	water-soluble ions
DRF	direct radiative forcing

1074 **Author Contributions.** JX designed the study, XZ, WZ, and JX wrote the manuscript.
 1075 JX and SK organized and supervised the field measurement campaigns, JX, XZ, WZ,
 1076 LZ, MZ, JS, JShi, YL, CX, YT, KL, XG, and QZ conducted the field measurements,
 1077 JX, XZ, WZ, and YT analyzed the data. All authors reviewed and commented on the
 1078 final form of the manuscript.

1079 **Competing interests.** The authors declared that they have no competing interests.

1080 **Acknowledgements.** We ~~appreciate~~extend our thanks to all our colleagues and
 1081 collaborators who participated the aerosol field measurements, maintained the
 1082 instruments, analyzed the data, and commented on the manuscript. We also show great
 1083 thanks to all the observation stations in this study for their logistical supports with the
 1084 field campaigns.

1085 **Financial support.** This work was supported by the National Natural Science
 1086 Foundation of China (41977189, 41771079, 41805106), the Second Tibetan Plateau
 1087 Scientific Expedition and Research program (STEP) (2019QZKK0605), the Strategic
 1088 Priority Research Program of Chinese Academy of Sciences, Pan-Third Pole

1089 Environment Study for a Green Silk Road (Pan-TPE) (XDA20040501), the State Key
1090 Laboratory of Cryospheric Sciences Scientific Research Foundation (SKLCS-ZZ-
1091 2023), and the Chinese Academy of Sciences Hundred Talents Program.

1431

1432

Figure 1. (a) Geographical locations of the observation sites (see Table 1 for full name and characteristics of each site) in the Tibetan Plateau and its surroundings in this study (The geographical base map is created with ArcGIS). Fieldwork photographs illustrate the real observation conditions and surroundings at each site. (b) The normal sampling setups of instruments during the online aerosol observations.

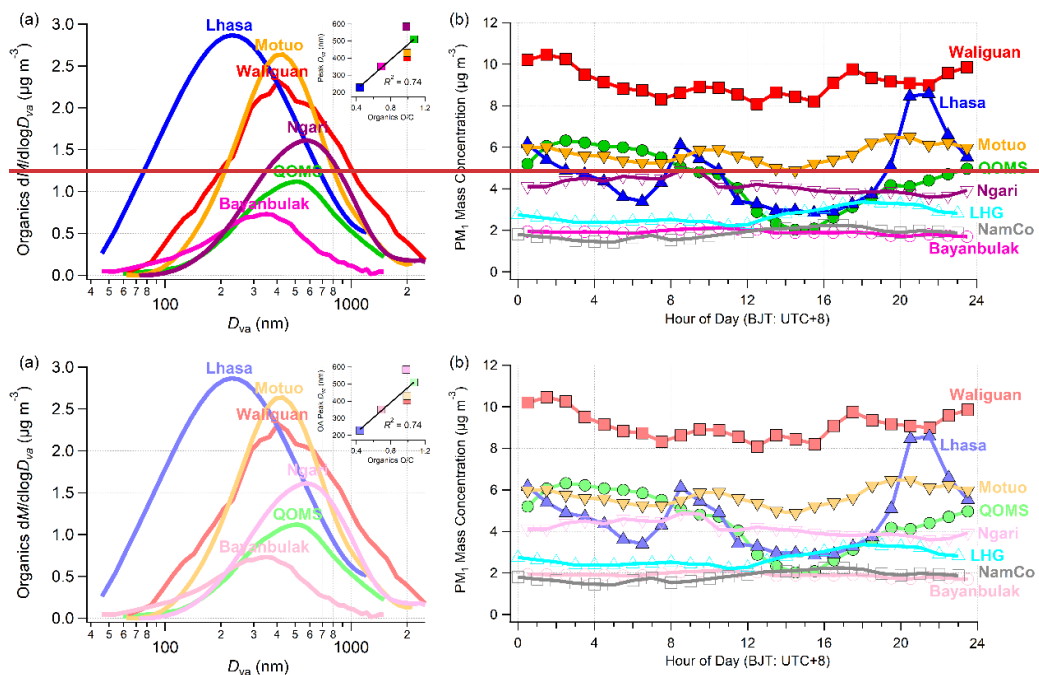

1433

1434 **Figure 2.** Regional distribution of average mass concentrations (values marked in the central of
 1435 each pie chart with unit of $\mu\text{g m}^{-3}$) and chemical compositions (percentage values around each pie
 1436 chart) of submicron aerosols (PM_{10}) during the eight online aerosol field measurements in the Tibetan
 1437 Plateau and its surroundings (The geographical base map is created with ArcGIS). The concentration
 1438 at each site is presented in ambient condition.

1439

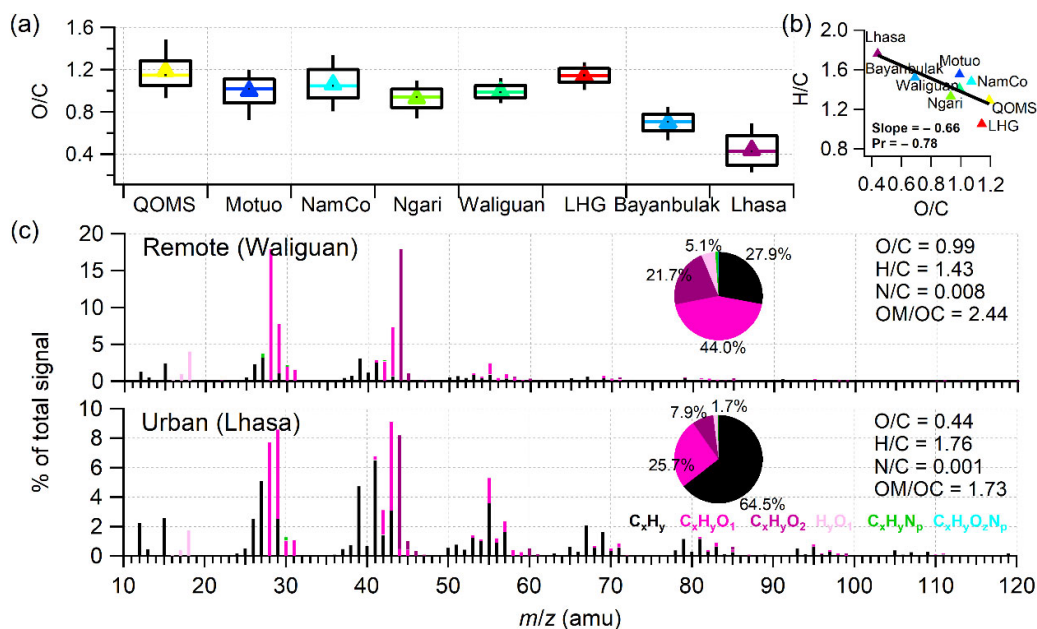

1440 **Figure 3.** Regional difference of bulk acidity of submicron aerosols based on the scatterplot analysis
 1441 and linear regression of measured NH_4^+ versus predicted NH_4^+ during the eight aerosol field
 1442 measurement campaigns in the Tibetan Plateau and its surroundings (The geographical base map is
 1443 created with ArcGIS).

1444

1445

1446 **Figure 4.** (a) Average size distributions of organic mass concentrations during six field
 1447 measurement campaigns in the Tibetan Plateau and its surroundings. (b) Diurnal variations of total
 1448 PM_{10} mass concentrations during the eight field measurement campaigns in the Tibetan Plateau and
 1449 its surroundings. Insert graph in (a) is the scatter plot of peak diameters in ~~thesethis~~ their size
 1450 distributions versus the average O/C ratio of organics.

1451

1452 **Figure 5.** (a) Box plots of the average O/C ratios and (b) Van Krevelen diagram of H/C versus O/C
 1453 among the eight field measurement campaigns in this study. (c) The average HRMSs of OA colored

1454 with different ion categories during the Waliguan and Lhasa measurement campaigns. The whiskers
1455 of boxes indicate the 90th and 10th percentiles, the upper and lower boundaries of boxes indicate the
1456 75th and 25th percentiles, the lines in the boxes indicate the median values, the markers indicate the
1457 mean values, and similarly hereinafter.

1458

1459 **Figure 6.** Regional distribution of OA components from PMF source apportionment during the eight
 1460 online aerosol field measurements in the Tibetan Plateau and its surroundings (The geographical
 1461 base map is created with ArcGIS). Values marked in the central of each pie chart are average OA
 1462 mass with unit of $\mu\text{g m}^{-3}$, while the percentage values around the pie chart are the mass contributions
 1463 of each OA component. The O/C ratio of each OA component is also marked around each pie chart.

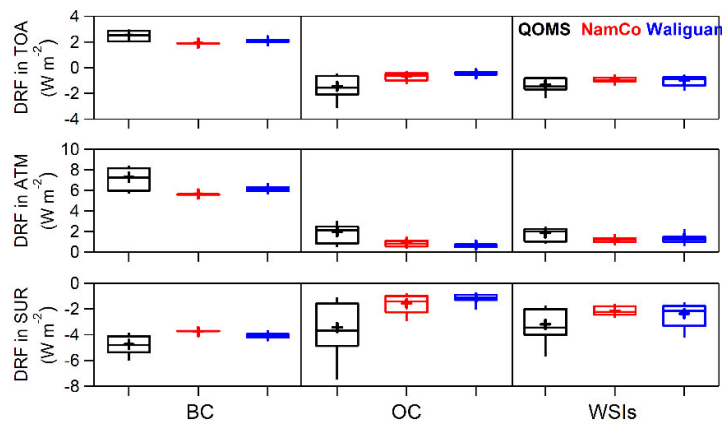

1464

1465 **Figure 7. (a)** Temporal variations of the size distributions of particle number concentrations during
 1466 the aerosol field measurement campaigns at QOMS, Motuo, LHG, and Lhasa sites. **(b)** The average
 1467 size distribution of particle number concentration during entire measurement period at each site.

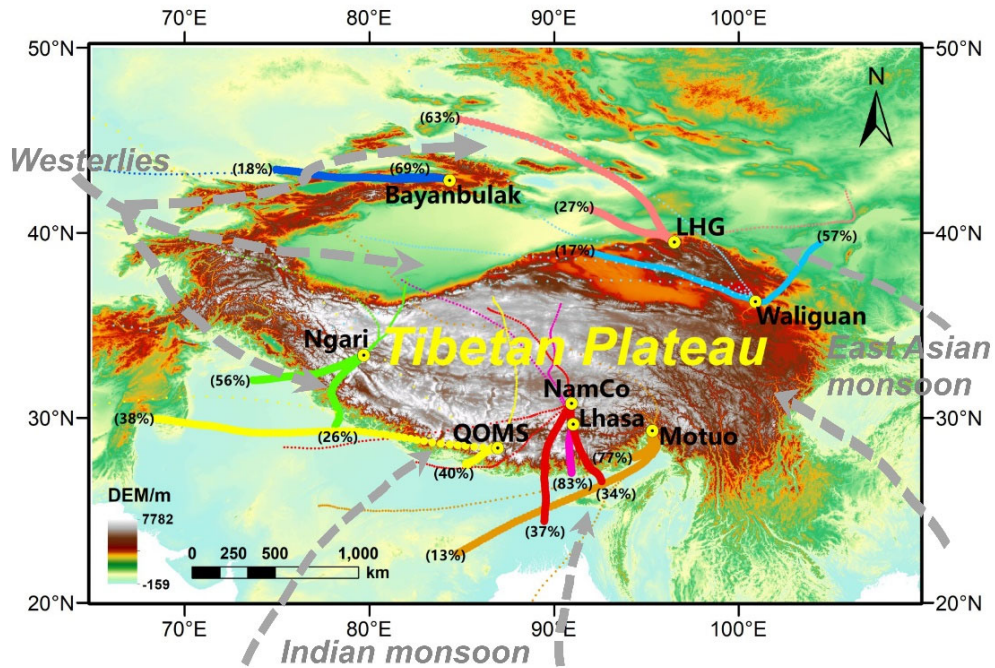

1468

1469 **Figure 8.** Box plots of (a) the average particle light scattering coefficient (B_{scat}), light absorption
 1470 coefficient (B_{abs}), and single scattering albedo (SSA) during the five aerosol field measurement
 1471 campaigns at QOMS, Motuo, Waliguan, Ngari, and Lhasa sites, and (b) the particle B_{abs} at seven
 1472 wavelengths measured by aethalometers at QOMS, NamCo, and Waliguan sites. The dashed lines
 1473 in the boxes in (b) show the power-law fit of the average B_{abs} as a function of wavelength. The
 1474 inserted plots in (b) are the apportioned contributions of BC and BrC to total B_{abs} at different
 1475 wavelengths.

1476

1477 **Figure 9.** Box-plots of the modelled direct radiative forcing (DRF) at the top of the atmosphere
 1478 (TOA), the atmosphere (ATM), and the earth's surface (SUR) caused by black carbon (BC), organic
 1479 carbon (OC), and water-soluble ions (WSIs) during the QOMS, NamCo, and Waliguan campaigns.
