15
16 **Abstract:** Land surface temperature (LST) serves as a crucial variable in characterizing
17 climatological, agricultural, ecological, and hydrological processes. Thermal infrared (TIR) remote
18 sensing provides high temporal and spatial resolution for obtaining LST information. Nevertheless,
19 TIR-based satellite-LST products frequently exhibit missing values due to cloud interference. Prior
20 research on estimating all-weather instantaneous LST has predominantly concentrated on regional
21 or continental scales. This study involved generating a global all-weather instantaneous and daily
22 mean LST product spanning from 2000 to 2020 using XGBoost. Multisource data, including
23 Moderate-Resolution Imaging Spectroradiometer (MODIS) top-of-atmosphere (TOA) observations,
24 surface radiation products, and reanalysis data, were employed. Validation using an independent

25 dataset of 77 individual stations demonstrated the high accuracy of our products, yielding RMSEs
26 of 2.787 K (instantaneous) and 2.175 K (daily). The RMSE for clear-sky conditions was 2.614 K
27 for the instantaneous product, slightly lower than the cloudy-sky RMSE of 2.931 K. Our
28 instantaneous and daily mean LST products exhibit higher accuracy compared to the MODIS
29 official LST product (RMSE=3.583 K instantaneous, 3.105 K daily) and the land component of the
30 5th generation of European ReAnalysis (ERA5-Land) LST product (RMSE= 4.048 K instantaneous,
31 2.988 K daily). Significant improvements are observed in our LST product, notably at high latitudes,
32 compared to the official MODIS LST product. The LST dataset from 2000 to 2020 at the monthly
33 scale, the daily mean LST on the first day of 2010 can be freely downloaded from
34 <https://doi.org/10.5281/zenodo.4292068>(Li et al. 2024), and the complete product will be available
35 at <https://glass-product.bnu.edu.cn/>.

37 **Keywords: land surface temperature, all-weather, global, XGBoost, MODIS**

1 Introduction:

Land surface temperature (LST) is the skin temperature of the Earth's surface, and one of the crucial parameters in the surface energy balance, and the hydrothermal cycle (Bastiaanssen et al. 1998; Tomlinson et al. 2011). LSTs retrieval from in situ measurements or satellites are widely used in many scientific fields (Kappas and Phan 2018), such as climate change (Auger et al. 2021; Weng 2009), urban heat island (Zhou et al. 2018), drought monitoring (Wan et al. 2010), longwave radiation estimation (Cheng and Liang 2016), evapotranspiration (Kalma et al. 2008; Yao et al. 2012), soil moisture estimation (Zhang et al. 2015), and air temperature estimation (Chen et al. 2021; Rao et al. 2019; Shen et al. 2020). High-precision measurements of LST aid in the recording of the long-term global temperature trends, thus, the International Geosphere and Biosphere Programme (IGBP) lists it as one of its priority parameters (Townshend et al. 2007). Owing to the complex and rapid variation in temporal and spatial scales, in situ measurements cannot provide regional LST or capture the spatial variation in LST. Remote sensing has become the only way to obtain LST with high spatial and temporal resolution from regional to global scales (Li et al. 2013).

Over the past few decades, substantial advancements have been made in the inversion of LST from remote sensing satellites. The retrieval of satellite LST products is predominantly accomplished using thermal infrared (TIR) remote sensing data (Li et al. 2013). These LST products typically exhibit a notable spatial resolution, exemplified by the Visible Infrared Imaging Radiometer Suite (VIIRS) boasting a resolution of 750 meters, the Advanced Very High Resolution Radiometer (AVHRR) with 0.05° (Li et al. 2023a; Ma et al. 2020a), and the Moderate-Resolution Imaging Spectroradiometer (MODIS) satellite with a resolution of 1 kilometer (Wan 2014; Wan and Li 1997). Nevertheless, due to the constrained penetration capability of thermal radiation, TIR data is exclusively applicable for observing LST under clear-sky conditions. Global average annual cloud coverage has been reported to exceed 70% (Mercury et al. 2012). The lack of data has significantly constrained the application of LST products. Consequently, all-weather LST estimation is one of the difficulties that need to be solved urgently.

Besides data gaps due to cloud contamination, extending the temporal scale of LST poses a significant challenge in retrieving LST remote sensing products, requiring urgent attention. LST, a dynamic physical attribute, exhibits temporal variation. However, satellite-derived LST captures only instantaneous observations at specific times and angles. Instead of focusing solely on instantaneous LST,

68 certain researchers emphasize the importance of daily, monthly, or yearly average LST to track the impact
69 of increasing LST on glaciers, ice sheets, and vegetation within the Earth's ecosystem (Lawrimore et al.
70 2011). Currently, for MODIS LST products, there exist daily instantaneous L2 products, daily gridded
71 instantaneous L3 products, and eight-day synthetic products (Wan 2014). Nevertheless, there's an
72 absence of L4 products encompassing daily mean, monthly, and annual LST data. Hence, it holds
73 significant importance to estimate daily mean LST based on limited MODIS observations. Acquiring the
74 daily mean LST allows estimation of monthly or annual mean LST, crucial for prolonged monitoring
75 across diverse research domains like climate change, agriculture, and drought studies.

76 As for filling LST gaps under cloudy-sky conditions, researchers have explored various methods
77 (Li et al. 2023c). One type of approach is based on space-time information, such as interpolation and
78 fusion methods (Pede and Mountrakis 2018). Interpolation methods usually utilize temporally or
79 spatially proximate clear-sky pixel information to fill in the pixels under the cloudy-sky condition.
80 Nevertheless, the efficacy of the interpolation method is contingent upon the accessibility of clear-sky
81 pixels. The reconstruction outcomes prove less satisfactory in instances of extensive missing regions or
82 prolonged periods of cloud cover (Metz et al. 2014; Zhang et al. 2018; Zhang et al. 2022). In recent years,
83 spatiotemporal fusion methods have been explored for obtaining all-weather LST (Chen et al. 2015; Long
84 et al. 2020; Wu et al. 2019). The essence of spatiotemporal fusion for LST involves deriving high spatial
85 resolution LST at time t_0 from its counterpart with coarse spatial resolution at the identical time instance,
86 achieved through the application of a scale conversion factor (Long et al. 2020; Wu et al. 2019). Due to
87 the algorithm's complexity, fusion methods are commonly evaluated within limited geographical scopes,
88 with their applicability constrained when extended to larger areas. Furthermore, both interpolation and
89 spatiotemporal fusion methods hinge on information derived from clear-sky pixels, yielding
90 reconstructed theoretical clear-sky LST rather than the real cloudy-sky LST. In order to obtain actual
91 LST under cloudy-sky conditions, one type of approach considering the physical processes of the surface
92 energy balance (SEB). Jin and Dickinson (2000) introduced a method utilizing SEB to account for
93 changes in solar radiation on LST during cloudy conditions. This approach corrects clear-sky LST using
94 the SEB equation to derive actual cloudy-sky LST. Over time, the SEB-based method has been refined
95 for geostationary satellites (Jia et al. 2022; Liu et al. 2023; Zhang et al. 2024) and MODIS data (Jia et al.
96 2021; Yu et al. 2014; Zeng et al. 2018). However, widespread application is limited due to gaps in data

97 coverage and the necessity of meteorological SEB parameters (e.g., air temperature, wind speed), which
98 are challenging to obtain accurate data on a large scale.

99 Apart from the mentioned methods for LST retrieval under cloudy-sky conditions, alternative
100 approaches utilize all-weather data like microwave data, reanalysis data, or model simulations to derive
101 the cloudy-sky information. Passive microwave (PMW) data are less affected by cloud contamination,
102 providing a possibility for all-weather LST estimations (De Jeu 2003; Duan et al. 2017b; Holmes et al.
103 2009). However, the existing microwave observations usually have coarse resolutions (e.g., AMSR-E
104 with 25km) (Mao et al. 2007). Since the land surface microwave emissivity is sensitive to land surface
105 characteristics and difficult to measure, the accuracy of the PMW LST data is relatively lower than that
106 of TIR LST(McFarland et al. 1990).In addition, PMW data basically have swath gaps, especially at low
107 latitudes, which makes it difficult to obtain full-coverage LST (Holmes et al. 2009; Zhou et al. 2015).
108 Thus, LST retrieval from PMW data cannot satisfy the requirements of high-precision and refined
109 applications. Some scholars have explored the possibility of combining PMW and TIR data to estimate
110 all-weather LST. These methods perform well at regional or national scales (Duan et al. 2017b; Wu et al.
111 2022; Xu and Cheng 2021; Zhang et al. 2020). However, owing to the availability of PMW data and the
112 complexity of algorithms, it is difficult to achieve long-term production at a global scale.

113 In comparison, reanalysis data can provide another way for all-weather LST estimation, with all-
114 weather observations, long-term and seamless characteristics. With the updating of reanalysis and
115 modeled data, spatial resolution and accuracy are improved (Muñoz-Sabater et al. 2021). Several studies
116 have attempted to utilize reanalysis data combined with TIR (Long et al. 2020; Tang et al. 2024; Zhang
117 et al. 2021) and PMW data (Zhang et al. 2020; Zhou et al. 2022) to obtain all-weather LST, which were
118 well implemented on the regional scale. In recent years, researchers have a growing interest in the
119 estimation of global all-weather LST. Shiff et al. (2021) integrated modeled temperature data to
120 supplement missing values in MODIS LST using the Google Earth Engine (GEE). Nevertheless, the
121 proposed approach solely addressed missing pixels, potentially introducing border effects. Globally,
122 continuous spatiotemporal LST data at a resolution of 0.05° have been generated, rectifying reconstructed
123 missing data under cloudy-sky conditions using reanalysis data (Yu et al. 2022). Additionally, global
124 seamless 8-day and monthly average LST data, featuring a 30 arcsecond resolution, were created by
125 integrating reanalysis data (Yao et al. 2023). These studies confirm the potential of reanalysis data for

126 estimating all-weather LST, yet there remains ample room for exploration at a spatiotemporal scale of
127 one kilometer per day.

128 Regarding daily mean LST, researchers have investigated acquiring it from polar-orbiting satellites.
129 Specifically, they have employed MODIS instantaneous LSTs to estimate the daily mean
130 LST(Williamson et al. 2014; Xing et al. 2021). The maximum-minimum method determined the daily
131 mean LST by averaging its maximum and minimum values, exhibiting a strong correlation with surface
132 air temperature (Williamson et al. 2014). Despite its relatively low accuracy, it presents a straightforward
133 means of estimating daily mean LST using the limited observations from polar orbiting satellites.
134 Another approach involves the diurnal temperature cycle (DTC), employing various nonlinear models
135 based on heat conduction and energy balance equations(Aires et al. 2004; Duan et al. 2012; Inamdar et
136 al. 2008; Sun and Pinker 2005), capable of retrieving daily mean LST. However, the DTC method
137 requires specific satellite observation counts within a daily cycle, existing challenges for all-weather
138 daily mean LST retrieval, especially for polar-orbiting satellites. Hong et al. (2021) proposed a
139 framework combining the annual temperature cycle (ATC) and DTC to retrieve all-weather daily mean
140 LST at a spatial resolution of $0.5^{\circ}\times 0.5^{\circ}$ (Hong et al. 2022). Xing et al. (2021) utilized global in situ
141 measurements and multiple linear regression to enhance the MODIS daily mean LST model accuracy
142 under clear-sky conditions. Then, Li et al. (2023b) integrated pre-2000 polar-orbiting satellite data to
143 improve the global daily mean LST model. Most mentioned methods are applicable exclusively under
144 clear-sky conditions, and all-weather estimation remains a challenge. Besides, the sine or cosine assumed
145 in the DTC and the multiple linear regression equations may not necessarily fit the relationship between
146 instantaneous observations and daily mean value. Thus, more appropriate relational models need to be
147 constructed. The main limitation of MODIS daily mean LST estimation has been their restricted
148 observations. MODIS data in swath type can provide more observations, which potentially improving
149 the accuracy, but few research has attempted it. Obtaining all-weather daily mean LST from polar-
150 orbiting satellite observations (e.g., MODIS), particularly at a global scale with a 1 km spatial resolution,
151 still remains a significant challenge.

152 Recently, machine learning and deep learning techniques have gained significant traction in remote
153 sensing due to their superior model fitting capabilities (Ma et al. 2019; Yuan et al. 2020). Scholars have
154 investigated LST retrieval using learning techniques across various satellite platforms (Li et al. 2021; Ma

155 et al. 2024; Mao et al. 2018; Wang et al. 2010). However, the majority of these methods utilized clear-
156 sky pixels as the true value to construct the model, possibly failing to capture the relationship under
157 cloudy-sky conditions. Additionally, learning methods have not yet been applied for estimating daily
158 mean LST. Our former research has estimated all-weather LST from MODIS data using a random forest
159 over the conterminous United States (Li et al. 2021). Considering the urgency of obtaining all-weather
160 LST on a large regional scale and expanding the daily mean time scale, this study refined our previously
161 developed algorithm for an all-weather instantaneous LST product and developed a new method for a
162 daily mean LST product at a global scale. The improvements over our previous study include: 1) More
163 sufficient information: MODIS top-of-atmosphere (TOA) information was taken into account; 2) Expand
164 the estimated LST time scale: a novel algorithm was proposed to estimate both instantaneous and daily
165 mean LST; and 3) Higher efficiency algorithm and larger region: the global all-weather LST products
166 were generated.

167 The rest of the paper is organized as follows. Section 2 describes the data used in this paper. Section
168 3 provides a summary of the proposed method. The results are presented in Section 4. A discussion part
169 is presented in Section 5. Section 6 is the data availability. Finally, Section 7 presents the conclusions.

170

2 Data

171
172 In this study, the remote sensing data, reanalysis data and in situ measurements from 2002-
173 2018 were used to construct all-weather LST models. These data, spanning 2000 to 2020, along
174 with the developed models, were used to generate the instantaneous and daily mean LST products.
175 In situ measurements validated the accuracy of the proposed algorithm and the generated products.
176 The data used are described in detail as follows:

2.1 Remotely sensed and reanalysis data

177
178 The remote sensing data and reanalysis data used in this study are summarized in Table 1. Among
179 them, remote sensing data are mainly from official MODIS products and the Global LAnd Surface
180 Satellite (GLASS) product suite. MOD021KM and MYD021KM are MODIS TOA observational
181 datasets. The shortwave bands (B1–B7, B19) and longwave bands (B27–B36) were selected as model
182 inputs. Geolocation information was obtained from MODIS geolocation data (MOD03 and MYD03).
183 The coordinates from MODIS geolocation data were used to match up with products and in situ
184 measurements, while height, solar zenith angle, solar azimuth angle, view zenith angle and view azimuth
185 angle were used as the model inputs. MODIS LST (MOD11L2/MYD11L2) was used for the comparison
186 and identification of cloudy-sky conditions. The GLASS product suite includes at least 12 land surface
187 variables, which have high spatial resolutions (1 km and 0.05°), long-term temporal coverage (1981–
188 present), spatial continuity, and high quality (Liang et al. 2021; Liang et al. 2013a; Liang et al. 2013b).
189 In this study, we used the following four products from the GLASS product suite: Broad band emissivity
190 (BBE), broadband albedo (albedo), downward solar radiation (DSR), and downward thermal radiation
191 (LWDN). BBE product was used to obtain in-situ LST (Cheng and Liang 2013, 2014). Albedo was used
192 as the model input to describe surface characteristics (Liu et al. 2013a; Qu et al. 2016; Qu et al. 2014).
193 Because LST is affected by both solar radiation and surface longwave radiation, DSR and LWDN were
194 also used in the model construction (Cheng et al. 2017; Zhang et al. 2019).

195 In recent years, an enhanced global dataset for the land component of the fifth generation of
196 European ReAnalysis (ERA5-Land) has been developed (Hersbach et al. 2020; Muñoz-Sabater et al.
197 2021). ERA5-Land describes a consistent long terms evolution of water and energy cycles over land. It
198 was generated through global high-resolution numerical integrations of the European Centre for
199 Medium-Range Weather Forecasts (ECMWF) land surface model driven by the downscaled

200 meteorological forcing from the ERA5 climate reanalysis. Compared with the previous ERA-Interim (80
 201 km) and ERA (31 km), ERA5-Land has a higher spatial resolution (9 km) and temporal resolution (1 h).
 202 Because ERA5-Land LST includes worldwide and all-weather data, it was used in the model construction
 203 as the background value and was also used for comparison. ERA5-Land LST is hereafter referred to as
 204 ERA LST.

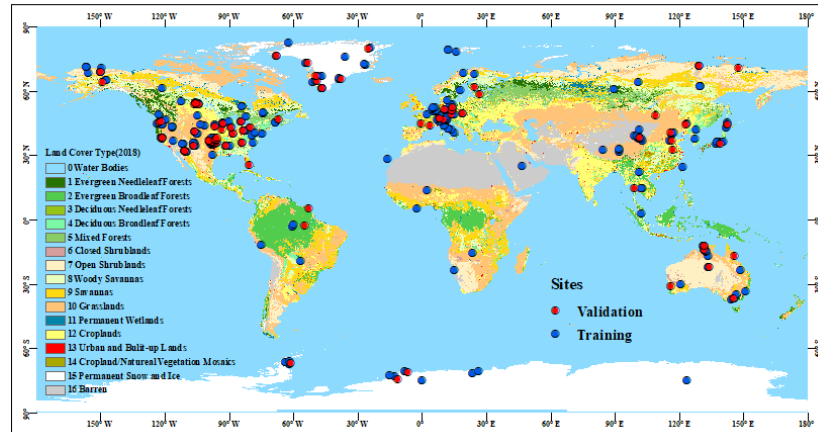

205 Table 1. Summary of remote sensing and reanalysis data

Product	Variables	Resolution (temporal /spatial)	Temporal coverage	Usage	Data link
MOD021KM /MYD021KM	Toa reflectance, brightness temperature	Instantaneous /1 km	2000-present	Model inputs

206

207 2.2 In situ measurements

208 To obtain in situ LSTs, we collected upwelling and downwelling longwave radiation measurements
 209 from 315 sites with different land cover types and geolocations on a global scale. Both instantaneous and
 210 daily mean in situ LSTs were retrieved from in situ measurements. As shown in Fig.1, ground
 211 measurements from 238 stations were used to develop the proposed network (blue circles), whereas the
 212 measurements from the remaining 77 stations (red circles) were selected as independent validation
 213 datasets to evaluate the performance of the trained model. The collection sites were mainly from eight
 214 observation networks, which are described in the following paragraphs.

215

216 Fig.1 Spatial distribution of the selected sites at a global scale. Land use cover types of 2018 (background color shading) were
 217 from the MODIS land use cover product MCD12C1. The site used for model training are shown with blue circles while the
 218 separated validation sites are shown with red circles.

219 AmeriFlux (<https://ameriflux.lbl.gov/>) is a network of stations that continuously measures
 220 ecosystem carbon dioxide, water, energy fluxes, and related environmental variables using eddy
 221 covariance techniques (Baldocchi 2003). The network was launched in 1996, and was established to
 222 connect research on field sites representing major climate and ecological biomes (Boden et al. 2013). The
 223 network has more than past and present flux towers, and sites with longwave radiation measurements
 224 were selected. These sites are distributed across North, Central, and South America. The observation
 225 interval of these sites was half an hour.

226 FLUXNET (<https://fluxnet.org/>) is a global network of micrometeorological tower sites that uses
 227 eddy covariance methods to measure carbon dioxide, water vapor, and energy fluxes (Baldocchi et al.
 228 2001). It has more than 500 flux towers worldwide are operating on a long-term basis. The overarching
 229 goal of the FLUXNET data collection is to provide information for validating remote sensing products,
 230 such as net primary productivity and energy fluxes. Sites with longwave radiation records were used in
 231 this study. The observation interval of the sites was half an hour.

232 The Baseline Surface Radiation Network (BSRN, <https://bsrn.awi.de/>) is a project of the Data and
 233 Assessments Panel of the Global Energy and Water Cycle Experiment (GEWEX) under the umbrella of
 234 the World Climate Research Programme (WCRP) (Ohmura et al. 1998). The purpose of this network is
 235 to provide validation materials for satellite radiometry and climate models. It further aims to detect long-
 236 term variations in the radiation field at the Earth's surface, which play a vital role in climate changes
 237 (Driemel et al. 2018). The stations (currently 74 in total, 58 active) are distributed in contrasting climatic

238 zones, covering a latitude range from 80° N to 90° S. The required longwave radiation measurements
239 were obtained with high accuracy and high time resolution (1 – 3 minutes).

240 AsiaFlux (<https://www.asiaflux.net/>) is a scientific community with the aim of developing
241 collaborative research and datasets on carbon, water, and energy cycles in key Asian ecosystems.
242 AsiaFlux has grown from a small network in 1999 to a multi-national science community with more than
243 400 members from 28 countries (Yamamoto 2005). Currently, there are 109 flux towers in Asia, and
244 more sites are underway. The biomes covered in AsiaFlux range from rainforests near the equator to
245 tundra in the Arctic and Antarctic, and from wetlands near sea level to grasslands at high altitudes, such
246 as the Tibetan Plateau. Most sites have a time resolution of 0.5 hour, while 15 minutes and 1 hour are
247 used for individual sites.

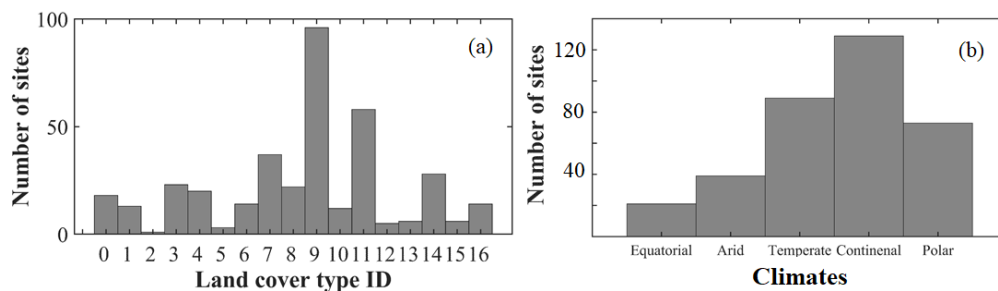

248 The Atmospheric Radiation Measurement (ARM, <https://www.arm.gov/>) Program, supported by the
249 U.S. Department of Energy, is a project for atmospheric measurement and modeling. The purpose of the
250 project was to detect processes that affect atmospheric radiation and describe these processes in climate
251 models (Stokes and Schwartz 1994). The quantities measured at these stations included longwave and
252 shortwave radiation, clouds properties, water vapor, other radiation-related quantities, and
253 meteorological variables. These sites had the high temporal resolution of 1 minute.

254 The Ice and Climate group at the Institute for Marine and Atmospheric Research of Utrecht
255 University (UU/IMAU, <https://www.projects.science.uu.nl/iceclimate/>) has deployed several Automatic
256 Weather Stations (AWS) on different glaciers around the world (Antarctica, Greenland, Alps, Norway,
257 Iceland, Svalbard), and in different climate regimes. The stations were designed to operate on a long-
258 term basis and measure meteorological and radiation variables in remote regions under harsh weather
259 conditions. The main purpose of these stations is to detect the energy balance in these regions in view of
260 climate change and, sea-level variation. The stations from the IMAU project have time resolutions of 1
261 and 2 hours.

262 Denmark launched the Programme for Monitoring of the Greenland Ice Sheet (PROMICE,
263 <https://www.promice.dk/>) to detect variations in the mass balance of the Greenland ice sheet. Several
264 weather stations were established on the ice sheet to provide field data for modeling and validation. The
265 weather stations were equipped with CNR1 or CNR4 instruments to measure radiation data with a time
266 resolution of 10 minutes.

267 The National Tibetan Plateau Data Center (TPDC, <http://data.tpdc.ac.cn>) has integrated and released
 268 various scientific data from the Qinghai-Tibet Plateau and surrounding regions. Integrated data resources
 269 include the atmosphere, cryosphere, hydrosphere, and energy balance. Among these data sources, there
 270 are various published ground measurements. We selected several stations in the Heihe Basin (Liu et al.
 271 2018), Haihe Basin (Liu et al. 2013b), and Qinghai-Tibet Plateau (Ma et al. 2020b). The time resolutions
 272 of these stations were 10 minutes, 30 minutes and 1 hour, respectively.

273 Some stations from various flux networks overlapped, and we curated observations with extended
 274 time series and heightened time resolution. Attaining high model accuracy necessitates superior in situ
 275 measurements, necessitating rigorous quality assessment. Initially, adjacent stations potentially causing
 276 interference were removed, alongside the manual elimination of anomalous observations and
 277 discontinuous measurements. Subsequently, the collection sites were strategically dispersed globally.
 278 Fig.2 depicts a histogram illustrating the distribution of land cover types and climate zones across the
 279 sites. Each land cover type was accounted for, and additional sites encompassing water bodies were
 280 incorporated to estimate LST for inland water. The stations were dispersed across five distinct climate
 281 zones, with a higher concentration in temperate and continental climates. Importantly, we meticulously
 282 gathered data from numerous high-latitude stations within a polar climate to address substantial
 283 estimation uncertainties in the area.

3.1 Data Preprocessing

300

3.1.1 In situ instantaneous LST

301

302

The in situ LST in this study was calculated from surface broadband emissivity and in situ upwelling and downwelling longwave radiation, according to Stefan–Boltzmann’s law, as follows:

303

$$T_S = \left(\frac{F_{up} - (1 - \varepsilon)F_{dn}}{\sigma \varepsilon} \right)^{\frac{1}{4}}, \quad (1)$$

304

305

306

where T_S represents the in situ LST, F_{up} is the upwelling longwave radiation, and F_{dn} is the downwelling longwave radiation, ε is surface broadband emissivity, and σ is the Stefan-Boltzmann constant ($5.67 \times 10^{-8} \text{ W/m}^2/\text{K}^4$).

307

Surface broadband emissivity was acquired from the GLASS BBE product through nearest

308 interpolation to derive daily values. F_{up} and F_{dn} were derived from in situ measurements. Due to
309 varying observation intervals across different networks, spanning from 1 minute to 1 hour, a linear
310 interpolation method was applied to determine the in situ LST corresponding to the MODIS satellite
311 observation time.

312 3.1.2 Daily mean LST

313 To construct a daily mean LST model, in situ daily mean LST and ERA daily mean LST are required.
314 Once the instantaneous LST from in situ measurements was obtained, the daily mean in situ LST was
315 calculated according to Eq. (2). The ERA daily mean LST was obtained using Eq. (3).

$$316 \quad LST_{DS} = \frac{1}{n} \sum_{i=1}^n LST(i)_{IS} \quad (2)$$

$$317 \quad LST_{DE} = \frac{1}{24} \sum_{i=1}^{24} LST(i)_{IE} \quad (3)$$

318 LST_{DS} and LST_{DE} represent the daily mean in situ LST and ERA daily mean LST respectively, and
319 n is the count of the in situ measurements per day. LST_{IS} and $LST(i)_{IE}$ are the instantaneous in situ
320 LST values calculated from Eq. (1) and ERA LST, respectively. If the in situ measurements were
321 incomplete in a day, the record for that day was not used.

322 One traditional daily mean LST method, which was retrieved from the official MODIS Aqua LST
323 for both daytime and nighttime (Williamson et al. 2014), was used for comparison. The equation can be
324 expressed as follows:

$$325 \quad LST_{DM} = 0.5 * LST_{AD} + 0.5 * LST_{AN} \quad , \quad (4)$$

326 where LST_{DM} represents the retrieval of the daily mean LST, and LST_{AD} and LST_{AN} represent
327 the daytime and nighttime LST, respectively from the official MODIS Aqua LST.

328

329 3.1.3 Data normalization

330 Due to discrepancies in spatial and temporal resolutions among the utilized products, preprocessing
331 was conducted. Albedo and BBE had an 8-day temporal resolution, and the daily data were acquired
332 through nearest interpolation. DSR and ERA LST were adjusted to a spatial resolution of 1 km via the
333 nearest-neighbor method. The ERA LST, with a temporal resolution of 1 hour, was interpolated linearly
334 to obtain the reanalysis LST at the satellite observation time. Matching of in situ measurements and

335 satellite data was performed based on coordinates from MOD03/MYD03 products.

336 **3.2 Developing the estimation algorithm**

337 Extreme Gradient Boosting (XGBoost) is an effective and scalable gradient boosting
338 implementation introduced by Chen and Guestrin (2016). It amalgamates multiple classification and
339 regression trees to create a robust learner. In regression, the initial tree is constructed based on split
340 features, followed by the creation of subsequent trees to capture residuals from the preceding ones.
341 Additional trees are iteratively generated until they meet the stopping criteria. Notably, the regression
342 trees within XGBoost are interrelated, progressively diminishing the residuals of predictions with new
343 trees. The ultimate prediction is derived by aggregating scores from each tree.

344 In contrast to the random forest method, which also employs decision trees (Breiman 2001),
345 XGBoost operates in parallel. Its algorithm design incorporates column blocks for parallel learning,
346 cache-aware access, and facilitates out-of-core computation, substantially boosting computational
347 efficiency. Owing to XGBoost's notable efficiency and precision, many studies in remote sensing have
348 adopted this algorithm for regression tasks (Kim et al. 2021; Liu et al. 2021; Zhang et al. 2023). In this
349 research, XGBoost was implemented using the Scikit-learn package in Python. Experiments were
350 performed on a computer equipped with a 3.60 GHz CPU and 64 GB RAM, utilizing the same dataset
351 and features. Detailed hyperparameters are elucidated in Section 3.3.

352 **3.3 Model development**

353 The dataset for 2002-2018 were compiled at a global scale. Samples from 238 sites were randomly
354 chosen for model training. The remaining samples from 77 sites were used as independent dataset for the
355 model validation. The features used to construct the instantaneous LST model, included MODIS TOA
356 observations, ERA LST, DSR, LWDN, albedo, and geolocation data. MODIS TOA observations were
357 used to describe the contributions of shortwave and longwave radiation to the LST, which is greatly
358 changed with solar radiation influenced by clouds. Hence, DSR was used to reflect the effect of solar
359 radiation on the LST (Zeng et al. 2018). Longwave radiation is less affected by the atmosphere, has a
360 certain penetration, and has a close correlation and interaction with the LST during the daytime and
361 nighttime. In this study, the LWDN was used to reflect the effect of thermal infrared radiation on LST.
362 LST is also influenced by land cover types, and broadband albedo was used to represent land surface

363 characteristics. In addition, geolocation information, such as solar angles, view angles and height, also
364 affects LST retrieval from satellites. All the input variables were all-weather conditions with high
365 resolution. In addition, ERA LST can provide all-weather LST, but with coarse resolution (0.1°). It was
366 considered as a background field and, provided an initial value for the model. After the instantaneous
367 model was constructed, the daily mean model was developed. Research has confirmed linear or nonlinear
368 relationships between the daily mean LST and instantaneous LSTs for polar orbiting satellites (Duan et
369 al. 2014; Xing et al. 2021). Hence, the instantaneous retrieval of all-weather LST data was used in the
370 daily LST model. In addition, the ERA daily LST rather than the ERA LST was used as the initial value
371 in the daily LST model. Except for these two variables, the inputs of the two models were the same.
372 Specifically, the daily mean LST finally retrieve from the average of multiple observations in one day.

373 Model tuning was performed to prevent over-fitting of the models. Several hyper-parameters in
374 XGBoost needed to be tuned, including the number of gradient boosted trees (`n_estimators`), maximum
375 depth of trees (`Max_depth`), minimum sum of weights of all observations required in a child
376 (`Min_child_weight`), minimum loss reduction required to make a split (`gamma`), fraction of observations
377 to be randomly samples for each tree (`subsample`), fraction of columns to be randomly sampled for each
378 tree (`Colsample_bytree`). Lambda and alpha represent the regularization of the weights in XGBoost,
379 which can improve the speed performance. A random search combined grid search was used to tune the
380 model. Table 2 presents the candidate values of the random search and the final settings for the two LST
381 models.

382 Table 2. Candidate values and selected values of hyper-parameters in XGBoost

Hpyer-parameter	Candidate values (start, end, step)	Selected values	
		Instantaneous model	Daily model
<code>n_estimators</code>	50,401,10	160	140
<code>Max_depth</code>	1,10,1	9	9
<code>Min_child_weight</code>	1,10,1	5	6
<code>gamma</code>	0,1,0.1	0.8	0.5
<code>subsample</code>	0.1,1,0.1	1	1
<code>Colsample_bytree</code>	0.1,1,0.1	0.8	0.8
<code>lambda</code>	0.1, 2, 0.1	0.6	1.4
<code>alpha</code>	0.1, 2, 0.1	1.6	1.19

383

384 **3.4 Evaluation approaches**

385 In this study, validation from training and independent datasets of separated ground measurements
386 was used to evaluate the instantaneous and daily mean LST models. A widely used ten-fold cross
387 validation (10-CV) method was used to evaluate the stability of the models. Then, model performance
388 was assessed for different weather conditions, and observation times. In addition, time series of
389 individual sites and spatial distribution at regional and global scales were chosen to further demonstrate
390 the effectiveness of the developed models. Finally, the proposed framework and generated products were
391 compared with those of previous studies and products.

4 Results

4.1 Model training and validation

In general, 70% of the dataset was used for the model training. The remaining dataset was used for model adjustment and validation, and was identified as training result. Independent validation and 10-CV results were used to evaluate the models. Fig.4 and Fig.5 show the accuracies of the instantaneous and daily mean LST models, respectively. From the scatter density plots, all the validation results for both the instantaneous and daily models are close to the 1:1 line, with R^2 values ranging from 0.974 to 0.990. The Root Mean Squared Error (RMSE) of the training and validation results were 2.413 K and 2.787 K for the instantaneous model, and while 1.758 K and 2.175 K for the daily mean LST model. Both models showed high accuracy in model training and validation, with no obvious overfitting. The 10-CV method is also used to comprehensively validate the models and the results of both models are also satisfactory, with RMSEs =2.421 K and 1.808 K for the instantaneous and daily mean LST models, respectively. Overall, the validations from the independent dataset and 10-CV results show acceptable accuracy and robustness of the two models. Both models are robust. The daily mean LST model show a higher accuracy than the instantaneous LST model. Probably because the daily mean LST is obtained by averaging multiple observations in one day, which reduces the uncertainty. In addition, some daily inputs (daily mean in situ LST and ERA LST) used in the daily model have less uncertainty than instantaneous observations.

Fig.4 The (a) training, (b) independent validation and (c) 10-CV results of the instantaneous LST model

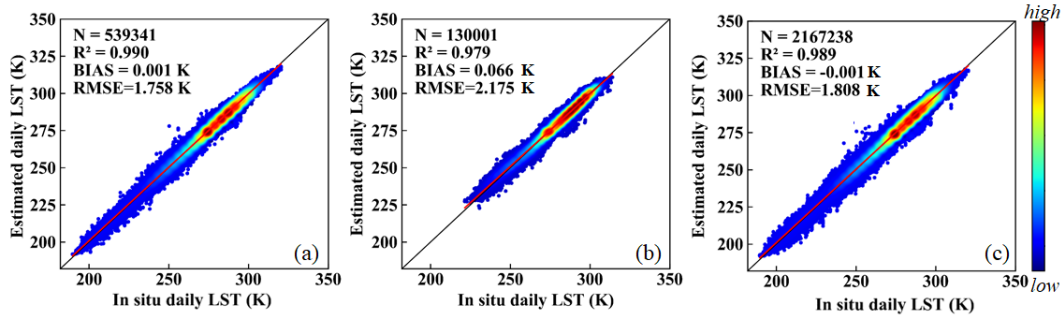

Fig.5 The (a) training, (b) independent validation and (c) 10-CV results of the daily mean LST model

In addition, we further verify the model performance under different conditions using an independent dataset. Table 3 presents the validation results for different observation times and satellites for the instantaneous model. The RMSEs are 3.03 K and 2.67 K for daytime and nighttime data respectively. The accuracy of nighttime data is higher than that of daytime data. It probably because of the absence of differential solar heating and higher spatial-temporal heterogeneity in daytime (Duan et al. 2019; Liu et al. 2023). In addition, the LST value during the daytime is higher than that during nighttime, which results in a higher RMSE value. For the validation of the MOD and MYD satellites, the RMSE of the MOD is nearest to that of the MYD. We further verify the accuracy in the presence and absence of clouds; the density plots are shown in Fig.6. The accuracy under clear-sky conditions was relatively higher with an RMSE= 2.614 K, whereas the RMSE is 2.931 K under cloudy-sky conditions. More effective observation information and higher accuracy of inputs under clear-sky conditions, result in a higher accuracy of clear-sky estimation. This phenomenon is also present in other studies (Duan et al. 2023; Ma et al. 2024). Furthermore, to explore whether clouds have an effect on daily mean LST retrieval, we calculate the accuracy under different cloud proportions, as shown in Table 3. The results show that with the RMSE values increasing slightly as the proportion of cloudy-sky observations increased. This demonstrates that the cloud contamination has a limited impact on the daily mean LST estimation in the proposed method.

Table 3. Validation for different observation times, satellites and weather condition of instantaneous the model, and the proportion of cloudy-sky MODIS observations of the daily LST model

	Groups	R ²	RMSE (K)	Bias (K)
Instantaneous LST model	Daytime	0.960	2.99	0.30
	Nighttime	0.980	2.61	0.05
	MOD	0.980	2.80	0.19

	MYD	0.980	2.82	0.17
Daily LST model	0-30	0.980	2.01	-0.07
(Proportion of cloudy	30-60	0.980	2.14	-0.16
MODIS observations %)	60-100	0.980	2.26	-0.04

4.2 Validation and assessment

439

4.2.1 Evaluation across individual sites

440

The validation of the instantaneous and daily mean LST for individual sites is shown in Fig.7. The color of the circles indicates the increasing level of errors. RMSEs rank from 1.16 to 4.90 K for instantaneous LST and 0.89 to 3.96 K for daily mean LST. The corresponding histograms show that the accuracy of nearly 75% of sites is below 3 K and 2.5 K for instantaneous and daily mean LST, respectively. Stations distributed in the continental United States with intensive LST monitoring generally have higher accuracy. High accuracy is also observed at stations in Alaska and Greenland, whereas a relatively lower accuracy is observed in the Antarctic. In Europe, most stations perform well, with the exception of some stations in the east. The stations in Asia are relatively discrete with relatively lower accuracy for individual sites in western China, which is probably due to the high elevation and complex terrain (Jia et al. 2023). In addition, several stations distributed in Australia, Africa, and South America also perform well in both models. In general, the results indicate a satisfactory predictive ability of both instantaneous and daily mean LST models at most individual sites.

456 **4.2.2 Evaluation across land cover types and elevation**

457 LST is closely related to land cover types. The validation results for different land cover types are
 458 presented in Table 4. The results indicated that the data had high accuracies for most land cover types.
 459 For instantaneous LST, the RMSEs of most vegetation types were below 3 K, except for shrublands with
 460 an RMSE of 3.04 K. Among the vegetation types, cropland had an outstanding RMSE of 2.55 K. The
 461 accuracies of vegetation types for daily mean LST were higher than that of instantaneous LST, with
 462 RMSEs of approximately 2 K, except for shrublands with an RMSE of 2.55 K. The accuracy in water
 463 bodies was also satisfactory, with RMSEs of 2.43 and 2.04 K for instantaneous and daily mean LST,
 464 respectively. For both models, the accuracy of instantaneous and daily mean LST in snow/ice with RMSE
 465 of 2.94 and 2.35 K, respectively were notably improved compared with that found in our previous study
 466 (Li et al. 2021). This is probably due to the higher number of samples from high latitudes, which
 467 improved the model robustness in snow/ice. However, the accuracy for urban and barren areas was
 468 relatively low. This is likely due to the high heterogeneity of urban areas, high albedo and low specific
 469 heat capacity of barren land (Duan et al. 2017a). In general, for different land cover types, the daily mean
 470 model showed higher accuracy than the instantaneous model, and both models had acceptable accuracy.
 471 In addition, we summarized the accuracy of the different elevation ranges in Table 5. The results indicate

472 that elevation has an impact on LST retrieval accuracy. The relatively poor accuracy at high elevations
 473 is probably due to the harsh natural environment and complex terrain, which was also reflected in another
 474 study (Zhao et al. 2019).

475 Table 4. Validation of instantaneous and daily LST models for various land cover types

	Instantaneous LST model			Daily mean LST model		
	R ²	RMSE (K)	Bias (K)	R ²	RMSE (K)	Bias (K)
Forest	0.941	2.82	0.11	0.960	2.08	-0.11
Shrublands	0.980	3.04	-1.05	0.980	2.55	-0.85

477 4.2.3 Comparison with other products

478 Official MODIS and ERA LST data were used for comparison with our LST products. Fig.8 presents
 479 the accuracy of ERA LST (RMSE = 4.048 K) and official MODIS LST (RMSE = 3.583 K), both of
 480 which were lower than the accuracy of the estimated LST proposed in this study (RMSE = 2.787 K, Fig.4).
 481 Furthermore, we noted that the official MODIS LST data had several abnormal points (Fig.8.(b)). The
 482 polar regions (Antarctica and the Arctic pole) were verified separately from the other regions, as shown
 483 in Fig.9. The results indicate that the majority of outliers were from stations located in Antarctica and the
 484 Arctic pole (Fig.9.(b)), probably because of cloud contamination. Owing to the spectral similarities
 485 between the ice and snow, the misjudgment of clouds leads to cloud top temperatures rather than LST
 486 (Liu et al. 2010; Østby et al. 2014). In contrast, the proposed method was unaffected by cloud
 487 contamination (Fig.9 (a)).

489
490

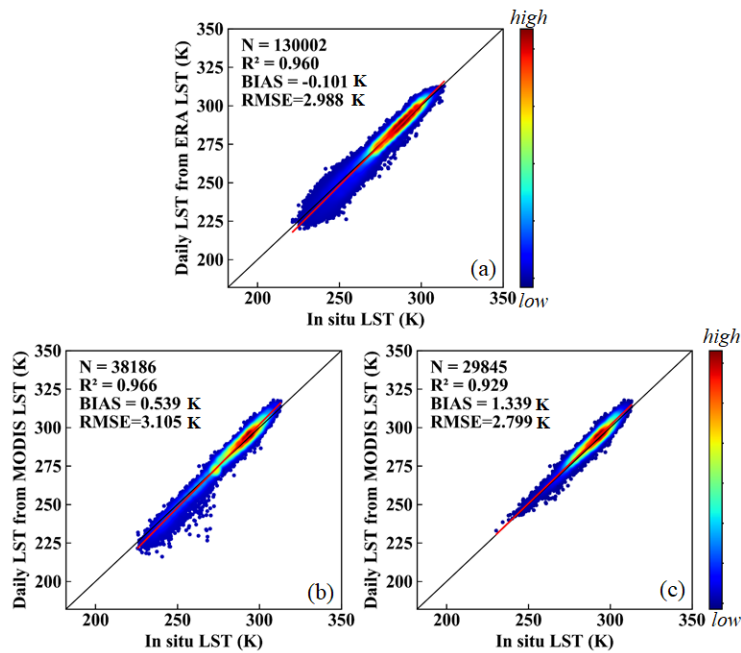

Fig.8 Density plots of (a) ERA LST and (b) MODIS clear-sky LST

491
492
493

Fig.9 Density plots of estimated instantaneous clear-sky LST (a, c) and MODIS LST (b, d) in polar regions (first row) and other regions (second row)

494 The daily mean LST from the ERA LST from Eq. (3), and official MODIS LST from Eq. (4)) were
495 used for comparison (Fig.10). The ERA daily LST had an acceptable accuracy, with an RMSE of 2.988
496 K. The RMSE of the daily mean official MODIS LST was 3.105 K. The accuracy of the MODIS official
497 LST was relatively lower compared to what was reported in a previous study. This may be due to the
498 large uncertainty in the official MODIS LST in polar regions. When removing the observations in polar
499 regions, the accuracy improved with an RMSE of 2.799 K, similar to the result in previous studies
500 (Williamson et al. 2014; Xing et al. 2021). The proposed method in this study has a higher accuracy than
501 the daily mean LST from ERA and official MODIS LST, with an RMSE of 2.175 K at the global scale
502 (Fig.4.(b)). Moreover, the daily mean LST obtained from official MODIS LST is only suitable under
503 clear-sky conditions, whereas the daily mean LST obtained in this study was for all-weather conditions.

507 4.3 Spatiotemporal performance

508 To further evaluate the temporal performance of the estimated LST, four in situ LST measurements
 509 from different latitudes in 2010 were evaluated. Initially, instantaneous LST was examined separately for
 510 daytime and nighttime, and MODIS LST was provided for comparison (Fig.11). The RMSE values of
 511 the comparable accuracy with MODIS LST. The nighttime LST was more concentrated than the daytime
 512 LST. The estimated LST curves are in good agreement with the in situ LST and MODIS LST curves, but
 513 are more continuous than the curve of MODIS LST. Discontinuities observed at high-latitudes stations
 514 (latitude:79.835, longitude: -25.166) were due to polar day and night phenomena. The daily mean LST
 515 was also examined using in situ LST measurements (Fig.12). The daily mean LST retrieved from MODIS
 516 official LST were used for comparison. The results indicated higher accuracy and better consistency
 517 compared to instantaneous LST. The estimated daily LST also depicted more complete curves than the
 518 daily mean LST from MODIS LST, and captured the seasonal variation trends. The results demonstrate
 519 that both the estimated instantaneous LST and daily mean LST can correctly reflect the temporal
 520 variations in LST.

521
522
523

524
525
526

Fig.12 Time series of the estimated daily mean LST, daily mean LST retrieved from MODIS LST, and in situ LST at four sites from different regions in 2010

527

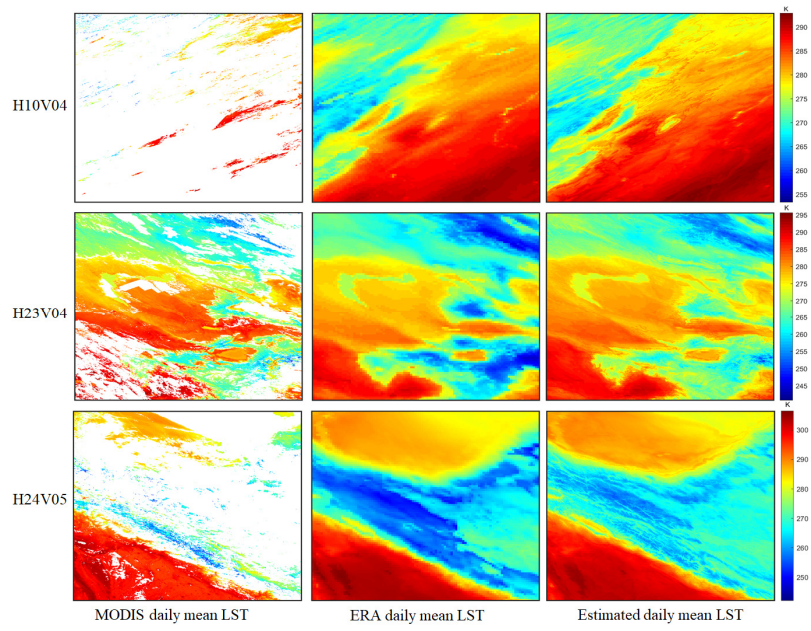

To further evaluate the spatial performance of the proposed methods, regional distributions and

528 global maps were compared. Fig.13 and Fig.14 present the spatial details of the estimated instantaneous
 529 LST and daily mean LST from tiles H10V04, H23V04 and H24V05. One of the grids, H24v05, is located
 530 on the Tibetan Plateau and contains mountainous terrain. The instantaneous and daily mean LST from
 531 ERA LST and MODIS LST were used for comparison. MODIS LST had missing values caused by cloud
 532 contaminants for both instantaneous and daily mean LST, while our method achieved spatially
 533 continuous estimation. In addition, the estimated LSTs had spatial patterns similar to those of MODIS
 534 LST under clear-sky conditions. Compared with the ERA LST, which was used as the model input, our
 535 results showed more spatial details and corrected the underestimation in some regions. In particular, the
 536 results of H24v05 reflect that the estimated LST has mountainous details. Demonstrates that our approach
 537 is equally applicable to mountainous regions with high heterogeneity. The spatial details of the daily
 538 mean LST show similar conclusions (Fig.14). Overall, for both instantaneous and daily mean LST, the
 539 proposed methods executed the spatially contiguous LST and, depicted the spatial LST details and
 540 variations.

541
 542 Fig.13 Spatial details of the MODIS LST, ERA LST and estimated instantaneous LST of three tiles, H10V04 (the first row),
 543 H23V04 (the second row) and H24V05 (the third row) from the ninetieth day in 2010

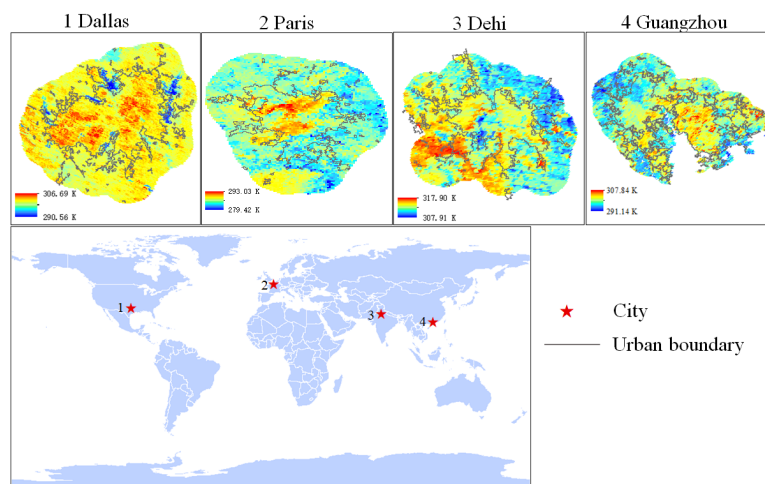

544

545

546 Fig.14 Spatial details of the daily mean LST retrieved from MODIS LST, ERA LST and estimated daily mean LST of three
 547 tiles H10V04 (first row) , H23V04 (the second row) and H24V05 (the third row) from the ninetieth day in 2010.

548 Urban heat island effect is one of the main applications of LST data. To further assess the spatial
 549 details of the estimated all-weather LST and the potential of urban heat island applications, we selected
 550 four cities in different regions around the globe. And demonstrated the estimated LST in conjunction
 551 with the boundary of urban regions extracted by using global artificial impervious area data (Li et al.
 552 2020), as shown in Fig.15. The figure shows that the built-up areas of four cities present higher LST than
 553 the periphery, and confirms that our estimated all-weather LST can capture the urban heat island
 554 phenomenon and present relevant details.

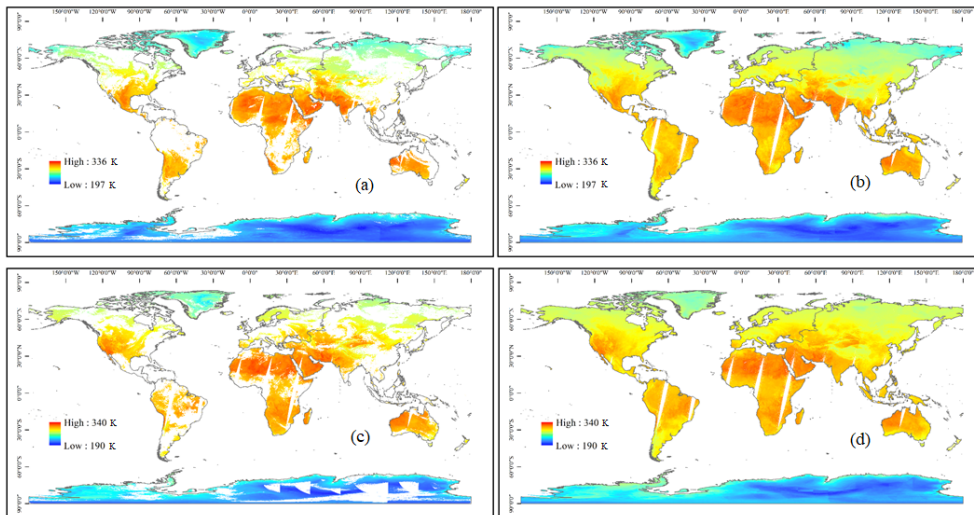

555

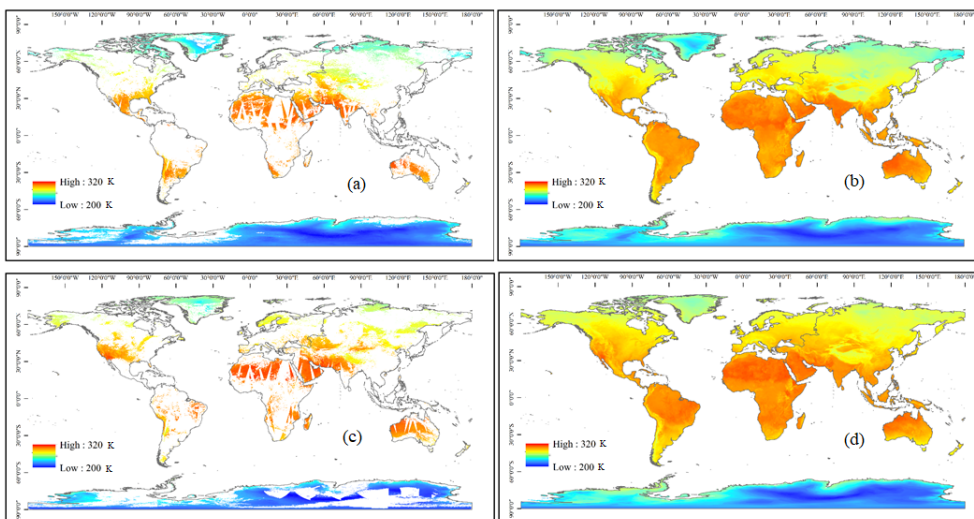

556 Fig.15 Spatial pattern of the estimated all-weather LST in four representative cities. The black lines are the boundary of
 557 urban regions extracted by using global artificial impervious area data.

558 In addition, Fig.16 and Fig.17 show the estimated instantaneous and daily mean LST at the global

559 scale on Days 90 and 270 of 2010. The instantaneous and daily mean LST from MODIS LST are shown
 560 for comparison. The estimated instantaneous and daily LST had similar spatial patterns to the
 561 corresponding LST from MODIS. All of the results reflected broad spatiotemporal variations. For
 562 instance, LSTs were relatively higher at middle and low latitudes, and lower in the Arctic and Antarctic.
 563 The instantaneous LST exhibited a larger range than the daily mean LST. In addition, the proposed
 564 method achieved the all-weather LST retrievals. For instantaneous LST (Fig. 16), a small number of gaps
 565 in tropical regions were due to the polar-orbiting satellite configuration. The daily mean LST (Fig. 17)
 566 was spatially continuous. Overall, the proposed instantaneous LST and daily mean LST perform well on
 567 a global scale.

568
 569 Fig.16 Spatial patterns of MODIS LST (a, c) and estimated instantaneous LST (b, d) at a global scale on the Days 90 (first
 570 row) and 270 (second row) of 2010.

571

 573 global scale on Days 90 (first row) and 270 (second row) of 2010.

5 Discussion

Although several LST satellite products have been published, they are missing data under cloudy-sky conditions. Existing research on all-weather LST has mostly been conducted at the regional scale. This study proposes a highly accurate and efficient algorithm to retrieve all-weather LST at a global scale from multi-source data, including MODIS TOA, surface radiation, reanalysis and in situ data. An all-weather daily mean LST algorithm was also proposed. Both the estimated instantaneous and daily mean LST had acceptable accuracy. In addition, it performs well based on independent ground measurements and space-time verification.

5.1 Effect of introducing MODIS TOA information and ERA LST

In view of the complexity of global climate conditions, and to include more information to estimate the all-weather LST, we introduced MODIS TOA data on the basis of using surface variables. In addition, since the Global Land Data Assimilation System (GLDAS) LST used in previous studies did not have global coverage (the Antarctica region was missing), we introduced the ERA LST in this study, which not only has global coverage, but also has a higher spatio-temporal resolution ($0.1^\circ, 1\text{ h}$). We conducted experiments with combinations of different features, to clarify the effect of introducing MODIS TOA information and ERA LST under different weather conditions. A comparison of the removal of ERA LST and MODIS TOA data in the models is shown in Table 6. The results show that when the ERA LST and TOA data were removed, the accuracy of the model was greatly reduced. The RMSEs increased from 2.787 to 3.536 K and 3.466 K when ERA LST and TOA data were removed, respectively. However, the accuracy changes in the two feature combinations under different weather conditions were significantly different. When ERA LST was eliminated, although the accuracies of both weather conditions were reduced, the RMSE increase for cloudy sky (0.95 K) was significantly greater than that for clear sky (0.09 K). When the TOA data was removed, the results were the opposite. The accuracy of clear-sky LST estimation decreased significantly. Overall, introducing MODIS TOA information and ERA LST significantly improved the model accuracy. In addition, it can be inferred that ERA LST provides more effective information for cloudy-sky LST estimation, while TOA data contributes more to clear-sky conditions.

603

Table 6. The accuracy of the independent dataset with different feature combinations for the instantaneous LST model

Feature combination	All-weather			Clear sky			Cloudy sky		
	RMSE (K)	Bias (K)	R ²	RMSE (K)	Bias (K)	R ²	RMSE (K)	Bias (K)	R ²
All features	2.787	0.178	0.974	2.614	0.082	0.982	2.931	0.240	0.965
No ERA LST	3.536	-0.012	0.959	2.730	-0.14	0.980	3.950	0.07	0.941
No Toa data	3.466	0.335	0.960	3.620	0.21	0.960	3.360	0.41	0.960

604

5.2 Effect of station density on the model accuracy

605

To further evaluate the station density on the model accuracy, experiments were conducted with station density and regional validation. Firstly, the stations were reduced randomly in the training dataset, and the model performance was evaluated based on the same test samples. The accuracies of the instantaneous and daily mean models were shown in the Table 7. The result shows that the accuracy of both models decreases as the number of stations in the training sample decreases. When the number of stations in the training sample is reduced from 238 to 158, the RMSE of the instantaneous model increases from 2.787 K to 2.988 K, and the RMSE of the daily model increases from 2.374 K to 2.479 K. The experiment indicates the model accuracy is affected by the station density, but to a limited extent when there is a sufficient amount of samples. It may be that the long time series of station data used in the experiment provided relatively sufficient samples.

615

Table 7. The training and testing accuracy of instantaneous and daily mean LST with the number of stations decreasing in the training model.

training stations	training samples	instantaneous model			daily mean model		
		RMSE (K)	Bias (K)	R ²	RMSE (K)	Bias (K)	R ²
238	1797803	2.787	0.178	0.974	2.374	0.100	0.978
218	1609953	2.828	0.203	0.974	2.397	0.121	0.978
198	1420496	2.867	0.211	0.973	2.421	0.116	0.977
178	1327160	2.877	0.243	0.973	2.426	0.140	0.977
158	1072730	2.988	0.239	0.971	2.479	0.160	0.976

617

5.3 Effect of multiple MODIS observations

618

In contrast to most studies using MODIS data in sinusoidal projection, we used swath-type MODIS data to estimate daily mean LST in this study. MODIS swath data can provide more observations, particularly at high latitudes. Furthermore, we statistically analyzed the relationship between the daily mean LST model error and MODIS observation frequency. Fig.18 shows that the error decreased with

621

622 an increase in the MODIS observation frequency. For high-latitude areas with more observations, the
623 model accuracy at high latitudes was improved. This demonstrates the superiority of using MODIS data
624 in swath types with more observations to construct a daily mean LST model.

625
626

Fig.18 Density plots of daily mean LST model error with respect to MODIS observation frequency

627 **5.4 Effect of in situ measurements in the model**

628 In contrast to previous studies that used machine learning algorithms, in situ measurements were
629 used to construct the model instead of clear-sky MODIS LST. In situ measurements can obtain the real
630 LST under cloudy-sky conditions, without obtaining the hypothetical LST from clear-sky MODIS LST.
631 In addition, LST from in situ measurements is close to hemispherical LST, or observing the LST from
632 the zenith. In contrast, MODIS LST is a directional LST with view angles ranging from 0° up to $>60^\circ$,
633 resulting in a significant thermal radiation directionality (TRD) effect (Cao et al. 2019; Ermida et al.
634 2017). This results in a difference in the LST of the same object at different observation angles.
635 Theoretically, the proposed instantaneous LST weakens the influence of the TRD effect, which was been
636 confirmed in our previous study (Li et al. 2021).

637 **5.5 Effect of the new algorithm on product generation**

638 In previous study, the random forest algorithm (RF) was used to estimate the all-weather LST over
639 the conterminous United States (Li et al. 2021). Although the RF algorithm performs well, the application
640 efficiency needs to be considered for generating global products. Hence, the model accuracy and
641 efficiency were compared using RF and XGBoost. The model accuracies of RF and XGBoost was
642 comparable, with RMSEs of 2.787 K and 2.801 K, respectively (Table 8). However, training the
643 XGBoost model significantly less time, taking up 3.33 minutes compared to 60.01 minutes for RF

644 training. XGBoost also had outstanding performance in model application. As an example, to produce
 645 100 LST swath-type images, the XGBoost took 8.93 minutes while the RF model took 38.85 minutes
 646 (Table 8). Considering the quantities of swath files at the global scale, XGBoost is a better choice for
 647 long-sequence product generation, with high accuracy and efficiency.

648 Table 8 Comparison of algorithms of model accuracy and efficiency.

Algorithm	Model accuracy			Model efficiency	
	RMSE (K)	Bias (K)	R ²	Training time(minute)	Application time (minute)
XGBoost	2.787	0.178	0.974	3.33	8.93
RF	2.801	0.196	0.974	60.01	38.85

649

650 5.6 Limitations

651 However, this study has certain limitations. Despite enhancements in LST accuracy on ice and snow
 652 surfaces, accuracy remains comparatively lower in barren and urban areas. Additionally, while the study
 653 aimed to select the highest possible number of representative ground stations for the long-term sequence,
 654 the spatial distribution was non-uniform, potentially impacting the generality of data-driven models.
 655 Furthermore, the accuracy of the high-altitude model was marginally lower, possibly attributed to the
 656 complex climatic environment and topographic conditions. Future investigations could employ advanced
 657 methods, such as deep learning, to develop a more adaptive model incorporating spatial and temporal
 658 information. Moreover, integration with other satellite sensors has the potential to extend the temporal-
 659 spatial resolution and time span of all-weather LST products.

660

6 Data availability

661

662 The global all-weather LST data at monthly scale from 2000-2020 can be freely downloaded from

663 <https://doi.org/10.5281/zenodo.4292068>(Li et al. 2024), the daily mean LST on the first day of year 2010

664 is freely available at (Li et al. 2024), all the data will be available at [https://glass-](https://glass-product.bnu.edu.cn/dload.html)

665 [product.bnu.edu.cn/dload.html](https://glass-product.bnu.edu.cn/dload.html).

666

7 Conclusion

LST is a crucial parameter of the Earth's energy budget, and current LST satellite products are affected by cloud contamination, resulting in missing values. This study attempted to retrieve all-weather instantaneous and daily mean LST at a global scale. A new framework that generating global, long-sequence LST product is proposed. Multiple all-weather datasets from MODIS TOA observations, surface radiation data, geolocation data, reanalysis data, and ground measurements were used to construct the models.

Based on the XGBoost algorithm and multisource data from 2002-2018, all-weather instantaneous and daily mean LST models were successively built. The validation of the independent dataset showed high accuracy. The ten-fold cross validation demonstrated the robustness of the models. For the instantaneous LST model, clear-sky LST showed higher accuracy than cloudy-sky LST, while cloud contamination had limited effects on daily mean LST estimations. Both models performed well for most land cover types and geolocation conditions. The time series for validation at the four sites from different regions was temporally contiguous. The results showed high consistency with in situ measurements and the corresponding official MODIS LST. The spatial distributions of MODIS tiles showed more spatial details than the ERA LST. Global mapping illustrated spatial continuity and similar patterns with instantaneous and daily mean LST from the official MODIS LST data.

Compared with previous products, adding TOA observations effectively improved the accuracy of the instantaneous model, especially under clear-sky conditions. Moreover, multiple effective swath-type observations from the MODIS data significantly improved the accuracy of the daily mean LST model. In contrast to the MODIS and ERA LST, the proposed all-weather method has a higher accuracy and is less affected by cloud contamination, especially at high latitudes. In terms of product generation, XGBoost has higher precision and efficiency compared with RF, and provides effective support for mass data production.

Overall, the proposed models were effective and robust, demonstrating the potential of estimating all-weather instantaneous and daily mean LST from multisource data. The constructed models can be used to generate long-sequence LST products from 2000 to present. The generated product is a 1 km all-weather instantaneous and daily mean LST products at a global scale. It has great significance for studies on climate change, surface energy balance, and many other scientific fields. In the future, new methods

696 involving spatial and temporal information, as well as other satellite sensors, should be considered to
697 expand the spatiotemporal monitoring capabilities of LST products.
