27 **Abstract**

28 The initial release of near real-time (NRT) atmospheric and oceanic science products from
29 Japanese Himawari-8/9 (H8/9) geostationary (GEO) satellites over the South China Sea (SCS)
30 was unveiled in 2024. The primary objective behind crafting these NRT H8/9 satellite products
31 is to facilitate weather and marine environment monitoring, enhance maritime security, and aid
32 ocean navigation, among other purposes. As part of this investigation, a novel NRT data
33 processing system was devised to generate a variety of regional H8/9 GEO satellite science
34 products within a resolution of 10 minutes and a gridded resolution of $0.05^\circ \times 0.05^\circ$ from
35 November 3, 2022 to the present. This algorithm system was built upon the preceding FengYun
36 (FY) geostationary satellite algorithm testbed (FYGAT), which was the prototype of FY-4 GEO
37 meteorological satellite science product operational processing system. These regional H8/9
38 GEO satellite science products encompass a range of crucial data such as cloud mask, fraction,
39 height, phase, optical and microphysical properties, layered precipitable water, sea surface
40 temperature, etc. We subjected these products to rigorous evaluations against high-quality
41 analogous satellite products and reanalysis data spanning one year in 2023. The validations
42 underscore a strong consistency between the H8/9 GEO satellite atmospheric and oceanic
43 science products over the SCS and the referenced products. Nevertheless, slight discrepancies
44 in these satellite science products were identified, primarily stemming from variations in
45 sensor/dataset characteristics, retrieval algorithms, and geometric conditions. These outcomes
46 demonstrate the suitability of the first edition of NRT atmospheric and oceanic science products
47 of H8/9 satellites over the SCS in supporting the intended quantitative applications. This NRT
48 GEO satellite data record is publicly accessible through the File Transfer Protocol (FTP)
49 provided by the Southern Marine Science and Engineering Guangdong Laboratory (Zhuhai) in
50 China. Free access to the dataset can be found at <https://doi.org/10.6084/m9.figshare.25015853>
51 (Liu Jian, 2024).

53 **Keywords:** Cloud; Geostationary Satellite; South China Sea; Layered Precipitable Water; Sea
54 surface temperature.

57 **1 Introduction**

58 The South China Sea is located to the south of mainland China and in the western
59 Pacific Ocean. It stands as the largest and deepest sea area in China, with an average
60 depth of 1212 meters and reaching a maximum depth of 5559 meters. Due to its
61 proximity to the equator, the SCS receives a substantial amount of solar radiation,
62 resulting in high local temperatures and humidity. The regional annual average air
63 temperature ranges from 298.15 K to 301.15 K. Even during the coldest months, the
64 average temperatures remain above 293.15 K, while extreme high-temperature events
65 can reach about 306.15 K. The average sea surface temperature (SST) in the SCS is
66 around 299.15 K, and the seasonal variation is not significant. Furthermore, the South
67 China Sea and the Western Pacific serve as abundant sources of water vapor, leading
68 to considerable precipitation in the SCS. Typhoon-related rainfall accounts for about
69 one-third of the total rainfall in the region. On average, the SCS experiences over 1300
70 mm of rainfall annually, with the majority concentrated in the summer half-year (Wang
71 et al., 2011; Wang et al., 2009; Ding and Liu, 2001).

72 The SCS region experiences a distinct tropical maritime monsoon climate.
73 Beginning in October each year, winter air currents originating from Siberia and the
74 Mongolian Plateau consistently flow toward the SCS (Martin and Howland, 1982). As
75 a result, from November to March of the following year, the SCS region is dominated
76 by the northeast monsoon. Starting in April, the SCS is influenced by tropical and
77 equatorial ocean air masses, inducing the prevalence of the southwest monsoon from
78 May to September. Additionally, the SCS is often affected by typhoons during the
79 summer and autumn seasons. About 70% of these typhoons originate from the Western
80 Pacific, east of the Philippines, and the vicinity of the Caroline Islands, while the
81 remaining 30% are generated locally in the sea areas near the Xisha and Zhongsha
82 Islands in the SCS (Ding and Liu, 2001; Wang et al., 2020; Niu and Feng, 2021; Jiang
83 et al., 2023).

84 Due to the lack of ground-based observations over the SCS, satellites, particularly
85 geostationary (GEO) meteorological satellites, have become the most effective means
86 of observing weather patterns, climate, and environmental changes in oceanic regions.
87 For instance, satellite-based rain rate, SST, outgoing longwave radiation (ORL), and
88 convective clouds, etc. are commonly used to identify the summer monsoon, marine
89 heatwave, rainfall, and convection over the SCS (Liu et al., 2014; Xu et al., 2021; Li et
90 al., 2022b; Koseki et al., 2013; Zhou et al., 2024). In recent years, countries across the

91 world, such as China, U.S., Japan, and Korea, have made their own remarkable progress
92 in the development of next-generation geostationary meteorological satellites.
93 Enhanced imaging capabilities in spectral, temporal, and spatial resolutions of the next-
94 generation GEO meteorological satellite allows for more detailed and accurate
95 observations of cloud formations, atmospheric conditions, and natural disasters like
96 hurricanes and typhoons, such as Fengyun-4A/B (FY-4) operated by the China
97 Meteorological Administration (CMA) and Himawari-8/9 (H8/9) satellites operated by
98 the Japan Meteorological Agency (JMA) (Yang et al., 2017; Schmit et al., 2017; Husi
99 et al., 2019; Kim et al., 2021). In addition to GEO advanced imager, many nations
100 have equipped their geostationary lightning and infrared hyperspectral sounding
101 detection sensors to track and analyze thunderstorms, lightning activities, atmospheric
102 temperature and humidity profiles, and even wind fields in real-time (Min et al., 2017b;
103 Ma et al., 2021; Li et al., 2022a).

104 Although the JAXA (Japan Aerospace Exploration Agency) official FTP site
105 (<ftp.ptree.jaxa.jp>) has already offered the freely download links for some H8/9 Level-2
106 (L2) science products, such as cloud phase and optical depth (Husi et al., 2019), from
107 July 7 of 2015, to the present with approximate two hours lag, the relatively low
108 timeliness and lack of variety of operational satellite science products have seriously
109 affected the data quantitative applications in weather and marine environment
110 monitoring over the SCS. Particularly, time-delayed GEO satellite products cannot be
111 utilized in maritime security and navigation fields, which are of vital importance as it
112 ensures the safety of crew members, transportation of goods, protection of the marine
113 environment, etc. (Soldi et al., 2021). However, as recommended by the JMA, the near
114 real-time down-sampling full-disk H8/9 Level-1B (L1B) radiance data (including 14
115 bands with horizontal resolutions of 1 km (visible, VIS) and 4 km (near infrared and
116 infrared, NIR and IR bands), and excluding two VIS bands at 0.47 μm and 0.51 μm)
117 are able to be received by using the compact and exclusive geostationary satellite data
118 receiving antenna from the JMA Himawari-Cast (Xia et al., 2023; Wang et al., 2019).
119 Therefore, based on the received real-time H8/9 full-disk L1B data, the primary goal of
120 this investigation is to develop several NRT L2 Atmospheric and Oceanic science
121 products over the SCS (abbreviated as NANO_SCS) that are released online. It is the
122 first edition of the NRT H8/9 GEO satellite science products generated by the
123 NANO_SCS system. The next sections will be devoted to the introduction and
124 validation of these NRT H8/9 GEO satellite scientific products. Both the NANO_SCS

125 satellite data processing and management systems are operated by the Southern Marine
126 Science and Engineering Guangdong Laboratory (Zhuhai) of China.

127 The subsequent sections of this study are meticulously organized as follows.
128 Section 2 briefly introduces the Himawari-8/9 satellites, elucidating the intricate details
129 of the main processing or production flow, as well as shedding light on the remarkable
130 NRT science products specifically tailored for the South China Sea region. Section 3
131 shows some sample results and verification of key science products in terms of
132 accuracy and reliability. Section 4 elucidates data download method. Finally, in Section
133 5, we summarize the main conclusions of this study, while also outlining our future
134 vision plans for further enhancing and expanding the scope of the NANO_SCS dataset.

135

136 **2 Data production**

137 *2.1 Data*

138 The Himawari-8/9 satellites, which are the new-generation and state-of-the-art GEO
139 meteorological satellites operated by the JMA, were successfully launched on October
140 7, 2014, and November 2, 2016, respectively. These advanced satellites operate in a
141 highly sophisticated three-axis stabilized mode, ensuring high spatial-temporal, precise
142 and stable observations. It is worth highlighting that on December 13, 2022, at 05:00
143 UTC, the H9 GEO meteorological satellite seamlessly replaced its predecessor, the H8
144 GEO satellite, marking a significant milestone in GEO satellite operations
145 (<https://www.data.jma.go.jp/mscweb/en/index.html>). This strategic location allows for
146 comprehensive full-disk observation mode, enabling the satellites to capture detailed
147 imagery of the entire Earth's disk, with a particular focus on the Japanese island and its
148 surrounding areas. The Advanced Himawari Imager (AHI), as a unique and highly
149 advanced optical sensor designed specifically for earth viewing, has 16 independent
150 earth-view bands, covering an extensive range of wavelengths from 0.45 to 13.3 μm .
151 These bands include three visible (VIS) bands, three near-infrared (NIR) bands, and ten
152 infrared (IR) bands, each serving a specific purpose in capturing and analyzing various
153 aspects of the Earth's atmosphere and surface. The AHI routinely operates in two
154 observation modes: a full-disk observation mode that captures full disk images within
155 a 10-minute time interval, and a fast regional scanning mode that allows for swift
156 maneuvering and scanning within a 2.5-minute interval. This regional scanning mode
157 is particularly useful for capturing high-resolution imagery of specific regions of

158 interest, enabling detailed analysis and examination of localized weather events. The
159 nominal spatial resolutions of the H8/9-AHI sensor vary depending on the specific band
160 being utilized. For the VIS band at 0.65 μm , the spatial resolution is 0.5 km. The NIR
161 bands have a spatial resolution of 1 km, while the IR bands have a spatial resolution of
162 2 km (Husi et al., 2019; Bessho et al., 2016; Letu et al., 2020; Min et al., 2019). In this
163 study, we only used the down-sampling H8/9 L1B radiance data mentioned before to
164 produce NRT dataset. The spatial resolution for the down-sampling VIS band at 0.65
165 μm was reduced to 1.0 km, while the other bands were down-sampled to 4.0 km. The
166 scope of this investigation covers the South China Sea region, specifically from 0° to
167 40°N latitude and 100°E to 140°E longitude. The utilization of IR bands with a spatial
168 resolution of 4.0 km limits the related L2 satellite science products to the same
169 resolution. Therefore, based on the products with the spatial resolution of 4.0 km, the
170 final regional L2 atmospheric and oceanic science products are analyzed and projected
171 into a user-friendly gridded resolution of $0.05^\circ \times 0.05^\circ$.

172 The NRT GEO satellite retrieval system (or NANO_SCS system) developed in this
173 study also utilizes the high-resolution operational numerical weather prediction (NWP)
174 data from Global Forecast System (GFS) as ancillary data, which has a gridded
175 horizontal resolution of $0.25^\circ \times 0.25^\circ$ and encompasses a 41 vertical layers ranging
176 from 1000 to 0.01 hPa within a 3-hour time interval. The GFS NWP data can be
177 effortlessly accessed and downloaded from the National Oceanic and Atmospheric
178 Administration (NOAA) website
179 (<https://nomads.ncep.noaa.gov/pub/data/nccf/com/gfs/prod>) at four distinct initial
180 forecast times (00_00, 06_00, 12_00, and 18_00 UTC). To ensure optimal efficiency
181 for the operations of subsequent day, only 9 continuous data (ranging from 018, 021,
182 024, ... to 042) generated at a fixed initial forecast time of UTC 06_00 are selectively
183 downloaded within a predefined time period each day (Whitaker et al., 2008).

184 We collect and use one year (2023) of Climate Data Records (CDR) from the latest
185 MODIS (Moderate Resolution Imaging Spectroradiometer) Collection-6.1 Level-2
186 cloud, land surface temperature (LST), and sea surface temperature (SST) products to
187 validate the NRT H8/9 GEO satellite science products (Platnick et al., 2003; Platnick
188 et al., 2017). MODIS, as a key optical sensor aboard NASA's Terra and Aqua polar-
189 orbiting satellites since 1999 and 2002 (respectively), can provide high resolution (1.0
190 km) L2 science products about the Earth's surface and atmosphere
191 (<https://search.earthdata.nasa.gov/search>). MODIS data are freely available to the

192 public and are widely used by scientists, government agencies, and researchers around
193 the world, which are often used to verify the other congeneric satellite products (Min
194 et al., 2020). Furthermore, we also compare the NRT layered precipitable water (LPW)
195 product over the SCS with matched ERA5 reanalysis data (the fifth-generation
196 European Center for Medium Range Weather Forecasts Reanalysis data). Note that,
197 ERA5 data assimilate infrared radiances and wind data (through atmospheric motion
198 vectors, AMV) from the Himawari satellites (Hersbach et al., 2020). The hourly layered
199 specific humidity data for the same year (2023) with a horizontal resolution of
200 $0.25^{\circ} \times 0.25^{\circ}$ have been downloaded freely from the ERA5 dataset. This data will be
201 employed for the validation of the layered precipitable water product of H8/9 GEO
202 satellite. You can access the data at <https://cds.climate.copernicus.eu/cdsapp#!/home>.

203

204 *2.2 NRT processing flow and science products*

205 As extensively discussed in the former study by (Min et al., 2017b), significant strides
206 were made in the development of the operational prototypes of FY-4 GEO satellite
207 science product algorithms. These remarkable advancements were achieved through
208 the collaborative efforts of the scientists in the FY-4 GEO satellite Algorithm Working
209 Group (AWG) in China, who successfully developed two highly robust Fengyun
210 science product algorithm testbeds (or FYGAT) specifically tailored for imagers and
211 sounders. For a comprehensive understanding of the intricate details of FYGAT,
212 interested readers are strongly encouraged to refer to the aforementioned literature
213 written by (Min et al., 2017b). The FYGAT for imager is the key module of the
214 NANO_SCS system for rapidly retrieving the first edition of NRT L2 science products
215 of H8/9 GEO satellites.

216 Figure 1 shows the comprehensive NRT processing flowchart of the NANO_SCS
217 system. The dark gray shading cylinder icons in the figure represent the key processing
218 modules of the system, including retrieval, projection, and drawing modules. Following
219 the synthesis of NRT satellite data, the retrieval module initially retrieves the cloud
220 mask product to identify clear and cloudy-sky pixels within the targeted SCS region.
221 Then, for cloudy-sky pixels, the retrieval module sequentially executes algorithms for
222 retrieving cloud fraction, cloud type/phase, cloud top properties, cloud optical and
223 microphysical properties, and cloud base properties products. However, the accurate
224 retrieval of science products from previous algorithms is crucial for the successful
225 execution of subsequent backend algorithms. For instance, the cloud optical and

226 microphysical properties algorithm relies on inputs such as cloud phase and top
227 properties to determine specific ice/water cloud optical and radiative properties lookup
228 tables (LUT) and atmospheric correction methods above the cloud (Platnick et al., 2017;
229 Walther et al., 2011) used in retrieval procedure. In a stark contrast, other science
230 algorithms for clear-sky pixels can be executed in parallel as they are independent of
231 each other, such as the algorithms for land surface temperature (LST) and sea surface
232 temperature (SST). It is important to note that due to retrieval efficiency and computing
233 resource limitations, the physics-based layered precipitable water (LPW) algorithm
234 (Zhu et al., 2023) is executed only once every half an hour.

235 Table 1 provides a list of the main NRT H8/9 GEO satellite atmospheric and oceanic
236 science products in the first edition, along with their corresponding variables, generated
237 by the NANO_SCS system from 3 November 2022 to the present. It includes the
238 variable name, valid value, and corresponding notes of satellite science products. These
239 products are stored in the Hierarchical Data Format-5 (HDF5) format within a 10-
240 minute interval. The NRT GEO satellite science product is typically referred to as
241 "AH19_L2_CLM_20230815_0650_4000M_proj.hdf5". In this naming convention, the
242 abbreviation of "CLM" stands for Cloud Mask (all abbreviations are three characters
243 long), while "20230815_0650" denotes the specific observation time of the satellite
244 data, including year, month, day, hour, and minute. Lastly, "4000M_proj" indicates the
245 spatial resolution of 4000 meters and projected data. Certain related variables, such as
246 cloud top temperature, pressure, and height, are stored in the same HDF5 format GEO
247 satellite science product file, specifically the CTP (Cloud Top Properties) product file
248 (refer to Table 1).

249 Figure 2 displays the quick view images of cloud top height, cloud mask, cloud base
250 height, and cloud optical depth at 03:00 UTC on July 31, 2023, as well as atmospheric
251 total precipitable water (from LPW product) and SST retrieved at clear-sky pixels at
252 10:00 UTC on August 15, 2023, over the SCS. These NRT product images are obtained
253 from the NANO_SCS system. The four cloud product subfigures from July 31, 2023,
254 capture the presence of Super Typhoon "Khanun" (its international number: 2306),
255 which originated in the southwestern waters of Guam on July 22, 2023. It has been
256 observed that the cloud system of Super Typhoon "Khanun" can reach maximum cloud
257 top heights exceeding 16 km and minimum cloud base height lower than 1 km. The
258 productions of all the NRT satellite science products and quick view images of the
259 NANO_SCS system are typically delayed by approximately 17 minutes from the

260 observation time. Besides, a user-friendly quick-view website
261 (<http://meteorsatellite.hellosea.org.cn/#/index>) has been created to provide users with a
262 convenient way to access and monitor the NRT H8/9 satellite data over the SCS.

263

264 **3. Results and validations**

265 *3.1 Cloud mask and fraction*

266 To differentiate between clear-sky and cloudy pixels in satellite earth-view image,
267 the cloud mask (CLM) product is firstly retrieved by the NANO_SCS system (refer to
268 Figure 1). This serves as a fundamental and primary L2 scientific output of GEO
269 satellite imaging sensors, playing a crucial role in generating high-quality subsequent
270 satellite products. As mentioned in the previous studies (Liang et al., 2023; Wang et al.,
271 2019; Heidinger et al., 2012), we used the new unified cloud mask algorithm (Wang et
272 al., 2019) of early development to retrieve and generate H8/9 CLM product firstly.
273 Utilizing the 0.64, 1.61, 3.88, 7.3, 11.2, and 12.3 μm channels of H8/9-AHI, the CLM
274 algorithm on this GEO satellite will perform 13 distinct cloud/clear-sky tests. These
275 tests are categorized into four groups: solar reflectance (SolRef), infrared (IR),
276 shortwave infrared (SWIR), and spatial uniformity tests (Wang et al., 2019; Xia et al.,
277 2024).

278 After successfully retrieving the cloud mask product, similar to the MODIS
279 algorithm (Zhao and Girolamo, 2006), cloud fraction (CLF) is calculated in a down-
280 sampled 5×5 neighboring pixel box as follows:

$$281 \text{Cloud Fraction} = 100\% \times (A + B) / (5 \times 5), \quad (1)$$

282 where A and B represent the total numbers of cloudy and probably cloudy pixels in the
283 same 5×5 neighboring pixel box, respectively. It is noting that the cloud fraction
284 product is also projected into a user-friendly gridded resolution of $0.05^\circ \times 0.05^\circ$. More
285 descriptions on these two products can be found in Table 1.

286 A pixel-to-pixel validation was performed on the H8/9 satellite CLM product over
287 the SCS using one year of MODIS data from the NANO_SCS system. To quantitatively
288 assess the quality of the GEO satellite CLM product, we employed four significant
289 scores: the probability of detection (POD) or recall rate, the false-alarm ratio (FAR),
290 the hit rate (HR) or accuracy, and the Kuiper's skill score (KSS). These metrics were
291 divided into PODcld, PODclr, FARcld, and FARclr, indicating clear and cloudy pixels
292 respectively. For detailed equations and meanings, please refer to previous literature
293 (Wang et al., 2019). In Figure 3a~3d, we present two cloud mask comparison samples

294 between H9/AHI GEO satellite and MODIS at 05:10 and 17:20 UTC on January 8,
 295 2023. It is evident that the CLM results from H9/AHI align well with the latest MODIS
 296 official products across both land and sea. Additionally, Figure 3e displays the POD,
 297 FAR, HR, and KSS scores of H9/AHI results for all matched pixels over land and ocean.
 298 Notably, both PODcld and HR exceed 0.90, consistent with our prior study (Wang et
 299 al., 2019), indicating a relatively high-quality CLM product. Moreover, considering
 300 that cloud fraction depends on the cloud mask product (refer to Eq. (1)), we opted
 301 against using similar products for verification in this analysis.

302

303 3.2 Cloud type and phase

304 Cloud type and phase as thermodynamics characteristics signify the state of water
 305 vapor and minuscule particles within the cloud. It plays a critical role in weather and
 306 climate research as different cloud phases influence the reflection and absorption of
 307 solar radiation, consequently impacting Earth's energy balance and climate change
 308 (Mülmenstädt et al., 2021). Due to the similarities in detection channels (using 7.3, 8.5,
 309 11.2, and 12.3 μm channels), the cloud type and phase (CLP) retrieval algorithm
 310 developed here for H8/9-AHI was based on the corresponding algorithm used for U.S.
 311 new-generation Geostationary Operational Environmental Satellites (GOES-R)
 312 (Pavolonis et al., 2005; Pavolonis, 2010b). The physical foundation of this algorithm is
 313 the radiative transfer equation or forward model for cloudy-sky at a specific infrared
 314 wavelength λ , which can be expressed as follows (Min et al., 2020):

$$315 I_{obs}(\lambda) = \varepsilon(\lambda)I_{ac}(\lambda) + \varepsilon(\lambda)T_{ac}(\lambda)B(\lambda, t_{eff}) + I_{clr}(\lambda)[1 - \varepsilon(\lambda)], \quad (2)$$

316 where I_{obs} is the observed radiance, I_{clr} is the clear-sky radiance, and I_{ac} is the above-
 317 cloud upwelling atmospheric radiance, respectively. I_{clr} can be precisely simulated by
 318 the coupled fast IR radiative transfer model in the FYGAT system with the input of
 319 matched GFS NWP data. ε and T_{ac} respectively represent the cloud emissivity and
 320 above-cloud transmittance. B and t_{eff} are the Planck function and the cloud effective
 321 temperature, respectively.

322 From Eq. (2), a pair of effective cloud emissivity from two different channels can be
 323 used to calculate the ratio of effective absorption optical thickness τ_{abs} of cloud, which
 324 is known as the beta ratio (β) and written as follows (Heidinger and Pavolonis, 2009;
 325 Parol et al., 1991):

$$326 \beta_{obs} = \frac{\ln[1-\varepsilon(\lambda_1)]}{\ln[1-\varepsilon(\lambda_2)]} = \frac{\tau_{abs}(\lambda_1)}{\tau_{abs}(\lambda_2)}, \quad (3)$$

327 Actually, this parameter represents the ratio of the effective absorption optical depth at
 328 two different channels or wavelengths. It can describe β_{obs} by utilizing the computed
 329 single scattering properties of cloud particles, along with a given cloud particle size
 330 distribution and optical properties. (Parol et al., 1991). The β_{theory} can be expressed as
 331 follows:

$$332 \quad \beta_{theory} = \frac{[1-\omega(\lambda_1)g(\lambda_1)]\alpha_{ext}(\lambda_1)}{[1-\omega(\lambda_2)g(\lambda_2)]\alpha_{ext}(\lambda_2)}, \quad (4)$$

333 where ω , g , and α_{ext} are the single scattering albedo, asymmetry parameter, and
 334 extinction cross section, respectively. Considering the weak impact of multiple
 335 scattering, Parol et al., (1991) demonstrated a good approximation of $\beta_{theory} \approx \beta_{obs}$ in the
 336 range of 8~15 μm . Eq. (4) is independent of satellite observed radiance, cloud altitude,
 337 or cloud optical thickness. By using β ratio instead of brightness temperature difference
 338 (BTD), it not only considers the contribution of clear-sky conditions to radiation but
 339 also provides a method to link observations with theoretical cloud particle distribution
 340 and optical properties.

341 Based on the differences in β ratios (i.e. $\beta[8.5/11.2\mu\text{m}]$, $\beta[12.3/11.2\mu\text{m}]$, and
 342 $\beta[7.3/11.2\mu\text{m}]$) between ice and water clouds, this algorithm effectively identifies cloud
 343 type and phase by integrating cloud emissivity ε with observed brightness temperature.
 344 More details of this algorithm can be found from the previous literatures (Pavolonis,
 345 2010a; Pavolonis, 2010b). The six specific cloud types of this CLP product include
 346 liquid water (cloud top temperature > 273K), supercooled water (liquid water clouds
 347 with cloud top temperature < 273K), mixed (which encompass both ice and water
 348 clouds), optically thick ice, optically thin ice, and multilayered ice clouds. The cloud
 349 phase product can be defined by summarizing the first three types of clouds and ice
 350 phase clouds using the last three different ice clouds (see Table 1).

351 Figure 4 illustrates the cloud phase comparisons between the H9/AHI GEO satellite
 352 and MODIS at 05:10 UTC on January 8, 2023, and 04:30 UTC on July 10, 2023. This
 353 comparison reveals consistent results between the two products. Notably, in Figures 4a
 354 and 4c, the new H9/AHI cloud phase product identifies some newly added mixed-phase
 355 cloud targets, a feature lacking in the MODIS official cloud phase product (King et al.,
 356 1997). However, despite this addition, the distribution pattern of cloud phases remains
 357 consistent between the two products as depicted in Figure 4. The POD and FAR for ice
 358 and water clouds (Lai et al., 2019) are 0.94/0.17 and 0.68/0.14, respectively.

359

360 *3.3 Cloud top and base properties*

361 Cloud geometry thickness (CGT), including top and base heights (CTP and CBP),
362 enables the profiling of the vertical structure of clouds, which is vital for understanding
363 global weather and climate systems (Viúdez-Mora et al., 2015; Wang et al., 2022).
364 Using the same beta ratio (β) theory discussed in Section 3.2, the optimal estimation
365 (OE) method (Rodgers, 2000), and observed brightness temperatures (BT) at 11.2, 12.3,
366 and 13.3 μm channels, a classical one-dimensional variational (1DVAR) algorithm
367 applies a cost function ζ (refer to Eq. 5) to estimate the cloud top temperature (CTT),
368 which can be written as follows :

369
$$\zeta = [x - x_a]^T Cov_a^{-1}[x - x_a] + [y - M(x)]^T Cov_y^{-1}[y - M(x)], \quad (5)$$

370 where x , y , x_a , $M(x)$, Cov_a , and Cov_y , represent the posterior state vectors, the
371 observation vectors (include $BT_{11\mu\text{m}}$, $BTD_{11-12\mu\text{m}}$, and $BTD_{11-13.3\mu\text{m}}$), the priori state or
372 first guessed vectors (include CTT, cloud emissivity ε at $11\mu\text{m}$, and $\beta[12/11\mu\text{m}]$), the
373 forward radiative transfer model (based on Eq. (2) in the CLP retrieval algorithm), and
374 the error covariance matrices of the priori state vectors (x_a) and the differences between
375 observations and the forward radiative transfer model of $M(x)$, respectively. As a
376 nonlinear least squares fitting problem, the classical Levenberg-Marquardt iteration
377 method is used here to minimize the cost function of ζ , which can be written as follows
378 (Levenberg, 1944):

379
$$\delta x = (Cov_a^{-1} + K^T Cov_y^{-1} K)^{-1} (K^T (Cov_y^{-1} [y - M(x)]) + Cov_a^{-1} [x_a - x]), \quad (6)$$

380 where K signifies the Jacobi or Kernel matrix. The optimal values of CTT, cloud
381 emissivity, and $\beta[12/11\mu\text{m}]$ will be obtained when the iteration converges the satellite
382 observation vectors of y . It is worth noting that the beta ratio (β) plays a specific role in
383 this retrieval algorithm by analytically solving equations in the Jacobi matrix stated in
384 Eq. (6), thereby resulting in a significant enhancement of operational processing
385 efficiency. After obtaining the optimal CTT, the matched GFS-NWP temperature
386 profile is utilized to interpolate the corresponding cloud top height and pressure. For
387 more detailed information on the CTP retrieval algorithm of H8/9-AHI, please refer to
388 the study from Min et al., 2020.

389 In contrast, the successful retrieval of cloud base properties requires more inputs such
390 as cloud mask, type, top height, and optical and microphysical properties (convert to
391 cloud water path, CWP, unit = g/m^2) as discussed in Sections 3.1, 3.2, and 3.4. Wang
392 et al. (2023) have recently developed and improved a new CBP retrieval algorithm for

393 GEO H8/9-AHI, which refers to the CLAVR-x cloud base properties algorithm (Clouds
 394 from AVHRR Extended, NOAA's operational cloud processing system for the AVHRR)
 395 (Wang et al., 2024; Noh et al., 2017). This algorithm can only be executed during the
 396 daytime (solar zenith angle $< 65^\circ$) because it relies on cloud top height (CTH) and cloud
 397 water path to calculate the two linear fitting coefficients, namely slope (A_1) and
 398 intercept (A_2) (Noh et al., 2017). These two coefficients are determined through
 399 piecewise fitting using the CTH, CWP, and cloud base height (CBH) data obtained
 400 from the joint CloudSat/CALIPSO (Cloud-Aerosol Lidar and Infrared Pathfinder
 401 Satellite Observation) product (Noh et al., 2017). Once the two corresponding fitting
 402 coefficients are obtained, the cloud geometric thickness can be calculated as follows:

$$403 \quad CGT = A_1 \times CWP + A_2, \quad (7)$$

404 After that, the CBH can be easily calculated using the formula $CBH = CTH - CGT$.

405 Previous studies have validated the CTH and CBH products obtained through the
 406 same algorithms used for the H8 satellite, leveraging joint CloudSat/CALIPSO product
 407 (Wang et al., 2024; Wang et al., 2022; Min et al., 2020; Min et al., 2017b). The mean
 408 absolute error (MAE) and standard deviation (STD) for GEO satellite CTH are reported
 409 as 3.18 km and 3.75 km, respectively, with a noticeable increase associated with higher
 410 CTH values. Additionally, the MAE and root-mean-square error (RMSE) for CBH,
 411 retrieved by the same GEO CLAVR-x algorithm, stand at 1.938 km and 2.91 km, as
 412 reported in prior studies (Wang et al., 2024; Min et al., 2020). In Figure 5, CTH
 413 comparisons between the H9/AHI GEO satellite and MODIS are presented for 18:50
 414 UTC on October 8, 2023, and 04:30 UTC on July 10, 2023. The figure well
 415 demonstrates consistent CTH values and horizontal distributions derived from both
 416 H9/AHI and MODIS datasets.

417

418 *3.4 Cloud optical and microphysical properties*

419 The cloud optical thickness (COT or τ_{cld}) and particle effective radius (CER or r_{cld} ,
 420 unit= μm) (or cloud optical and microphysical properties) primarily characterizes the
 421 radiative properties of clouds, highlighting their influence on the equilibrium of Earth's
 422 radiation budget (Platnick et al., 2017). These two parameters are commonly used in a
 423 general circulation model (GCM) to define cloud parameterization schemes for climate
 424 modeling (Chou et al., 1998). The cloud optical and microphysical properties algorithm
 425 during the daytime (solar zenith angle $< 65^\circ$) utilizes the reflected solar radiation
 426 measured by a non-absorbing channel ($0.64 \mu\text{m}$) to retrieve cloud optical thickness (τ_{cld}).

427 Additionally, it uses the reflected solar radiation measured by an absorbing channel
 428 (2.23 μm) to retrieve cloud particle effective radius (r_{cld}) (Walther et al., 2011). The
 429 fundamental physical principle of this algorithm is to leverage the sensitivities of the
 430 non-absorbing and absorbing channels to cloud optical thickness (τ_{cld}) and cloud
 431 particle effective radius (r_{cld}) in the atmospheric radiative transfer process, as
 432 demonstrated by a previous study (Nakajima and King, 1990).

433 The water and ice cloud optical and radiative properties look-up tables (LUT) with a
 434 modified Gamma size distribution for fast retrieval were built based on spherical
 435 particle with the scattering properties given by the Mie theory and MODIS Collection-
 436 6 severely roughened aggregated columns ice crystal (Min et al., 2017a; Platnick et al.,
 437 2017; Baum et al., 2007), respectively. By utilizing the similar 1DVAR algorithm
 438 discussed in Section 3.3, along with water/ice cloud LUTs, observed reflectance at 0.64
 439 and 2.23 μm channels, and additional ancillary data, the optimal cloud optical thickness
 440 (τ_{cld}) and cloud particle effective radius (r_{cld}) can be iteratively calculated using the OE
 441 algorithm (Walther et al., 2011). Differing from Equation (2), the variables or first-
 442 order partial derivative from forward cloud reflectance model in the Jacobi matrix are
 443 derived from a formula for solar reflectance observed by satellite, which can be written
 444 as follows (Nakajima and King, 1990):

$$445 \quad R_{obs} = R_{cld} + \frac{A_s}{1 - A_s R'_{cld}} T_{cld} T'_{cld}, \quad (8)$$

446 where R_{obs} is the total cloud bidirectional reflectance function at the top of the
 447 atmosphere (TOA). A_s is the albedo at the Lambertian surface of a uniform single-
 448 layer cloud. R_{cld} and T_{cld} signify the cloud reflectance and downward transmittance
 449 (diffuse and direct), respectively. R'_{cld} and T'_{cld} are the cloud spherical albedo and the
 450 transmittance below the cloud, respectively. After retrieving τ_{cld} and r_{cld} , ice and liquid
 451 cloud water paths (IWP/LWP) are calculated using empirical formulas (Bennartz, 2007;
 452 Heymsfield et al., 2007), which are expressed as follows:

$$453 \quad LWP = \frac{5}{9} \tau_{cld} r_{cld} \rho, \quad (9)$$

$$454 \quad IWP = \frac{\tau_{cld}^{1/0.84}}{0.065}, \quad (10)$$

455 where ρ is the density of liquid water (=1.0 g/cm^3).

456 Figure 6 shows the cloud optical depth and effective radius comparisons between the
 457 H9/AHI GEO satellite and MODIS (Platnick et al., 2017) at 05:40 UTC on October 30,
 458 2023. We find consistent retrieval results between these two different COT and CER

459 products. Besides, Figures 6e and 6f respectively show the comparisons of the one year
 460 COT and CER from MODIS and H9/AHI data over the SCS with the related scores,
 461 such as MAE, MBE, R and RMSE. The differences are likely to be attributed to the
 462 different spatial resolutions and retrieval algorithms used between these two satellite
 463 products (Letu et al., 2019; Wang et al., 2024). Specifically, in Figure 6f, the CER
 464 comparisons reveal more pronounced discrepancies, primarily due to the different ice
 465 cloud particle scattering models used in the two retrieval algorithms (Letu et al., 2019).

467 3.5 Layered precipitable water and atmospheric instability indices

468 The atmospheric temperature and humidity profiles provide valuable information
 469 about the vertical distribution of water vapor and temperature at various altitudes. This
 470 is very crucial for studying cloud formation, precipitation patterns, and the intricate
 471 processes of the water cycle, and accurate numerical weather forecasting and climate
 472 modeling (Charlesworth et al., 2023; Zheng et al., 2015; Li et al., 2016; Zhu et al.,
 473 2023). In this investigation, the layered precipitable water (LPW) product obtained
 474 from H8/9-AHI only provides clear-sky (refer to the flowchart in Figure 1) temperature
 475 and humidity profiles and atmospheric instability indices. The next few satellite
 476 products described in Sections 3.6 and 3.7 will also be processed only in clear-sky
 477 pixels. The temperature and humidity profiles will be integrated into three distinct
 478 layers for the output satellite product (High layer: from 700 to 300 hPa; Middle layer:
 479 from 900 to 700 hPa; Low layer: from the surface to 900 hPa).

480 This physics-based LPW retrieval algorithm uses the BT observations at 6.2, 6.9, 7.3,
 481 8.5, 10.4, 11.2, 12.3, and 13.3 μm channels to retrieve temperature and humidity
 482 profiles. Since the temperature and humidity profiles can only be retrieved from clear-
 483 sky pixels, we can express the forward IR radiative transfer equation observed by
 484 satellite sensor as follows (Li et al., 2012; Li et al., 2000):

$$485 \quad I_{obs}(\lambda) = \varepsilon_s(\lambda)B_s(\lambda)T_s(\lambda) - \int_0^{p_s} B(\lambda)dT(\lambda; 0, p) + [1 -$$

$$486 \quad \varepsilon_s(\lambda)] \int_0^{p_s} B(\lambda)dT'(\lambda; 0, p), \quad (11)$$

487 where T is the atmospheric transmittance above the pressure p . Subscript s signifies the
 488 surface, $T' = T_s^2/T$. Similar to the OE method mentioned above, the cost function for
 489 retrieving temperature and humidity profiles can be written as follows:

$$490 \quad \zeta = [x - x_a]^T \gamma Cov_a^{-1} [x - x_a] + [y - M(x)]^T Cov_y^{-1} [y - M(x)], \quad (12)$$

491 where the new added variable γ is the regularization parameter (or smoothing factor)
492 compared to Eq. (5). The introduction of the parameter γ aims to achieve faster
493 convergence and improve solution stability. The iterative 1DVAR algorithm can
494 increase or decrease parameter γ by determining the first-order variation of Eq. (11) (Li
495 et al., 2000). The first guessed temperature and humidity profiles for iterative retrieval
496 are obtained from spatial-temporally matched GFS-NWP data.

497 After retrieving the optimal temperature and humidity profiles, it will calculate five
498 atmospheric instability indices, including LI (Lifted Index), CAPE (Convective
499 Available Potential Energy), TT (Total Totals), KI (K Index), and SI (Showalter Index).
500 In weather forecasting, these indices can characterize the degree of development of
501 atmospheric instability features and provide the forecaster with a general idea of the
502 convective forcing. For instance, the LI represents the level of atmospheric
503 thermodynamic instability. A positive LI value indicates stability ($0 < \text{LI}$), while a
504 negative LI value suggests varying degrees of instability ($-3 < \text{LI} < 0$ marginally unstable,
505 $-6 < \text{LI} < -3$ moderately unstable, $-9 < \text{LI} < -6$ very unstable, and $\text{LI} < -9$ extremely unstable)
506 (Fernando et al., 2021). The valid ranges and usages of these five atmospheric
507 instability indices could refer to Table 1 and the study from Li et al., 2012. Note that,
508 considering the specific retrieval efficiency (processing LPW over the SCS region takes
509 approximately 20~25 minutes) of the H8/9-AHI LPW product, we have set the retrieval
510 frequency for LPW to 30 minutes.

511 Figure 7 presents a comparison between the LPW, encompassing total precipitable
512 water and water vapors at low, middle, and high layers, derived from the H9/AHI GEO
513 satellite and ERA5 reanalysis data at 09:00 UTC on January 4, 2023, specifically over
514 the SCS. The right column panel displays associated H9/AHI CAPE, K, LI, and
515 Showalter indices. Except for the water vapors at the high layer (700-300hPa), the
516 remaining LWP products exhibit negligible differences compared to the ERA5
517 reanalysis data in Figure 7.

518 To further validate the LPW products derived from H9/AHI, we conducted
519 comparisons against ERA5 reanalysis data for LPWs over a four-month period
520 mentioned above (January, April, July, and October of 2023). Figure 8 depicts the
521 comparison results for total precipitable water and LPWs at three distinct layers. The
522 correlation coefficients (R) for the LPWs at low, middle, and high layers, along with
523 total precipitable water, are respectively 0.919, 0.784, 0.725, and 0.876. These high

524 correlation coefficients indicate the relatively high quality of this product from the
525 NANO_SCS system.

526

527 3.6 Land and sea surface temperatures

528 Land and sea surface temperatures (LST and SST) are essential variables frequently
529 utilized in climate research community (Cai et al., 2022; Hong et al., 2022). In this
530 study, we incorporated a classical land surface temperature algorithm (Ulivieri and
531 Cannizzaro, 1985) into the NANO_SCS system, using split-windows channels of H8/9-
532 AHI (11.2 and 12.3 μm). This modified algorithm was also implemented as the
533 operational LST algorithm for the FY-4A GEO satellite (Dong et al., 2023) in China
534 Meteorological Administration (CMA), which can be easily expressed as follows:

$$535 \text{LST} = C + A_1 BT_{11\mu\text{m}} + A_2 (BT_{11\mu\text{m}} - BT_{12\mu\text{m}}) + A_3 \varepsilon_s + D (BT_{11\mu\text{m}} -$$
$$536 BT_{12\mu\text{m}}) (\sec\theta - 1), \quad (13)$$

537 where C , A_{1-3} , and D are the fitting coefficients, respectively. θ represents the satellite
538 zenith angle. ε_s is the surface emissivity. To account for the uncertainties in the LST
539 algorithm caused by water vapor, we conducted regression analysis using MODTRAN
540 V4.2 (Min et al., 2022; Berk et al., 2000; Dong et al., 2023) to derive fitting coefficients
541 for four distinct groups: daytime dry, daytime moist, nighttime dry, and nighttime moist
542 conditions. A threshold of water vapor content = 2.0 g/cm^2 was utilized to classify the
543 atmosphere as either dry or moist. This threshold value was obtained from matched
544 GFS-NWP data.

545 The classical and simplified Non-Linear Sea Surface Temperature (NLSST)
546 algorithm was used here to retrieve SST of H8/9-AHI (Walton et al., 1998), which is
547 expressed as follows:

$$548 \text{SST} = a_0 + a_1 BT_{11\mu\text{m}} + a_2 (BT_{11\mu\text{m}} - BT_{12\mu\text{m}}) + a_3 (BT_{11\mu\text{m}} -$$
$$549 BT_{12\mu\text{m}}) (\sec\theta - 1), \quad (14)$$

550 where a_{0-3} are the fitting coefficients. The NOAA latest OISST (optimum interpolation
551 sea surface temperature) are used here to obtain fitting coefficients in Eq. (14) (Huang
552 et al., 2021; Reynolds et al., 2007). This global SST dataset, with a $0.25^\circ \times 0.25^\circ$
553 horizontal resolution, covers the period from 1981 to the present.

554 Figure 9 shows the LST and SST comparisons between H9/AHI GEO satellite and
555 MODIS at 18:40 UTC on October 29, 2023. From this figure, we find consistent results
556 of LST and SST between our results and MODIS official products. Figures 9e and 9f

557 also shows the comparisons of the one year LST and SST from MODIS and H9/AHI
558 data over the SCS. The correlation coefficients (R) of these two products are about 0.96.
559

560 3.7 Vegetation and water indices

561 Vegetation and water indices, such as NDVI (Normalized Difference Vegetation
562 Index), NDSI (Normalized Differential Snow Index), NDWI (Normalized Differential
563 Water Index), and LSWI (Land Surface Water Index), are commonly utilized for
564 climate change, vegetation growth, urbanization, flood monitoring, etc. (Zheng et al.,
565 2021; Hall et al., 1995; Xiao et al., 2006; Gu et al., 2007). In the NANO_SCS system,
566 these indices are calculated for clear-sky pixels during daytime using H8/9-AHI and
567 are expressed as follows:

$$568 \text{NDVI} = (\text{Ref}_{0.86\mu\text{m}} - \text{Ref}_{0.64\mu\text{m}}) / (\text{Ref}_{0.86\mu\text{m}} + \text{Ref}_{0.64\mu\text{m}}), \quad (15)$$

$$569 \text{NDSI} = (\text{Ref}_{0.64\mu\text{m}} - \text{Ref}_{1.6\mu\text{m}}) / (\text{Ref}_{0.64\mu\text{m}} + \text{Ref}_{1.6\mu\text{m}}), \quad (16)$$

$$570 \text{NDWI} = (\text{Ref}_{0.86\mu\text{m}} - \text{Ref}_{2.23\mu\text{m}}) / (\text{Ref}_{0.86\mu\text{m}} + \text{Ref}_{2.23\mu\text{m}}), \quad (17)$$

$$571 \text{LSWI} = (\text{Ref}_{0.86\mu\text{m}} - \text{Ref}_{1.6\mu\text{m}}) / (\text{Ref}_{0.86\mu\text{m}} + \text{Ref}_{1.6\mu\text{m}}), \quad (18)$$

572 where *Ref* represents the reflectance observed by satellite visible and near infrared
573 bands during the daytime. Unfortunately, in this study, the lack of a 0.47 μm channel
574 prevents the computation of the Enhanced Vegetation Index (EVI). Figure 10 shows
575 the clear-sky NDVI, NDSI, NDWI, and LSWI maps from H9/AHI at 04:00 UTC on
576 December 1, 2023 over the SCS, which were generated by the NANO_SCS system.

577

578 4. Summary

579 This investigation provides a comprehensive introduction to the key GEO satellite
580 science products generated by the NANO_SCS system and their evaluation. It offers
581 near-real-time atmospheric and oceanic science products of Himawari-8/9
582 geostationary satellites over the South China Sea from November 13, 2022, to the
583 present. Positioned at 140.7°E and 0° latitude, the H8/9 geostationary satellites mainly
584 cover East Asia, Oceania, and the Indian Ocean. The standard NRT Level-2 satellite
585 science products encompass the region between 0° to 40°N latitude and 100°E to 140°E
586 longitude with a grid resolution of 0.05° × 0.05° and a 10-minute interval (except for
587 LPW products, retrieved every 30 minutes). These products are derived from 14
588 spectral channels with a 4km horizontal resolution.

589 The NANO_SCS system provides a range of atmospheric and oceanic products,
590 including cloud mask, fraction, height, phase, optical and microphysical properties,

591 layered precipitable water, land surface temperature, sea surface temperature, and more.
592 These near-real-time satellite products were rigorously evaluated against independent
593 datasets, including MODIS satellite-based products and ERA5 reanalysis data. The
594 results highlight strong consistency between NRT H8/9 geostationary satellite
595 atmospheric and oceanic science products and the reference data from similar sensors
596 and ERA5 over the South China Sea.

597 Future continuation of atmospheric and oceanic science products generated by the
598 NANO_SCS system is also operated and secured by the Southern Marine Science and
599 Engineering Guangdong Laboratory (Zhuhai) in China. Preparations are underway for
600 new products such as atmospheric motion vectors (AMV) and quantitative precipitation
601 estimates (QPE) in near-real-time production. Besides, the qualities of current GEO
602 satellite products will be further validated and enhanced. Chinese FY-4C GEO satellite,
603 scheduled for launch in 2025 or 2026, will offer higher spatial resolution and additional
604 channels, including an IR hyperspectral sounder, to further extend and improve the
605 NANO_SCS-system-based data records for atmospheric and oceanic parameters.

606

607

608 **Data availability** The Japanese Himawari-8 (H8) and Himawari-9 (H9) geostationary
609 (GEO) satellites are strategically positioned over the South China Sea (SCS), having
610 been launched on October 7, 2014, and November 2, 2016, respectively. It mainly
611 provides cloud mask, fraction, height, phase, optical and microphysical properties,
612 layered precipitable water, and sea surface temperature products, within a temporal
613 resolution of 10 minutes and a gridded resolution of $0.05^\circ \times 0.05^\circ$. Users can freely
614 access sample HDF-formatted files and data download instruction in PDF format of the
615 South China Sea datasets at <https://doi.org/10.6084/m9.figshare.25015853> (Liu Jian,
616 2024). Besides, for accessing related NRT satellite products, a quick-view website URL
617 is provided: [<http://meteorsatellite.hellosea.org.cn/#/index>]. Data can be downloaded
618 via FTP (File Transfer Protocol) using the address <ftp://www.hellosea.org.cn:10021>,
619 with the login credentials being 'smlweix' and the password 'sml#456@'.

945 **Tables and Figures**

946 **Table 1.** Primary NRT H8/9 GEO satellite atmospheric and oceanic science products
 947 and related variables generated by the NANO_SCS system.

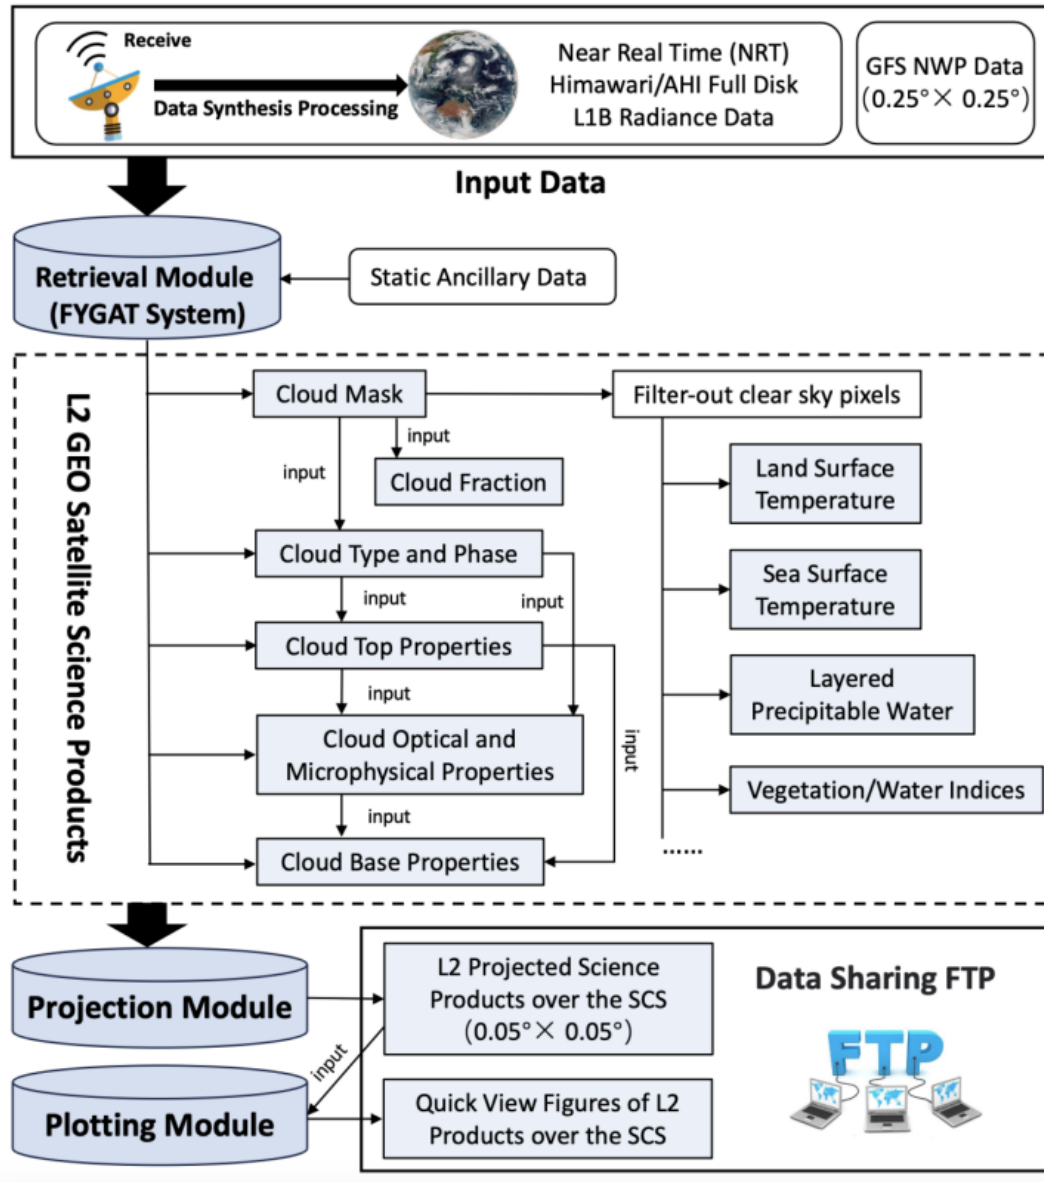

Product Name (Abbr.)	Variable Name	Valid Value	Unit	Note
Cloud Mask (CLM)	Cloud_Mask	0=Cloudy; 1=Probably cloudy; 2=Probably clear ; 3=Clear	None	
Cloud Fraction (CLF)	Cloud_Fraction	0-100	%	down-sampled 5×5 pixel box
Cloud Type and Phase (CLP)	Cloud_Type	0=Clear; 1=Spare; 2=Liquid water; 3=Supercooled water; 4=Mixed; 5=Optically thick ice; 6=Optically thin ice; 7=Multilayered ice; 8=Uncertainty	None	1=Spare: pixel with spare cloud cover
	Cloud_Phase	0=Clear; 1=Liquid water; 2=Supercooled water; 3=Mixed; 4=Ice; 5=Uncertainty	None	
Cloud Top Properties (CTP)	Cloud Top Height	0-30000	m	
	Cloud Top Pressure	0-2000	hPa	
	Cloud Top Temperature	0-400	K	
	Cloud Emissivity at 11μm	0-100	%	
Cloud Optical and Microphysical Properties (COT)	Cloud Optical Depth	0-150	None	only daytime
	Cloud Effective Radius	0-100	μm	only daytime
	Cloud Liquid Water Path	0-1000	g/m ²	only daytime
	Cloud Ice Water Path	0-1000	g/m ²	only daytime
Cloud Base Properties (CBP)	Cloud Base Height	0-30000	m	only daytime
	Cloud Base Pressure	0-2000	hPa	only daytime
Sea Surface Temperature (SST)	Sea_Surface_Temperature	0-400	K	
Land Surface Temperature (LST)	Land_Surface_Temperature	0-400	K	
Vegetation/Water Indices (NDI)	NDVI (Normalized Difference Vegetation Index)	0-1.0	None	only daytime
	NDSI (Normalized Differential Snow Index)	0-1.0	None	only daytime
	NDWI (Normalized Differential Water Index)	0-1.0	None	only daytime
	LSWI (Land Surface Water Index)	0-1.0	None	only daytime
Layered Precipitable Water (LPW)	Total Precipitable Water	0-1000	mm	
	Water Vapor High	0-1000	mm	700-300hPa
	Water Vapor Middle	0-1000	mm	900-700hPa
	Water Vapor Low	0-1000	mm	Surface-900hPa
	CAPE_Index (Convective Available Potential Energy)	0-10000	J/kg	
	K_Index	-100-100	K	
	LI_Index (Lifted)	-100-100	°C	
	Showalter_Index	-100-100	°C	
TT_Index (Total totals)	-100-100	°C
