**Abstract.** Accurate maps of irrigation extent and dynamics are ~~important to study~~crucial for studying food security and its far-reaching impacts on Earth systems and the environment. While several efforts have been made to map irrigated ~~areas~~area in China, few ~~of them~~ have provided ~~multi-year~~multiyear maps, incorporated national land surveys, addressed data discrepancies, and considered the ~~fraction~~fractional coverage of ~~irrigated~~ cropland (~~i.e., the mixed pixel issue~~). ~~In this study within coarse-resolution pixels. Here,~~ we addressed these important gaps and developed new annual maps of China's irrigated cropland from 2000 to 2020, named as CIrrMap250- (China's irrigation map with a 250 m resolution). We harmonized ~~irrigated area~~irrigation statistics and ~~land~~ surveys and reconciled them with remote sensing data. The refined estimates of irrigated area were then integrated with multiple remote sensing data (i.e., vegetation indices, hybrid cropland product, and paddy field maps) and an irrigation suitability map through a semi-automatic training approach. We ~~then~~ evaluated our CIrrMap250 maps using ~~independently interpreted~~ 20,000 reference ~~locations~~samples, high-resolution irrigation water withdrawal data, and existing local to nationwide maps. ~~Our evaluation results showed that~~Our CIrrMap250 agreed well with the reference points, with maps demonstrated an overall accuracy of 0.79-0.88 for the years 2000, 2010, and 2020, ~~respectively and outperformed currently available maps.~~ The CIrrMap250-estimated irrigatedirrigation area ~~can explain~~explained 50-60% of the variance in irrigation water ~~withdrawals~~withdrawal across China. ~~Our CIrrMap250 product showed superior performance than currently available ones (i.e., IrriMap\_CN, IAAA, and GFSAD).~~ CIrrMap250 revealed that China's irrigatedirrigation area has increased by about 180,000 km<sup>2</sup> (or 25%) from 2000 to 2020, with the majority (61%) being occurring in the water-unsustainable ~~and occurring in~~ regions facing ~~high to~~ severe to extreme water stress. Moreover, our product unveiled a noticeable northward shift of China's irrigatedirrigation area, attributed to substantial ~~expansion~~expansions in irrigated cropland across Northeast and Northwest

China. The accurate representation of irrigation are extent in CIrrMap250 will greatly support hydrologic, agricultural, and climate studies in China ~~for, aiding in~~ improved water and land resources management.

## 1 Introduction

Irrigation is increasingly important as an adaption strategy to climate change (Zaveri and B. Lobell, 2019; Bhattarai et al., 2023) and plays a vital role in ensuring food security by reducing both water and heat stresses of crops (Zhu and Burney, 2022; Zhu et al., 2022). ~~With Covering 20% of spatial coverage in global croplands and providing, irrigated agriculture contributes to 40% of global food production (Unesco World Water Assessment Programme, 2019), irrigated agriculture is a critical component of land and water resource management. Globally, agricultural irrigation accounts for. However, it uses 60-70% of total freshwater withdrawals and 80-90% of consumptive water uses (Qin et al., 2022; Wu et al., 2022). Large volumes-The~~  
40 ~~extensive use~~ of irrigation water use ~~intensify/intensifies~~ water management and ~~drives/drives~~ myriad Earth system and environmental impacts (Mcdermid et al., 2021; Mcdermid et al., 2023). These impacts include changes in hydroclimatic and biogeochemical cycling (Kang and Eltahir, 2018; Mishra et al., 2020; Thiery et al., 2020; Guo and Zhou, 2022; Yang et al., 2023), depletion of aquifers and surface water bodies (Cheng et al., 2014; Noori et al., 2021), freshwater salinization (Thorslund et al., 2021), and ~~landsides/landslides~~ (Lacroix et al., 2020). Given the vital importance of irrigation, ~~it is essential to know the exact/~~  
45 ~~knowing its precise~~ location and ~~its'~~ dynamics, ~~which, however, are is essential. However, this proves~~ challenging, due to the hidden nature of irrigation signals and the frequent confusion between irrigated and rainfed fields (Ozdogan and Gutman, 2008; Zhang et al., 2022d; Chen et al., 2023).

Remote sensing provides significant opportunities for cost-effective and spatially explicit mapping of land surfaces (Potapov et al., 2021). ~~While numerous land use/cover and thematic cropland products have been made available to the public, they often lack information on irrigation status.~~  
50 ~~Over the past decade, there has been a growing interest in using satellite-Earth observations to map irrigation extent/extent (Massari et al., 2021). Currently, The existing remote sensing methods for irrigation mapping irrigated areas are generally based on satellite data can be broadly categorized into three indicators: vegetation-based greenness, soil moisture-based, and integrated vegetation-soil moisture-integrated approaches. Various vegetation. Vegetation~~ indices derived from optical sensors, such as the normalized difference vegetation index (NDVI) (Rouse et al., 1974), green index (GI) (Gitelson, 2005), and normalized difference water index (NDWI) (Gao, 1996; Mcfeeters, 1996), have been ~~widely~~ employed to detect irrigated areas ~~using based on the underlying fact that irrigated fields typically exhibit higher productivity and greenness compared to adjacent rainfed ones, especially under drought conditions. Techniques used include~~  
55 ~~threshold splitting (Ozdogan et al., 2010; Zhu et al., 2014; Esmacili et al., 2023; Wang et al., 2023) methods, spectral matching-techniques (Ozdogan and Gutman, 2008; Lu et al., 2021), decision trees (Ozdogan and Gutman, 2008; Shahriar~~  
60 ~~Pervez et al., 2014; Ambika et al., 2016; Xiong et al., 2017), and supervised classification (Deines et al., 2017; Deines et al., 2019; Xie et al., 2019) algorithms.~~ ~~The underlying principle of the vegetation/soil moisture-based approach is that irrigated fields typically exhibit higher productivity, greenness, and moisture content compared to adjacent rainfed areas, especially~~

under drought conditions. Moreover, utilizes remotely sensed soil moisture signals from microwave and optical sensors has also been applied to detect irrigated areas by using similar techniques like threshold splitting methods (Yao et al., 2022), and supervised/unsupervised classification (Gao et al., 2018; Dari et al., 2021) algorithms, and remote sensing modeling comparison approaches. The rationale behind the soil moisture-based method this approach is that irrigation alters soil moisture and leads, leading to distinct spatiotemporal dynamics compared to adjacent rainfed areas. Additionally, the The vegetation-soil moisture integrated integration approach, which combines vegetation indices with soil moisture for irrigated area irrigation detection. This approach has also gained attention and achieved success in recent years (Pun et al., 2017; Elwan et al., 2022; Longo-Minnolo et al., 2022; Zuo et al., 2023). leveraging the strengths of both vegetation- and soil moisture-based methods for more accurate irrigation mapping.

Despite significant advancements in remote sensing technique for irrigation, broad-scale mapping, identifying of irrigated areas at large spatial scales (e.g., national and global levels) remains a grand challenge challenging due to substantial variations in irrigation practices, geographical landscapes, and climatic characteristics (Salmon et al., 2015; Zhang et al., 2022d). This challenge is further compounded by the lack of sufficient ground reference data (Xie et al., 2019; Xie and Lark, 2021). Consequently, high-precision irrigated area quality irrigation maps are still lacking globally and missing in most countries (Chen et al., 2023; Mpakairi et al., 2023). In recent years, researchers have sought to address the challenges of large-scale irrigation mapping by integrating remote sensing data with agricultural statistics, existing irrigation maps, and other relevant datasets, such as irrigation suitability (Meier et al., 2018; Xie et al., 2021; Zhang et al., 2022a; Zhang et al., 2022d) and existing irrigated area maps. They have successfully generated new irrigation maps at the global and national scales, featuring higher spatiotemporal spatial resolution and mapping accuracy compared to previous existing products. These efforts underscore the great potential of multisource data-fusion techniques for large-scale irrigation mapping.

China is a big agricultural country with the largest irrigated area in the world (International Commission on Irrigation and Drainage, 2018). With only 8% of the world's arable land cropland, China feeds 20% of the global population and has a tight connection with the food supply chain of other nations. Therefore, the development of developing reliable maps of irrigated cropland is particularly important for sustainable food production in China. Despite this, less attention has been devoted to mapping areas of irrigated cropland areas in China than in compared to other countries with extensive irrigation, such as the United States and India (Zhu et al., 2014; Zhang et al., 2022d). It is only in recent years that several maps of irrigated cropland specifically tailored for China have emerged, facilitated by the integration of multisource data, including remote sensing, reported statistics, and existing irrigation maps, and irrigation suitability land use/cover maps (Zhang et al., 2022e; Bai et al., 2022; Xiang et al., 2020; Bai et al., 2022; Zhang et al., 2022b; Zhang et al., 2022c; Zhang et al., 2022d).

While these previous studies have considerably improved our understanding of the spatial distribution of irrigated cropland in China, limitations remain. First, few studies provide have provided annual irrigation maps of irrigated cropland, hindering a spatiotemporal analysis of China's irrigated areas in China. As a result, it remains unclear where the expansion of irrigated changes in irrigation area is are water-sustainable (i.e., irrigated area expanded, g., irrigation expansion in places places without experiencing water stress) (Mehta et al., 2024). Second, irrigated irrigation area data from official statistical bureaus,

~~which were~~ collected through field-sampling surveys ~~in conjunction with~~ and bottom-up aggregation, have been extensively utilized to constrain the overall extent of irrigated cropland in previous studies. Besides statistical data, the National Land Surveys conducted by the State Council of China ~~actually also offer accurate and reliable information~~ provide estimates on irrigated cropland ~~areas~~ acreage. The ~~National Land Surveys~~ surveys involve ~~a great number of~~ many investigators and ~~rely~~ rely on ~~state-of-the-art~~ high-resolution satellite remote sensing imagery and advanced survey techniques (Chen et al., 2022). ~~The harmonization of irrigated area~~ Harmonizing irrigation statistics with the National Land Surveys ~~might~~ could potentially help to reduce biases and uncertainties ~~associated with irrigated area in each data source~~ (Yu et al., 2021),- but this has rarely been taken into account. Third, the majority of farms in China are small and fragmented, with the average farmland size being ~~less~~ smaller than a hectare (Teluguntla et al., 2018). This leads to ~~the~~ widespread presence of mixed pixels ~~in which both where~~ cropland ~~and~~ other land use/cover types ~~are present~~ coexist. However, ~~in~~ most previous studies ~~described irrigated, binary cropland in a Boolean fashion, where masks were used for irrigation mapping. These masks assign each pixel is entirely occupied by~~ either irrigated cropland or non-irrigated cropland, ~~neglecting the fractional coverage of cropland within coarse-resolution pixels.~~ This may lead to overestimation or underestimation of ~~irrigated cropland, depending on the proportion of cropland within the grid cell, irrigation extent.~~ Finally, it is worth noting that, apart from Zhang et al. (2022a) ~~the study conducted by,~~ many ~~other~~ studies assessed their ~~irrigation~~ maps with a ~~relatively~~ limited number of reference samples, potentially compromising the reliability of their evaluation results (Zhu et al., 2014; Xiang et al., 2020; Bai et al., 2022; Zhang et al., 2022d). Obtaining ~~a~~ sufficient ~~number of~~ reference ~~points~~ samples is crucial for ~~a~~ robust ~~evaluation~~ evaluations of national-scale irrigated cropland maps, a task that is, however, challenging due to the substantial cost and time involved.

Building on our previous work (Zhang et al., 2022d; Zhang et al., 2024), this study aims to bridge ~~the important~~ these gaps ~~mentioned above~~ and create new annual maps of irrigated cropland in China (2000-2020) by integrating ~~remotely sensed~~ remote sensing data (i.e., vegetation indices, hybrid cropland ~~products~~ maps, and paddy field maps), ~~irrigated area reported~~ statistics and surveys, and ~~an~~ irrigation suitability ~~to create new annual maps of irrigated cropland in China (2000-2020)-map.~~ The newly developed ~~irrigated cropland~~ maps (named as CIrrMap250) ~~have~~ feature a spatial resolution of 250 meters ~~and describe irrigated cropland distribution through fractional coverage. Our specific~~ at an annual frequency from 2000 to 2020. Our maps show the percentage of each 250 m by 250 m pixel that is covered by irrigated cropland (i.e.,  $\text{pixel value} = \frac{\text{irrigated area}}{\text{pixel area}} \times 100$ ). Other objectives ~~of this study~~ are: (i) ~~to assess~~ assessing the accuracy of CIrrMap250 using ~~a sufficient number of referencing points~~ ~20,000 reference samples and high-resolution ~~data on~~ irrigation water ~~withdrawals~~ withdrawal data; (ii) ~~to compare~~ comparing the performance of CIrrMap250 with ~~three~~ four existing ~~large-scale~~ local to nationwide irrigation maps ~~that cover the entire China~~, including IrriMap\_CN (Zhang et al., 2022a), IAAA (Siddiqui et al., 2016), ~~and~~ GFSAD (Thenkabail et al., 2016), ~~as well as a field scale map, i.e., and~~ OPTRAM30 (Yao et al., 2022); ~~and~~ (iii) ~~to investigate~~ investigating the spatiotemporal dynamics of China's ~~irrigated cropland~~ irrigation extent and ~~quantify~~ quantifying the water sustainability of changes in irrigated area.

## 130 2 Data acquisition and processing

### 2.1 Remote sensing data

We collected the Terra Moderate Resolution Imaging Spectroradiometer (MODIS) MOD13Q1 vegetation indices, i.e., NDVI and Enhanced Vegetation Index (EVI) (Huete et al., 1997), from the NASA's Earth Science Data Systems (<https://www.earthdata.nasa.gov/>). These indices ~~were~~are generated every 16 days with a 250 m spatial resolution ~~of 250 meters~~. Meanwhile, the MODIS band 4 (545-565 nm) surface ~~spectral~~ reflectance ~~of MODIS band 4~~ from the MOD09A1 product was used and resampled from the original 500 ~~meters~~m to 250 ~~meters~~ throughm using the nearest neighbor interpolation method (Debeurs and Townsend, 2008). ~~These~~The resampled data, ~~in conjunction~~ were then used together with the 250-~~meter~~m and 8-day band 1 (620-670 nm) surface reflectance ~~of band 1~~ from the MOD09Q1 ~~product, were used~~ to derive the Greenness Index (GI) (Supplementary Table S1). ~~All~~We extracted MODIS data ~~were for all cropland pixels in~~ China, using only high-quality ~~screened against quality and usefulness indicators, and only pixels free from clouds~~data on cloud- and snow/ice ~~that meeting the highest quality criteria were deemed reliable-free pixels~~ (Hilker et al., 2012). ~~The~~Low-quality MODIS data ~~for unreliable pixels~~ were ~~reconstructed~~excluded based on the quality band and were interpolated using a straightforward~~high-quality data from the~~ nearest ~~neighbor interpolation method~~neighboring cropland pixels.

We created a new high-30 m resolution (~~30 m~~) hybrid cropland product for China (CCropLand30) by fusing state-of-the-art remote sensing land use ~~and land-~~/cover products with the latest national land surveys (Zhang et al., 2024). CCropLand30 was generated at a 5-year interval from 2000 to 2020 and ~~it~~exhibited a higher accuracy compared to existing products (Zhang et al., 2024). Building upon CCropLand30, we developed 250-m resolution cropland layers for the years 2000, 2005, 2010, 2015, and 2020, which ~~describe cropland distribution using the fractional coverage method, i.e., estimating the show the cropland~~ proportion ~~of cropland in~~within each 250-meter m grid. ~~These layers serve as the foundation for mapping irrigated cropland~~. Additionally, we extracted paddy fields from China's Land-use/cover dataset (CLUD) for the years 2000, 2005, 2010, 2015 and 2020 (Liu et al., 2014; Xu et al., 2018). Paddy fields, which include cultivated land where rice and lotus roots are grown and supported by water and irrigation facilities, ~~and they could be~~were considered as part of irrigated cropland with high confidence (Zhang et al., 2022c).

### 155 ~~2.2 Irrigated area~~ Irrigation statistics and surveys

#### 2.2.1 Harmonization of ~~irrigated area~~irrigation statistics and surveys

We collected annual irrigation area data ~~on irrigated area~~ (2000-2020) from ~~diverse~~various statistical yearbooks provided by the National Bureau of Statistics of China and local statistical bureaus. These yearbooks ~~encompass~~include the Provincial Statistical Yearbook, the Rural Statistical Yearbook, the China Statistical Yearbook for Regional Economy, and the China Water Statistical Yearbook. The primary data ~~source for these datasets is~~were sourced from the China Economic and Social Big Data Research Platform (<https://data.cnki.net/>). We compiled high-resolution (i.e., county-level) irrigated area irrigation

data for ~~more than~~over 80% of ~~provinces in~~China and prefecture-level data for the ~~remaining provinces for each year from 2000 to 2020~~rest (Zhang et al., 2022d), which provide ~~substantially more detailed~~irrigation information ~~on the distribution of irrigated cropland for China~~ than earlier studies (~~Zhu et al., 2014; Xiang et al., 2020; Zhang et al., 2022b; Zhu et al., 2014~~).

165 In addition to statistical data, ~~we utilized~~ land survey ~~also provides accurate~~data to obtain ~~more detailed~~ and reliable information on irrigated areas. ~~for select years. Currently,~~ China has ~~currently~~ conducted three rounds of National Land Surveys in 1980s, 2010 and 2020~~, respectively~~. The ~~National Land Surveys~~surveys engaged a significant number of surveyors ~~nationwide~~ and utilized high-resolution satellite remote sensing imagery, along with advanced survey techniques ~~such as~~like mobile internet, cloud computing, and drones (Chen et al., 2022). ~~The results and maps from these land surveys were not made public until recently~~due ~~Due~~ to ~~the~~national security concerns. ~~The,~~ the land survey maps were not publicly available. ~~However, the~~ Ministry of Natural Resource ~~of the People's Republic of China has recently~~ released ~~the~~county-level survey results ~~(of the second and third National Land Surveys, including data on cropland and its subtypes, i.e., sub-categories (dryland, irrigated land, and paddy field) of the second and third National Land Surveys (https://www.mnr.gov.cn/). The Within the dataset, the surveyed area of irrigated land and paddy field reflects the extent of irrigated cropland, and eoverscovering the periods 2009-2016 and 2019-2022. During~~For the years with ~~available~~survey data, ~~irrigated area~~irrigation statistics were harmonized with the ~~surveyed irrigated areas~~survey data at the county scale using Eq. 1. ~~This process operated under the assumption that~~1. The data harmonization was based on two assumptions: (1) the maximum value between statistical and surveyed ~~irrigated~~irrigation area should be more reliable, and (2) ~~irrigated~~irrigation area should be ~~less~~smaller than the total cropland area. The first assumption ~~was made due to~~accounts for the ~~underestimation~~ tendency of both statistical and ~~surveyed~~survey data ~~due to underestimate irrigated area, owing to possible~~ insufficient and representative field sampling (Zhang et al., 2022a) and the prevalence of fragmented and small ~~croplands~~crop fields ([Teluguntla et al., 2018](#)). ~~We also tested alternative~~Alternative harmonization methods ~~(e.g., such as mean and minimum), values, were also tested but they demonstrated inferior performance compared to~~performed worse than the maximum harmonization approach. ~~In~~For years ~~lacking~~without survey data, the ~~irrigation area was estimated by adjusting the~~harmonized ~~irrigated area was determined~~data ~~from adjacent survey years~~ using Eq. 2, ~~assuming that the~~relative ~~change~~ information derived from the irrigation statistics (Eq. 2). This method preserved the ~~interannual~~ changes ~~observed~~ in statistical ~~irrigated~~irrigation area ~~are reliable~~while ~~enhancing data consistency across years~~.

$$A_{harm}^{ts} = \min(\max(A_{stat}^{ts}, A_{surv}^{ts}), CA_{surv}^{ts}) \quad (1)$$

$$A_{harm}^{t2} = \min\left(A_{harm}^{ts} \times \frac{A_{stat}^{t2} - A_{stat}^{ts}}{A_{stat}^{ts}}, \left(1 + \frac{A_{stat}^{t2} - A_{stat}^{ts}}{A_{stat}^{ts}}\right), CA_{surv}^{t2}\right) \quad (2)$$

190 where  $A_{harm}$ ,  $A_{stat}$  and  $A_{surv}$  represent the ~~county level areas of~~harmonized, statistical and surveyed ~~irrigated cropland~~irrigation area, respectively;  $CA$  is the surveyed area of cropland; and  $ts$  and  $t2$  indicate the year with and without land surveys, respectively.

## 2.2.2 Reconciliation between statistical/~~surveyed~~ survey data and remote sensing data

195 Cropland area statistics and survey data are inherently incompatible with remote sensing data due to ~~differences in~~ different measurement techniques. ~~The former measures~~ While statistical and survey data measure the net area of cropland, ~~while the latter~~ remote sensing data represents the gross area of cropland ~~that includes, including~~ subpixel, non-cropland features such as field ridges, linear elements, and scattered features (e.g., ~~like~~ roads, ponds, and ~~rural~~ houses) (Zhang et al., 2024). ~~Consequently,~~ As a result, statistical and surveyed cropland areas exhibit a negative and systematic bias compared to those derived from  
200 remote sensing data (Zhang et al., 2021; Zhang et al., 2022d). ~~Irrigated cropland is~~ Similarly, as a ~~part~~ subset of cropland, ~~and its irrigated cropland is also reported as a net area in~~ statistics and surveys ~~also indicate the net area of irrigated area.~~ Consequently, a gap exists between the irrigated area from statistics/surveys and that ~~derived is~~ different from remote sensing data. ~~Direct use of~~ Directly using the statistical/~~or~~ surveyed ~~irrigated~~ irrigation acreage to constrain remote sensing-based irrigated cropland ~~extent would likely leads to underestimation of irrigated croplands result in underestimating irrigation extent~~  
205 (Schepaschenko et al., 2015). To ~~fill~~ address this ~~gap~~ discrepancy, we adjusted the harmonized ~~irrigated~~ irrigation area data (Section 2.2.1) to reconcile the statistical/~~surveyed~~ and survey data with remote sensing data, as ~~seen~~ shown in Eq. 3. This adjustment was ~~implemented underperformed based on~~ the assumption that the ~~irrigation~~ proportion of irrigated cropland remains consistent in ~~both~~ the statistical/~~surveyed~~ survey data and the remote sensing-derived maps. For ~~example~~ instance, if ~~the statistical/or~~ survey data indicates ~~at that~~ 99% ~~irrigation proportion of the cropland in the croplands of~~ a given county ~~is~~  
210 ~~irrigated~~, the remote sensing-derived irrigation proportion should also be ~~as high as~~ approximately 99%.

$$A_{recon}^t = A_{harm}^t \times \frac{CA_{RS}^t}{CA_{surv}^t} \quad (3)$$

-where  $A_{recon}^t$  and  $A_{harm}^t$  are the reconciled and harmonized ~~irrigated~~ irrigation area, respectively, for the year  $t$ ;  $CA_{RS}^t$  is ~~the~~ remote sensing-derived cropland area ~~that was~~ estimated from our hybrid cropland product (Zhang et al., 2024);  $CA_{surv}^t$  is the surveyed cropland area;  $CA_{RS}^t/CA_{surv}^t$  ~~indicated~~ denotes the bias ratio of remote sensing-derived cropland area relative to  
215 surveys. This ratio was estimated for each county and constrained to the median value of all counties in its agricultural zones (Zhang et al., 2022c) to exclude extreme bias ratios and to ensure a conservative adjustment. In years lacking survey data, the bias ratio was estimated using a straightforward nearest-neighbor interpolation method.

## 2.3 Auxiliary data

220 This study utilized various auxiliary datasets, (~~Supplementary Table S2~~), including meteorological and environmental variables, irrigation water withdrawal, water scarcity index, and administrative boundaries. Daily meteorological observations, ~~including such as~~ precipitation, relative ~~humidity~~ humidity, air temperature and pressure, ~~at were collected from~~ approximately 2400 meteorological stations ~~were collected from~~ across China, provided by the National Meteorological Information Center (NMIC, <http://data.cma.cn/>). These datasets were ~~used in combination~~ combined with the MCD43A3 albedo product ~~for the~~

225 ~~computation of to compute daily~~ potential evapotranspiration (PET) ~~using the Priestley-Taylor method~~ (Priestley and Taylor, 1972) ~~and~~. The daily PET values were aggregated to annual values for the period from 2000 to 2020, which were then used to ~~derive the~~ aridity index ~~(i.e., defined as the ratio/ratio~~ of precipitation to PET). ~~Environmental data consists of. The environmental variables included~~ elevation, slope, ~~erocropping~~ intensity, soil type, and distance to water bodies. Elevation data ~~originated was sourced~~ from the Shuttle Radar Topography Mission digital elevation model (SRTM DEM), and the slope  
230 map was ~~derived generated from the SRTM DEM data~~ using the slope function in ArcGIS ~~software based on SRTM DEM data. Distance. The distance~~ to water bodies was ~~determined using the Euclidean distance tool in ArcGIS, employing calculated based on the~~ spatial distribution ~~data~~ of water bodies, ~~including~~ (rivers, lakes, reservoirs, canals, and ponds) ~~using the Euclidean distance tool in ArcGIS~~. The above auxiliary data ~~for this study~~ were ~~sourced~~ partly ~~obtained~~ from the National Tibetan Plateau (<https://data.tpdc.ac.cn/>) and ~~partly the remaining~~ from the Resource and Environment Science and Data Center  
235 (<https://www.resdc.cn/Default.aspx>).

~~Moreover, data on~~ ~~Additionally, the prefecture-level~~ irrigation water ~~withdrawals at medium-sized administrative units known as prefectures were compiled withdrawal data~~ for two distinct time frames (specifically, 2009-2011 and 2018-2020) ~~were compiled~~ from ~~Water Resources Departments of the 31 provinces/provincial water resources departments~~ and the local statistical bureaus. The prefecture-level data on ~~Water Scarcity Index/water scarcity index~~ (WSI) ~~spanning the period~~  
240 ~~from for~~ 2010 to 2020 were extracted from our ~~earlier/previous~~ study (Zhang et al., 2023b). ~~The~~ WSI ~~was computed is defined~~ as the ratio of total water ~~usage (use to water availability, as shown in Supplementary Table S2. Total water use encompasses both groundwater and surface water withdrawals for irrigation, industry, domestic water use, and other water use for purposes, forestry, livestock, and fishery, and ecology). Water availability refers to water availability (i.e., the total surface water and groundwater generated by precipitation).~~

### 245 3 Methodology

In this study, we ~~create CIrrMap250~~ ~~created annual maps of irrigated cropland in China~~ by integrating multisource data through a semi-automatic training approach (Xie et al., 2019; Zhang et al., 2022d). ~~Following the acquisition. After acquiring~~ and processing ~~of the~~ data, our methodology ~~began started~~ with the creation of training samples, as depicted in Figure 1. This step involves three major processes ~~that include~~: (i) generating intermediate irrigation maps through a threshold-calibration  
250 method; (ii) establishing a training pool (i.e., potential training data) via overlay analysis of the intermediate maps; and (iii) generating training samples through random sampling from the training pool. ~~Building upon~~ ~~Using~~ these training samples, we ~~classify/classified~~ irrigated and rainfed cropland in each county ~~on an annual basis/annually~~ using the random forest algorithm (Breiman, 2001). ~~The mapping outcomes resulting county-level maps~~ were then ~~then~~ mosaicked and post-processed to ~~obtain/produce the~~ annual maps of irrigated cropland in China, ~~denoted/referred to~~ as CIrrMap250. ~~Afterwards~~ ~~Subsequently~~,  
255 we evaluated the accuracy of CIrrMap250; and ~~conducted performance and visualization comparisons/compared it~~ with existing

products. ~~Lastly~~**Finally**, we examined the spatiotemporal changes in irrigated croplands and quantified the water sustainability of irrigation ~~area~~-expansion by ~~comparing it~~**relating them** with water stress areas.

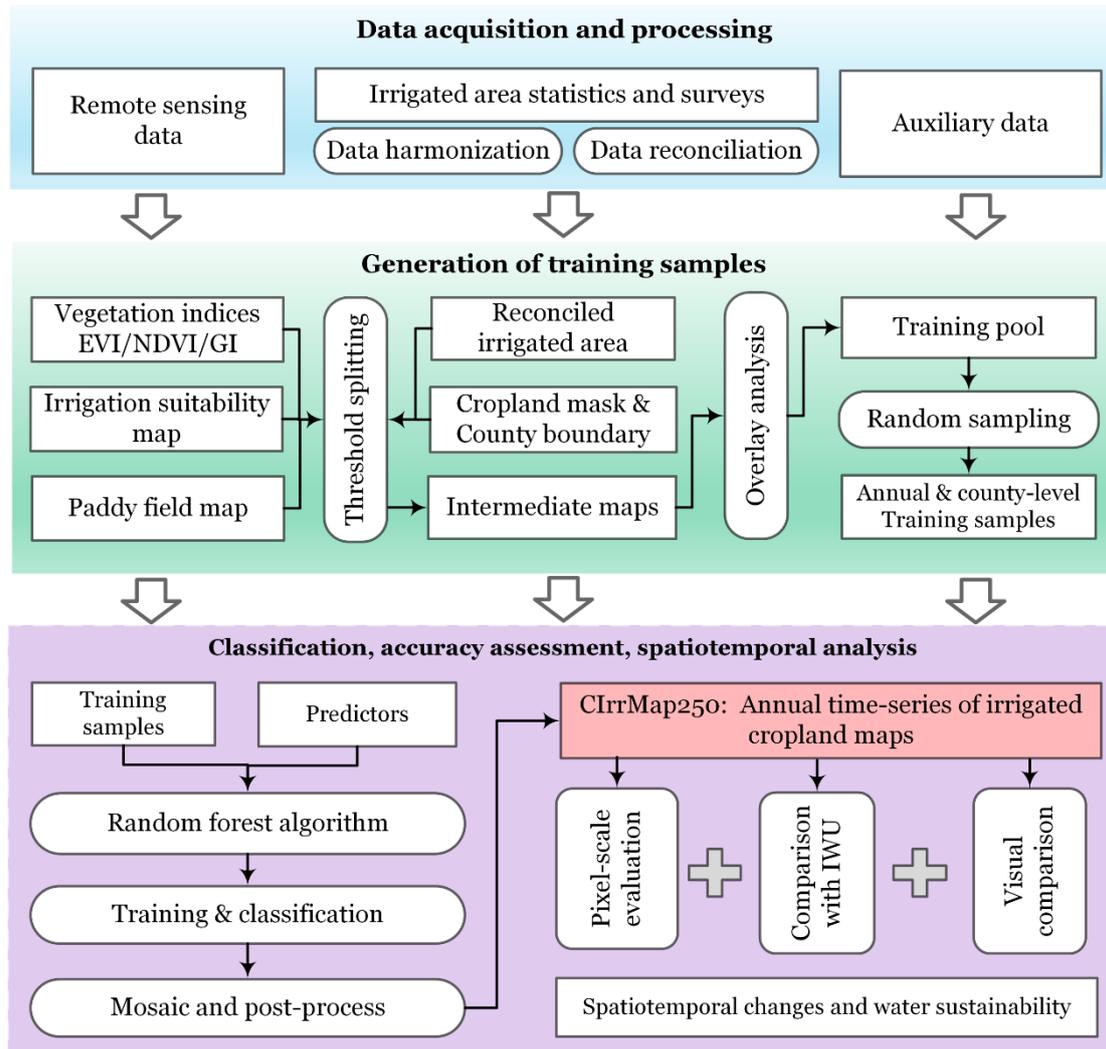

Figure 1. Workflow of this study

260

### 3.1 Generation of training samples

~~A~~**We applied a** threshold-calibration method ~~was applied~~ to automatically generate the training pool ~~for irrigated and rainfed cropland~~, following ~~the~~ previous studies ~~by~~ Xie et al. (2019; 2021) ~~and~~ Zhang et al. (2022d). ~~We~~. **With this method, cropland pixels with annual peak vegetation greenness exceeding an optimized threshold were classified as “irrigated”.** The threshold ~~was~~ individually calibrated for each county and year using available irrigation statistics and surveys. Based on the calculated ~~optimized thresholds~~, intermediate irrigation maps were generated at the county level. Pixels consistently classified as

265

“irrigated” in all intermediate maps were identified as irrigation candidates, while those classified as “non-irrigated” were considered potential non-irrigated samples.

In this study, we first calculated the peak ~~vegetation index~~ values of vegetation indices (NDVI, EVI, and GI) for cropland grids in each year and adjusted ~~it~~ them by irrigation suitability. ~~The growth period peak values of NDVI, EVI, and GI were determined for cropland grids in each year.~~ A static irrigation suitability map ~~was constructed~~ was created based on the elevation, slope, and aridity index of cropland. ~~As demonstrated by, these, These~~ factors ~~are pivotal~~ play a crucial role in ~~influencing~~ shaping the spatial distribution of irrigated cropland in China, ~~as demonstrated by~~ Liu et al. (2022). Cropland ~~with areas characterized by~~ lower elevation, gentler ~~slopes~~ slopes, and higher aridity ~~index was~~ indices were hypothesized to ~~have higher~~ exhibit greater irrigation suitability and potential, ~~in line with previous studies~~ (Worqlul et al., 2015; Worqlul et al., 2017; Li and Chen, 2020; Zhang et al., 2022d). Specifically, the ~~cropland~~ irrigation suitability map was derived by combining ~~the~~ irrigation suitability values of elevation, slope, and aridity index, as in Eq. 34.

$$S_{i,j,k} = \frac{1}{4}w_{1,k}SElev_{i,j} + \frac{1}{4}w_{2,k}SSlope_{i,j} + \frac{1}{10}w_{3,k}SArid_{i,j} \quad (34)$$

where  $S_{i,j,k}$  is the irrigation suitability for cropland cell  $i$  in county  $j$  of province  $k$ ;  $w$  is the weight of the influencing factors, which was determined ~~by~~ through a trial-and-error procedure;  $SElev$ ,  $SSlope$ , and  $SArid$  are the irrigation suitability values of elevation, slope, and aridity index, respectively (Supplementary Table S2S3). The peak vegetation index was subsequently adjusted by irrigation suitability (Eq. 4), ~~which~~ with the assumption that irrigated cropland ~~is not only, being~~ greener and more productive ~~but, is~~ also more suitable for irrigation ~~than~~ compared to rainfed cropland.

$$SVI_{i,j,k}^t = S_{i,j,k} \times Peak(VI_{i,j,k}^{g,t}) \quad (45)$$

where  $SVI$  denotes the irrigation suitability-adjusted peak vegetation index;  $VI$  denotes the ~~value of~~ vegetation index, ~~value~~;  $g$  and  $t$  represent the growth period and year, respectively.

We then generated three intermediate irrigation maps ~~for each year~~ annually from 2000 to 2020 utilizing the  $SVI$  (i.e., irrigation suitability-adjusted peak NDVI, EVI, and GI) and the paddy field maps. This was ~~accomplished~~ achieved through a threshold splitting method (Pervez and Brown, 2010; Zhu et al., 2014; Meier et al., 2018). Specifically, the  $SVI$  values for all ~~croplands~~ cropland pixels within each county were ranked in a descending order ~~within each county~~, and the cumulative irrigated area was sequentially ~~estimated. Subsequently, the~~ calculated. The accumulated area was ~~then~~ compared with the reconciled ~~irrigated~~ irrigation area. The  $SVI$  value ~~corresponding to the grid whereat which~~ the cumulative irrigated area closely matched the reconciled irrigated area was ~~determined~~ identified as the ~~optimal~~ threshold ~~value~~. Notably, for paddy fields, the  $SVI$  value was set to the maximum  $SVI$  ~~of the~~ among croplands ~~in~~ within a ~~given~~ county, prioritizing ~~it as irrigated~~ these areas ~~as “irrigated”~~. The ~~croplands~~ cropland grids were finally classified into “irrigated” and “rainfed” categories using Eq. 56.

$$cropland_{i,j,k} = \begin{cases} irrigated_{i,j,k}^t & SVI_{i,j,k}^t \geq threshold_{j,k}^t \\ rainfed_{i,j,k}^t & SVI_{i,j,k}^t < threshold_{j,k}^t \end{cases} \quad (56)$$

~~These~~The intermediate irrigation maps were finally overlaid and intersected; and to identify pixels consistently ~~identified by these maps~~classified as irrigated or rainfed cropland across these maps. These pixels were designated as potential training samples, ~~constituting~~forming the training pool for ~~a given each county and year and county~~. We, ~~From the training pool, we~~ randomly selected 200 rainfed ~~cropland grids~~pixels and 200 irrigated ~~cropland grids from the training pool for each county and each year, which~~pixels to train the random forest model. This selection ensures a balance between the ~~requirement~~need for ~~sufficient~~an adequate number of samples and ~~the~~ computational efficiency of the classification algorithm (Xie et al., 2019; Zhang et al., 2022d).

### 305 3.2 Classification of irrigated cropland using random forest

We employed the random forest algorithm (Breiman, 2001) to classify irrigated and ~~rain fed~~rainfed cropland using the random samples extracted from the training pool. ~~The implementation of the random forest algorithm was performed using the MATLAB TreeBagger function~~. The hyperparameters of ~~the random forest~~our model were optimized through a trial-and-error process. ~~These parameters include, including~~ the number of trees, the minimum number of observations per node, and the number of variables randomly sampled at each decision split (Supplementary Table S3). ~~The chosen predictors encompass~~4). The input features of our model encompassed both time-varying variables (i.e., vegetation indices, precipitation, temperature, PET, and aridity index) and ~~time invariant~~stable environmental variables (i.e., latitude, longitude, ~~crop~~cropping intensity, elevation, distance to water bodies, slope, and soil type). The classification ~~of irrigated and rainfed cropland~~ was conducted independently ~~in each county~~ for each county per year from 2000 to 2020. After ~~classification that~~, we merged the annual ~~and~~ county-level mapping results to generate ~~the~~preliminary binary irrigation maps ~~of in China (i.e., 1 for “irrigated” and 0 for “non-irrigated cropland in China. To enhance the accuracy of these maps, a spatial filter (a 7×7 window) was applied to eliminate isolated pixels (constituting <5% of the window area) and identify missed irrigated croplands (comprising >95% of the window area).”)~~.

~~We then employed a spatial filtering to remove isolated irrigation pixels and identify potentially omitted irrigated croplands. Specifically, we first calculated the irrigation proportion within a 7×7-pixel window for each preliminary irrigation pixel. Then, all cropland pixels within the moving window were assigned as “non-irrigated” if the calculated ratio fell below 5%. Conversely, if the ratio exceeded 95%, we assumed all cropland pixels within the moving window to be irrigated. The spatial filtering operation preserved the original spatial resolution of the maps (250 m).~~

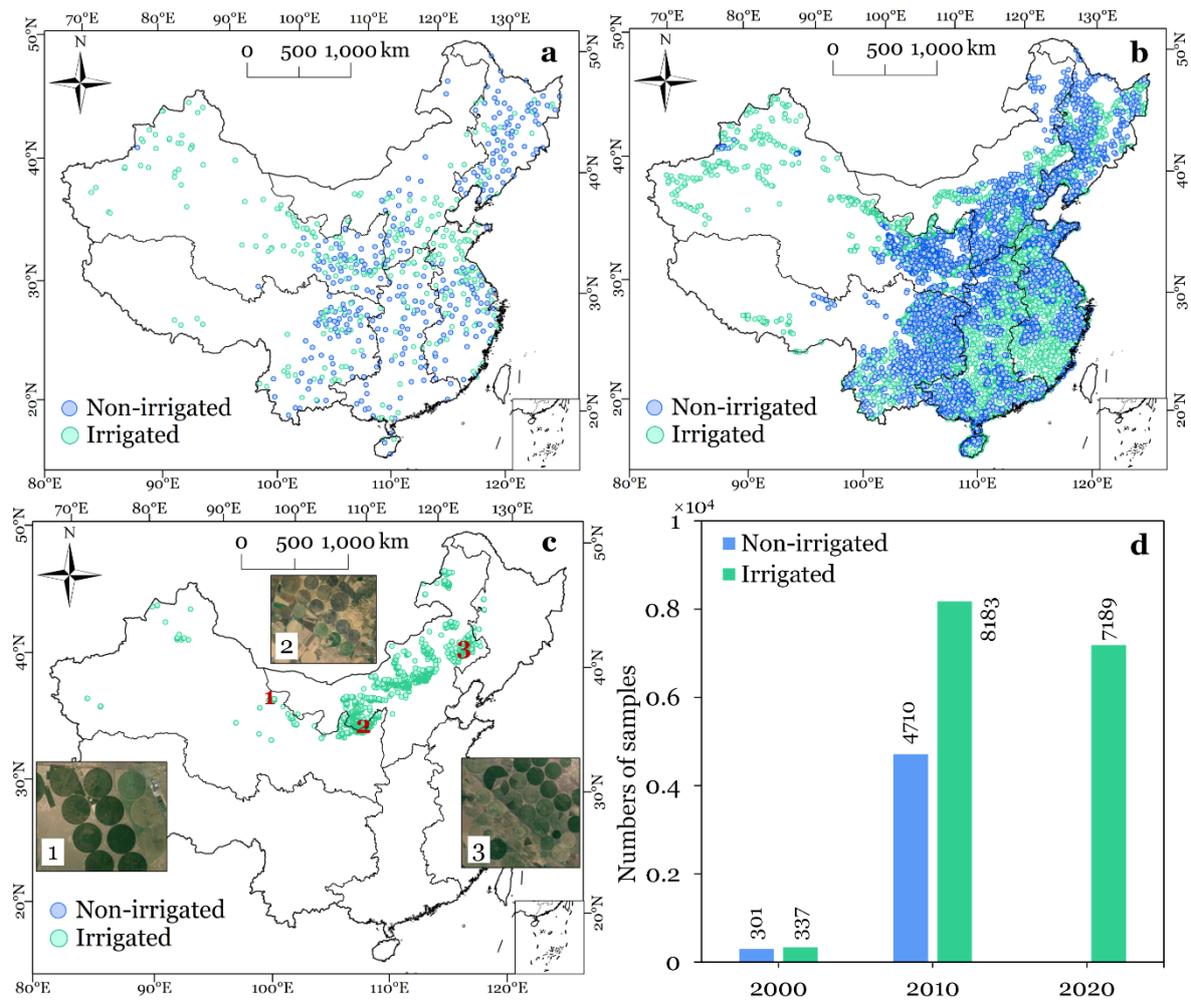

~~Finally, we multiplied the binary, spatially filtered irrigation maps by each corresponding cropland mask layers to generate annual irrigation maps for China. The final product, CIrrMap250, represents the percentage of a 250 m pixel covered by irrigated croplands (i.e., pixel value = irrigated area / pixel area ×100). Unlike simple binary maps, our product considers the fractional coverage of croplands within coarse-resolution MODIS pixels, thereby enhancing the accuracy of irrigation area estimates in China, where farms are typically small and fragmented.~~

### 330 3.3 Accuracy assessment and inter-comparison

The accuracy of CIrrMap250 was assessed from three distinct perspectives. First, pixel scale accuracy was evaluated using over 20,000 reference points collected from existing literatures and land use maps of the National Land Survey in China. Furthermore, the performance of CIrrMap250 was indirectly assessed by comparing its irrigated area estimates with high-resolution data on irrigation water withdrawal. In addition, we compared CIrrMap250 with three currently available large-scale irrigation maps, i.e., IrriMap\_CN, IAAA, and GFSAD, as well as a field-scale (30 m resolution) map in the Hexi Corridor of Northwest China (Yao et al., 2022).

#### 3.3.1 Assessment with reference points

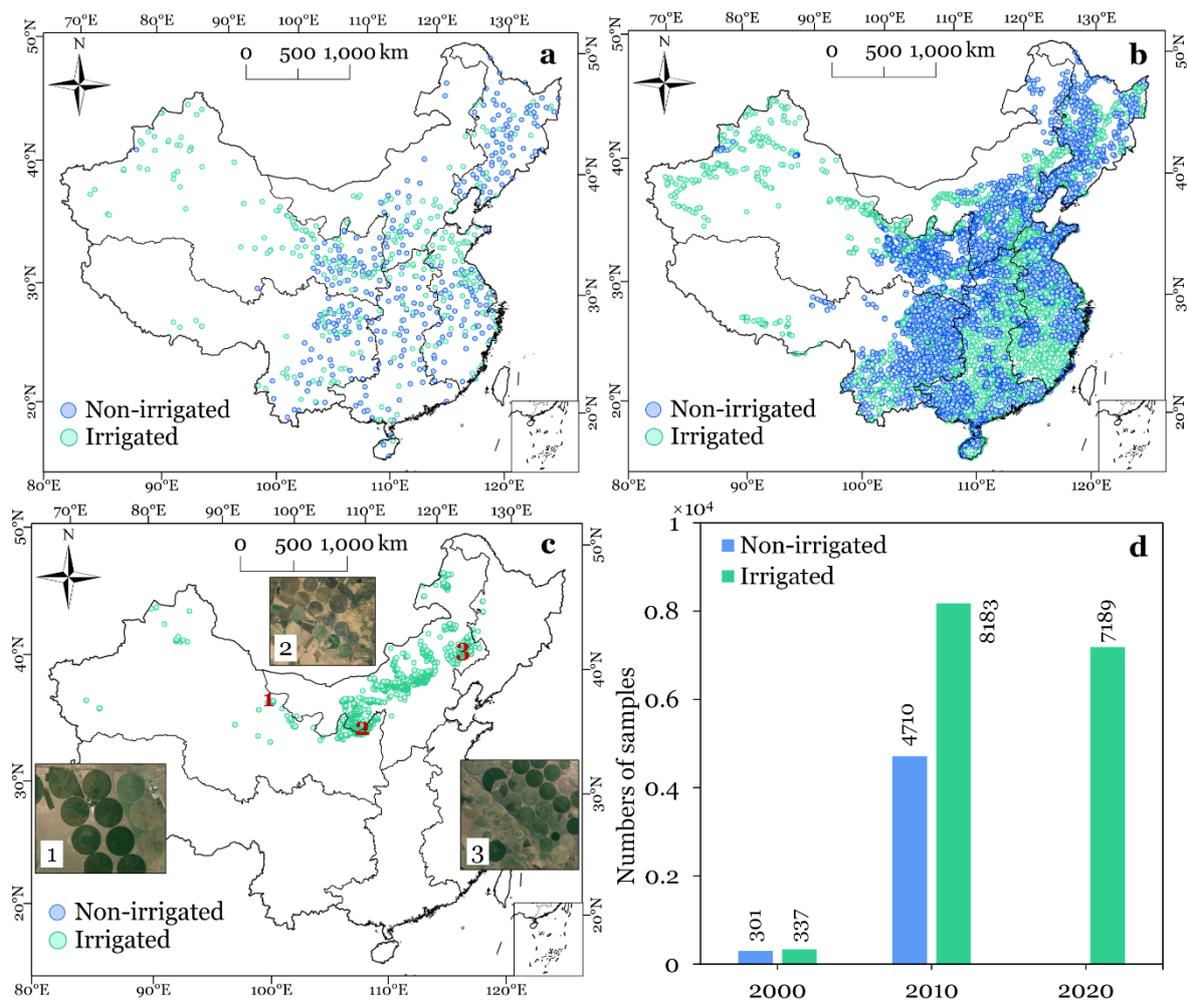

We assessed the accuracy of CIrrMap250 using three independent ~~datasets~~sets of validation samples (Figure 2). The first validation ~~samples~~dataset was for the year 2000 ~~were~~(Figure 2a), obtained from Zhu et al. (2014), ~~which were~~ primarily derived from the crop growth and soil moisture dataset provided by the China Meteorological Data Sharing Service System (<https://data.cma.cn/>). The second validation ~~samples~~dataset, for the year 2020 ~~were acquire~~(Figure 2c), was acquired from Chen et al. (2023), ~~who mapped that showed the global location of center pivot irrigation systems (CPIS) in global arid regions. The CPIS are characterized by a circular irrigation pattern centered on pivots, which creates a distinct circular pattern on the crop (Figure 2c). This characteristic enables a reliable identification of the CPIS from remote sensing images.~~ We extracted the CPIS polygons across China (mainly distributed throughout China and converted them into validation points (i.e., the center of each CPIS polygon), which are mainly located in in the Northern China.) and compared with our product. In addition, we retrieved the validation samples for the year circa 2010 (Figure 2b) from the provincial land-use maps of ~~the~~China's second National Land Survey ~~in China~~ (<https://www.mnr.gov.cn/>). ~~Due to the lack of georeferencing information, we~~We georeferenced these land use maps using the georeferencing tool in ArcGIS ~~in conjunction with~~. A total of 234 control points were selected from high-resolution images. The irrigated and provincial administrative boundaries for the georeferencing process (Supplementary Figure S1). The irrigation samples were taken randomly extracted from the patches of irrigated lands and paddy fields in the georeferenced land use maps, while non-irrigated samples were taken from dryland patches. Note that the surveyed land use maps of the third National Land Survey are not available currently. In total, weAs shown in Figure 2d, we totally obtained a more than 20,000720 reference samples, ~~enabling a robust assessment of the irrigation maps.~~

**Figure 2. Spatial distribution of validation samples.** **a** and **b**, Spatial distribution of the third party samples in 2000 and 2020, respectively. **c**, Spatial distribution of the samples for the year 2010 retrieved from provincial land-use maps of the second national land survey in China. **d**, Numbers of irrigated and non-irrigated samples for different years.

360 ——— The performance of CIrrMap250 was evaluated quantitatively using the overall accuracy (OA), F1-score, producer's accuracy (PA), and user's accuracy (UA) (Supplementary Table S4). CIrrMap250 describes irrigated cropland distribution through fractional coverage rather than in a binary manner. The pixel values in CIrrMap250 indicate the percentage of irrigated cropland within each grid cell. It's noteworthy that this percentage represents the proportion of cropland within the 250-meter grid cell (estimated from the 30-meter hybrid cropland product), not the proportion of irrigated cropland to total cropland.

365 Essentially, the cropland area within each 250-meter grid cell is categorized as either "irrigated" or "non-irrigated". Hence, for pixel-scale accuracy evaluation, CIrrMap250 was converted into binary maps, whereby pixels with values greater than 0 were coded as 1, representing irrigated cropland, while other pixels were coded as 0, representing non-irrigated area. S5).

**Figure 2. Spatial distribution of validation samples.** **a.** Spatial distribution of the third-party samples in 2000. **b.** Spatial distribution of the samples in 2010 retrieved from provincial land-use maps of China's second National Land Survey. **c.** Spatial distribution of the third-party samples in 2020. **d.** Numbers of irrigated and non-irrigated samples for different years.

### 3.3.2 Assessment with irrigation water withdrawal data

We further assessed the performance of CIrrMap250 by comparing its irrigated area estimates with high-resolution (prefecture-level) data on irrigation water withdrawals for the years circa 2010 and 2020. Since irrigated area is a major driver of irrigation water withdrawal (Lamb et al., 2021; Puy et al., 2021), irrigation water withdrawal can indirectly evaluate the accuracy of irrigation maps (Zhang et al., 2022a). A more accurate irrigated cropland map is expected to exhibit a more robust correlation between its irrigated area and irrigation water withdrawal compared to low-accuracy maps. The explanatory power

380 of the irrigation area estimates and actual irrigation water withdrawals, in contrast to maps with lower accuracy. The strength  
of this correlation was gauged using assessed by the coefficient of determination ( $R^2$ ) in  $R^2$  from a linear regression model,  
which quantifies fitted to the extent to which the variance in irrigation water withdrawals can be explained by changes in  
irrigated area withdrawal data using the least squares method.

### 385 3.3.3 Comparison with existing products

We compared evaluated C IrrMap250 with using three existing large-scale irrigation maps covering the entire China, including  
IrriMap\_CN (Zhang et al., 2022a), IAAA (Siddiqui et al., 2016), and GFSAD (Thenkabail et al., 2016). IrriMap\_CN  
are provides annual irrigated cropland irrigation maps across China at a 500-meter resolution spanning for the years from 2000  
to 2019. It at a 500 m resolution, which was recently developed using MODIS data and machine learning method based on the  
390 training samples generated from the existing irrigation maps downscaled from the statistical data (Zhang et al., 2022a). The  
IAAA are irrigated area irrigation maps at a 500-m resolution cover Asia and Africa for the years 2000 and 2020, covering Asia  
and Africa-2010 at a 500 m resolution. These maps were created by leveraging based on seasonal vegetation variations captured  
in multi-seasonal satellite images MODIS data (Siddiqui et al., 2016). GFSAD is a The 2010 global irrigated cropland irrigation  
map at a 1000-m, GFSAD, has the spatial resolution for the year 2010. It of 1000 m and was generated by overlaying the five  
395 dominant crops of the world with the remote sensing-derived irrigated and rainfed cropland area map (Thenkabail et al., 2016).

In addition Additionally, we obtained evaluated our maps for the Hexi Corridor using a field-scale remote sensing  
irrigation cropland map, denoted as OPTRAM30, developed by . OPTRAM30 was specifically created for the region (Yao et  
al., 2022). Hexi Corridor in Northwest China using the soil moisture change detection method with the optical trapezoid model.  
This map-The map, OPTRAM30, has a high 30 m resolution of 30 meters and demonstrates an accuracy approaching close to  
400 100% when validated against in situ datasets. Given the high accuracy and spatial resolution of OPTRAM30, it can serve as a  
valuable reference for the evaluation of large-scale irrigation maps. Hence, we additionally made a comparison of In addition  
to assessing C IrrMap250, we also evaluated IrriMap\_CN, IAAA, and GFSAD with using OPTRAM30 in the Hexi Corridor.

### 3.4 Changes in irrigated Irrigation area change and comparison its correlation with water stress areas

405 We examined the irrigation trends in irrigated areas in a spatially explicit manner using 21 years of data our new irrigation  
maps from 2000 to 2020. The trends were quantified by calculating as the slope of the regression line fitted to the time-series  
irrigation data of irrigated areas at the pixel scale using the least squares method. Furthermore, we adopted the concept of  
“center of gravity” to track the spatial dynamics of irrigated areas (Zeng and Ren, 2022). The gravity center of irrigated area  
( $X, Y$ ) is represented as:

$$410 \quad X^t = \frac{\sum_{i=1}^n IrrArea_i^t \times x_i}{IrrArea_i^t} \quad (67)$$

$$Y^t = \frac{\sum_{i=1}^n IrrArea_i^t \times y_i}{rrArea_i^t} \quad (78)$$

where  $IrrArea_i^t$  denotes the irrigated area in grid  $i$ ;  $x_i$  and  $y_i$  are the longitude and latitude of grid  $i$ , respectively;  $n$  is the number of irrigated cropland grids; and  $t$  is year.

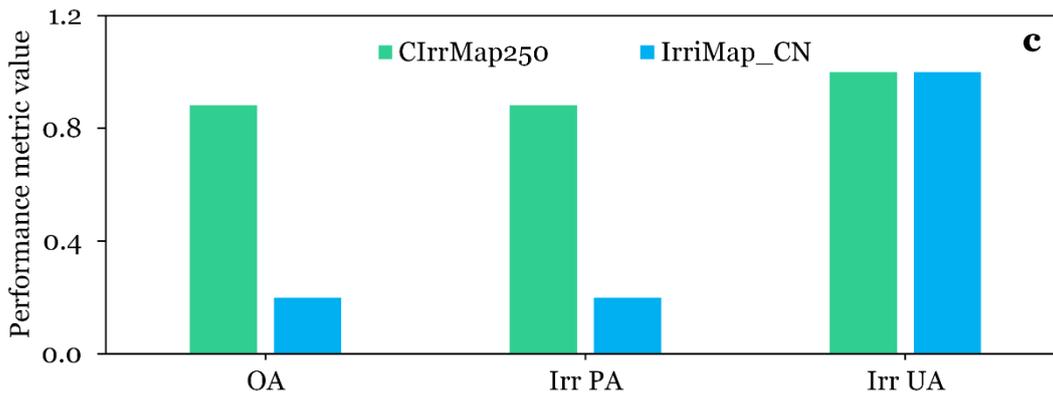

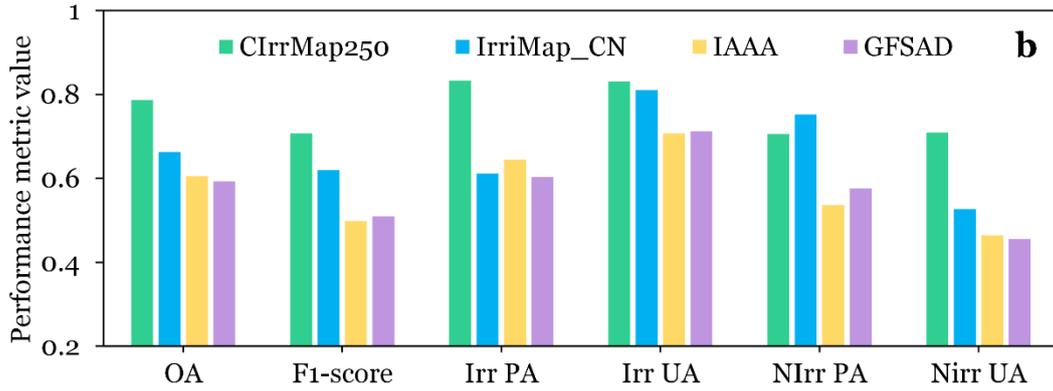

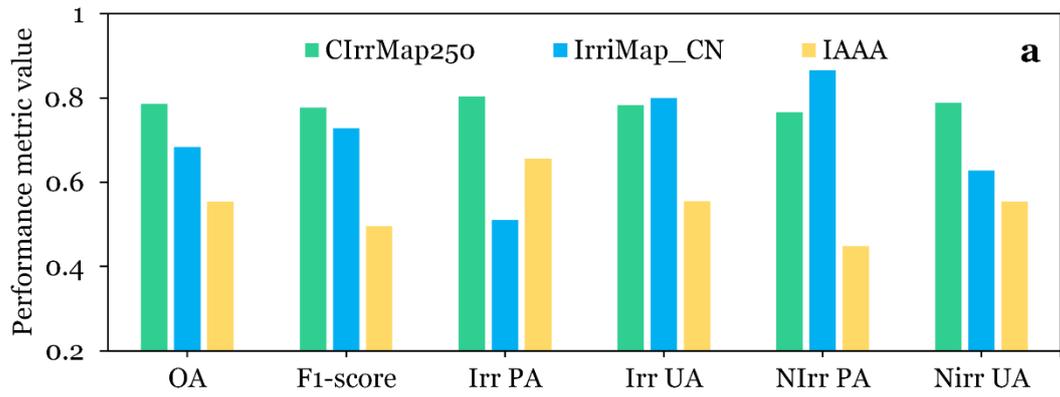

In addition, we quantified ~~the~~ water sustainability of ~~changes in irrigation areas. The~~ changes across China. To do so,  
 415 we first identified the expansion and decline in irrigated areas between 2000 and 2020 ~~were first identified at the pixel scale.~~  
~~To better visualize the results, we aggregated changes in irrigated area to a~~ a 5-<sub>km</sub> resolution, following previous studies  
 (Deines et al., 2019; Xie and Lark, 2021). ~~Subsequently, we compared these~~ the changes with a prefecture-level water stress  
 map derived from the mean values of WSI over the period 2010-2020. ~~The~~ WSI denotes the fraction of available water  
 resources appropriated by humans and is employed to categorize water stress ~~across different prefectures~~ into four levels: low  
 420 (WSI  $\leq 0.2$ ), moderate ( $0.2 < WSI \leq 0.4$ ), ~~high~~ severe ( $0.4 < WSI \leq 1.0$ ), and ~~severe~~ extreme (WSI  $> 1$ ) (Zhang et al.,  
 2023b). ~~Expansions of irrigated areas. Irrigation expansion~~ under severe to extreme water stress ~~were~~ was designated as  
 “unsustainable” due to ~~their~~ the potential ~~to exacerbate the~~ of exacerbating depletion of surface water and groundwater (Mehta  
 et al., 2024) ~~resources~~. Conversely, the expansion of ~~irrigated areas~~ irrigation under low to moderate water stress, or ~~reductions~~  
~~in irrigated areas~~ the shrinkage of irrigation under severe to extreme stress ~~were~~ was deemed “sustainable”.

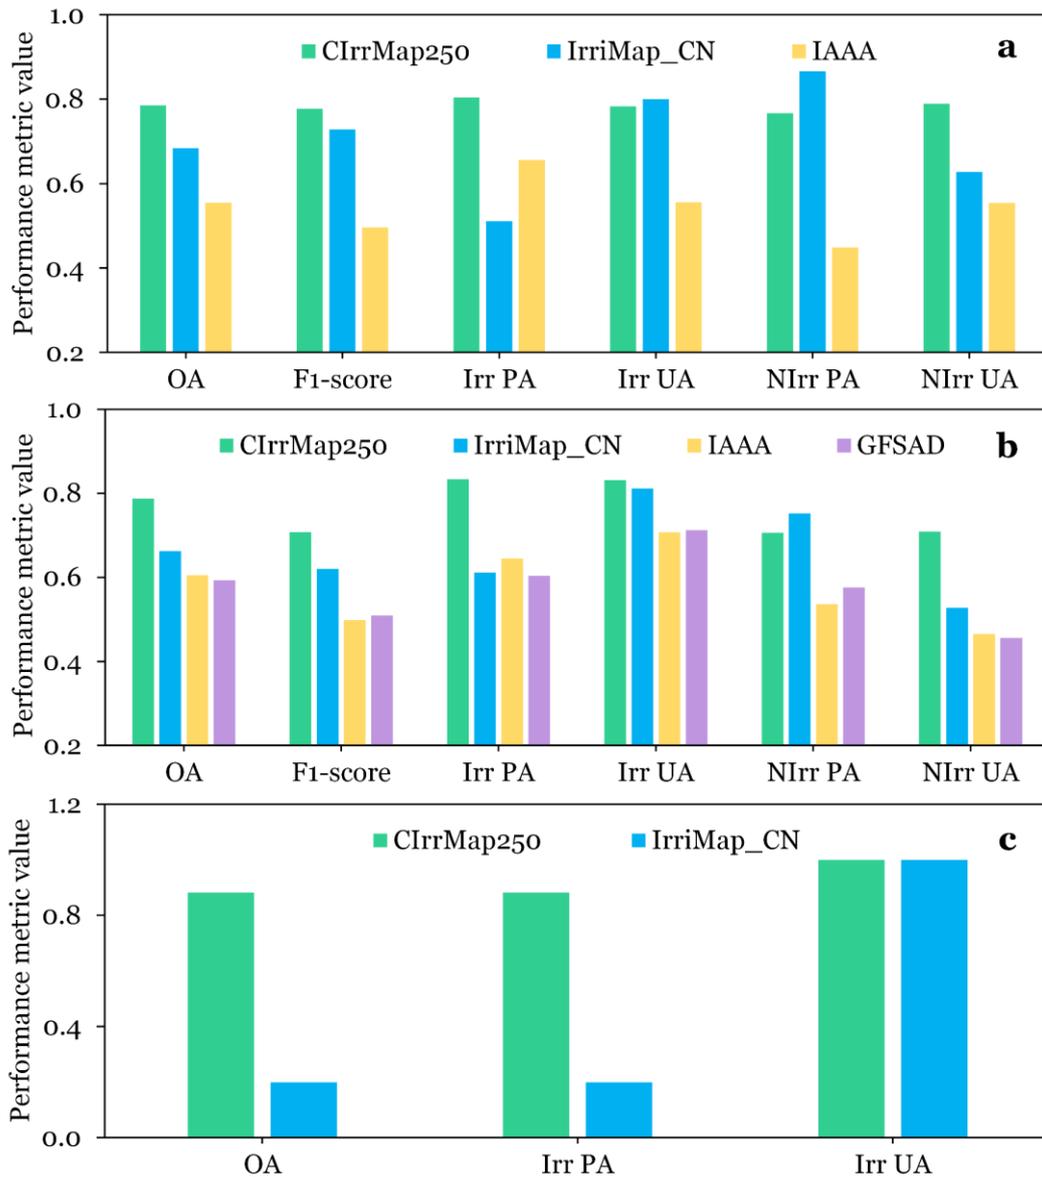

## 425 4 Results

### 4.1 Accuracy assessment ~~of irrigated cropland maps~~

#### 4.1.1 Pixel-scale assessment

As ~~depicted~~ shown in Figure 3 and Supplementary Table ~~S5~~ S6, CIrrMap250 attains an OA and F1-score of 0.79 and 0.78,  
 respectively, for the year 2000, surpassing the performance of IrriMap\_CN and IAAA. In the year 2010, CIrrMap250 achieves  
 430 a high OA of 0.79 and a F1-score of 0.71, whereas the existing maps attain OA values below 0.66 and F1 scores under 0.63.  
 For the year 2020, CIrrMap250 detects 88% of ~~the fields with~~ center pivot ~~irrigation systems~~ irrigated fields, while IrriMap\_CN  
 identifies only 20% (Figure 3c and Supplementary Figure ~~S1~~ S2). Note that both CIrrMap250 and IrriMap\_CN achieves a  
perfect user’s accuracy in 2020 mainly because all the reference points are irrigated samples (Section 3.31 and Supplementary  
Table S7). For irrigated samples, CIrrMap250 has significantly higher producer’s accuracy in 2000, 2010, and 2020, compared  
 435 to the existing products. CIrrMap250 and IrriMap\_CN performs similarly in user’s accuracy. For non-irrigated samples, the  
 producer’s accuracy of CIrrMap250 is relatively slightly lower than that of IrriMap\_CN, but the user’s accuracy is significantly  
 higher than that of IrriMap\_CN. In terms of producer’s accuracy and user’s accuracy, both CIrrMap250 and IrriMap\_CN  
~~obviously~~ outperform IAAA and GFSAD.

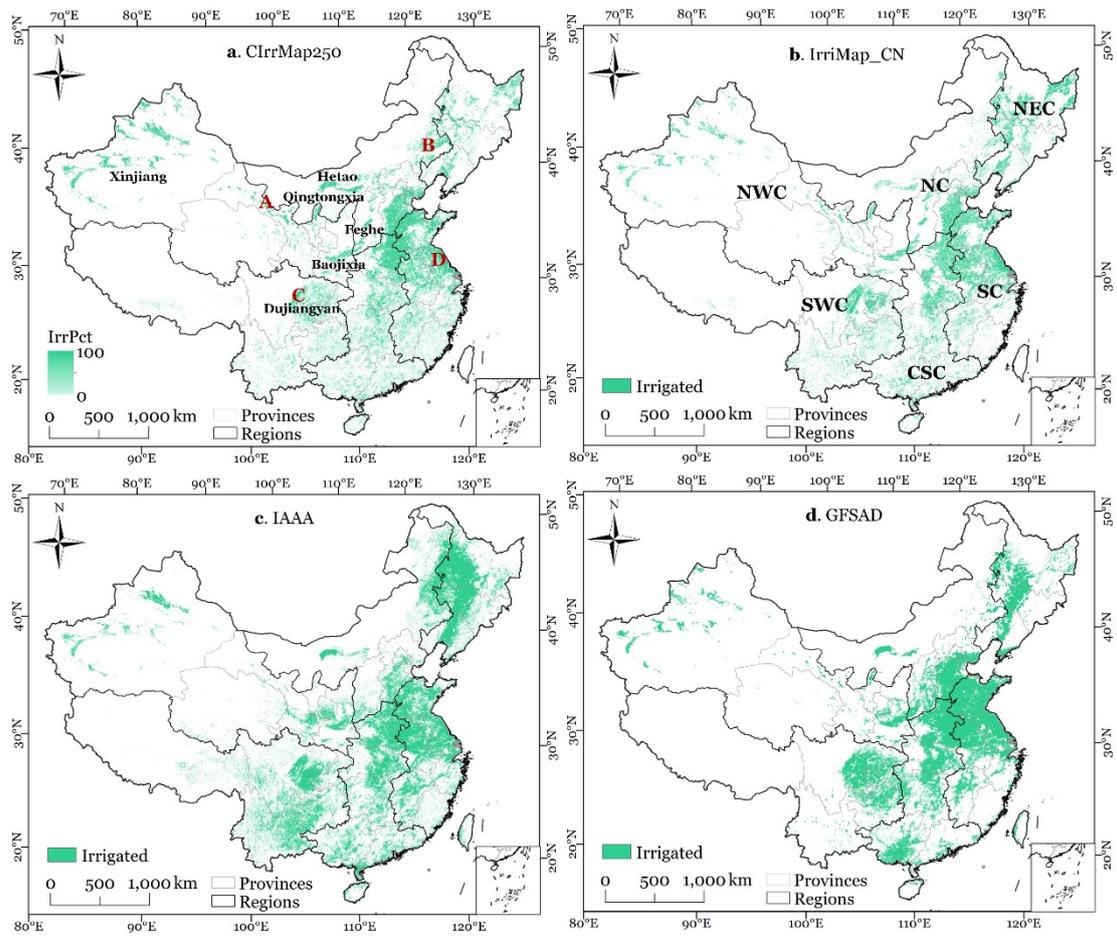

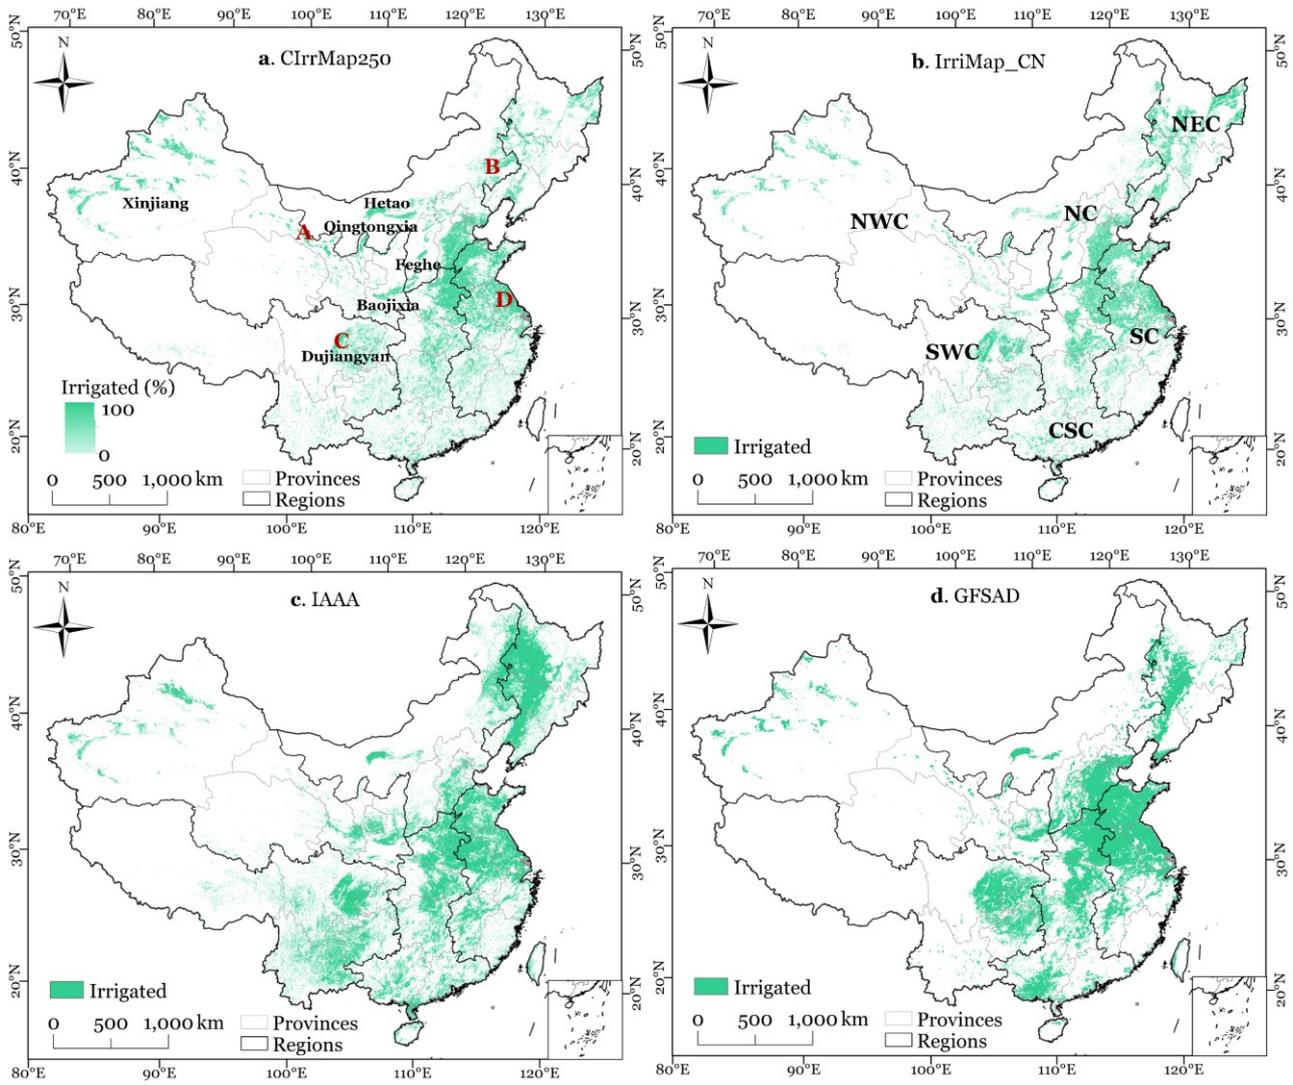

**Figure 3. Performance of CIrrMap250 and the existing irrigation maps (IrriMap\_CN, IAAA, GFSAD).** Panels a, b and c show the results for 2000, 2010, and 2020, respectively. OA, PU, and UA represent overall accuracy, producer's accuracy, and user's accuracy, respectively. Irr and NIrr indicate irrigated and non-irrigated samples, respectively.

#### 445 4.1.2 Nationwide and regional comparison with existing products

Figure 4 ~~compares~~shows the spatial distribution of irrigated cropland ~~in CIrrMap250 with the existing~~from different maps. At the national scale, CIrrMap250 and IrriMap\_CN, specifically developed for China, ~~can~~capture similar irrigation patterns. ~~Irrigation~~They both show some irrigation hotspots (e.g., North China Plain and Northwest China) and well-known irrigation districts like Hetao, Baojixia, Dujiangyan, Qingtongxia, and Fenhe ~~are consistently identified by these maps. The irrigated~~  
450 ~~croplands depicted by. However,~~ CIrrMap250 ~~are~~shows more ~~widely distributed~~widespread irrigation than ~~those portrayed~~  
~~by IrriMap\_CN across the majority in most areas~~ of China (Supplementary Figure S2). ~~CIrrMap250 yields~~S3. IrriMap\_CN ~~estimates~~  
estimates irrigation ~~ratios~~proportion (i.e., the ratio of irrigated cropland area to ~~the~~ total cropland area) ~~often~~to be 0.5847, 0.7037,  
and 0.96, ~~respectively~~,61 for China, Northern China, and Xinjiang Uygur Autonomous Region. ~~These values, respectively~~  
(Supplementary Figure S4). In comparison, the values derived from CIrrMap250 are 0.58, 0.70, and 0.96, respectively, which  
455 align more closely with the ~~reality and the official report~~reports (<https://gtdc.mnr.gov.cn/>), ~~in comparison to those derived from~~  
~~IrriMap\_CN, which are only 0.47, 0.37, 0.61, respectively (Supplementary Figure S2). However,~~ Nevertheless, CIrrMap250  
tends to yield lower estimates of irrigation area in Northeast China (NEC) when compared to IrriMap\_CN, ~~possibly due to~~  
inaccurate statistical and survey data in this region. In contrast to CIrrMap250 and IrriMap\_CN, IAAA notably underestimates  
irrigated croplands in Northwest China (NWC) and North China (NC), but overestimates ~~them~~ in NEC and Southwest China  
460 (SWC). This could be explained by the fact that IAAA was developed using unsupervised classification (Siddiqui et al., 2016),  
limiting its ability to characterize the spatial heterogeneity of irrigation in China (Tian et al., 2024). GFSAD shows  
overestimations of irrigated area in the Dujiangyan district and the North China Plain, but exhibits evident omission errors in  
sparsely distributed irrigation regions like NWC and ~~the southern part of~~ South China (SC). The large bias of GFSAD is  
understandable, as it is not an irrigation-specific product and only covers five irrigated crops (Thenkabail et al., 2016; Xie et  
465 al., 2021).

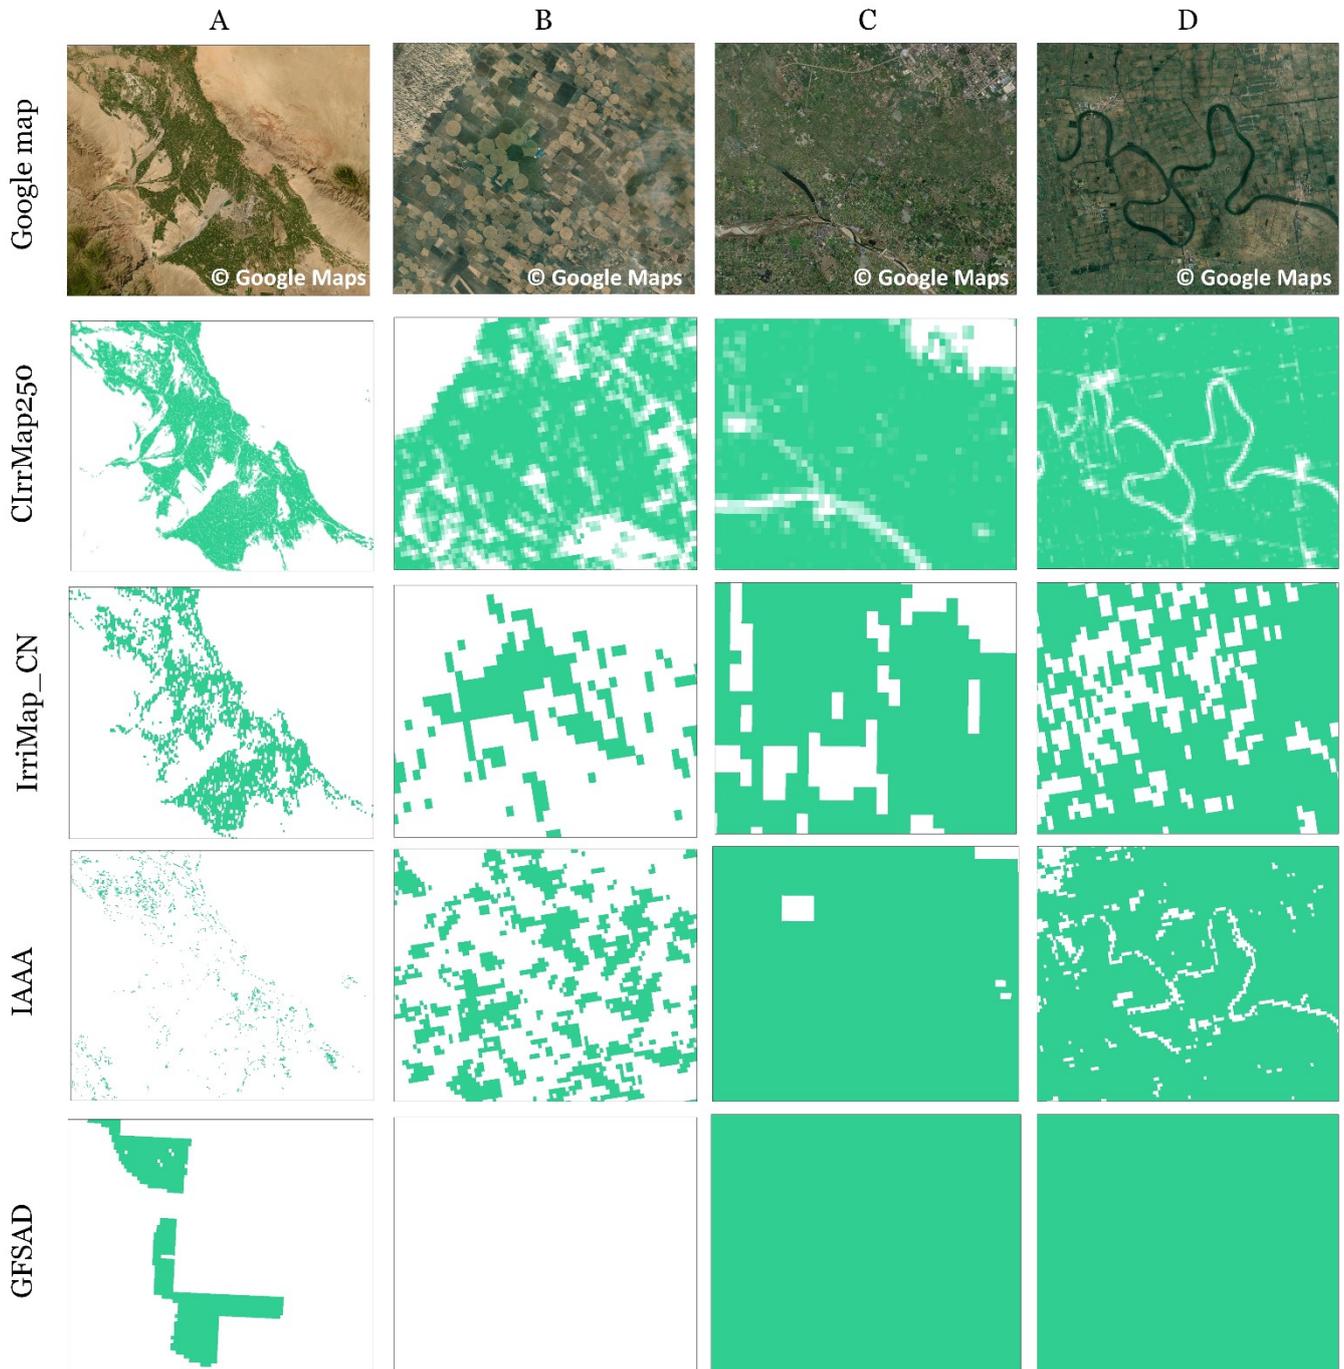

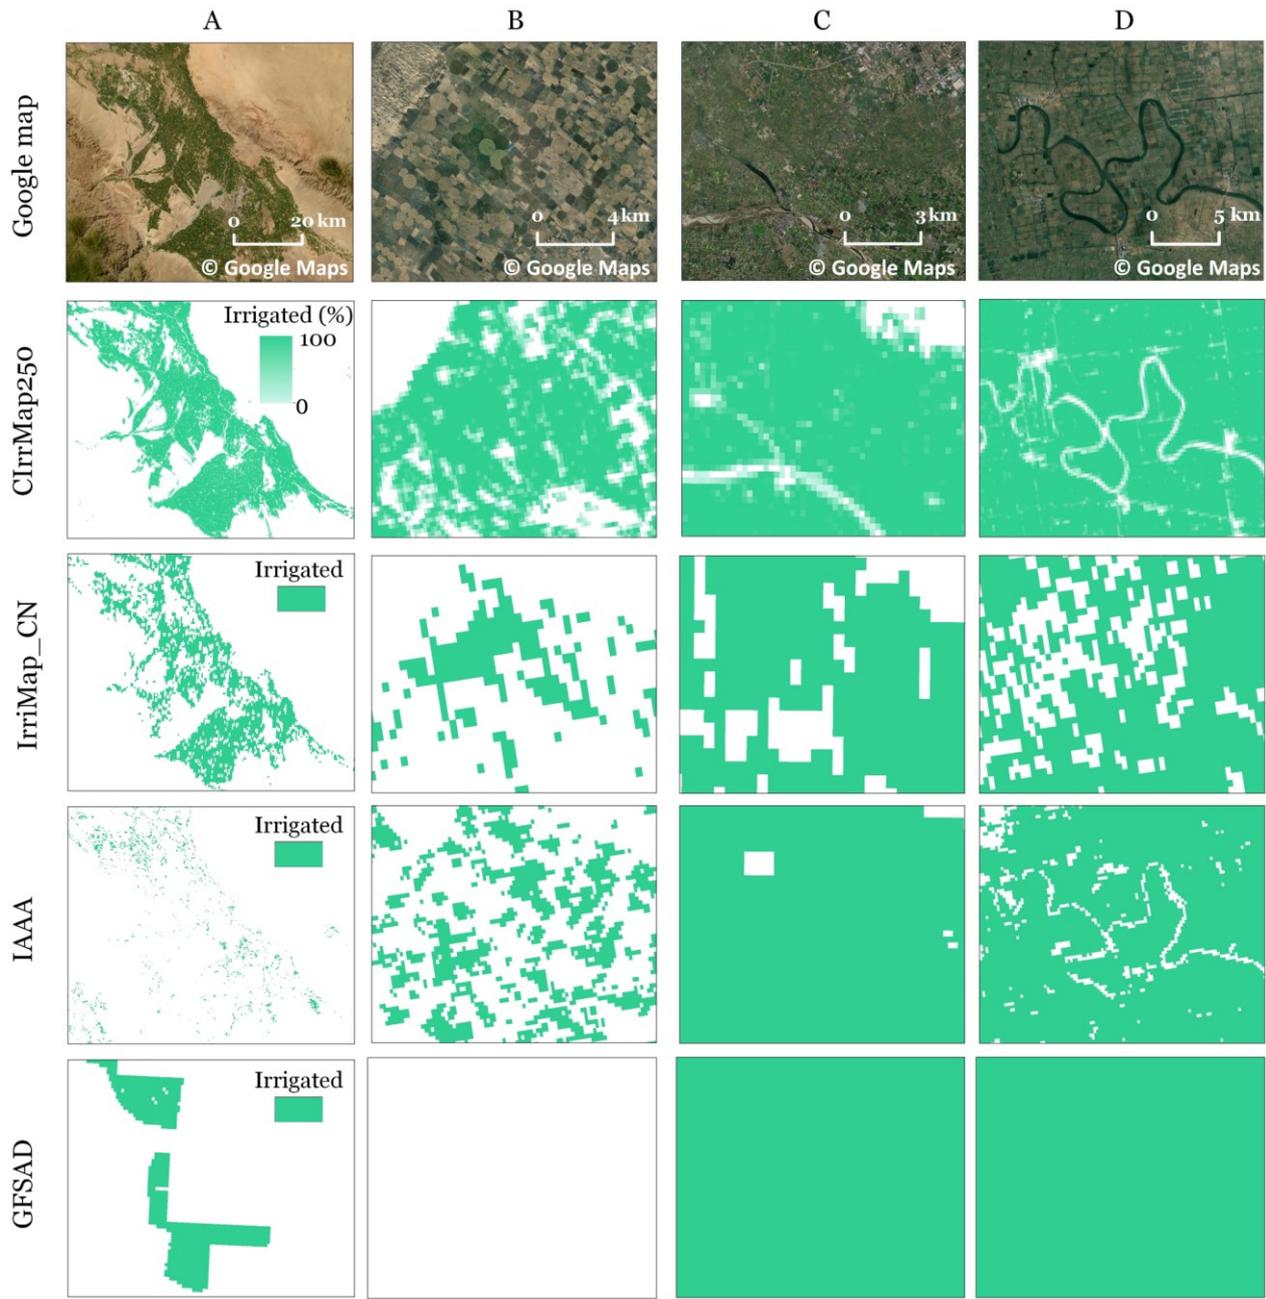

**Figure 4. Spatial distribution of irrigated cropland infrom different irrigation-maps for the year 2010. NEC, NC, NWC, SWC, SC and CSC are the abbreviations of represent Northeast China, North China, Northwest China, Southwest China, South China, and Central South China. IrrPet represents the proportion of irrigated cropland relative to the total area of a grid cell. —, respectively.**

We further compared ClrrMap250 with ~~the~~ existing maps in four heavily irrigated zones (A-D locations are shown in Figure 4a). Zones A and B are situated in arid regions where crop growth depends greatly on is not possible without irrigation, while Zones zones C and D are located-in humid regions where paddy rice is extensively cultivated widespread and relies heavily on supplemental irrigation. As depicted shown in Figure 5, ClrrMap250 accurately portrays the actual distribution of irrigated cropland in these zones. In contrast, IrriMap\_CN underestimates irrigation extent in zones A and B and lacks detailed information on irrigated cropland-in zones C and D. IAAA significantly underestimates the irrigated irrigation area in zone A,

480 incorrectly identifies ~~irrigated cropland~~ in zone B, and overestimates irrigated cropland in region C. The GFSAD product, with a relatively coarse resolution of 1 kilometer, haskm, shows the lowest agreement with ~~the distribution of actual irrigated~~ cropland among the four other maps.

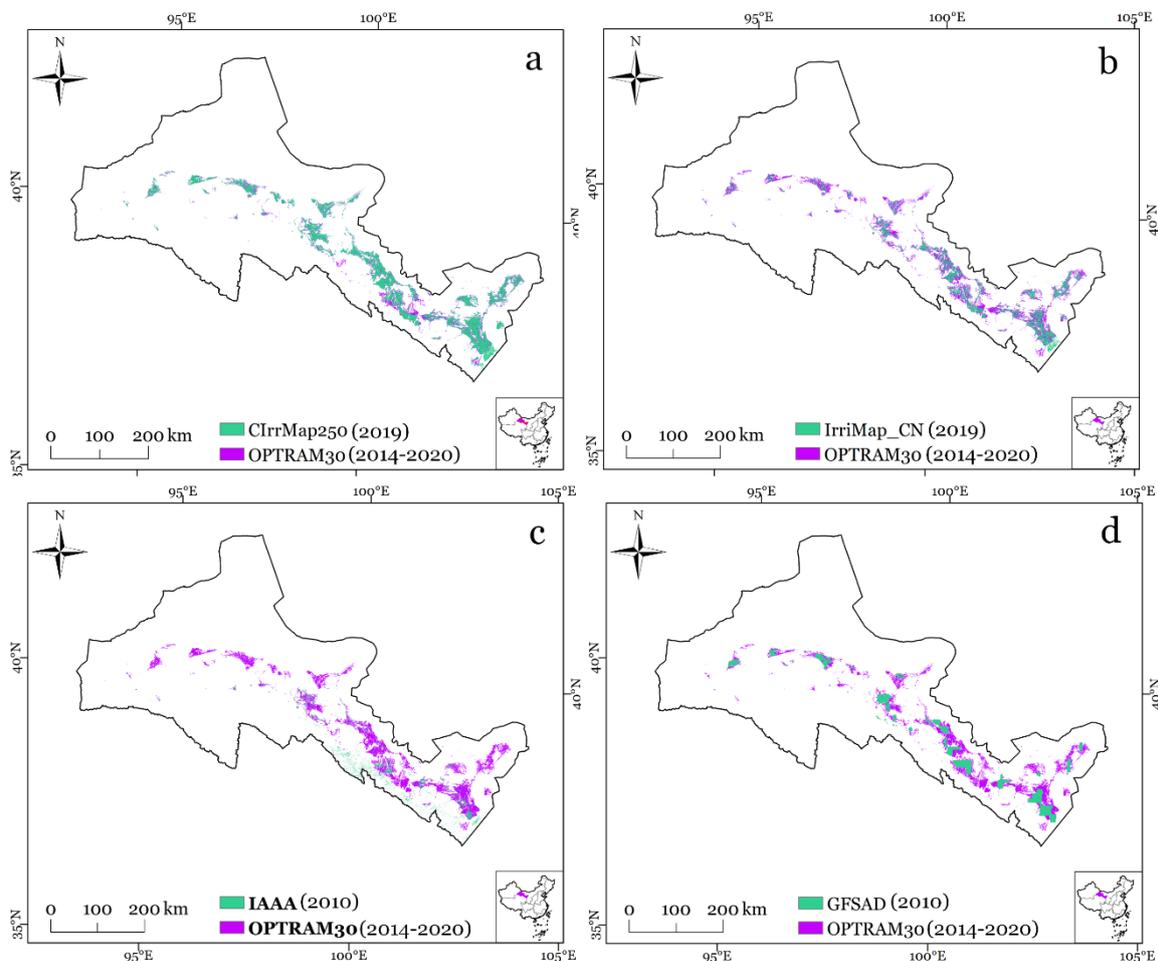

485 **Figure 5. -Visual comparison of C IrrMap250 with the existing maps.** The five rows from top to bottom correspond to the Google map, C IrrMap250, IrriMap\_CN, IAAA and GFSAD, respectively. Locations of the four selected zones are presented in Figure 4a.

and GFSAD, respectively. When examining Locations of the four selected zones are presented in Figure 4a.

490

Figure 6 provides an additional comparison of the aforementioned large-scale irrigation maps with the field-scale remote sensing irrigation map (OPTRAM30) in the Hexi Corridor of Northwest China. (Figure 6). CrrMap250 exhibits a robust high agreement with OPTRAM30 in mapping irrigated cropland. While IrriMap\_CN captures the general pattern of irrigated croplands patterns, it tends to underestimate the overall irrigation extent of irrigated cropland in this, as demonstrated in zones I and II of the region. In contrast, (Figure 6d). The IAAA product struggles to identify irrigated cropland in this area, displaying significant omission and commission errors. Similarly, GFSAD has a limited ability to accurately depict irrigated areas in the Hexi Corridor.

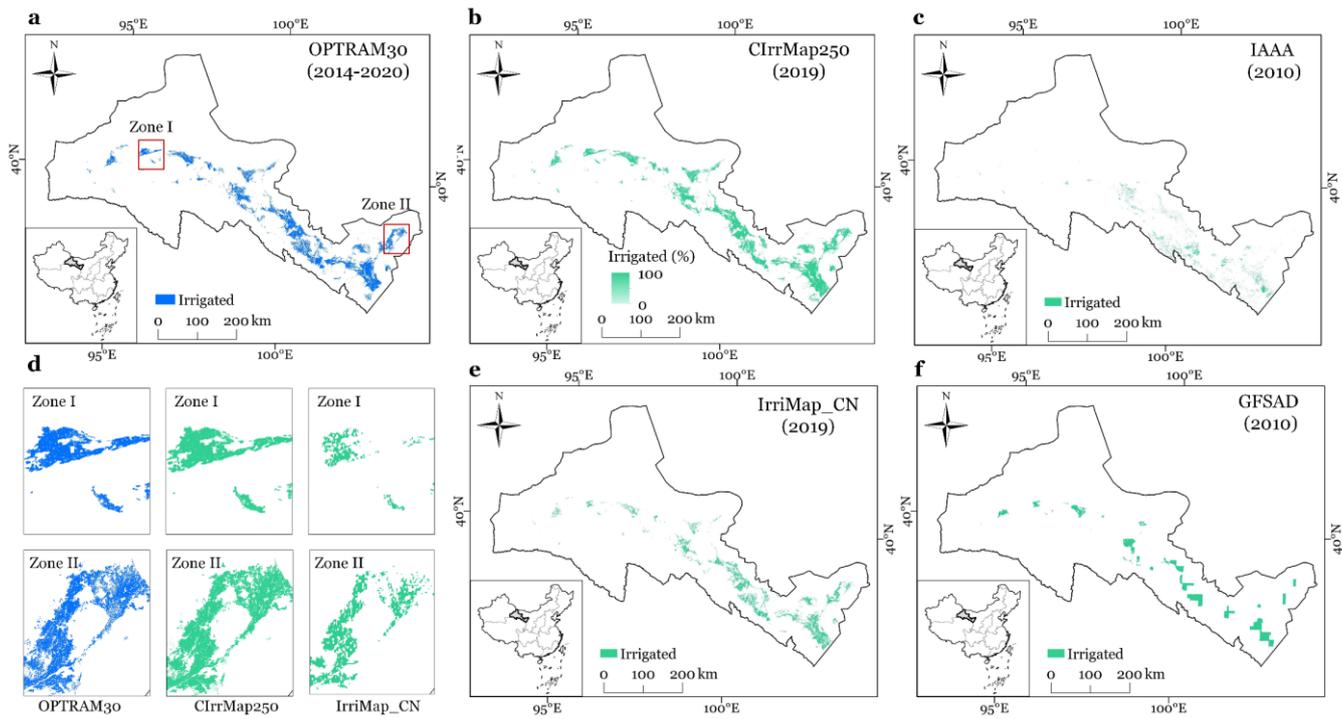

Figure 6. Comparison of large-scale irrigation maps (**CIrrMap250**, **IrriMap\_CN**, **IAAA**, **GFSAD**) with the field-scale remote sensing irrigation map (**OPTRAM30**) in the Hexi Corridor of Northwest China. Panels a, b, c, e, and f depict the distribution of

4.1.3 Comparison irrigated area-cropland in OPTRAM30, CIrrMap250, IAAA, IrriMap\_CN, and GFSAD, respectively. Panel d shows the comparisons of CIrrMap250 and IrriMap\_CN with OPTRAM30 in two local zones.

#### 4.1.3 Comparison high-resolution with irrigation water use data

As illustrated in Figure 7, there is a good correlation between the the CIrrMap250-estimated irrigated area and the irrigation water withdrawal. Changes in irrigated area determined by areas exhibit a notable correlation with irrigation water withdrawals. Irrigation area changes derived from CIrrMap250 account for approximately 50% and 60% of the variance in irrigation water withdrawals for the years circa 2010 and 2020, respectively. In contrast, changes variations in irrigated areas derived area obtained from IrriMap\_CN can only explain 40% and 48% of the variance in irrigation water withdrawals for the same periods, namely 2010 and 2020. The, respectively. As shown in Figures 7c and f, the irrigated area estimates of irrigated areas from the other two maps, namely (i.e., IAAA and GFSAD, are able to explain) demonstrate limited explanatory power, explaining only a small proportion 12% and 20% of the variances variation in irrigation water-withdrawals (i.e., 0.12 and 0.20), suggesting

a relatively low performance of these maps in China for the year 2010. These results indirectly imply the better a superior performance of CIrrMap250 over the existing irrigation maps.

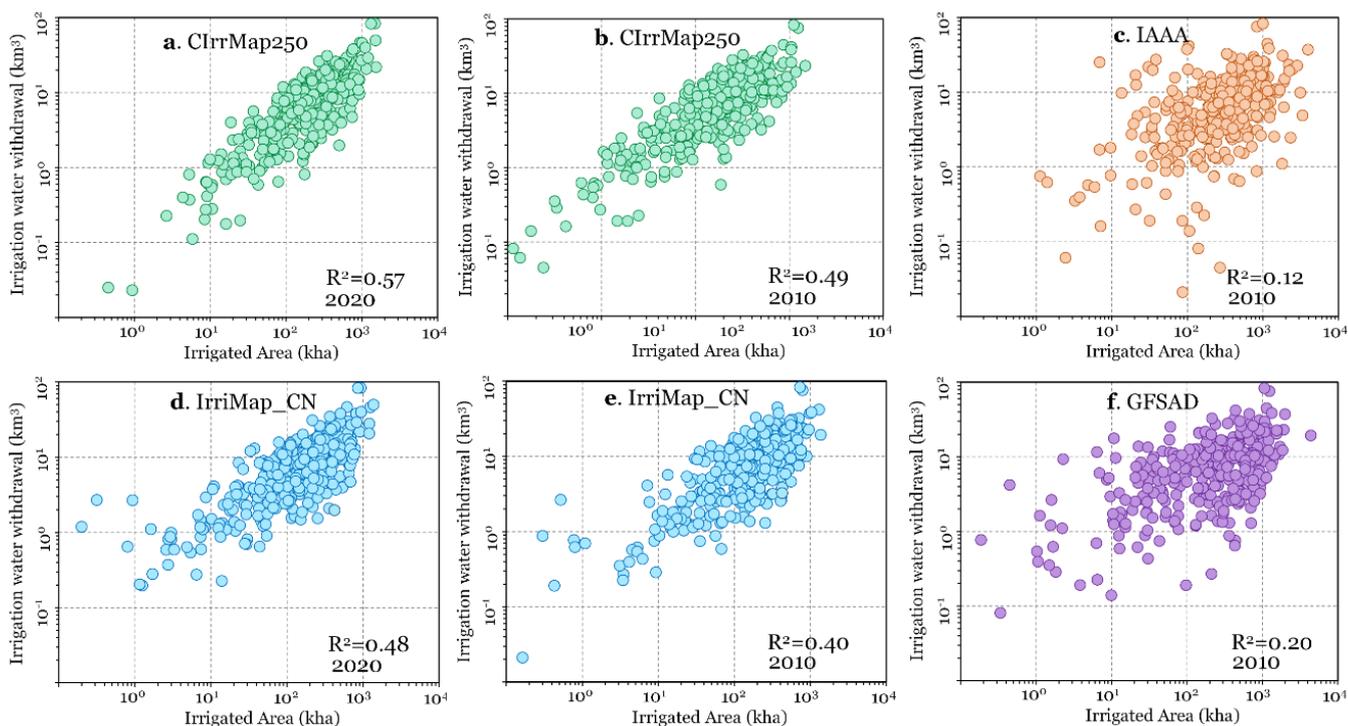

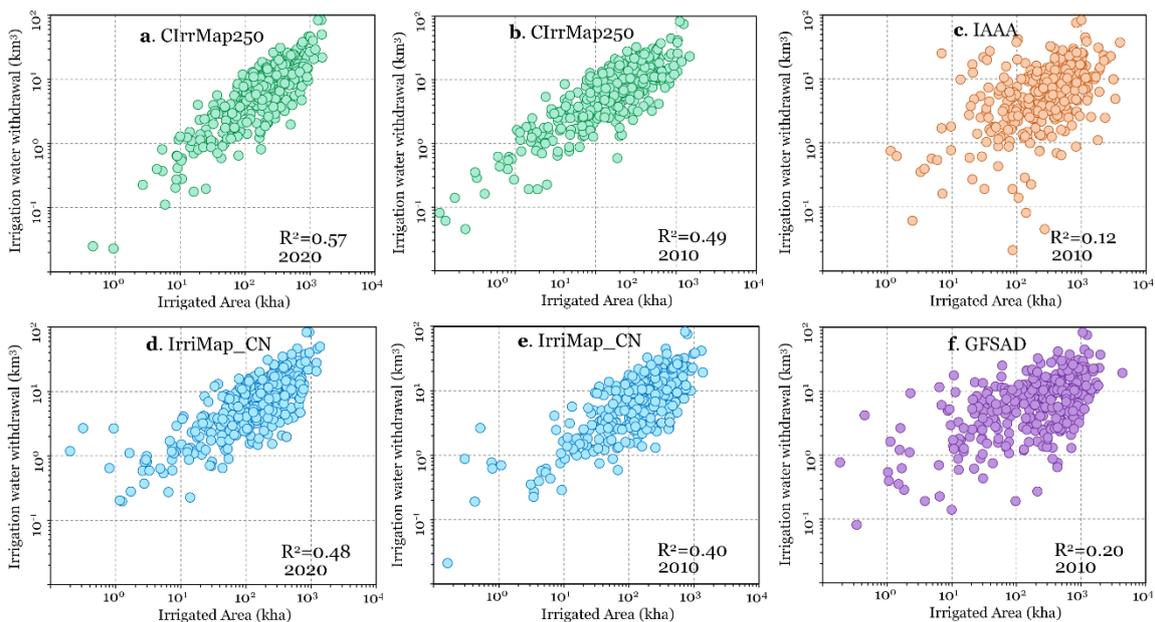

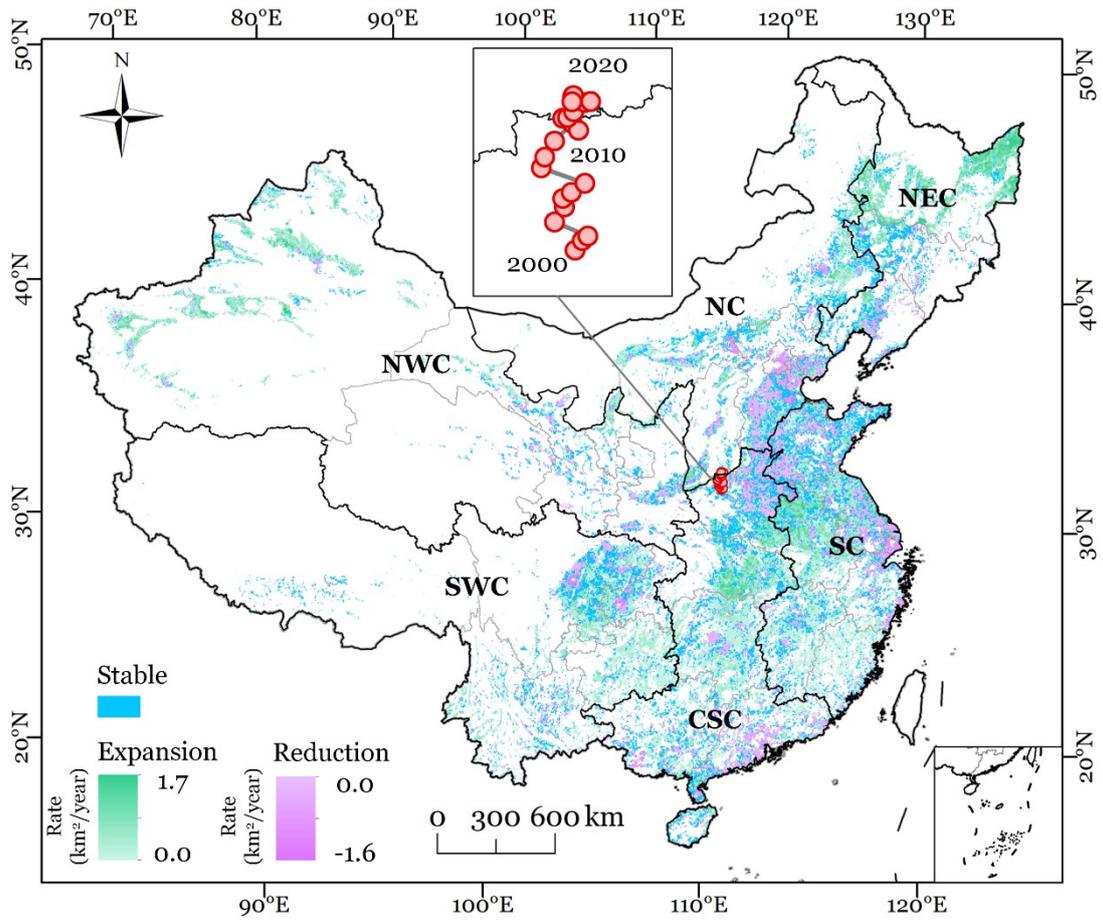

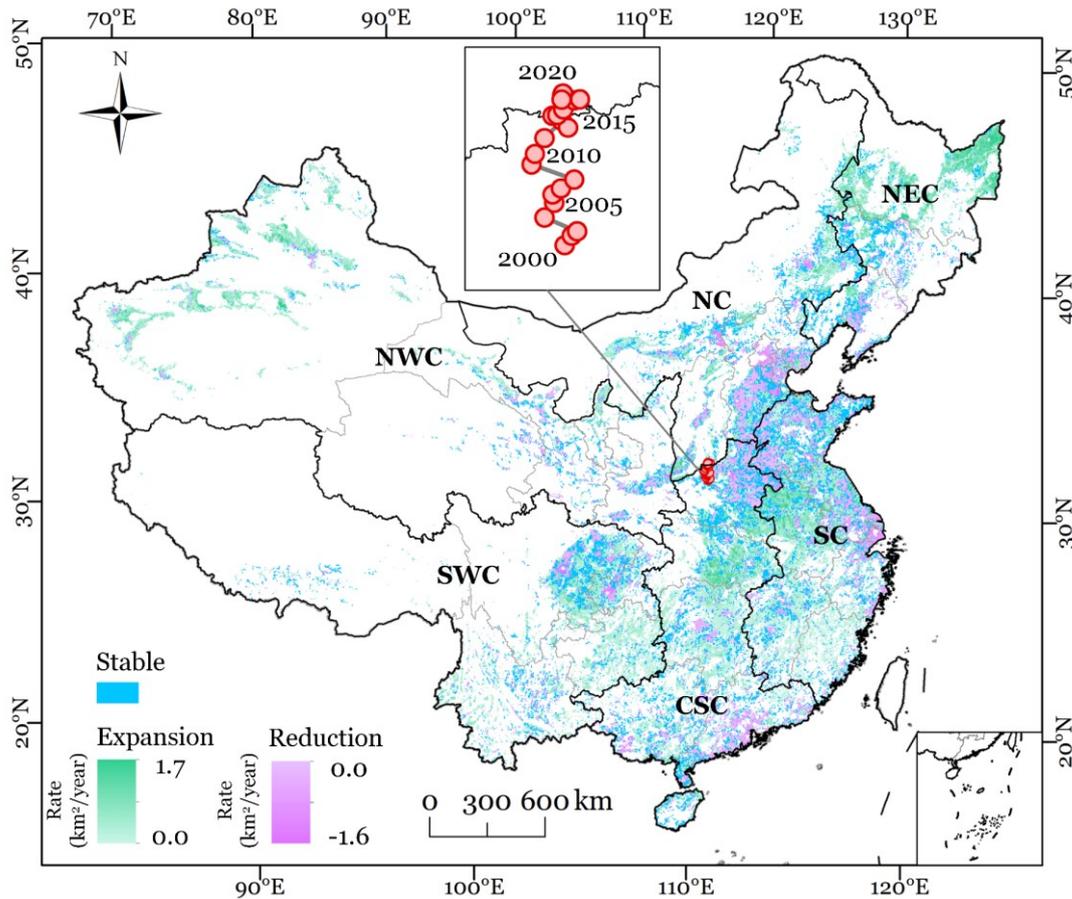

Figure 7. Scatterplots of ~~irrigated area estimates against~~ irrigation water withdrawals against irrigated area estimates from different products for the years circa 2010 and 2020.- The data are presented in logarithmic units to reflect both small and large values.

#### 520 4.2 Spatiotemporal changes of irrigated croplands

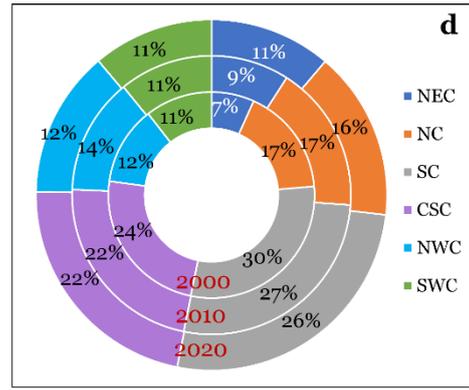

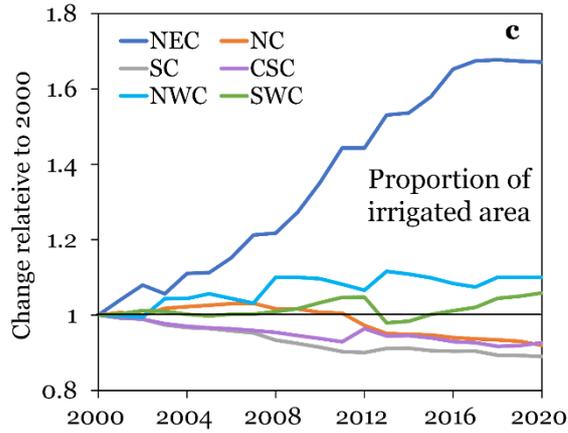

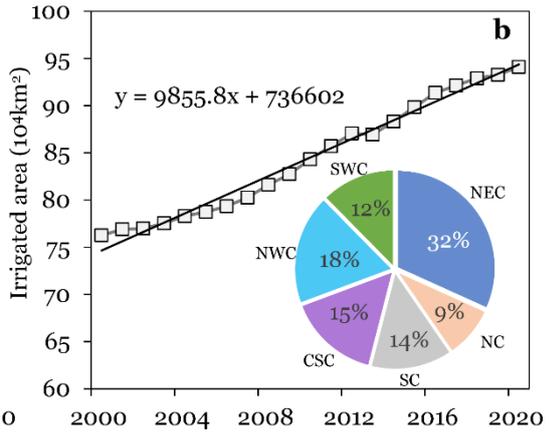

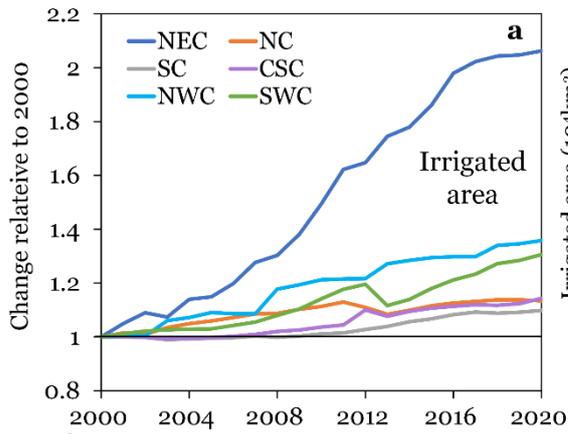

As depicted in Figure 8, ~~irrigated our CIrrMap250 revealed that irrigation area expands~~ expanded significantly in NEC and NWC from 2000 to 2020. Conversely, ~~it reduced notably~~ notable decreases in irrigated areas were identified in the northern parts of SC and CSC, the northeastern part of SWC, and the southern parts of CSC and NC. The decline in irrigated areas ~~tend~~ tended to be concentrated in populous areas, ~~which can be~~ attributed to the rapid urban expansion on ~~large areas of~~ cropland (Zhang et al., 2024). The gravity center of ~~gravity for irrigated area is~~ irrigation was situated on the border of NC and CSC, and ~~exhibit~~ exhibited a noticeable northward shift ~~from 2000 to 2020 during the study period~~. This northward ~~spatial trend in irrigated area~~ is likely to exacerbate the water crisis in Northern China (Li et al., 2023), which has only 20% of China's water resources but supports more than half of its population. The gravity center showed clear trends in NWC, NEC, and NC but was insignificant in the remaining subregions (Supplementary Figure S5). In NWC, irrigation significantly shifted to the northwest, while in NEC, it significantly shifted to the northeast. Meanwhile, there was a northward spatial trend in irrigation in NC.

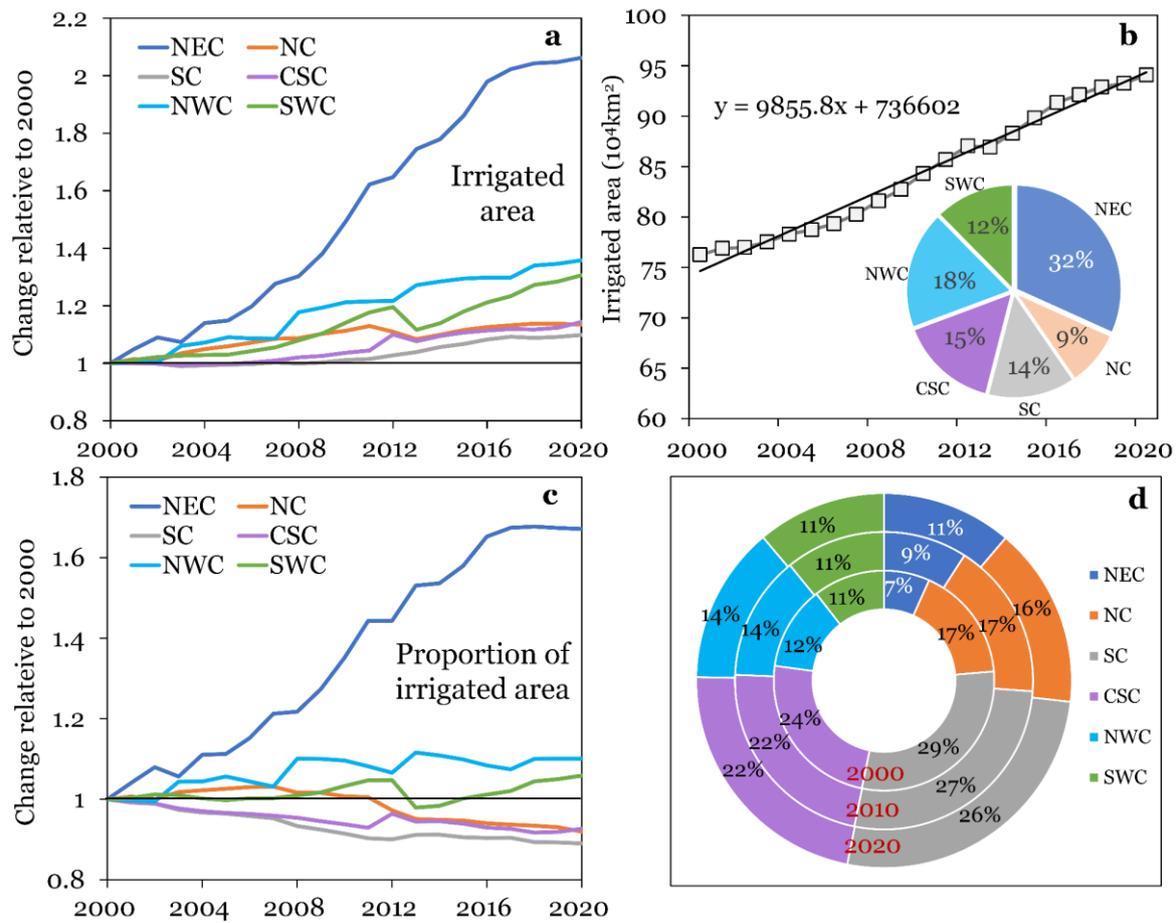

**Figure 8. Spatiotemporal changes in irrigated area from 2000 to 2020.** Pixels ~~with exhibiting~~ significant ~~increasing or~~ ~~decreasing trend~~ ~~interannual trends~~ ( $p < 0.05$ ) ~~marked in irrigated area were labelled~~ as “expansion” or “reduction”, while those with insignificant changes ~~are denoted~~ as “stable”. Pixels with ~~less than~~ 5% irrigated croplands were excluded from the map. ~~Inserted~~ ~~The inset~~ panel on the top of the figure depicts the center-of-gravity movement (~~spatial trend~~) of ~~China’s irrigated~~ ~~area areas at the national scale~~.

As shown in Figure 9, ~~our annual irrigation maps indicated that~~ all subregions ~~exhibit~~ ~~exhibited~~ an increasing trend in irrigated area from 2000 to 2020, with NEC expanding significantly faster than the other subregions. ~~The irrigated area of China increases~~ ~~More specifically, China’s irrigation aera increased~~ from ~~750~~ ~~about 760,000~~ to ~~950~~ ~~940,000~~ km<sup>2</sup> at ~~the an annual~~ rate of ~~about~~ 10,000 km<sup>2</sup>/year (or 1.29%/year). ~~Notably, NEC and NWC contribute to about half of this expansion.~~ Despite the ~~consistent overall~~ upward trend ~~in irrigated area, the relative,~~ changes in the proportion of irrigated areas, ~~in relation to China’s total irrigated area, are inconsistent across different subregions.~~ ~~The proportion of irrigated area in NEC area varied~~ ~~by subregion - upward trends in NEC and NWC and NWC shows an upward trend, whereas that decreasing~~ in SCS, SC, and NC ~~displays a downward trend.~~ SC ~~has accounted for~~ the largest proportion of irrigated cropland ~~in China~~ (26%-~~30~~29%), followed by CSC (22%-24%), NC (16%-17%), NWC (12%-14%), SWC (11%), and NEC (7%-11%).

550 **Figure 9. Changes in irrigated area across the six subregions of China during 2000-2020. a,** Relative changes in irrigated area. **b,** Changes in China's total irrigated area, with the contribution of different subregions depicted in the inserted pie chart. **c,** Relative changes in the proportion of irrigated area. **d,** Proportion of irrigated area for the years 2000, 2010 and 2020.

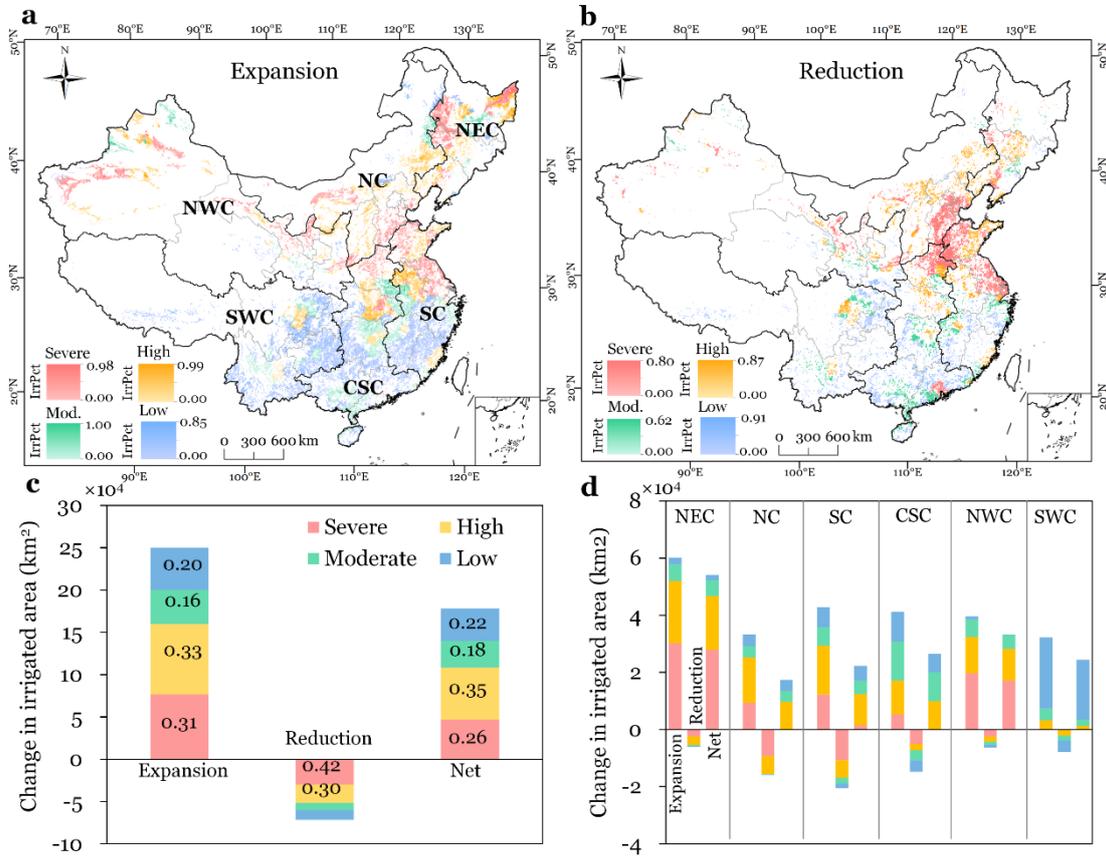

### 4.3. Irrigated cropland Irrigation changes under different water stress levels

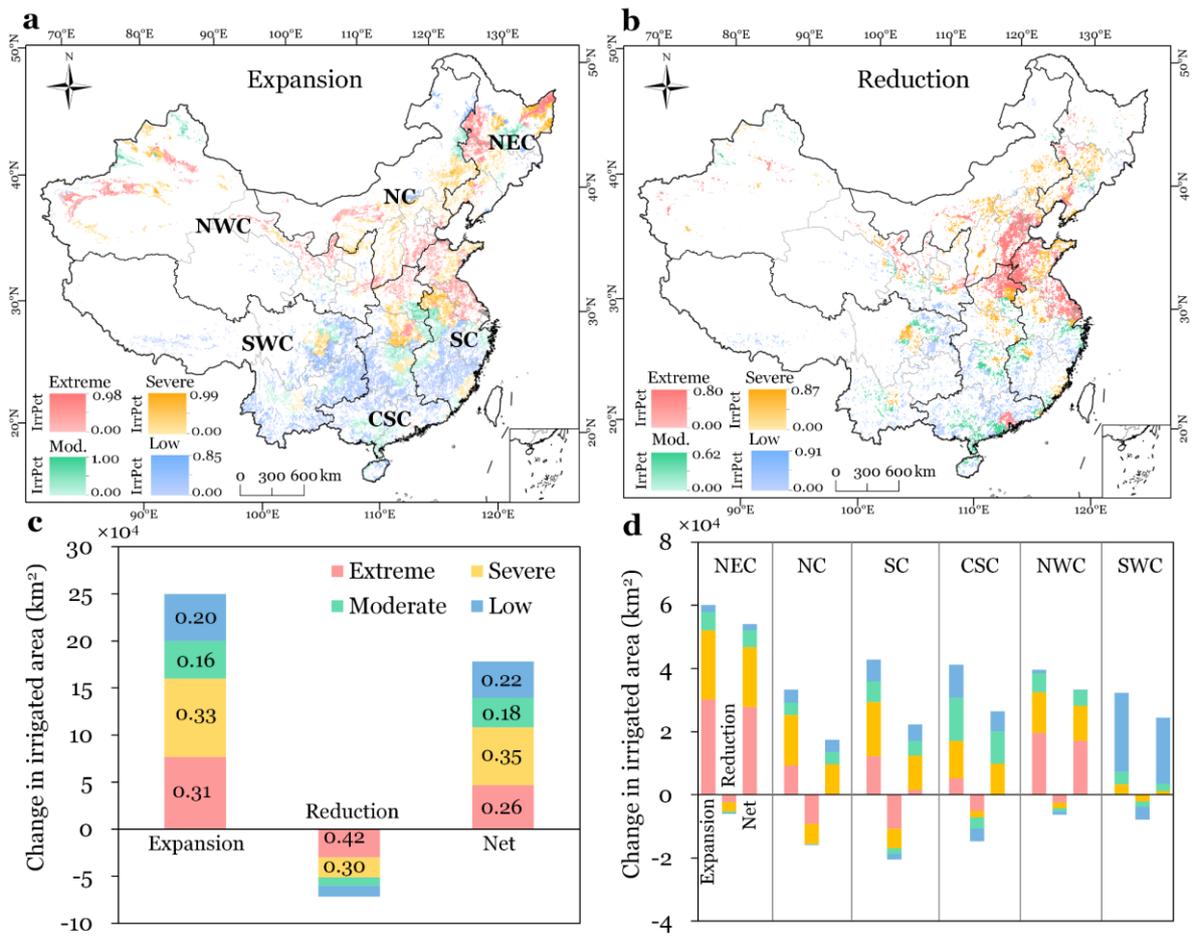

555 Figure 10 shows the irrigation changes in irrigated cropland under different levels of water stress levels. We find a gross irrigation expansion of irrigated area by about ~250,000 km<sup>2</sup> in China from 2000 to 2020, of which 64% is unsustainable from the perspective of water resources and has been in regions with high to severe to extreme water stress. The expansion of irrigated area is mainly situated in NWC, NEC, NC, and the northern parts of CSC and SC. The gross reduction in irrigated area is about 70,000 km<sup>2</sup>, of which 72% has been sustainable and located in regions with high to severe to extreme water stress. These and could be considered as sustainable. This sustainable reduction in irrigated area was primarily located in NC, CSC and SC, mitigates that partly mitigated the unsustainable irrigated cropland expansion in the regions. The

560

net expansion of irrigated area iswas about 180,000 km<sup>2</sup>, of which 61% iswas water unsustainable. The subregions NEC and NWC havehad a larger proportion of unsustainably expanded irrigated area compared to other subregions, accounting for about 70% of China's net unsustainable irrigation expansion. In contrast, the subregions CSC and SWC have a greater proportion of sustainably expanded irrigated area sustainable expansion than in other subregions due to the abundance of water resources and lower water stress there.

565

**Figure 10.** Changes in irrigated area between 2000 and 2020 under different water stress levels. Panels a and b show the spatial distribution of gross expansion and reduction in irrigated areas, respectively, under four categories of water stress (i.e., low, moderate, severe, and extreme). Panel c and d show the gross and net changes in irrigated area by water stress category for China, while panel d presents the results for the six subregions.

## 575 5 Discussion

### 5.1 Improvement of CIrrMap250 over existing products

Our CIrrMap250 product provides annual maps of China's irrigated cropland from 2000 to 2020, exhibiting higher accuracy compared to existing products. The improved performance of CIrrMap250 can be attributed to several key factors. First,

CIrrMap250 has digested unprecedentedly detailed ~~irrigated area~~irrigation statistics and reliable national land surveys, and  
580 ~~meanwhile at the same time~~, has ~~considered discrepancy been reconciled the discrepancies between~~ statistical/survey data and  
remote sensing data. We compiled county-level statistical data for ~~over~~ 80% of provinces in China, along with prefecture-level  
data for the remaining provinces. These datasets, for the first time, were harmonized with ~~the national land surveys~~China's  
~~National Land Surveys~~, greatly reducing the errors and uncertainties in ~~irrigated area~~reported statistics. The harmonized  
irrigated area data were further adjusted to reconcile the statistical/~~surveyed data with remote sensing data~~. ~~The reconciliation~~  
585 ~~was necessary because statistical and surveyed irrigated area represents the net extent of irrigated cropland, whereas remote~~  
~~sensing derived irrigated area indicates the gross extent. Without adjusting the original irrigated area statistics~~survey data with  
~~remote sensing data to account for their inconsistency. Without data harmonization and reconciliation~~, the irrigation extent  
would be significantly underestimated, leading to a decrease in irrigation mapping accuracy by 8%-26% (Supplementary  
Figure S4S6).

590 Furthermore, CIrrMap250 ~~describes irrigated cropland distribution through~~ ~~considered the~~ fractional coverage of  
~~cropland within coarse-resolution pixels~~, rather than ~~the using~~ binary ~~approach adopted~~ ~~cropland masks~~ in most existing  
products. The majority of farms in China are small and fragmented. ~~For instance, in the year 2020, we~~ ~~We~~ observed that ~~about~~  
37% of ~~the 250-m~~China's cropland grids ~~were occupied by less than half of croplands in China, while less than had cropland~~  
~~proportions below 50% for the year 2020, and only~~ 40% of cropland grids ~~were occupied by more than 90% of~~  
595 ~~croplands showed cropland proportions above 90%~~. Therefore, it becomes crucial to consider the fraction coverage of cropland  
in cropland masks for ~~the purpose of~~irrigation mapping ~~irrigated areas~~. ~~We~~. ~~To underscore this necessity, we~~ conducted an  
additional ~~irrigation mapping~~ experiment, ~~in which~~ ~~wherein we adopted~~ the 250-~~m~~ cropland ~~maps were~~ ~~masks that~~ described  
~~cropland distribution~~ in a binary manner ~~and resampled from the 30-m hybrid cropland product~~. (i.e., each pixel was classified  
~~as either cropland or non-cropland~~) for irrigation mapping. As depicted in Supplementary Figure S5S7, a substantial portion  
600 of irrigated cropland would be overlooked if the fractional coverage of cropland ~~is not taken into account~~ ~~were removed~~,  
particularly in South China. The accuracy of the ~~irrigated cropland map~~ ~~final irrigation maps~~ would decrease by approximately  
5%-6% ~~if we used such binary cropland masks~~ (Supplementary Figure S6S8).

605 Lastly, CIrrMap250 has incorporated an irrigation suitability ~~map, derived by combining irrigation suitability values~~  
~~of three influential factors elevation, slope, analysis, based on the premise that irrigated cropland should not only be greener~~  
and ~~aridity index~~ ~~using a weighted average method~~ ~~more productive but also more suitable for irrigation compared to rainfed~~  
~~cropland~~. To demonstrate the importance of integrating irrigation suitability into ~~the~~ irrigation mapping process, we randomly  
generated 250 sets of weights (assigned to the influencing factors) for all provinces in China, resulting in 250 distinct irrigation  
suitability maps. Based on these maps, we then created 250 different irrigated cropland maps for the year 2010 using the  
~~method~~ proposed ~~method of~~in this study. As shown in Supplementary Figure S7S9, regardless of the choice of irrigation  
610 suitability maps, these irrigation maps consistently outperform the baseline irrigation map, which ~~was created using the method~~  
~~in this study but excluded~~ ~~disregarded~~ irrigation suitability during the mapping process. Furthermore, there is a narrow range

(0.75-0.77) in the overall accuracy of these irrigation maps, implying the robustness (low sensitivity) of the mapping method to the use of different irrigation suitability maps.

## 615 **5.2 Uncertainties ~~and~~, limitations, ~~and~~ potential applications of CIrrMap250**

620 Despite the advancements ~~made in~~of CIrrMap250 compared to existing products, we acknowledge several uncertainties and limitations associated with the product. CIrrMap250 was developed by integrating data from multiple sources using a semi-automatic training method, leveraging joint information related to irrigation in each data source. However, each data source inherently presents uncertainties and deficiencies (Shahriar Pervez et al., 2014; Tian et al., 2024)~~Firstly, the accuracy of CIrrMap250 is intricately tied to irrigated~~. Irrigation area statistics ~~Despite our efforts to harmonize irrigation statistics with national land surveys, inherent biases and uncertainties persist~~, in particular, can contain significant uncertainties due to technical and political factors, such as variations in statistical ~~methods~~method and administrative ~~division~~ (Thenkabail et al., 2009; Meier et al., 2018)~~divisions~~, which have not been well characterized. These biases and uncertainties ~~are inevitably reflected~~would manifest in CIrrMap250, since our training samples were derived from these statistics-constrained irrigation maps. In this study, we addressed this issue by merging reported irrigation statistics with independent survey results. Nonetheless, uncertainties related to irrigated areas may remain unresolved in certain regions. For instance, we found considerable discrepancies between the statistical and surveyed irrigation areas in SC and NEC (Supplementary Figure S10a), implying greater uncertainties in these subregions compared to others. Furthermore, the irrigation statistics and surveys were reconciled with remote sensing data to address inconsistencies between the two sources. However, the bias ratio may be

625 inaccurately estimated in the reconciliation process, introducing additional uncertainties to the results.

630 Cropland mask layers used to distinguish cropland from non-cropland are another source of uncertainty. These layers were constructed using our hybrid cropland product (Zhang et al., 2024), which integrates five state-of-the-art remote sensing land use/cover products. This hybrid product significantly reduced uncertainties associated with cropland distribution in China. However, remote sensing-derived cropland data show large uncertainties in southern China. As illustrated in Supplementary Figure S10b, only 27% of croplands on average in SWC, SC, and CSC are consistently identified by remote sensing products, compared to 39% in northern subregions (NEC, NC, and NWC). These uncertainties are reflected in our hybrid cropland product, which shows greater accuracy in the northern subregions than in the southern ones (Supplementary Figure S10c). Meanwhile, the temporal resolution of the cropland layers is five years, which may not accurately capture changes in cropland distribution in regions experiencing rapid changes. The uncertainties and errors in the cropland mask layer, particularly in

635 southern China, could propagate into CIrrMap250.

640 An additional source of uncertainty is the MODIS-derived vegetation indices (i.e., NDVI, EVI, and GI). These indices are prone to data gaps due to cloud and cloud shadow contaminations. In this study, we filled the data gaps by using a simple nearest neighbor interpolation method, which may introduce uncertainties to CIrrMap250. Additionally, irrigated croplands in humid southern China are more sparsely distributed and show weaker contrast with rainfed fields compared to northern China.

645 ~~This makes the peak vegetation indices less effective and more uncertain in distinguishing irrigated from rainfed cropland (Xie et al., 2019; Zhang et al., 2022a) the statistics constrained irrigation maps. Furthermore, . Consequently, our CIrrMap250 product exhibits higher accuracy in NEC, NWC, and NC than in SC, CSC, and SWC subregions (Supplementary Figure S10d).~~

~~\_\_\_\_\_ Lastly, CIrrMap250 has the limitation of a relatively coarse spatial resolution of 250 meters-m and does not fully address the mixed-pixel problem. While the CIrrMap250 offers a higher spatial resolution of CIrrMap250 is higher than many~~

650 ~~existing large-scale irrigation maps, it may still not be applicable to smaller spatial scales (e.g., not be suitable for local applications, such as field or irrigation district levels. The mixed-pixel problem significantly affects the precision of cropland masks (Zhang et al., 2024) scales). In addition, the mix pixel problems could bring uncertainties to our mapping results. Despite the consideration of and weakens the distinction between vegetation indices for irrigated and rainfed cropland. Even though CIrrMap250 considers the fractional average coverage of cropland, CIrrMap250 cannot it does not differentiate between~~

655 ~~irrigated and rain fed/rainfed croplands at the subpixel scales., like many other existing irrigation maps. There are many small and fragmented croplands in the mountainous regions of South China with complex terrain and diverse vegetation types.southern China. CIrrMap250 should be used with caution in these regions/areas due to the wide existence/prevalence of the mixed pixels. The mix pixel problems could not only significantly affect the precision of cropland masks , but also the difference in vegetation indices between irrigated and rainfed cropland.~~

660 ~~\_\_\_\_\_ Despite these limitations, our CIrrMap250 makes a valuable contribution to the field of irrigation mapping and will greatly is poised to significantly support hydrologic, agricultural, hydrological, and climate studies, as well as water resource management in China. Efforts/Ongoing efforts to overcome the above/address these limitations and explore avenues for potential enhancements will undoubtedly improve the accuracy and utility of our irrigation maps in the future. One of the major applications of CIrrMap250 will be estimating irrigation water use or requirements, considering that irrigated area is a~~

665 ~~dominate driver of irrigation water withdrawal (Ozdogan and Gutman, 2008; Puy et al., 2021). Secondly, the spatial detail provided by CIrrMap250 can be integrated into crop, hydrological, and climate models to improve the simulations of water uses and land-atmosphere interactions (Uniyal and Dietrich, 2021; Mcdermid et al., 2023; Yang et al., 2023). This integration will advance our understanding of how irrigation practices influence crop yield, and hydrological and climatic processes from local to nationwide scales. Lastly, CIrrMap250 provides insights into irrigation changes and can assist in optimizing the spatial~~

670 ~~distribution of irrigated croplands (Rosa et al., 2020a; Rosa et al., 2020b), thereby supporting more informed decisions for sustainable water and land use.~~

## 6 Data availability

The annual maps of China's irrigated cropland from 2000 to 2020 (named as CIrrMap250) can be accessed at:

675 <https://doi.org/10.6084/m9.figshare.24814293.v1> (Zhang et al., 2023a). All maps are presented in the GeoTIFF format, with ~~the geographic coordinates using the coordinate of WGS84 reference system.~~ Pixel size is  $0.00225 \times 0.00225$  degree (~250 m

×250 m at Equator). The maps show the percentage of each 250 m pixel that is covered by irrigated cropland (i.e., pixel value = irrigated area / pixel area ×100).

## 680 7 Conclusions

~~This study outlines the development of China, as a big agricultural country with extensive irrigation, underscores the critical importance of developing reliable irrigation maps for sustainable land-water-food nexus management. This study presented new annual maps of irrigated cropland in China spanning from 2000 to 2020, denoted/referred to as CIrrMap250. The new product was These maps were developed by integrating multisource data, including remote sensing data (vegetation indices, hybrid cropland product, and paddy field maps), irrigated area, reported statistics and surveys, and an irrigation suitability map. The integration of these data was achieved through a semi-automatic training approach, which first generated training samples using a threshold calibration method and subsequently employed the random forest algorithm for classifying irrigated and rainfed cropland. We evaluated the accuracy of CIrrMap250 using over Validation against 20,000/720 reference collected from existing literatures and land use maps of the National Land Survey in China. Furthermore, an indirect assessment of CIrrMap250 was carried out using higher resolution data on irrigation water withdrawals. Our CIrrMap250 product was compared to three available large scale samples demonstrated that our irrigation maps (i.e., IrriMap\_CN, IAAA, and GFSAD) as well as a field scale map (i.e., OPTRAM30).~~

~~Results indicated that CIrrMap250 attained an overall accuracy of 0.79-0.88 for the years 2000, 2010 and 2020, surpassing the precision of the existing-achieved high accuracy and outperformed the currently available products. Furthermore, the CIrrMap250 estimated irrigated area can explain 50-60% of the variance in prefecture-level irrigation water withdrawals, and showed a stronger correlation with irrigation water withdrawals than the existing products. The visual comparison covering the entire China. The superiority of our product over existing maps were further confirmed the better performance of CIrrMap250 over the existing products. Leveraging through the assessments using irrigation water withdrawal data and local-scale visual comparisons. Based on the 21 years of data, we found a consistent/clear upward trend in the irrigated area across all subregions of China from 2000 to 2020. Notably, the growth rate in Northeast and Northwest China surpasses that of the remaining subregions. Consequently, the center of gravity of China's irrigated cropland shifted significantly and northward shift in China's irrigation area. The irrigation expansion is particular notable in water-scare regions like Northeast China and Northwest China, potentially exacerbating the water crisis in North China. Over the period from 2000 to 2020, we observed a net increase of about 180,000 km<sup>2</sup> (or 25%) in China's irrigated area. However, a significant portion (61%) of this expansion is deemed unsustainable from a water resources perspective and have been in regions facing high to severe water stress.~~

~~The performance improvement of CIrrMap250 over existing products can be attributed to the digestion of detailed irrigated area statistics and reliable national land surveys, the consideration of discrepancy been statistical/survey data and~~

710 ~~remote sensing data, the description of irrigation cropland distribution through fractional coverage, and the incorporation of~~  
~~irrigation suitability. We anticipate that our C IrrMap250 product scarcity concerns. C IrrMap250 will greatly support~~  
~~hydrologic, significantly enhance agricultural, hydrological, and climate studies, as well as water resource management in~~  
~~China for improved water and land resources management.~~

### Author contribution

715 LZ conceived the research, carried out the experiments, analysed the results, and prepared the manuscript with contributions  
from all co-authors. YX analysed the results, provided the technical support, reviewed and edited the manuscript. XZ and QM  
collected the validation dataset. LB reviewed and edited the manuscript, and supervised the work.

### Competing interests

The authors declare that they have no conflict of interest.

### 720 Acknowledgements

This study is supported by the National Natural Science Foundation of China (42271286 ~~and 41901045~~), ~~and~~ the Youth  
Innovation Promotion Association of Chinese Academy of Sciences (2023454), ~~and Key Research Program of Gansu Province~~  
~~(Grant No. 23ZDKA0004)~~. We greatly appreciate the Ministry of Natural Resource of the People's Republic of China for the  
data provision.
