15 **Abstract**. The hydration products of cement materials can absorb atmospheric CO_2, and this carbonation process provides an

important decarbonization pathway for the cement industry. Global carbon sequestration by cement materials has been reported,

but carbon uptake in different countries remains unquantified. Here, we quantify the national cement carbon uptake from 1928

to 2023 based on 58517 activity level data from 163 cement-producing countries and regions worldwide and 6186 carbonation

parameters from detailed data records of 42 countries, and project their trend to 2024. The global CO_2 uptake by cement

20 materials increases from 7.74 Mt yr^{-1} (95 % confidence interval, CI: 5.84-9.85 Mt CO_2 yr^{-1}) in 1928 to 0.84 Gt yr^{-1} (95 % CI:

0.71-1.00 Gt yr^{-1}) in 2023, and projected to rise to 0.86 Gt yr^{-1} (95% CI: 0.73-1.02 CO_2 yr^{-1}) in 2024. The accumulated CO_2

uptake from 1928 to 2023 is 21.26 Gt CO_2 (95% CI: 17.93-25.17 Gt CO_2), which offsets about 46 % of the cement process

emission (46.06 Gt CO_2) in past 96 years. Simultaneously, the dominance in cement carbon uptake has shifted from the USA,

Japan and some European countries to emerging economies such as China and India, which account for 38.0 % and 9.1 % of

25 total CO_2 uptake, respectively, in the last decade (2014-2023). By analysing the long time-series carbon emission and uptake

of the 42 countries with detailed data, we find they contributed 82.1 % of global cement CO_2 uptake from 1928 to 2023,

including 21 peaked countries and 21 non-peaked countries in cement emissions. The annual carbon offset level (the ratio of

uptake to process emission in a given year) shows a remarkable decrease due to the temporal lag of cement carbon uptake.

This is significant for countries with higher cement imports, for example, the cement industry in Australia and Japan have

30 achieved net-zero when considering the cement carbonation sink. This study provides a precise bottom-up quantification to

cement carbonation sinks at national and global levels. All the data described in this study are accessible at

https://doi.org/10.5281/zenodo.13827861 (Wu et al., 2024).

1 Introduction

The global cement industry is the third largest source of difficult-to-eliminate CO_2 emissions, after load-following electricity

35   and iron and steel (Davis et al., 2018; Shah et al., 2022), accounting for up to 8 % of anthropogenic CO_2 emissions (Cheng et

al., 2023; Farfan et al., 2019). Cement production CO_2 emissions arise from fossil energy inputs (about 40 %) and calcination

of carbonates (mostly $CaCO_3$) induced process emission (about 60 %). As the largest source of carbonate decomposition

emissions, global cement production process emissions in 2023 were about 1.6 Gt CO_2 (Andrew, 2019,

https://zenodo.org/records/11207133). Conversely, cement products such as concrete and mortar are important CO_2 sinks

40   because of their capacity to react with environmental CO_2 (Snæbjörnsdóttir et al., 2020). The carbonation mechanism of cement

is mainly attributed to alkaline hydration products (Xue et al., 2021), such as calcium hydroxide $[Ca(OH)_2]$, calcium silicate

$[(CaO)_3 \cdot xSiO_2]$ and calcium aluminate $[CaO \cdot xAl_2O_3]$, as described by the following equations (Goyal and Sharma, 2020):

$$Ca(OH)_2 + CO_2 \rightarrow CaCO_3 + H_2O \tag{1}$$

$$(CaO)_3 \cdot xSiO_2 + CO_2 \rightarrow xSiO_2 + CaCO_3 \tag{2}$$

45    $$CaO \cdot xAl_2O_3 + xH_2O + CO_2 \rightarrow xAl(OH)_3 + CaCO_3 \tag{3}$$

A substantial fraction of process CO_2 emissions from cement production is reabsorbed on a time scale of 50 years through

natural carbonation of cement materials (Xi et al., 2016). This mineral carbonation could be applied as a low-carbon cement

and concrete production technology, and provide a pathway for permanent CO_2 sequestration (Li et al., 2022).

Carbonation is a crucial pathway for achieving net-zero emissions for the cement industry. Although studies have demonstrated

50   the significant reduction of CO_2 emissions through the use of industrial by-products as substitutes for raw materials (Coffetti

et al., 2022; Kurtis, 2015) and the use of alternative fuels to meet the energy needs (de Lorena Diniz Chaves et al., 2021),

carbon sequestration of cement carbonation plays an essential role to reach the net-zero emission goal for the cement industry.

Therefore, there is an urgent need to scientifically quantify the contribution of cement carbonation in the decarbonization

efforts of the cement industry. Currently, the Roadmap to Carbon Neutrality, published by the Portland Cement Association

55   of the United States (PCA, 2024), highlights that buildings can reabsorb up to 10% of the CO_2 emitted during the cement and

concrete production process, and it underscores the significance of recognizing and validating cement carbonation. The

European Cement Association (CEMBUREAU, 2024) has proposed a cement net-zero ambition by 2050, with mineral

carbonation contributing about 6.4% (74kg CO_2/t reduction) to achieving this emissions goals. The report indicated explicitly

that the CO_2 absorption facilitated by concrete structures and infrastructure should be incorporated into national greenhouse

60   gas inventories. In addition, the estimates of cement carbon uptake are used by the Global Carbon Budget (Friedlingstein et

al., 2023) as an important part of anthropogenic carbon sink for modelling of the annual global carbon cycle. Therefore, it is

imperative that these uptake estimates are as precise as possible.

However, due to the lack of detailed activity data and precise carbonation parameters for various countries, there is still a gap in national-scale accounting of cement carbon uptake. Cement consumption, influenced by international trade, provides the

65   activity level data for estimating carbon sequestration (Ambec et al., 2024). In previous accounting, cement production was used as a proxy for consumption (Xi et al., 2016). However, while that is sufficient at the global level – since production and consumption are almost equal globally - to achieve more accurate results at the country level it is imperative to collect more precise activity data on cement consumption with improved spatial resolution. To establish a national cement carbon sink database, it is essential to refine cement carbonation parameters at the national level, including cement type, exposure

70   conditions, and building lifespan, which directly impact cement carbonation properties.

Many studies have made great contributions to a better understanding of cement carbon emissions. Andrew (2019) provided a long time series global cement carbon emissions database by calibrating carbon emissions from cement production processes across various countries. Cheng et al. (2023) offered bottom-up quantifications of emissions in developing countries. Some studies accounted for cement emissions and proposed reduction strategies, particularly in major emitters like China (Doh Dinga

75   and Wen, 2022; Liu et al., 2021) and India (Krishna Priya et al., 2024). Nonetheless, the corresponding carbon sequestration accounting for cement with the same accuracy has not yet been established. It is therefore imperative to enhance the spatial resolution of the cement carbon uptake database to understand the specifics of cement carbon sinks and their contributions to emission reductions across different countries.

This study is the fourth update of the Global Cement Carbon Uptake Database, providing a detailed bottom-up quantification

80   and revealing a shift in the main countries contributing to global cement CO_2 uptake. Key updates compared to previous versions are: (1) Global cement carbon uptake is now calculated as the sum of 163 countries and regions, offering a more comprehensive view than the previous coarse-scale partition summation. (2) To reduce accounting uncertainty, we have shifted from using cement clinker production to apparent consumption as the activity level data for national cement carbon sequestration accounting. (3) We have updated national-level cement carbonation parameters to improve accounting accuracy,

85   including factors such as cement utilization type, concrete strength class, and concrete exposure time. (4) The database has been updated to include time series from 1928 to 2023, with projected cement carbon uptake for 2024 aligning with the latest Global Carbon Budget. (5) This update also highlights the cement carbon sequestration characteristics at national-level and their carbon offset levels to emission.

Data Discussions

2 Methods and data sources

2.1 Data source and treatment

In this study, national cement clinker production data and emission factors were used to calculate carbon emissions from cement production processes. The cement clinker production data for 163 countries and regions were obtained from two sources: (1) Direct cement clinker production data submitted to the United Nations Framework Convention on Climate Change (UNFCCC) by 43 countries. (2) Estimated cement clinker production data, which were based on cement clinker ratios and cement production for 163 countries and regions from 1928 to 2022 obtained from USGS. For the year 2023, the cement production data was updated from the CCF2Up database website (https://ccf2up.com/). For countries lacking updated data for 2023 and all countries in 2024, projections were made based on historical data (see Sect. 2.3 for forecasting methods). The cement clinker ratio data for China and India aligned with our prior research (Xi et al., 2016; Guo et al., 2021; Huang et al., 2023). For other countries, the ratios are estimated using the methods outlined by Andrew (2020), with taking 95% cement clinker ratio for the years before 1970 and employing linear interpolation to estimate the ratio for the period after 1970, based on an assumption of steady increases in clinker substitution over time. Country-specific cement emission factors are obtained from the UNFCCC for 43 countries. For those not listed in the database, the default value of 0.507 kg CO_2/t clinker provided by the IPCC was used.

To provide a more precise national-level database of carbon uptake in cement, the following data updates have been made in this study based on previous work, incorporating the following modifications: (1) Cement consumption for 163 countries and regions. Cement consumption in different countries was adjusted using import and export data for cement clinker based on the cement production data collected and estimated for each country. (2) Cement utilization proportion in concrete and mortar for 42 countries. Statistics on the types of cement utilized in European countries were sourced from the European Ready-Mixed Concrete Industry (ERMCO, 2019). Data for South Africa (Muigai et al., 2013), India (Kumar and Kaushik, 2003) and Thailand were collected from the literatures. For China and the USA, the data remains consistent with previous work. (3) Concrete strength class for 42 countries. For European countries, concrete strength class data were derived and updated from ERMCO statistics (ERMCO, 2019). For other countries like Brazil, Egypt, South Africa, Saudi Arabia, India, Malaysia, Thailand, and the UAE, the concrete categories were estimated based on building types from CEIC Data (CEIC, 2024). (4) Building lifespan for 42 countries. This factor determines the exposure time of concrete during service, and actual statistics were prioritized for carbon uptake calculation, followed by engineering design data, and last for model simulation when both are unavailable (Ji et al., 2021). Altogether, there are 58517 activity level data for 163 cement-producing countries and regions worldwide, and 6186 carbonation parameters for 42 countries were updated and enriched in the calculate model of global cement carbon uptake.

2.2 Estimating for cement process CO_2 emissions

120   The methodology recommended by IPCC is widely used for estimating CO_2 emissions from industrial processes. In this study, we used Tier 2 method to estimate country-specific emissions (Eq. 4):

$$E_{process,i} = P_{cement,i} \times f_{clinker,i} \times EF_{CO_2,i} \tag{4}$$

where $E_{process,i}$ represents process CO_2 emissions from cement industry in country i; $P_{cement,i}$ refers to weight (mass) of cement produced, $f_{clinker,i}$ is clinker-to-cement ratios, $EF_{CO_2,i}$ is the country-specific emission factor for clinker.

125   ## 2.3 Estimating for cement CO_2 uptake

We employ national geographic boundary as the accounting boundary for cement carbon uptake, aligning with the accounting methods for carbon emissions from cement production. The accounting model for cement CO_2 uptake (Table 1) in this study adheres to the model constructed in our prior research, which can be summarized as follows:

$$C = W \times f \times \gamma \times F \times M \tag{5}$$

130
$$W = P_{clinker} - Ex + Im \tag{6}$$

$$F = d/D \tag{7}$$

$$d = k \times \sqrt{t} \tag{8}$$

$$k = \beta_{csec} \times \beta_{ad} \times \beta_{CO_2} \times \beta_{cc} \tag{9}$$

The cement carbon uptake (C) obtained by combining the clinker consumption (W) with proportion of CaO in cement clinker

135   (f), fraction of CaO converted to $CaCO_3$ of cement material (γ), annual carbonation ratio (F) and molar ratio (Eq. 5). Where W is adjusted by clinker production ($P_{clinker}$) with its exports (Ex) and imports (Im) (Eq. 6). F is the ratio of carbonation depth (d) to total thickness (D) (Eq. 7). d is the carbonation depth over a certain period of time (t) that can be calculated by Fick's second law of diffusion (Eq. 8). k represents carbonation rates, which is calibrated by exposure conditions (β_{csec}), cement additives (β_{ad}), CO_2 concentration (β_{CO_2}) and coating and cover (β_{cc}) (Eq. 9).

140   Considering the carbon uptake mechanism of cement in different life cycles, cement carbon uptake has been categorized into four types: (1) concrete use, (2) mortar use, (3) construction-loss, and (4) cement kiln dust (CKD) landfills. For concrete, the carbon uptake takes into whole life cycle of concrete service, demolition, and secondary-use. For cement mortar, there are comprise three kinds of use: rendering and plastering mortar, maintenance and repairing mortar, and masonry mortar. Concrete and mortar loss are both carbon sinks for construction-loss cement. The carbon uptake of CKD occurs during landfill disposal.

145   Table 1 lists the carbon sequestration accounting equations for different cement materials.

Table 1: Accounting Model for Cement CO₂ uptake

Cement type	Disposal method or Life stages	Accounting formula
	Service	$C_{li} = W_{li} \times F_{li} \times f_{clinker} \times f_{CaO} \times \gamma \times \dfrac{M_{CO_2}}{M_{CaO}}$ $F_{li} = d_{li}/D_{li}$ $d_{li} = 2k_{li} \times \sqrt{t_l}$
(1) Concrete	Demolition	$C_d = W_{di} \times F_{di} \times f_{CaO} \times \gamma \times \dfrac{M_{CO_2}}{M_{CaO}}$ $F_{di} = \begin{cases} 100\% - \dfrac{\int_a^b \frac{\pi}{6}(D - D_{di})^3}{\int_a^b \frac{\pi}{6} D^3} \times 100\%, & (a > D_{di}) \\ 100\% - \dfrac{\int_{D_{di}}^b \frac{\pi}{6}(D - D_{di})^3}{\int_a^b \frac{\pi}{6} D^3} \times 100\%, & (a \le D_{di} < b) \\ 100\%, & (b \le D_{di}) \end{cases}$ $D_{di} = 2d_{di} = 2k_{di} \times \sqrt{t_d}$
	Secondary-use	$C_s = W_{si} \times F_{si} \times f_{CaO} \times \gamma \times \dfrac{M_{CO_2}}{M_{CaO}}$ $F_{si} = \begin{cases} 100\% - \dfrac{\int_a^b \frac{\pi}{6}(D - D_{si})^3}{\int_a^b \frac{\pi}{6} D^3} \times 100\% - F_{di}, & (a > D_{si}) \\ 100\% - \dfrac{\int_{D_{si}}^b \frac{\pi}{6}(D - D_{si})^3}{\int_a^b \frac{\pi}{6} D^3} \times 100\% - F_{di}, & (a \le D_{si} < b) \\ 100\% - F_{di}, & (b \le D_{si}) \end{cases}$ $D_{si} = 2d_{ti} = 2k_{si} \times \sqrt{t_{si} + t_{di} + \Delta t_i}$
	Rendering and plastering mortar	$C_{rpt} = \sum_0^t W_m \times r_{rp} \times f_{rpt} \times f_{clinker} \times f_{CaO} \times \gamma_1 \times \dfrac{M_{CO_2}}{M_{CaO}}$ $f_{rpt} = \dfrac{d_{rpt} - d_{rp(t-1)}}{d_{Trp}} \times 100\%$ $d_{rp} = K_m \times \sqrt{t}$
(2) Mortar	Maintenance and repairing mortar	$C_{rmt} = \sum_0^t W_m \times r_{rr} \times f_{rmt} \times f_{clinker} \times f_{CaO} \times \gamma_1 \times \dfrac{M_{CO_2}}{M_{CaO}}$ $f_{rmt} = \dfrac{d_{rmt} - d_{rm(t-1)}}{d_{Tmp}} \times 100\%$ $d_{rm} = K_m \times \sqrt{t}$
	Masonry mortar	$C_{rmat} = \sum_{i=0}^2 W_m \times r_{rm} \times r_{rmat-i} \times f_{rmat-i} \times f_{clinker} \times f_{CaO} \times \gamma_1 \times \dfrac{M_{CO_2}}{M_{CaO}}$ $f_{rmat-0} = \begin{cases} \dfrac{2(d_{rmat-0} - d_{ram(t-1)-0})}{d_w} \times 100\%, & (t \le t_r) \\ 100\% - 2d_{rmat-0-sl}/d_w \times 100\%, & (t_r \le t \le t_{sl}) \end{cases}$

$$d_{rmat-0} = 2K_m \times \sqrt{t}$$

$$f_{rmat-1} = \begin{cases} \dfrac{d_{rmat-1} - d_{ram(t-1)-1}}{d_w} \times 100\%, & (t_r \le t \le t_{sl}) \\ 100\% - \dfrac{(2d_{rmat-1-sl} - 2d_{Trp})}{d_w} \times 100\%, & (t = t_{sl} + 1) \end{cases}$$

$$d_{rmat-1} = \begin{cases} K_m \times \sqrt{t}, & (t \le t_r) \\ K_m \times \sqrt{t} + (K_m \times \sqrt{t} - d_{Trp}), & (t_r \le t \le t_{sl}) \end{cases}$$

$$f_{rmat-2} = \begin{cases} 0, & (t \le t_r) \\ \dfrac{d_{rmat-2} - d_{ram(t-1)-2}}{d_w} \times 100\%, & (t_r \le t \le t_{sl}) \\ 100\% - \dfrac{(d_{rmat-2-sl} - 2d_{Trp})}{d_w} \times 100\%, & (t = t_{sl} + 1) \end{cases}$$

$$d_{rmat-2} = \begin{cases} 0, & (t \le t_r) \\ 2(K_m \times \sqrt{t} - d_{Trp}), & (t > t_r) \end{cases}$$

(3) Construction-loss	Waste concrete	$C_{wastecon} = (\sum_{1}^{n} W_{ci} \times f_{con} \times r_{con}) \times f_{clinker} \times f_{CaO} \times \gamma \times \dfrac{M_{CO_2}}{M_{CaO}}$
	Waste mortar	$C_{wastemor} = (\sum_{1}^{n} W_{mi} \times f_{mor} \times r_{mor}) \times f_{clinker} \times f_{CaO} \times \gamma_1 \times \dfrac{M_{CO_2}}{M_{CaO}}$
(4) CKD	Landfill	$C_{CKD} = W_{clinker} \times r_{CKD} \times r_{landfill} \times f_{CaO} \times \gamma_2 \times \dfrac{M_{CO_2}}{M_{CaO}}$

150 **Annotation:** (1) Concrete: W_{li}, W_{di}, W_{si}: cement consumption for i grade strength concrete in the construction services, demolition and secondary use phases; F_{li}, F_{di}, F_{si}: carbonization ratio for i grade strength concrete in the construction services, demolition and secondary use phases; D: particle size of concrete debris in the demolition phase of construction; D_{li}: Wall thickness during concrete service; D_{di}, D_{si}: maximum particle size of i grade strength concrete for complete carbonization in the construction demolition and secondary use phases; **a, b**: maximum and minimum particle size of waste

155 concrete debris; d_{li}, d_{di}, d_{si}: carbonation depth of i grade strength concrete in the construction services, demolition and secondary use phases; k_{li}, k_{di}, k_{si}: carbonation rate of i grade strength concrete in the construction services, demolition and secondary use phases; t_l, t_d, t_{si}, t_{di}, Δt_i: use time of i grade strength concrete buildings, exposure time during the demolition phase, secondary use time of burial, and carbonation lag time for burial; f_{CaO}: proportion of CaO in cement clinker; γ: fraction of CaO converted to $CaCO_3$ of concrete; M_{CO_2}, M_{CaO}: molar mass of CO_2 and CaO.

160 (2) Mortar: W_m: cement consumption for mortar; r_{rp}, r_{rr}, r_{rm}: proportion of mortar used for rendering and plastering, maintenance and repairing, masonry; r_{rmat-i}: proportion of masonry mortar that does not have plaster (i=0), plaster on one side (i=1) and plaster on both sides (i=2); f_{rpt}, f_{rmt}, f_{rmat-i}: carbonization ratio in year t for three mortars; γ_1: fraction of CaO converted to $CaCO_3$ of mortar; d_{rpt}, d_{rmt}, d_{rmat-i}: carbonation depth of different types mortar in year t; $d_{rp(t-1)}$, $d_{rm(t-1)}$, $d_{rma(t-1)-i}$: carbonation depth of different types mortar in year t-1; d_{Trp}, d_{Tmp}, d_w: thickness of mortar used for

165   rendering and plastering, maintenance and repairing, masonry; K_m: carbonation rate of mortar; t: mortar exposure time; t_r:

time required for complete carbonation of plaster mortar at thickness.

(3) Construction-loss: W_{ci}, W_{mi}: cement consumption for i grade strength concrete and mortar; f_{con}, f_{mor}: loss rate of

concrete and mortar during the construction phase; r_{con}, r_{mor}: carbonation ratio of lost concrete and lost mortar during the

construction phase.

170   (4) CKD: $W_{clinker}$: cement clinker production; r_{CKD}: production rate of CKD; $r_{landfill}$: proportion of cement kiln ash used

for landfill disposal; γ_2: fraction of CaO converted to $CaCO_3$ of CKD

2.4 Projection of 2024 cement uptake

We provide a projection of cement carbon emission and uptake for 163 countries and regions in the year 2024. We use the

autoregressive integrated moving average model, or ARIMA (p, d, q), a time-series analysis method commonly used for yield

175   forecasting. This regression-based model forecasts values by regressing the variable's past values using various lag lengths,

along with the current and past values of the error term (Cox and Vladescu, 2023). Based on extensive long-term cement

production data spanning from 1928 to 2023 for 163 countries and regions, we use the ARIMA model to forecast cement

production for the year 2024. Our forecasts are further validated by industry economic reports from major cement-producing

nations. For example, 2023 Cement Industry Economic Operation Report published by the China Cement Association (CCA,

180   2024) considers upstream raw materials prices and the downstream real estate market, projecting a 2-3% decline in cement

production by 2024. This prediction aligns with our model's 2.1% decline. Similarly, for United States, the USGS provided

monthly data on cement production, showing a 4% year-over-year decline in the first half of 2024 that is consistent with our

model's trend prediction. The 2024 cement clinker consumption data is adjusted based on import and export data in recent

years and used to forecast cement carbon uptake in 2024.

185   **2.5 Uncertainty analysis**

We employed the Monte Carlo method suggested by the IPCC to simulate the cement carbon emission and uptake 10,000

times to assess the uncertainty in cement production process emissions and carbon sequestration in cement materials. We

identified 24 variables that contribute to uncertainty in cement carbon uptake. This count is two less than previous version due

to the revised cement clinker production and cement clinker ratio. The 24 variables include: 3 variables related to cement

190   clinker, namely CaO content, MgO content, and the proportion of CaO converted to $CaCO_3$; 10 variables for concrete,

including strength class, proportion of cement for concrete, carbonation rate, building lifespan, particle size distribution,

demolition exposure time, and correction factor; 6 variables for mortar, including proportion of cement for mortar, type of

utilization, mortar thickness, and carbonation rate; 2 variables for building loss, including utilization ratio and carbonation

period; and 3 variables for CKD, including production rate, landfill ratio, and CaO content.

195   Compared to our previous study, this study reduces the uncertainty of global cement carbon uptake estimations. The

improvements in accuracy are reflected in three aspects: (1) The activity level data used in this study is based on the annual

apparent consumption of cement clinker in each country, which is adjusted by the international trade (import/export) of clinker.

This updated national level activity data reduces the uncertainty range of [-30.0%, 30.6%] in previous estimations, which arose

due to the approximated substitution of cement production data for consumption data. (2) The cement clinker ratios used in

200   the previous versions were based on IPCC guideline-recommended values (86%, with an uncertainty range of [75%, 97%]),

while in this study we have refined the cement clinker ratio by conducting annual fitting for each country, which further reduces

the uncertainty. (3) We updated the country-specific cement carbonation parameters, including cement utilization proportion

in concrete and mortar, concrete strength classes, building service life, and building wall thickness, which greatly improved

the accuracy compared to using global clustered parameters for carbon uptake calculation in our previous reports.

205   **3 Results and Discussions**

3.1 Global cement carbon emission and uptake

Global cement emissions and carbon uptake. Global cement process emissions have increased from 34.58 Mt CO_2 yr^{-1} in

1928 to 1.58 Gt CO_2 yr^{-1} in 2023, with an average annual growth rate of 4.1 %, and a cumulative emission of 46.07 Gt CO_2

over past 96 years (Fig. 1a). The increase of global cement process emission is closely linked to the significant expansion in

210   cement clinker production, which increased 45-fold since 1928, with an average annual growth rate of 4.1 %. Correspondingly,

global carbon uptake by cement has increased from 7.74 Mt CO_2 yr^{-1} (95 % CI: 5.84-9.85 Mt CO_2 yr^{-1}) in 1928 to 0.84 Gt CO_2

yr^{-1} (95 % CI: 0.71-10.03 Gt CO_2 yr^{-1}) in 2023. Notably, 79.2 % of cement carbon sinks occurred since 1990. The total amount

of CO_2 uptake by cement over the years is estimated to be 21.26 Gt CO_2 (95 % CI: 17.93-25.17 Gt CO_2), indicating that cement

has reabsorbed approximately 46.1 % of the process emissions from its production process. Unsurprisingly, the carbon offset

215   level (uptake-to-emission ratio, Fig. 1b) tends to increase when cement production decreases. For instance, during the Second

World War in 1944, when global cement clinker production declined by 28.2 %, the carbon offset level rose to 45.0 %, an

increase of 15.8 % compared to the previous year. Conversely, periods of rapid growth in cement carbon emissions, such as

the period between 2000 and 2007, which saw an average annual growth rate of 7.0 % in cement clinker production due to

accelerated urbanization and industrialization, witnessed a decline in the carbon offset level at an average annual rate of 0.7 %.

220   This trend is primarily due to the temporal lag of cement carbonation, such that much of the carbonation occurs in the years

following the cement's production. According to our forecast, global cement carbon uptake is expected to reach 0.86 Gt CO_2

(95 % CI: 0.73-10.23 Gt CO_2 yr^{-1}) in 2024, making an increase of 2.0 % from 2023 levels.

Global carbon uptake by different cement products. The carbon uptake of all cement material types increased steadily (Fig.

1c). Mortar is the most important cement product for CO_2 sequestration, with an average annual uptake of 0.37 Gt yr^{-1} (95 %

225   CI: 0.32-0.42 Gt CO_2 yr^{-1}) in last decade (2014-2023), accounting for 48.0 % of the total (Fig. 1d). This is largely explained

by mortar's much higher surface-to-volume ratio than concrete's. Since 1928, mortar's CO_2 uptake has increased from 4.64

Mt yr^{-1} (95 % CI: 3.55-5.95 Mt yr^{-1}) to 0.39 Gt yr^{-1} (95 % CI: 0.34-0.44 Gt yr^{-1}), with an average annual growth rate of 4.7 %.

The CO_2 uptake by concrete also played a significant role, with an average annual uptake of 0.32 Gt yr^{-1} in the last decade,

contributing to 41.5 % of the total. Its uptake increased from 1.43 Mt yr^{-1} (95 % CI: 1.11-1.67 Mt yr^{-1}) in 1928 to 0.37 Gt yr^{-1}

230   (95 % CI: 0.31-0.45 Gt yr^{-1}) in 2023, with an average annual growth rate of 6.0 %. CKD and construction-loss cement absorbed

respectively 0.05 and 0.025 Gt CO_2 yr^{-1} in last decade, contributing 7.2 % and 3.3 % of the total carbon uptake, with average

annual growth rates of 4.1 % and 4.4 % from 1928 to 2023. We project that mortar, concrete, CKD, and construction-loss in

2024 will absorb 0.40, 0.38, 0.06, and 0.027 Gt CO_2 yr^{-1}, respectively. From the share of carbon sinks by different cement

materials, we find that the share of concrete carbon uptake has similar trend with carbon offset level (Fig. 1b). Notably, concrete

235   is the main material contributing to the time-lag effect of cement carbon sinks due to its exposure conditions and larger

fragment particle size which reduce the carbonation occurring within the first year.

This underscores that inter-industry collaboration is necessary to maximize CO_2 absorption through cement materials,

particularly within the construction industry (Miller et al., 2021). Such collaboration should focus on optimizing concrete

design and construction practices, along with implementing effective waste management measures for building demolition

240   waste to enhance carbon sequestration. Moreover, the potential of carbon capture, utilization and storage (CCUS) can

contribute 36 % of the reduction for the cement industry to achieve net-zero emissions (IEA, 2024). Many studies have

explored the mechanisms and properties of accelerated carbonation in cement materials, including concrete (Alshalif et al.,

2021, 2022), cement paste (Castellote et al., 2008; Morandeau et al., 2015), slag cement (Mo and Panesar, 2013), and CKD

(Pu et al., 2023). It is essential to promote and adopt relevant technologies to fully realize the potential of cement carbon sinks

245   in mitigating climate change.

Time-lag effect of cement carbon uptake. The cement carbon uptake in both current-year and historical-year shows

increasing trend (Fig. 1e). The current-year carbon uptake, which represents the absorption of CO_2 by cement produced in the

current year, has increased from 9.08 Mt CO_2 yr^{-1} in 1928 to 0.54 Gt CO_2 yr^{-1} in 2023, with an average annual growth rate of

4.4 %. While the historical-year uptake refers to the absorption of CO_2 by cement produced in the historical year which

250   continues to carbonize in the current year, increasing to 0.42 Gt yr^{-1} in 2023. Our projections indicate that in 2024, the current-

year uptake and historical-year uptake will reach 0.45 and 0.41 Gt CO_2 yr^{-1}, respectively, with increases of 0.9 % and 3.2 %

compared to 2023. Current-year uptake is the main contributor to the global cement uptake, with an average annual share of

62.7 % during the 1928-2023 period (Fig. 1f). Mortar and CKD, with their faster carbonation rates, are the primary cement

materials contributing to current-year uptake, while concrete is the main driver of historical-year uptake. It is noteworthy that

255   the trend in the share of historical-year uptake aligns with the carbon offset level. In 1944, when cement consumption decreased,

the share of historical-year carbon uptake rose to 47.0 %. Conversely, during the period from 2000 to 2007, when cement

consumption increased rapidly, the share of historical-year carbon uptake decreased at an average rate of 1.5 %. This pattern

suggests that the carbon offset level of cement carbonation sinks will increase as cement production and consumption decline

in the future.

3.2 Spatial distribution of cement carbon uptake

265　In this study, we gathered carbonation parameters from 42 countries to enrich the cement uptake accounting model. Figure 2 shows the share of cement CO$_2$ uptake by 42 countries and the rest of world (ROW) during 1928-2023. The cumulative carbon uptake by cement in these 42 countries is 16.60 Gt CO$_2$ in the past 96 years, accounting for 78.1 % of the global total. Their contributions peaked in 1928 (95.6 %) and were minimal in 1984 (72.9 %). It is evident that cement CO$_2$ uptake by China and other emerging economies, including South Africa, Indonesia, Vietnam, Korea, India, Turkey, Mexico, and Brazil, have

270　gradually replaced the leading roles played by the USA, Japan, and countries in European like the United Kingdom, Spain, Italy, Germany, France, Canada, and Belgium after 1982. Specifically, the USA was the largest contributor to cement carbon uptake with an average contribution of 23.6 % between 1928 and 1991. From 1928 to 1966, Germany and the UK were major contributors alongside the USA, with contribution of 8.7 % and 6.9 % respectively. From 1967 to 1982, Japan became the second-largest contributor with an average contribution of 8.2 %. After that, between 1983 and 1991, China replaced Japan

275　with an average contribution of 11.9 %. Since 1992, China has been the country with largest amount of cement carbonation sinks, reaching a maximum contribution of 43.5 % in 2020. Additionally, since 2008, India has been the second-largest contributor, replacing Japan's position during 1992-2006. In 2023, the cement carbon uptake in China and India were 0.33 Gt CO$_2$ yr^{-1} (38.0 % of global, CI: 0.25 - 0.41 Gt yr^{-1}) and 0.07 Gt CO$_2$ yr^{-1} (9.1 %, 0.06-0.09 Gt yr^{-1}), respectively.

280　**Figure 2: Share of cement carbon uptake from 1928 to 2023 by 42 countries and rest of world (ROW).** The full names corresponding to the country abbreviations are as follows: AUS (Australia), AUT (Austria), BEL (Belgium), BGR (Bulgaria), CAN (Canada), HRV (Croatia), CYP (Cyprus), CZE (Czechia), DNK (Denmark), FIN (Finland), FRA (France), DEU (Germany), GRC (Greece), HUN (Hungary),

IRL (Ireland), ITA (Italy), LUX (Luxembourg), NLD (Netherlands), NOR (Norway), POL (Poland), PRT (Portugal), ROU (Romania), SVK (Slovakia), SVN (Slovenia), ESP (Spain), SWE (Sweden), CHE (Switzerland), GBR (United Kingdom), USA (USA), MEX (Mexico), BRA (Brazil), EGY (Egypt), TUR (Turkey), IRN (Iran), SAU (Saudi Arabia), IND (India), CHN (China), KOR (Korea, Republic of), JPN (Japan), VNM (Vietnam), IDN (Indonesia), ZAF (South Africa).

Based on the clinker production data for 163 countries and regions worldwide and the carbonation parameters for 42 countries, we estimated and projected the carbon uptake across these 163 entities. From the spatial distribution of the cement CO_2 uptake in 2024, We find that the dominant countries of carbon uptake by cement are still distributed in Asia, particularly due to the region's high demand for infrastructure development. China leads the global charge with 326.84 Mt CO_2 (44.0% of the total), followed by India and Saudi Arabia with 78.25 and 43.76 Mt CO_2, respectively. Japan and South Korea are ranked 7th and 10th with 25.99 and 19.33 Mt CO_2 sequestration, respectively. Southeast Asian countries like Vietnam, Indonesia, Thailand, Philippines, and Laos also contribute significantly, sequestering 19.91, 17.54, 9.34, 7.68 and 5.68 Mt CO_2, respectively. For America, the main countries for CO_2 uptake are in USA, Brazil, Mexico, and Canada, with 37.91, 11.03, 10.53 and 5.20 Mt respectively, which ranked 4th, 12th, 14th, and 28th in the world. In Africa, cement carbon uptake is concentrated in Egypt, Nigeria, Algeria and South Africa, which sequester 7.49, 4.30, 4.17 and 2.53 Mt CO_2, respectively. In Europe, key countries for CO_2 sequestration via cement are Germany, Italy, France, Spain, United Kingdom, and Poland, with amounts of 11.00, 6.82, 6.35, 5.97, 5.11 and 4.46 Mt, respectively.

3.3 National cement carbon emission and uptake

In this study, we enriched the national cement carbon emission and uptake database. We categorized the countries into two sets according to the trends of their cement carbon emissions curves (Table 2). Group 1 comprises 21 countries where the
305   carbon emissions have shown a peaking trend during 1928-2024. These countries can be further divided into 2 categories based on their net emissions trends: 9 countries with a neutral trend (category a1) and another 12 countries that have peaked but do not exhibit a neutral trend (category a2). Meanwhile, Group 2 includes 21 countries where the carbon emissions are still increasing and have not peaked, but their net emissions trend encompass both peaked (category b1) and non-peaked (category b2) categories, with 4 and 17 countries respectively.

310   **Table 2: List of country classifications.**

Groups	Emissions trend	Categories	Net emissions trend	No. of countries
Group1	Peaked	a1	Neutral	9
		a2	Peaked	12
Group2	Non peaked	b1	Peaked	4
		b2	Non peaked	17

Figure 4 shows cement carbon emission and uptake for 42 countries from 1928 to 2024. Group 1 (Fig. 4a) predominantly comprises European countries, which were early producers and consumers of cement. In category a1 countries, carbon emissions from cement production have peaked and followed a steady decline, but carbon sinks from cement consumption in these countries have not decreased, resulting in the net-zero or even negative emissions with increasing uptake. For instance,
315   the cement emissions in Australia peaked at 2.91 Mt in 1974 and then decreased at an average rate of 0.8 %. While its cement carbon uptake was 1.17 Mt in 1974 (offset level 40.3 %) and then continued to rise, especially from 2000 to 2024, with an average increase rate of 3.3 %. By 2009, net cement emissions had turned negative with -0.02 Mt CO_2 yr^{-1} and reached -2.7 Mt CO_2 yr^{-1} in 2024. This is due to the fact that, despite Australia produce less clinker than they used to, their cement consumption has not deceased through substantial clinker imports, with import penetration ratio of 52.8 % in 2023. Countries
320   like Netherlands, Japan, United Kingdom, Hungary, Italy, France, Czech and Germany have exhibited similar trends. In category a2 countries, the net emissions are not yet neutralized, but offsets from cement carbon sequestration effectively reduce actual cement emissions. For instance, in most category a2 countries like Sweden, Luxembourg, Finland, Norway and Belgium, the increase in cement carbon uptake outpaces the growth in carbon emissions, leading to a rapid decline in net emissions after peak year.

325   In Group 2 countries (Fig. 4b), the cement process emissions have not peaked. However, net emissions have peaked in category b1 countries, such as USA, South Korea, Austria and Denmark, due to carbon sequestration by cement consumption. For instance, a constant demand for cement in USA, carbon emissions are expected to reach 39.57 Mt CO_2 in 2024. However, as the leading importer of cement, USA has shown a peaked trend in net emissions when considering the carbon uptake of cement consumption. Specifically, from 2009 to 2024, the average carbon offset level in USA has been 89.0 %. The non-peaked

330   countries (category b2) are primarily developing countries, and their cement production and consumption have expanded significantly, albeit later than Group 1 countries. China, India, Vietnam, Iran, and Indonesia are notable examples, having experienced rapid growth in cement demand after the 1980s. The cumulative carbon uptake from cement in these countries between 1980 and 2023 accounts for more than 95 % of their totals from 1928 to 2023. Notably, Saudi Arabia has recently witnessed a sharp increase, with 39.21 Mt of cement CO_2 uptake in 2023, an increase of 1.7-fold compared to 2020, likely due

335   to its recent economic diversification policies. Due to the higher production and lower imports in category b2 countries, the trends in emissions and uptake from cement in these countries are similar, with net emissions increasing in line with the process emissions. It's worth mentioning that some countries in category b2 have shown decreasing trends in recent years. For instance, the cement process emissions in China, Brazil and Ireland have decreased for three consecutive years (2022-2024). However, these decreases primarily stem from the decline in cement production rather than from offsets in cement carbonation sink, as

340   their carbon uptake also show a decreasing trend with projections of -1.1 %, -1.1 % and -5.0 % in 2024, respectively. In summary, the carbon offset by cement CO_2 uptake is more significant in peaked countries than in non-peaked countries. Nowadays, many studies have indicated carbon leakage due to outsourcing from these peaked countries (Allevi et al., 2017; Grubb et al., 2022), our results show that the gap in cement carbon emissions between countries will further widen if the carbon uptake were taken into account.

345   There exists a time lag of cement carbon emissions and uptake among different countries. The majority of Group 2 countries are in the initial phases of cement production compared to Group 1 countries. As shown in Figure 5, the trends in four countries are with comparable cement production levels but vary peak years. Germany and France, which began using cement before 1930, experienced a rapid increase in cement carbon emission and uptake during 1950s-1970s, peaking in the 1970s. Korea and Ireland has similar trends, but with about 20-year time lag.
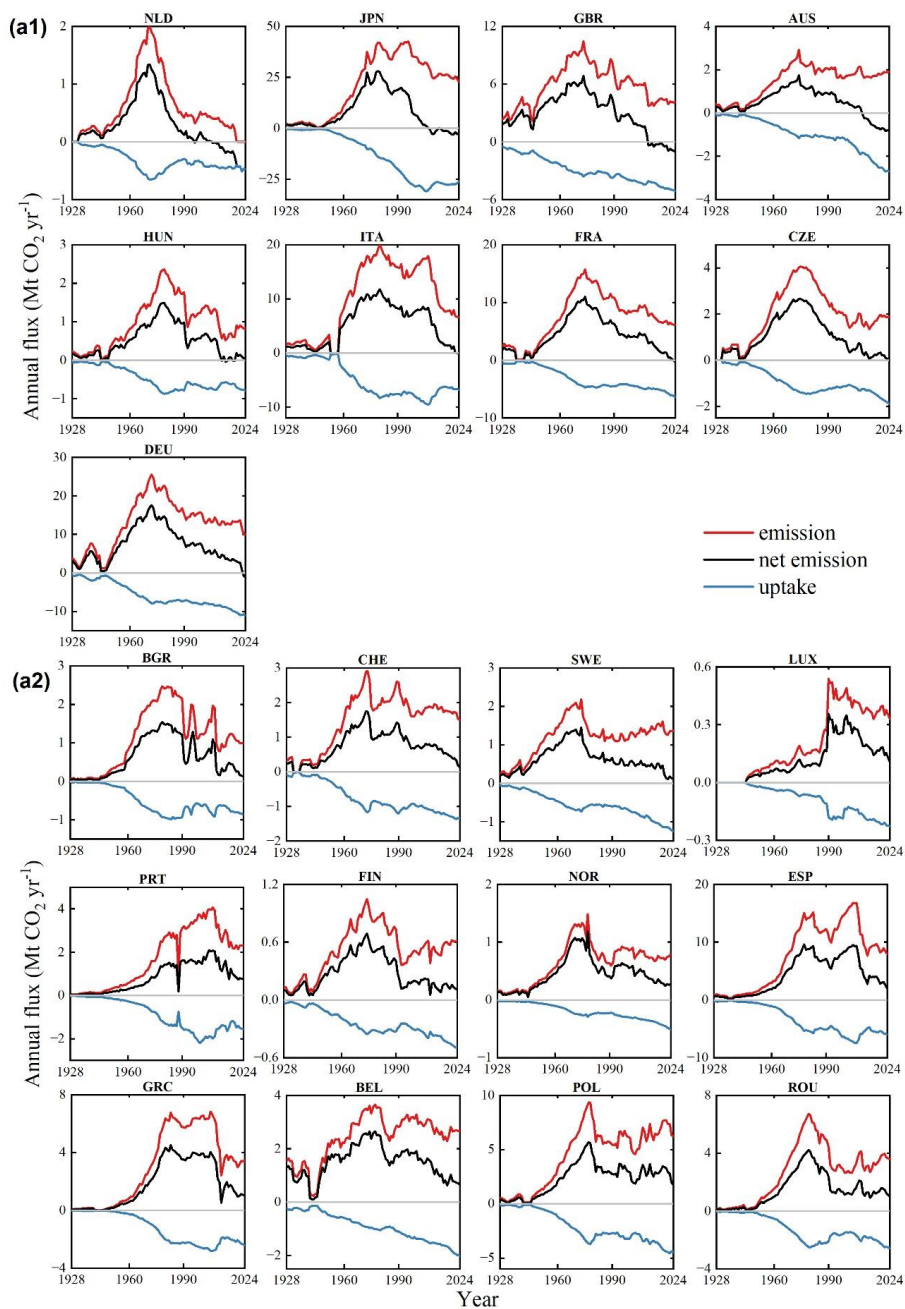

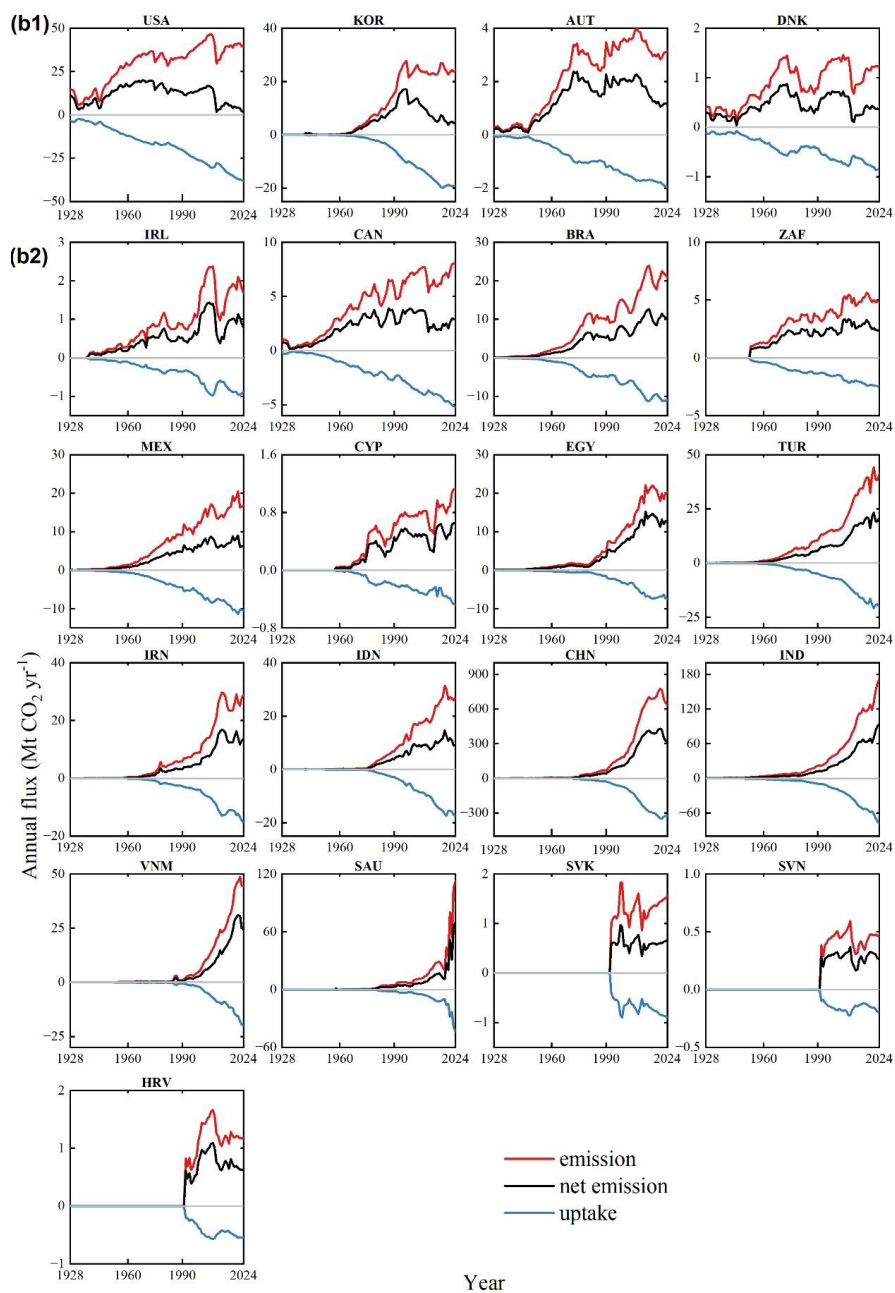

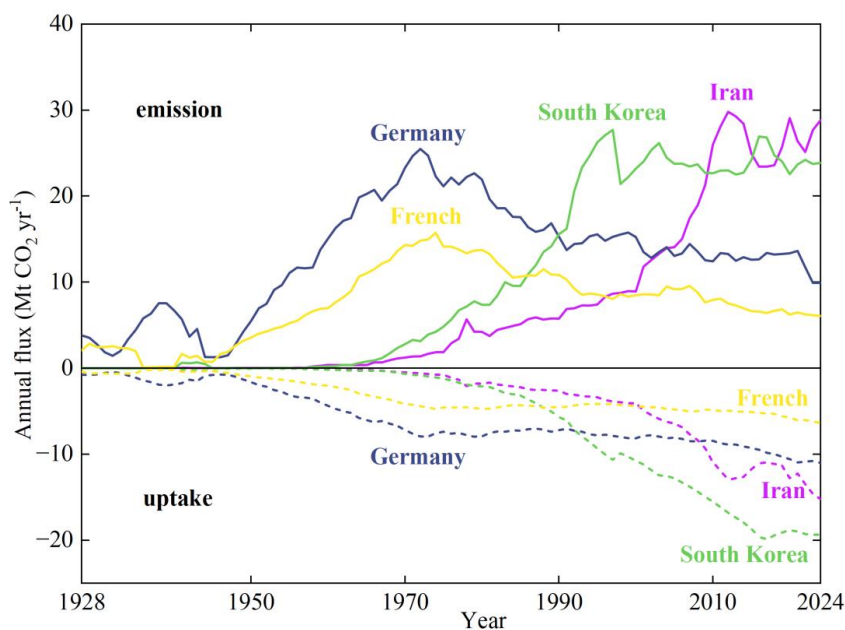

Figure 4: Cement carbon emission and uptake in 42 countries during 1928-2024. (a) 21 countries in Group 1 that the cement process emissions have reached peaking. (b) 21 countries in Group 2 with carbon emissions non-peaked.

4 Data availability

All of the original datasets utilized for estimating cement emission and uptake, as well as the results and associated uncertainties in this study, can be accessed on Zenodo at https://doi.org/10.5281/zenodo.13827861 (Wu et al., 2024).

5 Conclusions

In this study, we further advance research on cement carbon uptake accounting system to enrich both temporal scale (1928-2024) and spatial distribution (163 countries and regions) of global cement carbon uptake database, and provide a more precise bottom-up quantification. Our study reveals that the global and national CO_2 uptake from cement material carbonation cannot be negligible. From 1928 to 2023, global cement materials have absorbed a cumulative total of 21.26 Gt CO_2 (95 % CI: 17.93-25.17 Gt CO_2), offsetting 46.1 % of the emissions from production process. In 2023, global carbon uptake by cement is 0.83 Gt CO_2 yr^{-1} (95 % CI: 0.71-1.00 CO_2 yr^{-1}), with projections for 2024 at 0.86 Gt CO_2 yr^{-1} (95 % CI: 0.73-1.02 CO_2 yr^{-1}). The updated national-level databases in this study offer more detailed insights of cement carbon uptake. We find emerging economies are gradually becoming major contributors to global cement carbon uptake since 1982, with increasing cement production, particularly in China and India. In contrast, some Southwest Asian countries have achieved net-zero cement carbon emissions, having been major contributors from 1928 to 1981. Moreover, according to the characteristics of the carbonation

370   kinetic, cement carbonation is a dynamic process, and the share of carbon uptake from historical legacy will gradually increase. It means that the carbon offset by cement carbonation will become more significant in relative terms as cement production decreases in the future, driven by carbon reduction policies across various countries.

The accounting of global carbon uptake by cement is continually improving, and refinements in activity data and carbonation parameters are critical in the accurate carbon sequestration inventory. In this study, we focus on updating the country-specific

375   cement consumption activity data and carbonation parameters based on concrete materials in their service stage, leveraging the extensive civil engineering research available. Considering the increasing demand for cement in emerging economics and their significant contribution to global carbon uptake, optimizing these parameters of these countries in the future study is crucial. It is necessary to refine the carbonation parameters related to concrete demolition and secondary use, as well as other cement products. Especially for cement mortar, which consume less but contribute more to cement carbonation uptake. Efforts

380   should be made to optimize methodological, enabling organisations to rely on better estimates for integrating cement carbonation absorption accounting into national GHG inventories.

Author contributions

LN design the study, collected and assembled the data, prepared, reviewed and edited the manuscript.

SW design the study, conducted modelling, constructed the database, collected and assembled the data.

385   RMA collected and assembled the data, and revised the manuscript.

ZS collected and assembled the data.

JW revised the manuscript.

FX led the project, design the study, and revised the manuscript.
